

## American Society of Human Genetics 68<sup>th</sup> Annual Meeting

### POSTER ABSTRACTS

Abstract Topic	Abstract/Poster Board Numbers	
	Start #	End #
Genome Structure and Function	373	447
Prenatal, Perinatal, and Reproductive Genetics	448	540
Genetic Counseling, ELSI, Education, and Health Services Research	541	654
Cancer Genetics	655	975
Mendelian Phenotypes	976	1340
Bioinformatics and Computational Approaches	1341	1707
Omics Technologies	1708	1823
Epigenetics and Gene Regulation	1824	2015
Developmental Genetics and Gene Function	2016	2114
Complex Traits and Polygenic Disorders	2115	2664
Evolution and Population Genetics	2665	2786
Molecular and Cytogenetic Diagnostics	2787	3062
Cardiovascular Phenotypes	3063	3249
Statistical Genetics and Genetic Epidemiology	3250	3567

**Posters should remain on the board for all three days (Wednesday through Friday)**

The program and abstract/poster board number next to each listing is followed by an **W** (Wednesday), **T** (Thursday), or **F** (Friday) to indicate the day on which authors must be present at their poster boards.

## 976T

**Unravelling the genetic mechanisms of neonatal diabetes mellitus: An Egyptian experience.** R. Elkaffas<sup>1,3</sup>, H. Madani<sup>1</sup>, B. AlKholi<sup>1</sup>, N. Musa<sup>2</sup>, Y. Shalaa<sup>2</sup>, R.M.H. Elkaffas<sup>2</sup>, M. Hassan<sup>2</sup>, M. Hafez<sup>2</sup>, S. Flanagan<sup>2</sup>, E. DeFranco<sup>2</sup>, K. Hussain<sup>2,5</sup>. 1) Chemical pathology, Faculty of medicine-Cairo university, Cairo, Giza, Egypt; 2) Pediatric department, Cairo university; 3) UCL GOS Institute of Child Health, UCL, UK; 4) Institute of Biomedical and Clinical Science, University of Exeter Medical School, UK; 5) Sidra Medical & Research center, Qatar.

**Background:** Neonatal Diabetes Mellitus (NDM) is a rare monogenic form of Diabetes Mellitus presenting typically before the age of 6 months. NDM can be transient (TNDM) with 70% of these cases caused by a methylation defect in 6q24 or permanent (PNDM) with 40% caused by mutations in potassium channel subunits coding genes (*KCNJ11*, *ABCC8*). It may present in an isolated form or as a part of syndrome. Several studies have reported the genetic causes of NDM among different populations but to the best of our knowledge no previous studies had reported the genetic mechanisms of NDM among the Egyptian population. **Objective and hypotheses:** Our aim was to understand the genetic causes of NDM in Egyptian neonates presenting before the age of 6 months referred to a tertiary diabetes centre between the period 2013-2016. **Method:** In a cohort of 22 patients, anti-GAD antibodies and C-peptide testing were done in some cases to exclude type 1 Diabetes Mellitus. Sanger sequencing for *KCNJ11*, *ABCC8*, *INS* and *EIF2AK3* genes was done as a first tier genetic analysis for all cases. In absence of a causative mutation in these genes, we further undertook methylation analysis of 6q24 in cases presenting with TNDM, while in those presenting with PNDM targeted next generation sequencing (tNGS) for the coding regions and conserved splice sites of another 18 known genes to cause NDM were done. Targeted gene analysis was done in 4 syndromic cases with a distinctive phenotype suggesting a candidate gene. **Results:** Genetic causes were identified in 15/22 (68%) patients. These included 10 missense, 3 nonsense, 2 frameshift mutations and a complete loss of maternal methylation on chromosome 6q24. Mutations involved different genes; 4 in *ABCC8*, 3 in *GCK*, 3 in *EIF2AK3*, 2 in *KCNJ11*, 1 in *NEUROD1*, 1 in *ZFP57* and 1 in *SLC19A2*. Most of these patients (11/15) had previously reported mutations. In 4 patients, no mutation was identified in the first tier analysis but insufficient DNA was available for tNGS. In 3 patients no genetic cause could be identified.

## 977F

**The Personalized Diabetes Medicine Program: Identification, diagnosis and treatment of monogenic diabetes.** H. Zhang<sup>1</sup>, J.W. Kleinberger<sup>1</sup>, T.J. Mathias<sup>1</sup>, Y. Guan<sup>2</sup>, K.A. Maloney<sup>1</sup>, E.A. Streeten<sup>1</sup>, K. Blessing<sup>3</sup>, M.N. Snyder<sup>2</sup>, L. Bromberger<sup>4</sup>, J. Goehring<sup>5</sup>, A. Kimball<sup>6</sup>, C.M. Damcott<sup>7</sup>, C.O. Taylor<sup>8</sup>, M. Nicholson<sup>1</sup>, D.C. Nwaba<sup>1</sup>, K. Palmer<sup>1</sup>, N. Ambulos<sup>1</sup>, L.J.B. Jeng<sup>1</sup>, A.R. Shuldiner<sup>9</sup>, P. Levin<sup>9</sup>, D.J. Carey<sup>9</sup>, T.I. Pollin<sup>1</sup>. 1) Division of Endocrinology, Diabetes, and Nutrition, University of Maryland School of Medicine, Baltimore, MD; 2) Rollins School of Public Health, Emory University, Atlanta, GA; 3) Geisinger Health System, Danville, PA; 4) MODEL Clinical Research, Research Division of Bay Endocrinology Associates, Baltimore, MD; 5) Harvey Institute for Human Genetics, Greater Baltimore Medical Center, Baltimore, MD; 6) Division of General Internal Medicine; Johns Hopkins University School of Medicine, Baltimore, MD; 7) University of Maryland Marlene and Stewart Greenebaum Cancer Center, University of Maryland School of Medicine, Baltimore, MD; 8) Regeneron Genetics Center, Tarrytown, NY; 9) Bay West Endocrinology Associates, Baltimore, MD.

**Background** Monogenic diabetes, including maturity onset diabetes of the young (MODY) comprises approximately 1-2% of all diabetes but is usually misdiagnosed as type 1 diabetes (T1D) or type 2 diabetes (T2D) and currently diagnosed correctly only ~5% of the time. A genomic diagnosis of monogenic diabetes informs proper treatment (sulfonylureas for *HNF1A/HNF4A* MODY, no treatment for *GCK* MODY vs. insulin for T1D, and for example, metformin for T2D) and familial risk assessment. The Personalized Diabetes Medicine Program (PDMP), part of the NIH IGNITE (Implementing GeNomics In PracTice) Network, was designed to implement, disseminate and evaluate a sustainable method for identifying, genomically diagnosing, and promoting individualized therapy for monogenic diabetes. Methods Patients were recruited into the program through a screening questionnaire completed in the waiting room or online or clinician- or self-referral. Patients suspected of monogenic diabetes underwent next generation sequencing for 40 genes, including 13 MODY genes as well as genes implicated in neonatal diabetes, lipodystrophy, syndromic diabetes, severe obesity and hyperinsulinemia. Automated filtering generated a list of nonsynonymous exonic or splicing variants with <5% minor allele frequency, which were then classified by the 2015 ACMG/AMP Guidelines. Results To date, 312 probands with suspected monogenic diabetes have enrolled and 269 have been sequenced. Among 362 high quality variants classified, 24 pathogenic or likely pathogenic variants were found in 26 patients, for a hit rate of 26/269 (9.7%). The variants were found in *GCK* (13), *HNF1A* (5), *LMNA* (2), and *INS* (2), *KCNJ11* (1) and *MC4R* (1). We also found 176 benign or likely benign variants and 162 variants of uncertain significance. Among the 14 patients with *GCK* variants, prior to sequencing, only two patients were suspected to have MODY, nine were diagnosed with T2D, two were diagnosed with diabetes with no type and one had pre-diabetes. Follow-up of these patients to assess effects of genomic diagnosis of monogenic diabetes on diagnosis, treatment, clinical outcomes, healthcare utilization/cost-effectiveness of screening, and cascade testing is in progress. Results will be used to inform a clinical service model to assure that all individuals and families with monogenic diabetes have access to diagnosis and customized treatment and more broadly access to personalized medicine across disease areas.

**978W**

**High resolution ex vivo magnetic resonance imaging of the mucopolysaccharidosis I canine brain and associated white matter pathology.** P. Dickson<sup>1,2</sup>, M. Egeland<sup>2</sup>, S. Chen<sup>3</sup>, I. Nestrasil<sup>4</sup>, S.Q. Le<sup>1,2</sup>, S. Kan<sup>2</sup>, J. Jens<sup>5</sup>, E. Snella<sup>6</sup>, N.M. Ellinwood<sup>6</sup>, M. Guzman<sup>6</sup>, L.E. White<sup>7</sup>, J.D. Cooper<sup>1,2</sup>, J. Provenza<sup>3</sup>. 1) Department of Pediatrics, Washington University School of Medicine, Saint Louis, MO; 2) Department of Pediatrics, Los Angeles Biomedical Research Institute at Harbor-UCLA Medical Center, Torrance, CA; 3) Department of Radiology, Duke University, Durham, NC; 4) Department of Pediatrics, University of Minnesota, Minneapolis, MN; 5) Department of Animal Science, Iowa State University, Ames, IA; 6) Department of Pathology, Saint Louis University School of Medicine, Saint Louis, MO; 7) Department of Orthopedic Surgery, Duke University, Durham, NC.

Mucopolysaccharidosis I (MPS I) is a lysosomal storage disorder causing progressive physical and neurological disability. Neurological manifestations include progressive white matter hyperintensities on brain magnetic resonance imaging (MRI) that are thought to reflect dysmyelination. To explore white matter in MPS I brain, we performed high-resolution, ex vivo brain MRI in the canine model of MPS I and performed comparative neuropathology. MPS I and unaffected heterozygous control animals were sacrificed at seven weeks (n=3/group) or eighteen weeks (n=2 MPS and 4 controls). Following perfusion and fixation in formalin and gadolinium, excised brains were imaged on a 7T small-animal MR imaging system at Duke Center for In Vivo Microscopy as previously published (Middleton et al; *Neurorad J.* 2017; Middleton et al; *Neurorad J.* 2017). We placed 5 non-overlapping regions of interest 12px by 12px per slice on the left and right anterior and posterior internal capsule and anterior and posterior corticospinal tract in each contiguous slice containing the structures. Diffusion tensor imaging showed normal to slightly high fractional anisotropy of all white matter regions of MPS dogs at 7 weeks (p=NS). In the 18-week group, fractional anisotropy was lower in both MPS dogs compared to controls in the white matter regions. Luxol-fast blue staining of internal capsule showed reduced percent thresholding in 18-week MPS dogs versus controls. Additional work is underway to evaluate the composition of white matter. Diffusion tensor imaging may permit sensitive, early detection of abnormal myelination in MPS I brain.

**979T**

**Screening strategy to classify mutations in a rare Mendelian disease: Glycogen storage disease type 1a.** K.L. Plona<sup>1</sup>, E.M. Ponting<sup>1</sup>, M.L. Drumm<sup>1,2</sup>. 1) Department of Genetics and Genome Sciences, Case Western Reserve University School of Medicine, Cleveland, OH; 2) Department of Pediatrics, Case Western Reserve University School of Medicine, Cleveland, OH.

The source of clinical heterogeneity among patients with the same monogenic disorder is largely speculative and may reflect genetic differences, stochastic events, or environmental sources. Understanding sources of clinical variation between patients with the same monogenic disorder can provide insight into treatment strategies. Our work uses glycogen storage disease 1a (GSD1a [MIM 232200]) as a Mendelian disease model and focuses on understanding how different mutations in *G6PC* [MIM 613742] contribute to differences in molecular phenotype. GSD1a is a rare metabolic disease characterized by an inability to break down glycogen to release glucose from cells during fasting, resulting in life-threatening hypoglycemia. Currently there are no curative therapies, and patients rely on symptomatic treatment and a regimented diet to maintain normoglycemia and sustain life. It is well established that a reduction in glucose-6-phosphatase enzyme function causes GSD1a, however it remains unclear how each of the 85+ reported pathogenic mutations in the *G6PC* gene, along with variants of unknown significance, alter the function of G6PC protein. Further molecular classification of the mutations can help inform which therapeutic strategies may be appropriate. We have developed an initial screening system in which *G6PC* cDNAs, fused in frame with a C-terminal fluorescent reporter, are transiently transfected into cultured cells. Our initial studies compare a panel of 11 mutations reported as pathogenic and 2 variants of unknown significance, assessing molecular outcomes for each. We have selected the panel to represent multiple mutation types, gene locations, protein domains, and patient ethnicities. Using high-throughput fluorescent imaging we have assessed these mutations for G6PC protein presence, relative quantity, and localization. As expected, one frameshift and two nonsense mutations abolish protein production. We also discovered that four of the nine tested missense mutations, including the most prevalent mutation (p.R83C), result in reduced protein levels. Functional studies are now underway to determine the relative amounts of catalytic activity each variant possesses, providing an opportunity to relate enzymatic function to clinical outcome and predict which preclinical tests would be most the appropriate next step for a given mutation. We hope to use this systematic approach as a model to enhance understanding of molecular pathogenesis in other rare diseases.

**Improved survival and amelioration of disease-related liver pathology in a mouse model of homocystinuria with a novel homocysteine degrading enzyme.** C.L. Daige<sup>1</sup>, M. Bonem<sup>2</sup>, W. Lu<sup>2</sup>, J. Wiggins<sup>1</sup>, G. Agnello<sup>1</sup>, J. Wooldridge<sup>1</sup>, G. Georgiou<sup>2</sup>, E. Stone<sup>2</sup>, S. Rowlinson<sup>1</sup>. 1) Aeglea BioTherapeutics, Austin, TX; 2) University of Texas, Austin, TX.

**Background:** Classical homocystinuria (HCU) is an inherited disorder of sulfur metabolism due to a genetic defect in cystathionine- $\beta$ -synthase (CBS). The enzyme deficiency leads to homocysteine accumulation, which plays a key role in the progressive and serious disease-related complications, including skeletal abnormalities, neuropsychiatric impairment, and thromboembolism. Current disease management, which includes dietary protein and methionine restriction, is problematic with poor compliance. We investigated the potential of an alternative approach to disease management utilizing a novel homocysteine degrading enzyme derived from human cystathionine gamma lyase (CGL). **Methods:** *In vivo* efficacy of ACN00121 was tested in a murine model of homocystinuria (CBS<sup>-/-</sup>) that presents with growth impairment and severe hepatopathy and results in 90% mortality during the first 2 weeks of neonatal life (PMID: 7878023). ACN00121 (25 mg/kg, i.p., twice per week) was administered to CBS<sup>-/-</sup> mice (supplemented with betaine through weaning) starting on post-natal day 10 until day 50. The effect of treatment on lifespan, and liver histopathology was assessed. **Results:** Untreated CBS<sup>-/-</sup> mice survived a median of 25 days and severe liver abnormalities, including marked hepatic steatosis, was observed. Treatment with ACN00121 markedly improved survival with no deaths at study termination on day 60. The reduction in mortality was accompanied by marked improvements in liver abnormalities, including resolution of the steatosis. **Discussion:** Enzymatic reduction of plasma homocysteine levels prevents neonatal death and corrects pathological liver manifestations in a homocystinuria mouse model. Given the limitations of current disease management approaches, ACN00121 warrants further investigation as a new potential treatment approach for this devastating disorder. **Disclosures:** C. Daige, G. Agnello, J. Wiggins, J. Wooldridge, and S. Rowlinson are employees of and have an equity interest in Aeglea BioTherapeutics, Inc. E. Stone and G. Georgiou have an equity interest in Aeglea BioTherapeutics, Inc. .

**20p11.2 deletions cause Hyperinsulinemic Hypoglycemia.** T.W. Laver<sup>1</sup>, W.N. Wakeling<sup>1</sup>, R. Caswell<sup>1</sup>, B. Bunce<sup>2</sup>, J.A.L. Houghton<sup>3</sup>, M. Kershaw<sup>3</sup>, V. Saraff<sup>4</sup>, E.M. Honey<sup>4</sup>, N. Murphy<sup>5</sup>, I. Banerjee<sup>6</sup>, K. Hussain<sup>7</sup>, S. Ellard<sup>1,2</sup>, S.E. Flanagan<sup>1</sup>. 1) University of Exeter Medical School, Exeter, United Kingdom; 2) Department of Molecular Genetics, Royal Devon & Exeter NHS Foundation Trust, Exeter, United Kingdom; 3) Birmingham Children's Hospital, Birmingham, United Kingdom; 4) Department of Biochemistry, Genetics and Microbiology, University of Pretoria, Pretoria, South Africa; 5) Department of Paediatric Endocrinology, Children's University Hospital, Dublin, Ireland; 6) Department of Paediatric Endocrinology, Royal Manchester Children's Hospital, United Kingdom; 7) Department of Paediatric Medicine Sidra Medical & Research Center OPC, Doha, Qatar.

Large deletions are an important cause of rare genetic disease which are often associated with syndromic disorders as a result of multiple genes being disrupted. Large deletions can provide important insights in gene discovery studies as they can act to narrow the potential list of causative genes. An example of a disease where new genetic aetiologies remain to be discovered is congenital hyperinsulinism, a disorder of unregulated insulin secretion causing severe hypoglycaemia, where screening of the known genes does not identify a mutation in 55% of patients. We screened 44 patients with permanent hyperinsulinism without a genetic diagnosis for large deletions (>100kb) using genome sequencing. We found one deletion within the cohort; this was a 3.8Mb *de novo* deletion on chromosome 20p11. We subsequently searched for 20p11 deletions using off-target reads in a cohort of 435 patients with permanent hyperinsulinism without a genetic diagnosis who had a sample sequenced by targeted next generation sequencing. We identified two further patients with an overlapping deletion on 20p11 (minimal deleted region 20:202000000-226000000). All three deletions were confirmed by digital droplet PCR (ddPCR). Two were shown to have arisen *de novo* in the proband while no parental samples were available for the third family. In all three patients ddPCR confirmed that the minimal deleted region encompasses the coding regions of seven genes and that the expression of an eighth gene, *FOXA2*, is potentially eliminated by disruption of the topologically associating regulatory domain. Three of the genes within the minimal deleted region (*NKX2-2*, *INSM1* and *FOXA2*) are known to have a role in the regulation of insulin secretion from the pancreatic beta cell. Functional studies will be required to determine which of the eight genes is causative of the hyperinsulinism in our patients. We have identified 20p11 deletions in three unrelated patients with hyperinsulinism confirming this as a novel genetic aetiology for this condition. None of our patients had been flagged for screening of deletions based on their phenotype, highlighting the utility of routinely searching for large deletions in gene discovery studies.

**982T**

**Characterization of a murine model of glycogen storage disease type VI.** Y. Lee<sup>1,3</sup>, A. Estrella<sup>1,3</sup>, D. Weinstein<sup>1,2,3</sup>, T. Chengsupanimit<sup>3</sup>, L. Brown<sup>3</sup>. 1) GSD Program, Dept. of Pediatrics, University of Connecticut School of Medicine, Farmington, CT; 2) GSD Program, Connecticut Children's Medical Center, Hartford, CT; 3) GSD Program, University of Florida College of Medicine, Gainesville, FL.

Glycogen storage disease type VI (GSD-VI, OMIM232700) is an autosomal recessive disorder caused by deficiency of liver isoform of glycogen phosphorylase (PYGL). GSD-VI patients manifest hepatomegaly, growth retardation, ketotic hypoglycemia after an overnight fast and mild hypoglycemia after prolonged fasting. The disease symptoms are relatively mild in infancy and childhood, however, severe and recurrent hypoglycemia, severe hepatomegaly, and post-prandial lactic acidosis have been described before. The affected patients have increased risk of hepatic adenoma formation in late childhood and adulthood. Corn starch therapy may prevent hepatomegaly and hypoglycemia. And the secondary complications such as short stature, delayed puberty and osteoporosis will be improved with better metabolic control. To develop therapies and investigate the detailed mechanism of the disease, we generated and characterized in detail of the phenotypes *Pygl* deficient mouse (*Pygl*<sup>-/-</sup>) model by inserting promoter driven cassette in between exon 2 and 3 of *Pygl* gene. In this study, as like affected human patients, GSD-VI mice showed mild hypoglycemia with normal growth patterns. In fasting glucose test and blood biochemistry, GSD-VI mice also showed mild hypoglycemia during fasting but with normal blood metabolites concentrations compared to wild type (*Pygl*<sup>+/+</sup>) or heterozygous (*Pygl*<sup>+/-</sup>) mice. However, histological analysis showed increased accumulation of glycogen in the liver of *Pygl*<sup>-/-</sup> mice. With continued hepatomegaly, fibrosis and fibrotic lesions were found in aged GSD-VI mouse livers. In conclusion, the *Pygl*<sup>-/-</sup> mice successfully mimic human disorder of GSD-VI. This animal model will help to understand detailed phenotypes the human disease and contribute future development of therapies.

**983F**

**An 11-year-old with lysinuric protein intolerance presenting with xanthomas, failure to thrive, and hepatic adenomas.** D.T. Segarra<sup>1,2,3</sup>, R. Bonilla-Guerrero<sup>4</sup>, K. Spence<sup>2</sup>, A. Sanchez-Valle<sup>1,2,3</sup>. 1) University of South Florida Morsani College of Medicine, Tampa, FL; 2) Department of Pediatrics, Division of Genetics and Metabolism, USF Health, Tampa, FL; 3) Tampa General Hospital, Tampa, FL; 4) Quest Diagnostics, Inc., San Juan Capistrano, CA.

**Background:** Lysinuric protein intolerance (LPI) is an autosomal recessive metabolic disorder caused by a mutation in the solute carrier gene *SCL7A7*, which leads to renal reabsorption and intestinal absorption defect of the cationic amino acids lysine, arginine, and ornithine. In infancy, this disorder typically presents with vomiting and diarrhea. Other early clinical features include stupor and/or coma after protein rich meals, poor feeding, failure to thrive, hepatomegaly/splenomegaly, and muscular hypotonia. LPI is a rare inborn error of metabolism that should be included in the evaluation of children with severe failure to thrive and other systems' involvement such as hepatic adenomas. Typical failure to thrive work-up for inborn errors of metabolism would not necessarily identify these cases, as urine amino acids analysis is not part of the usual assessment. **Objectives:** To emphasize important clinical considerations and expanded testing for failure to thrive and liver involvement. **Case description:** We present an 11-year old male referred for genetics evaluation due to hepatic adenomas and a liver biopsy suggestive of a glycogen storage disease. On evaluation, he was found to have short stature, poor appetite, failure to thrive and significant leg xanthomas. His metabolic evaluation revealed a mildly elevated ammonia of 81 (ref <49umol/L) and an increased urinary excretion of lysine and arginine suggestive of LPI. DNA analysis of the *SCL7A7* gene confirmed a homozygous deletion of exons 6-11. **Conclusions:** Although LPI is a rare metabolic disorder, it should be considered in cases of failure to thrive with multiple organ involvement. Our patient had not been diagnosed even though he had been evaluated with plasma amino acids, urine organic acids and acylcarnitine profile. Urine amino acids analysis is essential in these cases.

**984W**

**Would double heterozygotes of *SLC3A1* and *SLC7A9* pathogenic variants symptomatic for cystine stones? A perspective from population genetics and biostatistics.** C. Wu<sup>1</sup>, B. Eisner<sup>2</sup>, N. Meeks<sup>3</sup>, A. Tsai<sup>4</sup>, G. Berry<sup>4</sup>. 1) Harvard Medical School Affiliated Hospitals, Boston, MA; 2) Massachusetts General Hospital, Boston, MA; 3) University of Colorado School of Medicine, Denver/Aurora, CO; 4) Boston Children's Hospital, Boston, MA.

**INTRODUCTION AND OBJECTIVES:** Cystine stones are caused by cystinuria, the most commonly-seen inborn error of metabolism. Gene mutations at *SLC3A1* and *SLC7A9* have been mapped as the causes of the disease. The inheritance model for cystine stones is autosomal recessive. However, would double heterozygotes of *SLC3A1* and *SLC7A9* (individuals who carry both *SLC3A1* and *SLC7A9* pathogenic variants in heterozygote state) present with cystine stones? Is there a synergistic heterozygosity effect? Since the prevalence of pathogenic variants is low, the probability of direct observation of double heterozygotes is even lower. We, therefore, designed this study with genomic and biostatistics approaches to answer this question. **METHODS:** We've parsed the 1000 Genomes Database Phase 3 (1KG) for identification of variants in the general population. To identify pathogenic mutations, we parsed the Human Gene Mutation Database (HGMD). We hypothesized that double heterozygotes do not present with cystine stones. With a neutral phenotype, no symptoms, no natural selection effect, we calculated the theoretical double heterozygote frequency based on Hardy-Weinberg Equilibrium (HWE) and Mendel's Law of Independent Assortment. One-sample proportion statistical test was performed to compare observed frequency to the theoretical frequency. **RESULTS:** In 1KG, the pathogenic variants have an allele frequency of 0.52% for *SLC3A1* (q1), and 0.24% for *SLC7A9* (q2). There were no homozygotes, compound heterozygotes, double homozygotes, or double heterozygotes. Based on HWE, the theoretical pathogenic *SLC3A1* carrier rate (2p1q1) is calculated as 1.03%, and 0.48% for *SLC7A9* (2p2q2). The two genes are located on different chromosomes and will obey Mendel's Second Law. Thus the theoretical double carrier frequency (2p1q1\*2p2q2) would be  $4.94 \times 10^{-5}$ . By one-sample proportion statistical test, we compared the theoretical double heterozygote rate (2p1q1\*2p2q2) to the observed double heterozygote rate (0). Z value is 0.352, and p-Value is 0.7251. The statistical null hypothesis that two proportions are equal is not rejected. **CONCLUSIONS:** We did not find any double heterozygotes for *SLC3A1* and *SLC7A9* mutations. However, this observation is not significantly different from the theoretical frequency under the hypothesis that double heterozygotes have a neutral phenotype with no cystine stone symptoms. Therefore, statistically, double heterozygotes would be asymptomatic and do not present with cystine stone.

**985T**

**Clinical and functional characterization of Melanocortin 4 Receptor (*MC4R*) variants in African-American and Hispanic children with severe early onset obesity (SECO).** M.C. De Rosa<sup>1</sup>, A. Ches<sup>2</sup>, S. McCormack<sup>2</sup>, B. Weaver<sup>3</sup>, M. McDonald<sup>4</sup>, K. Liimatta<sup>1</sup>, M. Rosenbaum<sup>1</sup>, C. Doege<sup>1</sup>, J.N. Hirschhorn<sup>1</sup>, S. Grant<sup>2</sup>, V.V. Thaker<sup>1</sup>. 1) Columbia University Medical Center, New York, NY; 2) Children's Hospital of Philadelphia, Philadelphia, PA; 3) Boston University Medical School, Boston, MA; 4) Boston Children's Hospital, Boston, MA.

**Introduction:** *MC4R* mutations are the most common cause of monogenic obesity in children of European ancestry, with 2.5-6% prevalence. Data are limited on the prevalence of *MC4R* mutations in children with SECO in African-American and Hispanic ancestry/ethnicity. The objective of this study was to identify the prevalence of rare variants in *MC4R* in this population and perform their functional characterization. **Methods:** We assessed the prevalence of rare variants in *MC4R* in children with SECO, defined as body mass index > 120% of the 95<sup>th</sup> percentile for age, documented before age 6, and present for at least 6 months. Subjects were recruited from 3 tertiary care U.S. hospitals and identified through clinical encounters or by using a validated algorithm for identification of SECO from Electronic Health Records (PMID: 27452794). Longitudinal analysis of BMI trajectory was performed using Super Imposition by Translation and Rotation (SITAR) to generate size, tempo, and velocity estimates for individual subject (PMID: 20647267). DNA was obtained under institution approved consent from the Biobank, or in-person recruitment. *MC4R* variants were identified by whole exome or targeted Sanger analysis. For 3 novel variants, we performed functional assessment of cAMP response to its native ligand,  $\alpha$ -MSH, and measured expression by surface biotinylation assay in HEK293 cells. **Results:** Our cohort comprised of 298 children, 86% were African-American and 20% were Hispanic by self-reported ancestry/ethnicity, and 51% were female. We identified 8 individuals with heterozygous rare variants (MAF < 1%, R7S, F202L (n=2), M215I, G252A, V253I, I269N, F284I) and 15 with common variants (V103I, I198=, Q156=, I251L). Three of these were novel (M215I, G252A, F284I). In an *in vitro* system of *MC4R* overexpression in HEK293 cells, the initiation of cAMP response to  $\alpha$ -MSH required 10-fold higher concentration in M215I & G252A, and 1000-fold higher in F284I. The peak cAMP response achieved in WT protein was not seen in the tested variants with increasing concentrations of  $\alpha$ -MSH. All of the identified variants were deemed pathogenic based on our functional studies and/or prior literature reports. **Conclusions:** In our cohort of children with severe and persistent early onset obesity from underrepresented minorities, 2.7% of the children had rare, pathogenic heterozygous variants in *MC4R*. We established the pathogenic nature of 3 novel variants in *MC4R* in our cohort by *in vitro* functional studies.

## 986F

**Variation in the Apolipoprotein L1 (APOL1) gene —a search for pleiotropy beyond renal disease.** A. Ihegword<sup>1</sup>, D. Carranza-Leon<sup>1</sup>, W.Q. Wei<sup>2</sup>, L. Bastarache<sup>2</sup>, J.C. Denny<sup>2</sup>, Q. Feng<sup>3</sup>, C.M. Stein<sup>1,3</sup>. 1) Division of Clinical Pharmacology, Department of Medicine, Vanderbilt University Medical Center, Nashville, TN; 2) Department of Biomedical Informatics, Vanderbilt University Medical Center, Nashville, TN; 3) Department of Pharmacology, Vanderbilt University, Nashville, TN.

**Objective:** 1) To assess for pleiotropic clinical effects of 2 *APOL1* variants. 2) To determine if 1 *APOL1* variant imparts increased renal risk. **Background:** Risk of end stage renal disease (ESRD) is increased 3-5 fold in African Americans (AAs). Two common *APOL1* variants, G1 and G2, contribute to this disproportionate risk; ~15% of AAs carry 2 *APOL1* variants and have a marked increased risk of ESRD (OR ~7). *APOL1* protein is widely expressed and has roles in trypanolysis, autophagy and other immune mechanisms, apoptosis, anti-viral activity, and lipid biology; thus, there is substantial potential for pleiotropy. In some studies, in addition to renal risk, cardiovascular risk was increased with 2 *APOL1* variants; however, the pleiotropic clinical consequences of *APOL1* variants are undefined. Also, the risk of renal disease with 1 *APOL1* variant is unclear. **Methods:** We performed a genome wide association scan (PheWAS) to identify pleiotropic effects of G1 and G2 *APOL1* alleles in 4,960 AA patients in BioVU, a DNA biobank linked to de-identified EHR. The G1 allele (rs73885319/rs60910145) was available on standard platforms. The G2 allele was imputed using rs12106505 [in high LD ( $r^2 > 95\%$ ) with rs71785313]. Analyses were adjusted for age, body mass index, and sex. PheWAS significance was set at  $2.75 \times 10^{-5}$ . **Results:** Of 4,960 patients, 1455 (29.3%) were heterozygous and 286 (5.8%) homozygous for G1 (MAF 0.23), and for G2, 805 (16.2%) were heterozygous and 87 (1.8%) homozygous (MAF 0.14). Two *APOL1* risk alleles were present in 643 patients (13%) and 2057 (41.4%) carried neither variant. Comparing individuals with 2 risk alleles to those with 0 or 1, the top 30 consecutive PheWAS hits were all related to renal disease (e.g., dialysis (OR 3.89,  $P=4.91 \times 10^{-27}$ ), ESRD (OR 3.33,  $P=1.73 \times 10^{-16}$ ), kidney transplantation (OR 3.69,  $P=3.37 \times 10^{-16}$ ), nephritis (OR 3.02,  $P=2.45 \times 10^{-12}$ ), and chronic renal failure (OR 2.20,  $P=1.49 \times 10^{-17}$ ). There was no strong evidence of clinical pleiotropy; the strongest non-renal association was acute upper respiratory infection (OR 0.64,  $P=5.92 \times 10^{-4}$ ). Comparing G1/G0 or G2/G0 to G0/G0 individuals, no phenotypes were significant for either allele. **Conclusion:** There was a strong association between the presence of 2 *APOL1* risk alleles and renal disease, but no strong evidence for pleiotropic clinical risk. The presence of 1 *APOL1* risk allele was not associated with renal disease. .

## 987W

**Confirmation of ACER3-related recessive neurodegeneration, and preliminary evidence for feasibility of biochemistry-based ACER3 variant classification.** P. Bauer<sup>1</sup>, C. Cozma<sup>1</sup>, A.M. Bertoli-Avella<sup>1</sup>, C. Beetz<sup>1</sup>, A. Shukla<sup>2,3</sup>, N. Kamath<sup>3,4</sup>, K.M. Girisha<sup>2,3</sup>, M. Alfadhel<sup>5</sup>, K.K. Kandaswamy<sup>1</sup>, O. Paknia<sup>1</sup>, O. Brandau<sup>1</sup>, A. Rolfs<sup>1,6</sup>. 1) Centogene AG, Rostock, Germany; 2) Department of Medical Genetics, Kasturba Medical College, Manipal, India; 3) Manipal Academy of Higher Education, Manipal, India; 4) Department of Paediatrics, Kasturba Medical College, Mangalore, India; 5) Genetics Division, Department of Genetics, King Abdulaziz Medical City, Riyadh, Saudi Arabia; 6) Albrecht-Kossel-Institute for Neuroregeneration, Medical University Rostock, Rostock, Germany.

Ceramidases cleave ceramides into fatty acids and sphingosine; they are thereby important enzymatic players in lipid metabolism. *ACER3* encodes alkaline ceramidase 3, i.e. one of the five human ceramidases. Knockout of the murine homologue *Acer3* results in dysregulation of sphingosine, sphingosine-1-phosphate and various ceramides in the brain, and is associated with adult onset degeneration of Purkinje cells. In humans, the homozygous *ACER3* missense variant c.98A>G (p.Glu33Gly) was recently suggested to underlie progressive leukodystrophy in two patients from a single family. We investigated two unrelated children which had initially developed normally, but started to loose motor milestones and became underweight at around 6 months of age. Routine biochemical workup revealed lactic acidosis, and brain MRIs were suggestive of delayed myelination and diffuse cerebral atrophy. The patient from family 1 is currently 17 months old, whereas the patient from family 2 deceased at age three years. Upon whole exome sequencing and confirmatory Sanger sequencing we identified homozygous *ACER3* variants in both index cases (c.53T>C (p.Leu18Pro) in family 1; c.399delC (p.Thr133Thrfs\*6) in family 2). Consistent with findings on the *Acer3* knockout mouse, targeted blood-based metabolomics revealed elevated levels of several ceramides and dihydroceramides in the index of family 2. Interestingly, the heterozygous parents appeared to be intermediate between patient and controls in these analyses. We therefore turned to untargeted metabolomics, and compared 16 wild-type controls with 17 healthy heterozygous carriers of rare *ACER3* coding variants (absent from gnomAD or minor allele frequency of 0.0006) incl. the parents from family 2. Principal component analysis and unsupervised clustering of the metabolomics data completely separated both groups. Our study confirms *ACER3* as a novel recessive disease gene in humans, and extends the clinical and mutational spectra. Our biochemical analyses suggest that the pathogenicity of *ACER3* variants in heterozygous carriers can be predicted by metabolic profiling. An extension of this concept to other recessive metabolic and potentially even non-metabolic disorders has the potential to significantly impact on the interpretation of variants of unclear significance.

**Common genetic variation contributes to the variable expressivity of monogenic familial hypercholesterolemia.** *M.T. Oetjens, J.B. Leader, A.C. Sturm, L.K. Jones, C.L. Martin, D.H. Ledbetter on behalf of the DiscovEHR collaboration.* Geisinger, Danville, Pennsylvania, USA.

Familial Hypercholesterolemia (FH) is a genetic condition of high cholesterol that if untreated can lead to aggressive coronary artery disease. While FH is amongst the most prevalent monogenic diseases (~1:250), it remains underdiagnosed despite routine screening of cholesterol. FH exhibits variable expressivity where individuals can range from low/normal to extremely high levels of low-density lipoprotein cholesterol (LDL-C) even amongst carriers of the same genomic variant. To understand the factors that contribute to variable expressivity in FH, we tested the hypothesis that common genetic variation contributes to LDL-C levels in addition to the presence of a monogenic FH variant. In our genotype-first approach, we analyzed ~90,000 DiscovEHR individuals exome-sequenced and genotyped on whole-genome arrays, screened for FH variants, and evaluated for LDL-C polygenic risk scores (PRS<sub>LDL-C</sub>). We included all *LDLR* sequence variants identified as likely pathogenic or pathogenic (LP/P) loss-of-function variants as well as one known pathogenic exonic duplication. *LDLR* missense variants were also included if annotated in ClinVar as LP/P with a two-star review status. In total, we identified 260 individuals with pathogenic *LDLR* variants. Maximum EHR-documented LDL-C (maxLDL) was used as an approximation of the untreated state. The PRS<sub>LDL-C</sub> was calculated from 207 variants that passed genome-wide significance in an external cohort and in linkage equilibrium. Compared to non-carrier first-degree relatives (FDRs) the *LDLR* carriers' LDL-C levels were on average 88.53 mg/dL higher (44 pairs; non-carrier: mean=143.00 mg/dL, SD=41.40 mg/dL; carrier mean=231.53 mg/dL, SD= 85.29 mg/dL). When we restricted our analysis to unrelated individuals, one SD of the PRS<sub>LDL-C</sub> increased maxLDL by 22.61 mg/dL (p = 0.0019). We next applied the same approach to another monogenic FH gene, *APOB* (n=127) and did not find evidence of an association (b=-2.00 mg/dL; p=ns), suggesting a gene-specific effect of the PRS<sub>LDL-C</sub> on FH. We confirm that rare pathogenic *LDLR* variants increase LDL-C by ~2 SD and demonstrate that common variation contributes to the variability in FH expression (~0.5 SD per PRS<sub>LDL-C</sub> SD). These findings provide a potential explanation for asymptomatic monogenic FH and may provide a precision medicine approach to predicting clinical severity and CAD risk based on rare and common genetic variation.

**989F**

**Marked hypertriglyceridemia as a biochemical hallmark of familial partial lipodystrophy caused by LMNA mutations.** *L. Rutkowska, K. Salacinska, I. Pinkier, D. Salachna, L. Jakubowski, A. Gach.* Polish Mother's Memorial Hospital Research Institute, Department of Genetics, Lodz, Poland.

Familial partial lipodystrophy (FPL; MIM 150330) is a rare AD transmitted disorder mostly caused by mutation in *LMNA* gene, located on the long arm of chromosome 1. The *LMNA* gene (MIM 151660) encodes lamin A and lamin C proteins providing integrity of cell membranes. Typical clinical features in patients with FPL are excessive subcutaneous fat accumulation in the neck and face, reduced subcutaneous fat in the arms and legs and muscular definition with variable muscular hypertrophy and prominent superficial veins. The extent of adipose tissue loss usually determines the severity of the associated metabolic complications such as hyperglycemia, hyperinsulinemia, diabetes mellitus, increased serum triglycerides, hepatic steatosis, pancreatitis, high blood pressure, and premature atherosclerosis with an increased risk of coronary heart disease. What's more, after puberty some women may develop polycystic ovary syndrome (PCOS). A group of 60 patients with familial atherogenic dyslipidemia were tested using custom NGS panel. In two patients R482Q alteration in *LMNA* gene was found. We have analysed genotype-phenotype correlation in affected family members in 2 generations. The two probands were referred for genetic counselling due to history of infertility and atypical adipose tissue distribution. Medical history of 36-year old woman and 30-year old woman, showed severe hypertriglyceridemia, PCOS and insulin resistance with diabetes mellitus and impaired glucose tolerance, respectively. Detection of a heterozygous missense mutation at codon 482 c.1444C>T in *LMNA* gene, confirmed the diagnosis of FLPD2. In the Family 1 study revealed presence of FLPD2 in 8 family members in two generations. In Family 2 *LMNA* mutation was confirmed in proband's mother. Interestingly, most of them did not demonstrate phenotype as evident as the probands. The only common feature, shared by all affected family members was significant hypertriglyceridemia ranging 400-580 mg/dl. Spectrum of other clinical problems was wide, but we observed strong variation in the feature severity and distribution. To conclude, it is great diagnostic challenge to identify FPL patients, in terms of clinical diagnosis and qualification for molecular diagnostic, based on abnormal fat distribution and other physical features, especially in men. It seems to be that only common symptom is severe hypertriglyceridemia, therefore it is reasonable to diagnose the patient, with very high triglycerides level, for FPL.

**AAV8-mediated hLDLR gene transfer in patients with homozygous familial hypercholesterolemia: Interim analysis of the safety profile in the first 6 subjects.** M. Cuchel<sup>1</sup>, R. Carr<sup>1</sup>, A. Bajaj<sup>1</sup>, C. Brent<sup>1</sup>, P.B. Duell<sup>1</sup>, J.C. Tardif<sup>1</sup>, M. Linton<sup>2</sup>, R. Fiorentino<sup>3</sup>, S. Yoo<sup>3</sup>, E.A. Meagher<sup>4</sup>, D.J. Rader<sup>5</sup>. 1) Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; 2) Oregon Health and Science University, Portland, OR; 3) Montreal Heart Institute, Montreal, Quebec; 4) Vanderbilt University, Nashville, TN; 5) Regenxbio, Rockville, MD.

AAV-based vectors are emerging as an effective tool for gene transfer targeting the liver. Bi-allelic mutations in the LDL receptor (*LDLR*) gene are the most common cause of Homozygous Familial Hypercholesterolemia (HoFH), which is characterized by markedly elevated cholesterol levels and early atherosclerotic cardiovascular disease. Reconstituting functional *LDLR* in the liver may be a valuable treatment strategy. We are conducting a first-in-human trial of AAV8-mediated *hLDLR* gene transfer in HoFH subjects with documented *LDLR* mutations. We enrolled 6 subjects, 3 subjects in each of 2 dosing cohorts that received a single IV administration at the doses of  $2.5 \times 10^{12}$  GC/kg and  $7.5 \times 10^{12}$  GC/kg respectively. Weekly blood sampling was performed during the first 12 weeks, followed by further safety assessment up to 52 weeks post-vector administration. One subject who received the lower dose experienced a mild transitory activation of the innate immune system accompanied by hypotension and elevation in transaminases approximately 22 hours post dosing that resolved within a day. All three subjects who received the higher dose experienced an elevation in transaminases 4-6 weeks post-dosing. The peak ALTs were 165, 331, and 1496 IU/L in the 3 subjects (normal range: 6-41 IU/L). All 3 subjects were asymptomatic and responded rapidly to the initiation of prednisone at 60 mg/day followed by a slow taper. A sustained transgene expression has been observed in AAV-mediated gene transfer trials in hemophilia, and could be preserved by the administration of steroids after mild to moderate increases in transaminases observed in some subjects that were attributed to a T-cell response. Similarly, a T-cell response is likely to be the cause of the transaminases elevations observed in the 3 subjects that received the higher dose of the AAV8-*hLDLR* vector. However, the earlier timeframe and the degree of the elevation were unexpected, suggesting that HoFH phenotype or the *LDLR* transgene may alter the immunological response following AAV vector administration. Our ability to assess short-term efficacy on LDL-C levels is confounded by the hepatocyte injury and the steroid therapy. These results highlight the need to further our understanding of the host response of HoFH patients to the administration of AAV-based vectors and provide insights for a more appropriate design to evaluate the safety and efficacy of AAV8-*hLDLR* gene therapy in HoFH patients.

**Genetic and dietary manipulation of stearate levels rescues a model of retinal degeneration and ER stress.** R.A.S. Palu, C.Y. Chow. Human Genetics, University of Utah School of Medicine, Salt Lake City, UT.

An important goal of the Precision Medicine Initiative is to address the phenotypic heterogeneity that impedes diagnosis and treatment in both Mendelian and complex genetic diseases. Cryptic genetic variation is a key contributor to this heterogeneity, but the underlying genetic architecture and modifiers are largely unknown. Understanding the roles of genetic modifiers in disease processes will enable the development of individualized therapeutic approaches. One process that commonly contributes to phenotypic heterogeneity is the ER stress response. In a previous study, we utilized the *Drosophila* Genetic Reference Panel, a collection of ~200 genetically diverse and fully sequenced fly lines, to study the effects of natural genetic variation on a model of ER stress-associated retinal degeneration. Overexpression of a mutant, misfolded rhodopsin protein (*Rh1<sup>G69D</sup>*) induces ER stress in the developing eye, ultimately resulting in apoptosis and a small, degenerate adult eye that is incredibly variable among DGRP strains. Using genome-wide association methods, we identified 84 conserved candidate modifiers, many of which are associated with ER stress and apoptosis. One of these, *ELOVL6*, is an ER-associated fatty acid elongase that extends palmitate to stearate. Both *ELOVL6* activity and high stearate concentrations have been linked to ER stress, insulin sensitivity, and obesity in mammals. We demonstrate that loss of *ELOVL6* activity rescues cell death and retinal degeneration by reducing activation of the IRE1 and PERK branches of the ER stress response and JNK pro-apoptotic signaling in the *Rh1<sup>G69D</sup>* model. Loss of *ELOVL6* in other tissues and cell types reduces ER stress and cell death in a similar manner, suggesting that *ELOVL6* is a general modifier of ER stress. Intriguingly, we find that administering dietary stearate during development is sufficient to increase degeneration and ER stress signaling, bypassing the need for *ELOVL6*. This suggests that *ELOVL6* regulates the ER stress response by controlling stearate concentration. These results raise the possibility that reducing *ELOVL6* function or stearate levels genetically, with small molecules, or through the diet could be a useful therapy that reduces ER stress signaling. Our findings suggest that *ELOVL6* is a general modifier of the ER stress response and a possible therapeutic target not only in retinal degeneration, but in many ER stress-associated diseases.

**The human transcriptional profile of Berardinelli-Seip congenital lipodystrophy.** L.C. Ferreira<sup>1,2,3</sup>, J.G. Lima<sup>1,4</sup>, F.P. Freire-Neto<sup>1,2,3</sup>, C.O. Mendes-Aguilar<sup>1,3</sup>, S.M.B. Jeronimo<sup>1,2,3</sup>. 1) Federal University of Rio Grande do Norte, Natal, Brazil; 2) Department of Biochemistry; 3) Institute of Tropical Medicine of Rio Grande do Norte; 4) Department of Clinical Medicine.

Mutations in *AGPAT2* (1-acylglycerol-3-phosphate O-acyltransferase 2) and *BSCL2* (codes for seipin protein) are the main cause of Berardinelli-Seip syndrome, a rare autosomal recessive disorder. *AGPAT2* catalyzes the reaction that produces phosphatidic acid, while seipin is a structural protein involved with lipid droplet biogenesis. The syndrome comprises complex metabolic disarrangement characterized by insulin resistance and diabetes. Of note, only *BSCL2*-affected individuals develop cognitive and intellectual disabilities. The mechanism linking genetic mutations to the clinical symptoms is still unsolved. This study aimed to compare the transcriptional profile in peripheral blood mononuclear cells (PBMC) from 23 individuals, grouped as: wild type control (WT, n=3); heterozygous for *BSCL2* mutation (*BSCL2*het, n=6); homozygous for *BSCL2* mutation (*BSCL2*mut, n=11) and homozygous for *AGPAT2* mutation (*AGPAT2*mut, n=3). All comparisons were performed using WT as the reference group. It was detected 28 differentially expressed genes (DEG) in *BSCL2*mut, with *NUAK2* as the top1. This finding is consistent with the notable hypertrophy in these patients, since *NUAK2* is a key regulator of muscle mass. Surprisingly, the unaffected *BSCL2*het group had 68 DEG. No gene achieved the genome wide significance threshold for comparison WT vs *AGPAT2*mut. Gene set enrichment analysis revealed key pathways for energy metabolism (Glycolysis, Krebs' Cycle and Oxidative Phosphorylation) and neurodegenerative diseases (Alzheimer's, Huntington and Parkinson's diseases) as enriched in *BSCL2*mut while *BSCL2*het individuals presented a remarkable inflammatory signature including the up-regulation of genes *IL1R2*, *CXCL1*, *IL8RB* and *IL8* ( $P_{adj} < 0.05$ ). In addition, potential candidate genes for cardiovascular (*OLR1*,  $\log_2FC = 2.55$ ,  $P_{adj} = 0.00048$ ) and neurodegenerative (*TOR4A*,  $\log_2FC = 1.75$ ,  $P_{adj} = 0.033$ ; *KIF5C*,  $\log_2FC = -1.28$ ,  $P_{adj} = 0.045$ ; and *ACTG1*,  $\log_2FC = 0.88$ ,  $P_{adj} = 0.048$ ) diseases were differentially expressed in *BSCL2*het and *BSCL2*mut, respectively. A better understanding about the molecular mechanism of Berardinelli syndrome may shed light into our current knowledge concerning diseases such as atherosclerosis and Alzheimer.

**993W**

**Distinguishing between monogenic and polygenic inheritance of extreme phenotype: Quantifying the value of family history in cases of extreme LDL-C.** O. Soylemez<sup>1,2,3</sup>, Z. Ahmad<sup>4,5</sup>, S. Sunyaev<sup>1,2,3</sup>. 1) Brigham and Women's Hospital, Boston, MA; 2) Harvard Medical School, Boston, MA; 3) Broad Institute, Cambridge, MA; 4) Division of Nutrition and Metabolic Diseases, Center for Human Nutrition, UT Southwestern Medical Center, Dallas, TX; 5) Department of Internal Medicine, UT Southwestern Medical Center, Dallas, TX.

Extreme values of quantitative traits or rare severe phenotypic presentations can be caused by individual mutations of very large effects segregating in Mendelian fashion. Alternatively, such phenotypes may reflect extremes of polygenic or oligogenic genetic inheritance. Beyond importance for basic genetics, this distinction is practically important for the design of genetic studies that can follow either Mendelian or complex trait paradigm. Currently, sequencing studies of rare phenotypes attribute only a fraction of cases to an obvious monogenic cause. Frequently, individuals with extreme phenotype have family members with milder presentation. Thus, it is expected that family history is informative about genetic architecture of severe phenotypes. We investigated this hypothesis in a series of population genetics computer simulations and the analysis of cases of severe familial hypercholesterolemia (FH). Recent work on FH in patients without known causative mutations in *LDLR*, *APOB* and *PCSK9* suggests that a large fraction of such cases may be attributed to polygenic inheritance whereby a large number of small-effect mutations collectively result in extreme LDL-C levels that are comparable to levels in patients with monogenic FH. It remains unclear to what extent the family history is informative to distinguish monogenic and polygenic FH patients with extreme LDL-C levels. We developed a population genetics framework to simulate families of individuals with extreme LDL-C levels and calculated the fraction of monogenic FH cases conditional on population genetics parameters (effect size distribution of FH mutations, demographic history), varying penetrance, and pedigree structure. Our simulation results show that the fraction of monogenic FH in patients with extreme LDL-C levels increases when the mutation's effect on LDL-C level and its selective effect are tightly coupled and decreases when the mutational target size is highly polygenic including hundreds of genes. Furthermore, we show that the family history is informative only for sufficiently large pedigrees. We applied our framework to real pedigrees that are clinically ascertained to have autosomal dominant FH with no causative mutations, and corroborated our simulation results. These findings have significant implications for study design of rare and unexplained genetic conditions as well as genetic testing strategies for new gene discovery, prevention and treatment of cardiovascular diseases.

**994T**

**10-year experience with identification of cerebrotendinous xanthomatosis in newborns in Northern Israel; newborn screening followed by treatment from birth onward provides a “functional cure”.** *T.C. Falik-Zaccari<sup>1,2</sup>, A.E. DeBarber<sup>3</sup>, M. Yusim<sup>2</sup>, S.B. Haroush<sup>1</sup>, N. Chasnyk<sup>1</sup>, N. Samra<sup>4</sup>, L. Even<sup>5</sup>, B. Higazi<sup>2</sup>, N. Kfir<sup>1,2</sup>, D. Savitzki<sup>6</sup>, A. Fedida<sup>1,2</sup>, V.F. Sheffer<sup>7</sup>, H. Mandel<sup>8</sup>, E.S. Shinwell<sup>8</sup>, L. Kalfon<sup>8</sup>. 1) Institute of Human Genetics Galilee Medical Center Naharia, 22100, Israel; 2) The Azrieli Faculty of Medicine, Bar Ilan University, Safed, Israel; 3) Physiology & Pharmacology Department, Oregon Health & Science University (OHSU), Portland, OR; 4) Unit of Medical Genetics, Ziv Medical Center, Safed, Israel; 5) Department of Pediatrics and pediatric endocrinology, The Galilee Medical Center, Naharia, Israel; 6) Pediatric Neurology unit, The Galilee Medical Center, Naharia, Israel; 7) Department of Neonatology, Galilee Medical Center, Naharia, Israel; 8) Department of Neonatology, Ziv Medical Center, Tzfat, Israel.*

Cerebrotendinous Xanthomatosis (CTX), an autosomal recessive disorder of bile acid synthesis manifested by progressive multisystem damage, is rare worldwide but highly prevalent among several populations in Israel. Disease progression may be fully prevented by treatment with bile acids but when diagnosis is delayed neurodegeneration is not readily reversed by treatment. We describe our experience in Northern Israel performing population screening for CTX in one Druze village and performing biochemical screening for CTX in a high-risk newborn population. We genetically screened the child-bearing age population in an isolated Druze village for carriers of a pathogenic c.355delC founder genetic variant in the *CYP27A1* gene, ascertaining couples at risk and providing the option of genetic counseling and prenatal diagnosis. We then tested newborns and their siblings for this variant, providing 2-12 year follow-up and treatment for affected newborns and siblings identified. We recently expanded our screening program to perform screening for CTX in a high-risk newborn population. Newborn dried bloodspots obtained were subject to biochemical testing for CTX. Ten percent of samples consecutively collected were analyzed to identify CTX-causing founder genetic variants common among Druze and Moroccan Jewish populations. For individuals residing in the isolated Druze village a carrier rate for the c.355delC genetic variant of 1:7 was determined, leading to an estimated disease prevalence of 1:400. For Druze newborns from different villages born at local hospitals and screened for CTX a carrier rate of 1:17 was determined for the c.355delC genetic variant leading to an estimated disease prevalence of 1:1,200 in this newborn population. Five affected neonates born in the isolated Druze village were identified. Four were treated with chenodeoxycholic acid from age 1 month onward. One newborn was treated with cholic acid. Clinical outcomes were significantly improved for patients treated from infancy, with normal growth and no neurological symptoms, compared to six patients diagnosed and treated between ages 2-14. Our results validate prenatal diagnosis and newborn screening for CTX, and define pre-symptomatic treatment with bile acids as a functional cure preventing its common symptoms in childhood. The newborn screening pilot study data supports the feasibility of screening newborn dried bloodspots for CTX, setting the stage for large-scale prospective pilot studies.

**Homozygous mutation in *USP43*, a deubiquitinase gene, is linked to a novel interferon-mediated autoinflammatory disease.** *I. Aksentijevich, H. Wang, D. Beck, D.L. Kastner.* National Human Genome Research Institute, Bethesda, MD.

Autoinflammatory diseases are a distinct group of rheumatologic diseases that are driven by abnormal activation of the innate immune system leading to recurrent episodes of systemic inflammation and a broad spectrum of other comorbidities. Autoinflammatory diseases are caused by dysregulation in critical immune regulatory complexes such as inflammasomes, cytokine receptors or inhibitors, enzymes, and proteasome complex. The excessive secretion of inflammatory cytokines can lead to chronic and debilitating phenotypes and may be life-threatening. These disorders are particularly amenable to treatment with targeted biologic agents such as cytokine inhibitors. Here, we report a patient from a founder population who presented with early-onset recurrent fevers, rash, subcutaneous nodules, lipodystrophy, and arthritis suggestive of CANDLE (Chronic Atypical Neutrophilic Dermatitis with Lipodystrophy and Elevated Temperature) syndrome. Based on the phenotypic similarities with CANDLE, we suspected that the patient might have an interferon-mediated disease. We found an upregulated type I interferon gene expression signature in peripheral blood, high basal levels of phospho-STAT1 in IFN $\alpha$ -stimulated PBMCs, and increased production of many inflammatory cytokines in serum and supernatants of stimulated primary cells. Similar to CANDLE, proteasome activities, especially the chymotrypsin activity, were significantly reduced in patient's EBV-B cells. After failing to identify mutations in genes associated with CANDLE, WES was performed and identified a novel predicted deleterious homozygous candidate variant within a poorly characterized deubiquitinase, *USP43* (p.G837K), present only in the proband. Deubiquitinases catalyze removal of ubiquitin chains from target proteins, many of which are marked for proteasome-mediated protein degradation. Analysis of stimulated patient's EBV-B cells and fibroblasts, or 293T cells depleted of *USP43*, led to increased levels of intracellular ubiquitinated (Ub) proteins, and this cellular phenotype was rescued by transfection of wild-type *USP43*. TNF-stimulated fibroblasts displayed higher levels of K48 ubiquitin chains, which suggests a dysregulation in proteasome function. The patient has responded well to treatment with JAK inhibitors that are known to ameliorate interferon-mediated diseases. Thus, mutations in *USP43* lead to a novel interferonopathy and *USP43* may function as a novel regulator of proteasome assembly.

Hornig-Do<sup>15</sup>, Z. Chrzanowska-Lightowlers<sup>15</sup>, K.J. Moore<sup>14</sup>, A.M. Cuervo<sup>13</sup>, A.R. Concepcion<sup>2</sup>, S. Feske<sup>2</sup>. 1) University Hospital Centre Zagreb, Zagreb, Croatia; 2) University of Zagreb School of Medicine, Zagreb, Croatia; 3) New York University School of Medicine, New York, USA; 4) The Jackson Laboratory for Genomic Medicine, Framington, USA; 5) INSERM UMR Laboratory of the Immunogenetics of Pediatric Autoimmune Diseases, Paris, France; 6) INSERM UMR Imagine Institute, Paris Descartes-Sorbonne, Paris Cite University, Paris, France; 7) The Study Center for Primary Immunodeficiencies, Necker-Enfants Malades Hospital, Necker Medical School, Paris, France; 8) Schulich School of Medicine and Dentistry, Western University London, London, United Kingdom; 9) ImmunoGenes, Budapest, Hungary; 10) Center for Pediatrics, University of Freiburg, Freiburg, Germany; 11) Center for Chronic Immunodeficiency, Medical Centre, University of Freiburg, Freiburg, Germany; 12) Dalhousie University, Halifax, New Scotia, Canada; 13) Department of Developmental and Molecular Biology, Albert Einstein College of Medicine, Bronx, NY 10461, USA; 14) Department of Medicine, New York University School of Medicine, New York, NY 10016, USA; 15) Wellcome Trust Centre for Mitochondrial Research, Institute of Neuroscience, Newcastle University, Newcastle upon Tyne NE2 4HH, UK.

We present 4 patients with EDA-ID, autoimmunity, myopathy, mitochondrial dysfunction and disturbed lipid metabolism caused by novel *null* mutations in *ORA11* (p.V181SfsX8, p.L194P, p.G98R) and abolished Store-Operated Ca<sup>2+</sup> Entry (SOCE). Patients had dry and exfoliate skin, thin and fragile hair, enamel defects, attacks of facial flushing, tachycardia, tachypnea and hypertension, anhidrosis with heat intolerance due to Ca<sup>2+</sup>-activated chloride channel TME-M16A dysfunction suggesting that SOCE is important for eccrine sweat glands function. Patients were prone to infections, especially with viruses (CMV, EBV, RSV, rotavirus). SOCE defects were associated with T cell dysfunction and reduced numbers of invariant NK T cells and regulatory FOXP3<sup>+</sup> Treg cells, and altered composition of  $\gamma\delta$  T cell and NK cell subsets. Patients had lymphadenopathy, hepatosplenomegaly, autoimmune-mediated pancytopenia and antiphospholipid syndrome, loss of naive CD45RA<sup>+</sup> T cells and concomitant expansion of CD45RO<sup>+</sup> or HLA-DR<sup>+</sup> activated T cells. Patients also had reduced numbers of CD25<sup>+</sup>FOXP3<sup>+</sup> Treg cells suggesting that SOCE is required for immunological tolerance. At the cellular level, we observed dysmorphic and dysfunctional mitochondria in cells of SOCE-deficient patients that were characterized by reduced mitochondrial volume and abnormal cristae structure, reduced expression of mitochondrial proteins, increased basal mitochondrial membrane potential but decreased electron and proton transport and superoxide production. Furthermore, we found reduced free fatty acid oxidation and decreased expression of neutral lipases, resulting in accumulation of lipid droplets in cells of SOCE deficient patients. Collectively these findings demonstrate severe mitochondrial dysfunction in the absence of SOCE, which likely contributes to the myopathy, EDA and immunodeficiency in our patients. The characterization of the pathophysiological mechanisms underlying EDA-ID contributes to the early recognition of these patients and potential new treatment options such as mitochondrial cocktail and regulated diet providing more favorable outcomes.

## 997T

**A severe case of Aicardi-Goutières Syndrome-7 with novel pathogenic variant in IFIH1.** T. Kaname<sup>1</sup>, S. Amari<sup>2</sup>, M. Iso<sup>1</sup>, K. Hata<sup>3</sup>, K. Okamura<sup>4</sup>, N. Kobayashi<sup>1</sup>, K. Yanagi<sup>1</sup>, A. Ishiguro<sup>5</sup>, Y. Matsubara<sup>6</sup>. 1) Genome Medicine, National Center for Child Health and Development (NCCHD), Tokyo, Tokyo, Japan; 2) Neonatology, NCCHD, Tokyo, Tokyo, Japan; 3) Maternal-Fetal Biology, NCCHD, Tokyo, Tokyo, Japan; 4) Systems Biomedicine, NCCHD, Tokyo, Tokyo, Japan; 5) Hematology, NCCHD, Tokyo, Tokyo, Japan; 6) Research Institute, NCCHD, Tokyo, Tokyo, Japan.

Aicardi-Goutières syndrome (AGS) is a rare inflammatory disorder characterized by early onset encephalopathy and neurologic impairment. Till now, up to the present seven different subtypes of causative genes are known. Type 7 (AGS 7) presents with delayed psychomotor development, axial hypotonia, spasticity and brain imaging abnormalities, and is milder than other subtypes. Here we report a very severe case of AGS 7 who had fetal dysfunction and died of 3 months after birth with a combination of prolonged anemia and thrombocytopenia after birth. The patient was pointed out fetal heart expansion and significant pericardial fluid at 29 weeks of pregnancy, was diagnosed as fetal dysfunction together with Non-Stress Test, and was delivered by emergency caesarean section. After birth he showed symptoms of severe inflammation. There was no obvious calcified lesion in the brain by ultra sound but Lenticulostriate vasculopathy was observed. Neither Toxoplasma, parvovirus, rubella virus, cytomegalovirus, or herpes simplex virus was detected in the blood by PCR. Platelet transfusion almost every day since birth, nearly every day from the birth two days after birth required red blood cell transfusion due to severe inflammation. The effect of dexamethasone and vasodilator administration to him was not enough and he died of three month after birth. Whole exome analysis with trio was performed using the SureSelect Human All Exon V6 kit for capturing and a HiSeq2500 for sequencing with 101-bp paired-end reads. Then, a novel variant of the IFIH1 gene, NM\_022168:c. A2439T:p.E813D, was found in the patient. The variant was validated by Sanger sequencing and was *de novo*. The variant is at the Helicase domain and is predicted as disease causing by PolyPhen-2, SIFT, and mutation tasting software. We concluded that AGS 7 might have a phenotypic heterogeneity from mild case to severe case.

**Beyond whole exome sequencing--molecular diagnosis for patients of primary immunodeficiency diseases who failed to have causal mutations identified after whole exome sequencing approach.** J. Yang, W. Yang, P.P.W. Lee, Y.L. Lau. University of Hong Kong, Hong Kong, China.

Eighty-eight primary immunodeficiency diseases (PID) patients who have gone through whole exome sequencing (WES) but failed to have causal mutations identified are reexamined through systematic reanalysis of WES data, resequencing on the most updated PID genes with whole gene coverage, whole genome sequencing and RNA-seq, as well as PID-specific algorithms on data analysis. WES data are reevaluated to reflect the newest understanding on PID diagnosis and modified strategies. For those still without definitive diagnosis, a PID gene panel are designed and captured in their entirety, followed by deep sequencing to increase sensitivity. A data analysis algorithm is also being developed, which considers sequence specificities of each PID gene. For those still being negative on causal mutations, whole genome sequencing and/or RNA-seq are applied. Functional annotations and analysis algorithms are developed to help identify novel PID genes, making use of information such as immune related functions, protein interaction with known PID genes, phenotypes in animal models, expression and pathway analysis, and regulation patterns based on ENCODE data. These approaches are currently evaluated in terms of potential increase in detection sensitivity for PID patients who failed WES.

**A novel CYCS mutation in the  $\alpha$ -helix of the CYCS C-terminal domain causes non-syndromic thrombocytopenia.** Y. Uchiyama<sup>1,2</sup>, K. Yanagisawa<sup>3</sup>, S. Kunishima<sup>4</sup>, M. Shiina<sup>5</sup>, Y. Ogawa<sup>3</sup>, M. Nakashima<sup>1,6</sup>, S. Miyatake<sup>1</sup>, S. Mitsuhashi<sup>1</sup>, A. Takata<sup>1</sup>, N. Miyake<sup>1</sup>, K. Ogata<sup>5</sup>, H. Handa<sup>3</sup>, N. Matsumoto<sup>1</sup>, T. Mizuguchi<sup>1</sup>. 1) Department of Human Genetics, Yokohama City University Graduate School of Medicine, Yokohama, Kanagawa, Japan; 2) Department of Oncology, Yokohama City University Graduate School of Medicine, Yokohama, Japan; 3) Department of Hematology, Gunma University Graduate School of Medicine, Gunma, Japan; 4) Department of Medical Technology, Gifu University of Medical Science, Seki, Japan; 5) Department of Biochemistry, Yokohama City University Graduate School of Medicine, Yokohama, Japan; 6) Department of Biochemistry, Hamamatsu University School of Medicine, Hamamatsu, Japan.

We report a patient with thrombocytopenia from a Japanese family with hemophilia A spanning four generations. Various etiologies of thrombocytopenia, including genetic, immunological, and hematopoietic abnormalities, determine the prognosis for this disease. In this study, we identified a novel heterozygous mutation in a gene encoding cytochrome c, somatic (CYCS, MIM123970) using whole exome sequencing. This variant (c.301\_303del:p.Lys101del) is located in the  $\alpha$ -helix of the cytochrome c (CYCS) C-terminal domain. *In silico* structural analysis suggested that this mutation results in protein folding instability. CYCS is one of the key factors regulating the intrinsic apoptotic pathway and the mitochondrial respiratory chain. Using the yeast model system, we clearly demonstrated that this one amino acid deletion (in-frame) resulted in significantly reduced cytochrome c protein expression and functional defects in the mitochondrial respiratory chain, indicating that the loss of function of cytochrome c underlies thrombocytopenia. The clinical features of known CYCS variants have been reported to be confined to mild or asymptomatic thrombocytopenia, as was observed for the patient in our study. This study clearly demonstrates that thrombocytopenia can result from CYCS loss-of-function variants.

Smejkal<sup>4</sup>, J. Gumulec<sup>5</sup>, V. Fiamolj<sup>6</sup>, S. Pospisilova<sup>1,2</sup>, M. Doubek<sup>1,2</sup>.* 1) Central European Institute of Technology (CEITEC), Masaryk University, Brno, Czech Republic; 2) Department of Internal Medicine, Hematology and Oncology, University Hospital and Faculty of Medicine, Brno, Czech Republic; 3) Department of Hematologic Oncology, University Hospital and Palacký University, Olomouc, Czech Republic; 4) Department of Clinical Hematology, University Hospital, Brno, Czech Republic; 5) Department of Hematologic Oncology, University Hospital, Ostrava, Czech Republic; 6) Department of Pediatric Hematology, University Hospital, Brno, Czech Republic.

Inherited thrombocytopenias (IT) are a heterogeneous group of rare disorders. To date, forty genes have been described as being associated with IT. Pathogenic variants in these genes usually lead to the disruption of megakaryopoietic and thrombopoietic processes and present as the thrombocytopenia phenotype. Patients are occasionally misdiagnosed with the more common idiopathic thrombocytopenic purpura and unsuccessfully treated with steroid therapy and splenectomy. Additionally, IT patients are often identified incidentally during blood examination in adulthood, due to the absence of spontaneous or life-threatening bleeding that is a usual characteristic of IT. In some patients, accurate diagnosis of IT can only be established based on the results of molecular genetic testing. In our patient cohort, we identified four families with at least two thrombocytopenia patients. Proband from two of the families presented with macrothrombocytopenia and probands from the other two families presented with normal platelet size and volume; one of them had hematological disease in their medical history. Germline DNA analysis was performed on all available samples and somatic DNA analysis was done for the oncological patient. Sequencing libraries were prepared according to the NimblegenSeqCap EZ Exome v3 protocol and sequencing was performed on NextSeq500. Within each family, the obtained variants were compared between the individuals with thrombocytopenia phenotype and their disease-free relatives. Using Exome sequencing, we identified a unique variant segregating with thrombocytopenia phenotype for each of the four families: *GP1BA*:NM\_000173 exon2:c.176T>G:p.L59R and exon2:c.98G>A:p.C33Y, *CYCS*:NM\_018947 exon2:c.59C>T:p.T20I and *RUNX1*:NM\_001754 exon8:c.866delG:p.G289fs. *In silico* analysis revealed a structural defect of amino acid changes found in the protein structures, indicating that all of the variants are likely pathogenic. We identified a causal variant for each of the families analysed. Accurate diagnosis of IT would allow clinicians to conduct further examinations if the identified variant poses additional risk to the carrier, i.e., a higher risk of oncological disorders. Thus, patients could receive appropriate treatment and avoid the unnecessary side effects from long-term interventions such as steroids and splenectomy. The research was done according to the Declaration of Helsinki. Supported by Ministry of Health of the Czech Republic, grant No 16-29447A.

**1001F****Genetics and pathogenesis of familial multiple sclerosis. C. Vilari-**

*no-Guell<sup>1</sup>, M. Encarnacion<sup>1</sup>, C. Bernales<sup>1</sup>, I. Yee<sup>1</sup>, M. Criscuoli<sup>1</sup>, A. Traboulsee<sup>2</sup>, Z. Wang<sup>3</sup>, B. Herculano<sup>3</sup>, W. Song<sup>3</sup>, A. Zimprich<sup>4</sup>, E. Reinthaler<sup>5</sup>, A. Deuschländer<sup>6</sup>, A.D. Sadovnick<sup>1,2</sup>.* 1) University of British Columbia, Vancouver, BC, Canada; 2) Division of Neurology, Faculty of Medicine, University of British Columbia, Vancouver, Canada; 3) Townsend Family Laboratories, Department of Psychiatry, University of British Columbia, Vancouver, Canada; 4) Department of Neurology, Medical University of Vienna, 1090 Austria; 5) Department of Neurology, Department of Clinical Genomics, and Department of Neuroscience, Mayo Clinic Florida, USA.

**Background:** Multiple sclerosis (MS) is an inflammatory autoimmune disease of the central nervous system characterized by myelin loss and neuronal dysfunction. Although the majority of patients do not present a family history of MS, the prevalence of familial aggregation has been estimated at 12.6% globally. Mutations identified in families are likely to account for the highest attributable risk towards disease, and provide a better understanding of the biological processes underlying the genesis of MS. This is critical for the development of therapeutic options addressing the cause of disease, in addition to managing the clinical symptoms, as currently available treatments primarily target inflammatory components and have a modest impact on disease progression. **Methods:** We implemented whole-exome sequencing (WES) in 132 MS patients from 34 families for the identification of disease-causing mutations. Candidate variants were assessed for co-segregation with MS within families, and genotyped in a large multi-ethnic cohort that includes over 13,000 samples from 2,054 MS families, to confirm pathogenicity. **Results:** WES analysis of MS families identified 12 mutations co-segregating with disease in genes of the fibrinolysis and complement pathways (*PLAU*, *MASP1*, *C2*), inflammasome assembly (*NLRP12*), Wnt signaling (*UBR2*, *CTNNA3*, *NFATC2*, *RNF213*), nuclear receptor complexes (*NCOA3*), and cation channels and exchangers (*KCNG4*, *SLC24A6*, *SLC8B1*). Biological characterization of these mutations suggest a disruption of interconnected innate immunity and pro-inflammatory pathways as the initial events in the pathophysiology of familial MS. **Conclusions:** Our data demonstrates the existence of Mendelian forms of MS, which can be attributed to a single mutation of major effect that is largely responsible for the onset of MS and its transmission across generations. The genes identified in this study play critical roles in cellular cation homeostasis, and the regulation of transcription and activation of inflammatory mediators; suggesting a disruption of the innate immune system as the biological mechanism of disease. Identified mutations highlight targets for therapeutic development, and provide the foundations for the generation of cellular and animal models based on human genetic etiology in which to assess their efficacy. In addition, screening for these mutations in MS patients and healthy family members can be used for disease confirmation, risk prediction and prognosis.

**Expedited whole exome sequencing diagnoses activated PI3K-delta syndrome-1 in an infant presenting with chronic diarrhea.** *J.P. Schacht<sup>1</sup>, C. Umandap<sup>1</sup>, A. Carey<sup>2</sup>, A. Iglesias<sup>2</sup>.* 1) Department of Pediatrics, Division of Clinical Genetics, Columbia University Medical Center, New York City, NY; 2) Department of Pediatrics, Division of Pediatric Critical Care Medicine, Columbia University Medical Center, New York City, NY.

**Introduction:** Chronic diarrhea presents a diagnostic challenge due to the robust differential diagnosis. Diagnosis of rare etiologies frequently involves time consuming and invasive approaches including endoscopy and biopsy, which may be nondiagnostic, or difficult to implement in acutely ill patients. Expedited whole exome sequencing (WES) may be a more feasible diagnostic tool. We present a case of an infant presenting with chronic diarrhea diagnosed with activated PI3K-delta syndrome-1 via expedited WES. **Case Description:** A 36 day old ex full term male presented with a one day history of fever, and worsening of chronic diarrhea since birth. Initial exam was notable for a nondysmorphic infant with respiratory distress, sunken fontanel, and height, weight, and head circumference all less than the 5<sup>th</sup> centile. Initial labs showed hyperchloremic, hypernatremic, metabolic acidosis with an elevated anion gap. Infectious evaluation with respiratory, GI, and CSF PCR was negative. Differential diagnoses considered included infection, formula intolerance, inborn errors of metabolism, cystic fibrosis, and other genetic diseases. Metabolic studies showed ketosis but were otherwise normal. Hospital course was complicated by dural venous sinus thrombosis. Based on all of the above, an expedited WES was ordered as part of an ongoing study. **Methods/Results:** Expedited trio WES, with turnaround time of 16 days, was completed at a commercial lab using current standardized NGS technology, and demonstrated a de novo missense variant, p.Leu855Arg (CTG>CGG):c.2564 T>G, in exon 20 of the *PIK3CD* gene, classified as likely pathogenic following ACMG guidelines for variant interpretation, as it has not been reported previously, causes non-conservative amino acid substitution, and in-silico analyses support a deleterious effect. *PIK3CD* pathogenic variants cause activated PI3K-delta syndrome-1 (APDS1). **Conclusions:** Expedited WES results were consistent with APDS1, which is associated with chronic diarrhea in a minority of patients. As no other etiology for diarrhea was found, we believe these results explain the phenotype. This diagnosis was reached much faster than the typical turnaround time for routine WES. These results quickly clarified the etiology of the diarrhea and demonstrated the need for immunologic evaluation. This case proves that expedited WES can aid the diagnosis and management of acutely ill patients.

**1003T**

**Gene expression analysis of endothelial cells from sickle cell anemia patients and its relation with stroke.** *M.B. Melo<sup>1</sup>, M.T. Ito<sup>1</sup>, S.M. Silva-Costa<sup>1</sup>, L.C. Baptista<sup>1</sup>, G.Q. Carvalho-Siqueira<sup>1</sup>, D.M. Albuquerque<sup>2</sup>, F. Cendes<sup>3</sup>, S. Ospina-Prieto<sup>3</sup>, C. Lanaro<sup>3</sup>, V.M. Rios<sup>1</sup>, M.C. Ozello<sup>2</sup>, F.F. Costa<sup>2</sup>.* 1) CBMEG, University of Campinas, Campinas, São Paulo, Brazil; 2) Hematology and Hemotherapy Center, University of Campinas, Campinas, São Paulo, Brazil; 3) Neuroimaging Laboratory, University of Campinas, Campinas, São Paulo, Brazil.

Sickle-cell anemia (SCA) results from the homozygosity of a single mutation at position 6 of the  $\beta$ -globin locus. The clinical aspects of this disease are very heterogeneous and hence different patients may present significantly different clinical evolution. Almost all organs can be affected, with emphasis on the Central Nervous System (CNS), where transient ischemic events, infarcts and cerebral haemorrhage are observed, affecting approximately 25% of the patients with SCA. Although sickle cell anemia is characterized by calcification of red blood cells, the vascular endothelium plays an important role in the pathophysiology of this hemoglobinopathy. Differences in the expression of molecules produced by endothelial cells may be associated with clinical heterogeneity among individuals affected by vascular diseases. In this study, we investigated the differential expression of genes involved in the endothelial cell biology in patients with SCA with and without stroke. Endothelial cells from four patients with SCA with stroke and six patients with SCA without stroke (confirmed by magnetic resonance imaging) were evaluated. The approach included the isolation and culture of BOECs (blood outgrowth endothelial cells) and expression analysis of 84 genes by PCR Array (Human Endothelial Cell Biology RT<sup>2</sup> PCR Array). The analysis of the array showed that 18 genes were upregulated and 11 were downregulated, from which 10 have been chosen for validation (5 upregulated - *FLT1*, *IL6*, *MMP1*, *PGF* and *PROCR* and 5 downregulated - *CCL2*, *ICAM1*, *KDR*, *SELPLG* and *TNFSF10*). *PGF*, *MMP1*, *ICAM1* and *TNFSF10* genes have been validated by qRT PCR. Among these genes, *MMP1* is noteworthy once its expression was 204.64 higher in patients with stroke than in patients without stroke ( $p=0.000428$ ). In stroke, *MMPs* may be involved in damage of the blood-brain barrier, degradation of components of the extracellular matrix (ECM), facilitation of cellular migration through the ECM, cleavage of cytokine precursors from the cell surface and exacerbation of post ischemic edema. These results may help to understand the mechanisms involved in the development of stroke in patients with the disease, in the preventive diagnosis and also contribute to the employment of useful approaches for their treatment.

**1004F**

**Single cell transcriptomes of sickle cell disease PBMC identifies markers of disease severity in distinct cell populations.** S. Lessard, H. Ling, D. Levasseur. Bioverativ, Waltham, MA.

Each year, around 300,000 individuals are born with sickle cell disease (SCD), a recessive genetic disorder caused by a single base pair mutation in the  $\beta$ -globin gene. SCD patients display altered circulating immune cell populations and reticulocyte counts, which can complicate transcriptome studies of peripheral mononuclear cells (PBMCs). Here, we sequence the transcriptome of PBMCs from healthy and SCD donors using a single-cell approach to account for this heterogeneity. We purified PBMCs from 2 SCD and 4 healthy donors. Single cell library preparation using the 10X Genomics 3' gene expression assay (v2) and high throughput sequencing was performed at Johns Hopkins University genetics resource core facility. We processed reads using Cell Ranger (v2.1.0) and used Seurat (v2.2.1) to aggregate all 6 datasets and to perform differential gene expression analyses. In total, we sequenced 24,524 cells with a mean of 85,034 reads/cell ( $1.8 \times 10^9$  total reads) achieving on average ~92% sequencing saturation. We identified a mean of 573 genes per cell. We found that SCD samples displayed a greater T cell fraction (53%), along with fewer monocyte counts (20%) compared to PBMCs from healthy volunteers (32% and 42% respectively). One SCD sample, "SCDB", exhibited particularly altered PBMC fractions, with few monocytes (6%) and greater T cell (65%) and B cell fractions (22%). SCD cell clusters showed a global down-regulation of immunity-related genes. Monocytes displayed increased expression of the ferritin heavy chain gene *FTH1*, a marker of iron balance, and *GPX1*, a marker of oxidative stress. Cytotoxic T-cells and natural killer cells showed increased expression of *S100B*. *S100B* serum levels are increased following stroke or brain hypoxia. Finally, we found that monocytes from SCDB showed strong up-regulation of *IL8*, which has been proposed as a marker of sickle cell crisis. We sequenced 6 PBMC transcriptomes from healthy and SCD patients at the single cell level. PBMCs from SCD samples showed altered PBMC populations compared to healthy donors. Monocytes showed the largest changes in gene expression in SCD samples, expressing markers of iron overload and SCD complications. In conclusion, single cell transcriptomics can help account for different cell composition and identify cell-specific gene expression changes that could possibly be markers of disease.

**A new mechanism and vulnerability for fibrosis.** M.A. Seman-Senderos<sup>1</sup>, D.H. Kim<sup>1</sup>, J.D. Beckett<sup>1</sup>, V. Nagpal<sup>1</sup>, R.A. Gould<sup>1,2</sup>, T.J. Creamer<sup>3</sup>, Y. Chen<sup>1</sup>, D. Bedja<sup>4</sup>, J.T. Butcher<sup>5</sup>, W. Mitzner<sup>6</sup>, R. Rouff<sup>7</sup>, S. Hata<sup>8</sup>, D.S. Warren<sup>9</sup>, H.C. Dietz<sup>1,7,8,9</sup>. 1) McKusick-Nathans Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, Maryland, USA; 2) Meinig School of Biomedical Engineering, Cornell University, Ithaca, New York; 3) Department of Surgery, Johns Hopkins University School of Medicine, Baltimore, Maryland, USA; 4) Department of Cardiology, Johns Hopkins University School of Medicine, Baltimore, Maryland, USA; 5) Department of Environmental Health Sciences, Johns Hopkins University Bloomberg School of Public Health, Baltimore, Maryland, USA; 6) Department of Advanced Science for Biomolecules, Tokyo Metropolitan Institute of Medical Science, Tokyo, Japan; 7) Howard Hughes Medical Institute, Chevy Chase, Maryland, USA; 8) Department of Pediatrics, Division of Pediatric Cardiology, Johns Hopkins University School of Medicine, Baltimore, Maryland, USA; 9) Department of Medicine, Johns Hopkins University School of Medicine, Baltimore, Maryland, USA.

Fibrosis is a common pathologic outcome of chronic disease resulting in the replacement of normal tissue parenchyma with a collagen-rich extracellular matrix. The mechanisms by which transforming growth factor  $\beta$  (TGF $\beta$ ) – the dominant profibrotic cytokine – drives fibrosis are varied but include obligate mesenchymal transition (MT) of progenitor cells to invasive and synthetic myofibroblasts. In a candidate culture-based screen we identified dimeric calpain activity as an essential effector of TGF $\beta$ -induced MT using a variety of progenitors. Furthermore, calpain activity was also required for maintenance of myofibroblast differentiation and performance despite ongoing exposure to TGF $\beta$ . siRNA-based gene silencing demonstrated the specific requirement for induction of expression of calpain 9 (CAPN9), an isoform previously thought to be restricted to the gastrointestinal tract. Mice lacking functional CAPN9 due to biallelic targeting of *Capn9* were viable and fertile, but showed overt protection from bleomycin-induced lung fibrosis, carbon tetrachloride-induced liver fibrosis, and angiotensin II-induced cardiac fibrosis and dysfunction. In order to determine if CAPN9 inhibition had the potential to modify a chronic and naturally-occurring (as opposed to acute and chemically-provoked) fibrotic predisposition, we assessed for therapeutic modification of arrhythmogenic cardiomyopathy (ARC) – caused by homozygosity for targeted *Dsg2* alleles – on the *Capn9*-null background. ARC mice, as with affected patients, show early onset and highly penetrant myocardial fibrosis in association with progressive heart failure. CAPN9 deficient ARC mice showed dramatic protection from heart fibrosis, as assessed by histomorphometric and biochemical analyses, in association with complete preservation of myocardial function, as assessed by echocardiographic measurement of ventricular size, ejection fraction and shortening fraction. Database analyses revealed that a human SNP that disrupts the obligate splice acceptor for exon 4 in CAPN9, leading to out-of-frame exon skipping and predicted loss-of-function, is common in Southeast Asia, with the frequency of homozygosity (~1%) matching the prediction of Hardy-Weinberg equilibrium; together with the highly spatially-restricted pattern of CAPN9 expression under physiologic circumstances and the heartiness of the murine knockout, these data provide a strong signature for tolerance of therapeutic strategies aimed at CAPN9 antagonism.

**1006T**

**Type IA isolated growth hormone deficiency due to *GH1* gene complete homozygous deletion.** *M. Manotas*<sup>1,2</sup>, *E. Castaño*<sup>1,2</sup>, *R. Quero*<sup>1,2</sup>, *A. Paredes*<sup>1,2</sup>, *C. Cespedes*<sup>1,2</sup>, *F. Suarez*<sup>1,2</sup>. 1) Pontificia Universidad Javeriana, Bogotá D.C., Colombia; 2) Hospital Universitario San Ignacio.

Isolated GH deficiency type IA (IGHDIA [MIM 262400]) is an infrequent cause of severe congenital growth hormone deficiency. Underlying genetics are predominantly *GH1* gene deletions, although nonsense or frameshift mutations have also been reported. *GH1* gene is located on 17q22–24, within a cluster of 65 kb including five homologous genes that predispose to deletions after unequal recombination and crossing over at meiosis. The deletion of the *GH1* gene of 6.7 kb is involved in 76% to 83% of the reported cases. The appearance of neutralizing anti-GH antibodies (anti-GH Abs) upon recombinant human GH (rhGH) treatment is a characteristic feature of IGHDIA. We present the case of a 16-year-old male who was referred to our genetic unit after several years of lapsed follow-up. The patient was diagnosed in early childhood with severe growth retardation (-8.89 S.D. at 9 months years of age). Birth length at 35 weeks of gestation was already poor with and height of 43.6 cm and weight of 1524 gm. In infancy, he had a delay in the motor development. Hormonal analysis revealed undetectable IGF-1 and serum GH concentration was below the detection limit even after administration of clonidine. Other pituitary hormonal axis functions were normal, and the pituitary MRI did reveal the gland in a normal position, however relatively small. rhGH supplementation was started at the 18-month years, but no significant increase in growth was achieved, compatible with the development of anti-GH Abs. Directed del/dup analysis revealed a complete homozygous *GH1* gene deletion. Actually, his height is 83 cm (-8.75 S.D.), he has a disproportionately short stature with particular phenotypic features such as immature facies, slightly down-slanting palpebral fissures, depressed bridge of nose, absence of secondary sexual characteristics and mildly impaired cognition. He also suffers from asthenia and osteomuscular pain. The patient described herein is, to our knowledge, the first case of IGHDIA due to *GH1* gene complete homozygous deletion described in the literature. GH complete absence and the consequent severe IGF1 deficiency may underlie the patient's present puberty delay, osteomuscular symptoms, impaired cognition and youthful face. It should be noted, that although evidence about growth hormone and aging is currently controversial, the juvenile face, noncorresponding with his chronological age, can be a clinical signal of delayed aging associated with GH deficiency.

**1007F**

**OFD1 and autophagy: Implication for renal cystic disease.** *M. Manuela*<sup>1,2</sup>, *U. Formisano*<sup>1</sup>, *S. Brillante*<sup>1</sup>, *D. Iaconis*<sup>1</sup>, *A.S. Maione*<sup>1</sup>, *E. Damiano*<sup>1</sup>, *R. Tammaro*<sup>1</sup>, *C. Settembre*<sup>1,2</sup>, *B. Franco*<sup>1,2</sup>. 1) Telethon Institute of genetics and Medicine, Pozzuoli, Naples, Naples, Italy; 2) Medical Genetics Unit, Department of Translational Medicine, University of Naples "Federico II", Naples, Italy.

The OFD1 protein is codified by the gene mutated in Oral-facial-digital type I syndrome (OFD type I), an X-linked ciliopathy characterized by abnormalities of face, oral cavity and digits, involvement of the central nervous system and renal cystic disease. OFD1 is a centrosomal/basal body protein necessary for primary cilia formation. Interestingly, recent data established a link between autophagy, cilioproteins and renal cystic disease (CK). In particular it has been shown that autophagy activation rescues renal cystogenesis in autosomal dominant polycystic kidney disease. Mass spectrometry analysis revealed, among putative OFD1 interactors, autophagy related proteins and we thus sought to determine whether OFD1 might have a role in this process. We demonstrated that OFD1-inactivated human renal cells (KO-OFD1) show increased autophagic flux and autophagosome biogenesis, by analysis and quantification of a) LC3 and WIPI2 puncta; b) autophagosome-lysosome fusion rates; d) rate of delivery of autophagosomes to lysosomes using an RFP-GFP tandem tagged LC3 protein. The specificity of our findings was supported by the observation that OFD1 overexpression rescues the autophagic phenotypes observed *in vitro* and results in decreased autophagosome biogenesis in renal control cells. Using a variety of approaches we also determined that the increased autophagic flux is not due to decreased mTORC1 activity. These data suggest that OFD1 acts as inhibitor of the autophagy. In addition, we demonstrated *in vivo* enhanced autophagic flux both at precystic and cystic stages in different *Ofd1*-inactivated models. Finally, to test the role of autophagy modulation on CK *in vivo* we achieved conditional inactivation in the kidney of both *Ofd1* and *Atg7*, an essential gene for autophagy. Histological analysis showed a significant reduction in the number and size of cysts in *cre<sup>Ksp</sup>;Ofd1<sup>fl</sup>;Atg7<sup>fl/fl</sup>* mutants compared to *cre<sup>Ksp</sup>;Ofd1<sup>fl/fl</sup>;Atg7<sup>+/+</sup>* mice, suggesting that the increased autophagy might be strictly associated to renal cystogenesis in OFD type I syndrome. These data suggests that alterations of autophagy may be a common pathogenic mechanism in CK. The dissection of the molecular mechanisms underlying the initial phases of renal cyst formation in OFD type I could allow elucidating the role of autophagy in CK and could disclose new therapeutic avenues for renal cystic disease. .

## 1008W

**Investigating *PRSS1* copy number variants showing MLPA peak height ratio sensitivity.** M.J. Deshotel<sup>1</sup>, G. Pont-Kingdon<sup>1</sup>, E. Lyon<sup>1,2</sup>. 1) Molecular Genetics, ARUP Laboratories, Salt Lake City, UT; 2) Department of Pathology, University of Utah, Salt Lake City, UT.

Hereditary chronic pancreatitis (HCP [MIM 167800]) is caused by pathogenic variants in four or more genes. One gene, *PRSS1*, codes for cationic trypsinogen, and pathogenic variants in this gene cause premature activation of trypsinogen within the pancreas, leading to pancreatic calcifications and exocrine insufficiency. While Sanger sequencing identifies the causal mutation in about 80% of HCP patients, about 6% of cases are due to increased copy number of *PRSS1*. Our laboratory is evaluating the multiplex ligation-dependent probe amplification (MLPA) kit from MRC-Holland to detect *PRSS1* and *SPINK1* copy number variants in HCP patients. We first tested whether 9 common polymorphisms and pathogenic SNPs located under MLPA probe binding sites would obstruct detection; we found no evidence of interference. However, in 3 out of 21 wild-type patient samples tested during assay development, we observed lower than average peak height ratios around 0.8 in the 6 *PRSS1* probes. *PRSS1* deletions are not pathogenic, but to avoid potential misinterpretation of results in patient samples, we explored possible explanations for the reduced ratios. We considered pseudogene interference, differences in DNA elution buffers, and lower input concentrations for MLPA. Probe competition with the pseudogene *PRSS3P2/TRY6* was a possible cause for the lower ratios because it shares 90.1% identity with *PRSS1* and deletions have been described in many different ethnicities. To test this hypothesis, we designed and tested qPCR primers specific to *PRSS1* and *TRY6*. The qPCR results did not reveal differences in *PRSS1* or *TRY6* copy number, but did reflect the MLPA data, with average  $2^{-\Delta\Delta C_T}$  gene dosage ratios of 0.72 for both *PRSS1* and *TRY6* measured in the samples with low *PRSS1* peak height ratios. To further exclude pseudogene interference, we tested Coriell DNA samples with the rs1323002 SNP, which was previously shown to be in 100% linkage disequilibrium with *TRY6* deletion. When tested with MLPA, these samples did not show a dose-dependent *TRY6* influence on the *PRSS1* probes. We also performed ethanol precipitations, which increased the MLPA ratios from an average of 0.81 to 0.86, closer to expected values. Additionally, running MLPA on the aberrant samples with low input concentrations of DNA (10 ng/ $\mu$ L) did not resolve the low *PRSS1* ratios. Our results highlight the importance of carefully choosing wild-type reference samples in clinical laboratories.

## 1009T

***FOG2* and *GATA4* haploinsufficiency is a novel cause for primary ovarian insufficiency.** D. Baetens<sup>1</sup>, A. Bachelot<sup>2</sup>, N. De Vriese<sup>3</sup>, F. De Zegher<sup>4</sup>, N. Reynaert<sup>5</sup>, R. Colombo<sup>6</sup>, Y. Van Bever<sup>6</sup>, J. Dulon<sup>6</sup>, P. De Sutter<sup>6</sup>, P. Touraine<sup>6</sup>, M. Cools<sup>7</sup>, E. De Baere<sup>1</sup>. 1) Center for Medical Genetics Ghent, Ghent University and Ghent University Hospital, Ghent, Belgium; 2) UPMC Université Pierre et Marie Curie, Université Paris, Paris, France; 3) Pediatric Endocrinology, University Hospital Gasthuisberg, University of Leuven, Leuven, Belgium; 4) Center for the Study of Rare Hereditary Diseases, Niguarda Ca' Granda Metropolitan Hospital, Milan, Italy; 5) Department for Clinical Genetics, Erasmus Medical Center Rotterdam, Rotterdam, The Netherlands; 6) Department of Obstetrics and Gynaecology, Ghent University and Ghent University Hospital, Ghent, Belgium; 7) Department of Pediatric Endocrinology, Ghent University and Ghent University Hospital, Ghent, Belgium.

**Background:** Primary ovarian insufficiency (POI) is a major cause of female infertility. Although many POI genes have been identified, the genetic cause remains unknown in the majority of cases. The starting point of this study was a 3.2 Mb deletion encompassing *Friend of GATA 2 (FOG2)* in a patient with a 46,XY disorder of sex development (DSD). This deletion was inherited from his mother, displaying low levels of serum anti-Müllerian hormone (AMH), suggestive of a decreased ovarian reserve. Based on this human case and supported by the role of the *Fog2/Gata4* complex in murine ovarian development, we hypothesized that haploinsufficiency of the *FOG2* and the *GATA binding protein 4 (GATA4)* genes could contribute to the pathogenesis of POI. **Methods:** Targeted next-generation sequencing of *FOG2* and *GATA4* was conducted in a Belgian-French POI cohort (n=388). Functional validation of the identified variants consisted of luciferase assays, co-immunoprecipitation of mutated *FOG2* and *GATA4* and *in silico* structural analysis. **Results:** A heterozygous deletion was found in a child with isolated 46,XY DSD and his mother with presumed POI. Subsequent targeted resequencing of *FOG2* and *GATA4* in a Belgian-French POI cohort revealed monoallelic likely pathogenic variants in *FOG2* (n=5) and *GATA4* (n=4). An altered transcriptional activation of the mutated *FOG2/GATA4* complex was shown for several of the identified variants, substantiated by co-immunoprecipitation and *in silico* structural analyses. **Conclusion:** Our study put forward *FOG2* and *GATA4* as novel POI genes, supporting a role for both genes in human ovarian maintenance. We expand the phenotypic spectrum of *FOG2* and *GATA4* haploinsufficiency, thus far only associated with cardiac anomalies, congenital diaphragmatic hernia and 46,XY DSD. .

Minneapolis, MN 55455, USA; 3) Surgical Neurology Branch, National Institute of Neurological Disorders and Stroke (NINDS), National Institutes of Health (NIH). 10 Center Drive, CRC, Room 3D20, Bethesda, MD 20892-1414, USA; 4) Newborn Screening Program, Wadsworth Center, New York State Department of Health, P.O. Box 509, Albany, NY 12201-0509, USA; 5) Epidemiology Branch, Division of Intramural Population Health Research, Eunice Kennedy Shriver National Institute of Child Health and Human Development (NICHD), National Institutes of Health (NIH). 6710B Building, Room 3117. Bethesda, MD 20892, USA.

**Introduction:** Although most patients present sporadically, Cushing's disease (CD) may occur in the setting of various syndromes of familial isolated pituitary adenoma (FIPA) or multiple endocrine and non-endocrine neoplasia. Such cases are found in the literature as individual case reports or small case series; therefore, the frequency of inherited forms of CD and their genetic causes remain largely unknown. Given that familial pituitary adenomas usually develop at a young age, pediatric patients represent an excellent population for estimating the prevalence of known genetic defects leading to CD and for gene discovery. **Methods:** We studied 268 pediatric CD patients (10.3±3.3 years at disease onset and 12.4±3.5 years at diagnosis) referred to our Center between 1997-2018, including 111 males (41.4%) and 157 females (58.6%). Seventy-one patients were screened for germline mutations in pituitary adenoma-associated genes (*AIP*, *CDKN1B*, *CDKN2C*, *MEN1* and *PRKAR1A*) by Sanger sequencing as part of a previous study. Ninety-eight patients (including 29 from the previous study) underwent whole-exome sequencing and, based on the results, one or more genes were analyzed in up to 153 additional patients by Sanger (42 from the previous study). Relevant data were obtained from the clinical records or directly from the patients. **Results:** Seven patients (2.6%) had familial disease: five cases presented as multiple endocrine neoplasia type 1 (four of them with confirmed *MEN1* mutations) and two cases presented as FIPA (unknown genetic cause). Among the 261 sporadic patients (97.4%), genetic analyses identified nine simplex cases (3.4%) with mutations in the *AIP* (n=1), *CABLES1* (n=2), *CDKN1B* (n=2), *MEN1* (n=1), *PRKAR1A* (n=1), *TSC2* (n=1), or *USP8* (n=1) genes. Altogether, cases with potentially inherited genetic causes (familial and simplex) accounted for 6% (16/268) of all patients. There were no statistically significant differences in age at disease onset, age at diagnosis or tumor diameter between patients with potentially inherited genetic defects and the rest of the cohort, although there was a trend toward larger tumors (median 6.5mm [interquartile range: 4.3-10.8] vs 4 mm [4-6.7]  $P=0.0589$ ) in the former group. **Conclusions:** Known germline genetic defects cause a small but not negligible fraction of the CD cases presenting in childhood. Identifying such cases should lead to a more precise genetic testing and counselling, as well as to developing more targeted therapeutic strategies.

White<sup>7,8,14</sup>, Z. Stark<sup>7,8,14</sup>, E. Wilkins<sup>7,15</sup>, L. Wardrop<sup>8</sup>, C. Quinlan<sup>8,9,14</sup>, *The KidGen Collaborative*. 1) Clinical Genetics Department, Austin Health, Heidelberg, Melbourne, Victoria, Australia; 2) Department of Nephrology, Austin Health, Heidelberg, Melbourne, Victoria, Australia; 3) Department of Nephrology, Royal Melbourne Hospital, Parkville, Melbourne, Victoria, Australia; 4) Adult Genetics Service, Royal Melbourne Hospital, Parkville, Melbourne, Victoria, Australia; 5) Department of Nephrology, Monash Medical Centre, Clayton, Melbourne, Victoria, Australia; 6) Monash Genetics, Monash Medical Centre, Clayton, Melbourne, Victoria, Australia; 7) Victorian Clinical Genetics Service, Parkville, Melbourne, Victoria, Australia; 8) Murdoch Children's Research Institute, Parkville, Melbourne, Victoria, Australia; 9) Department of Nephrology, Royal Children's Hospital, Parkville, Melbourne, Victoria, Australia; 10) Department of Nephrology, Monash Children's Hospital, Clayton, Melbourne, Victoria, Australia; 11) Department of Paediatrics, Monash University, Melbourne, Victoria, Australia; 12) Department of Medicine, Monash University, Melbourne, Victoria, Australia; 13) Department of Medicine, University of Melbourne, Victoria, Australia; 14) Department of Paediatrics, University of Melbourne, Melbourne, Australia; 15) Melbourne Genomics Health Alliance, Melbourne, Australia.

**Background:** Genetic kidney disease accounts for up to 70% of children and 20% of adults with end stage kidney disease. The emergence of genomic technologies has the potential to lead to better delineation of these conditions, the identification of new renal disease genes and subsequent targets for therapy. We describe the patient characteristics of 100-sequential referrals for individuals with genetic kidney disease across four Renal Genetics clinics in Victoria, Australia, and outline early results from exome sequencing in an initial consignment of 19 patients from this cohort. **Methods:** Patients were seen according to the KidGen clinic model and recruited through the Australian Genomics and Melbourne Genomics Renal Genetics Flagships. Demographic features, diagnosis at referral, and reason for referral were recorded. Preliminary results from whole exome sequencing (WES) were available in the first 19 patients. **Results:** The majority of patients (87) were referred by Nephrology, approximately half (51) were female, and 53 reported at least one affected first-degree relative. The reasons for referral included genetic testing (86), diagnosis (41), management (5), and genetic counselling (58). Common diagnoses at referral were Alports/hereditary nephritis (17), nephrotic syndrome (17), cystic kidney disease (7), ADTKD (7), ARPKD (6), Nephronophthisis (4) and ADPKD (2). Of the first 19 cases where WES results were available, a molecular diagnosis was suspected in 15 patients, leading to a revised diagnosis in seven. **Conclusions:** Ongoing analysis of this cohort will allow comparison of WES to current diagnostic methods, health economic analysis, and the identification of clinical characteristics or conditions that are more predictive of a positive molecular diagnosis. Early results suggest that a significant proportion may receive a revised diagnosis after WES, further highlighting the utility of identifying a specific molecular aetiology.

**1012T**

**Chronic intestinal pseudo-obstruction: Successful genetic diagnosis through whole exome sequencing.** *F. Djukiadmodjo<sup>1</sup>, P. James<sup>1,2</sup>, Z. Stark<sup>2</sup>, M. Walsh<sup>1,2</sup>.* 1) Genomic Medicine, The Royal Melbourne Hospital, Melbourne, Victoria, Australia; 2) Victorian Clinical Genetics Services, Murdoch Children's Research Institute, Melbourne, Victoria, Australia.

**Introduction** Chronic intestinal pseudo-obstruction (CIPO) is characterised by symptoms and signs of intestinal obstruction, but without evidence of a physical occlusion. It represents the severe end of a spectrum of gut motility disorders resulting in significant mortality (10-25%) and morbidity, with up to 80% of childhood-onset CIPO requiring total parenteral nutrition (TPN). Most cases are sporadic, with an estimated incidence of 1 in 40,000-100,000, but an increasing number of inherited causes are being described. **Aim** To describe two unrelated probands with causative *ACTG2* variants identified on whole exome sequencing (WES). **Methods** Family 1 presented with a four-generational history of CIPO. 9 of 28 family members were affected suggesting an autosomal dominant inheritance with high penetrance. The proband presented at 2 years of age and had steadily increasing severity of her condition, requiring multiple bowel resections and long-term TPN. Extensive genetic tests, including molecular karyotype and an extended panel for mitochondrial disorders, were negative. In contrast, the second proband is a neonate born at 36 weeks gestation who was found to have an atonic bladder at birth requiring ongoing catheterisation, following an antenatal diagnosis of an abdominal cyst. She did have initial bilious vomiting and required short-term TPN. **Results** WES performed in the proband of Family 1 identified a heterozygous novel missense variant (c.739C>A) at a highly conserved amino acid in the *ACTG2* gene (p.Gln247Lys). Segregation testing of other family members enabled us to confirm pathogenicity. The second patient was found to have a likely pathogenic heterozygous missense variant in *ACTG2* (c.613G>A, p.(Ala205Thr)) and she has been closely monitored for signs of intestinal obstruction. *ACTG2* encodes gamma ( $\gamma$ )-2 actin, a sarcomeric component of enteric smooth muscle involved in peristalsis. Inherited *ACTG2* gene mutations are associated with dominant visceral myopathy and de novo mutations have been found to be responsible for megacystis-microcolon-intestinal hypoperistalsis syndrome. **Discussion** CIPO is a rare but serious condition. Through WES, we identified *ACTG2* as the cause of CIPO in two families with contrasting presentations. This molecular diagnosis would enable early diagnosis and better management of CIPO that could avoid the need for bowel resection and the associated significant morbidity. It also enables reproductive testing options for affected family members.

**1013F**

**Pancreatic cancer in a hereditary pancreatitis kindred is associated with a mutation in a pancreatic cancer susceptibility gene.** *D.C. Whitcomb<sup>1,2</sup>, C.A. Shelton<sup>1,2</sup>, W. Zhan<sup>1</sup>, P.J. Greer<sup>1</sup>, D. Yadav<sup>1</sup>.* 1) Division of Gastroenterology, Hepatology & Nutrition, University of Pittsburgh & UPMC, Pittsburgh, PA; 2) Department of Human Genetics, University of Pittsburgh, Pittsburgh, PA.

Hereditary pancreatitis (HP) is an autosomal dominant syndrome of recurrent acute and chronic pancreatitis typically caused by mutations in *PRSS1*. HP is associated with an increased risk for pancreatic cancer (7.2%-40% by age 70). However, incidence of pancreatic cancer can vary dramatically between families and does not correlate well with age of onset or severity. HP probands and their family members were prospectively recruited into the HP study. Minimum three-generation pedigrees were constructed, subjects completed questionnaires, and medical records were obtained. DNA was tested for core pathogenic *PRSS1* mutations and patients were followed up to 20 years. Cause of death information was obtained from the family and the National Death Index (NDI). We identified clustering of HP-pancreatic cancer cases in HP kindreds, which suggests the presence of additional modifying factors. Whole exome sequencing (WES) was performed on available DNA from 6 individuals (of 4 *PRSS1* R122H kindreds) that developed pancreatic cancer (3 affected *PRSS1* carriers, 2 unaffected *PRSS1* carriers, and 1 non-*PRSS1*). Variants were filtered for known pancreatic cancer germline risk genes and evaluated for pathogenicity. Three study participants that developed pancreatic cancer were identified in one *PRSS1*-HP kindred, and all three were found to harbor a known cancer-susceptibility variant (rs664143) in the *ATM* gene – a critical component of DNA double-strand break repair. This kindred did not have known pathogenic variants in other familial pancreatic cancer-associated genes analyzed (*BRCA1*, *BRCA2*, *PALB2*, *SPINK1/2*, *GGT1*, *CTRC*, *CFTR*, *TP53*, *SMAD3*, *CHECK2*, *CDKN2A*, *STK11*, *PTEN*, *BARD1*, *FANCA*, *FANCC*, *FANCG*, *FANCM*, *MLH1*, *MSH2/6*, *PMS2*, *EPCAM*, *POLN*, *POLQ*, *NBN*, *PALLD*, *APC*). The fact that *ATM* is a known oncogene adds biological plausibility to the argument that this variant contributed to development of pancreatic cancer in these cases. Ten  $\geq 4$  generation pedigrees were further investigated for incidence of cancer. Families exhibited high variability in pancreatic cancer age of diagnosis and incidence, ranging from (0% -28.6% of HP individuals  $\geq$  age 50). These data demonstrate that in addition to smoking, risk for cancer in patients with HP may be linked to germline mutations in pancreatic cancer risk genes. Family history for pancreatic cancer should be considered when counseling HP patients for risk of pancreatic cancer.

### 1014W

**Identifying causative genetic variants of pheochromocytoma and paraganglioma by next-generation sequencing (NGS) in Taiwan.** Y.T. Chou<sup>1</sup>, C.S. Chen<sup>2</sup>, P.L. Chen<sup>1,2,3,4</sup>. 1) Graduate Institute of Molecular Medicine, National Taiwan University, Taipei City, Taiwan; 2) Department of Medical Genetics, National Taiwan University Hospital, Taipei, Taiwan; 3) Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan; 4) Graduate Institute of Medical Genomics and Proteomics, National Taiwan University, Taipei, Taiwan.

Pheochromocytoma (PCC) and paraganglioma (PGL) are neuroendocrine tumors arising from adrenal and extra-adrenal chromaffin cells respectively. They mostly present benign, yet show high morbidity and mortality due to the overproduction of catecholamine, which leads to hypertension, arrhythmia and even ischemia stroke. About one thirds of PCC/PGL are caused by germline genetic variants; therefore, here we established a NGS panel to detect possible disease-causing variants. After literature review, we aimed at the top 12 PCC/PGL causative genes (*RET*, *VHL*, *NF1*, *FH*, *SDHA*, *SDHAF2*, *SDHB*, *SDHC*, *SDHD*, *MAX*, *TMEM127*, *EGLN1*(*PHD2*)), 10 somatic mutation genes (*ARNT*(*HIF1β*), *ATRX*, *BRAF*, *CSDE1*, *EPAS1*(*HIF1α*), *FGFR1*, *HRAS*, *IDH1*, *SETD2*, *TP53*), 3 fusion genes (*BRAF*, *MAML3*, *NGFR*) and other 7 genes (*CDKN2A*, *H3F3A*, *IDH2*, *KMT2D*, *MDH2C*, *MERTK*, *MET*) which were reported relative to PCC/PGL. Paired-end reads were generated from Illumina MiSeq platform and analyzed with in-house pipeline (BWA-MEM, Picard SortSam, MarkDuplicates, GATK-BQSR and ANNOVAR). Variants were filtering according to the allele frequencies in gnomAD, ExAC and Taiwan Biobank, and the pathogenicity interpretation were facilitated by disease/gene database, scientific literature and the 2015 ACMG Guidelines. In this study, we sequenced 41 probands and yielded approximately 25% diagnosis rate with identifying 6 different disease-causing variants and several variants of unknown significant (VUS). Among the results, 5 unrelated probands carried a same causative variant in *SDHD* (c.3G>C, p.M1X, NM\_003002), which implied a founder mutation in Taiwan. One variant in *TMEM127* and one variant in *VHL* show co-segregation pattern in their pedigrees but remain absent in literature so far, which necessitated further functional assay.

### 1015T

**Genotype and phenotype correlation in Turkish Alport syndrome patients with different COL4A3, COL4A4 and COL4A5 mutations.** P. Ata, T. Celik, T. Pak, A. Isik, H.C. Yakut, S. Yildirim, A. Turkyilmaz. MARMARA UNIVERSITY , SCHOOL OF MEDICINE, ISTANBUL, TURKEY.

**Introduction and Purpose:** The clinical effects of *COL4A3*, *COL4A4* and *COL4A5* genes mutations differ from patient to patient. Herein we aimed to search the correlation between the genotype and differing phenotypes at Alport Syndrome. **Method:** This is a cross-sectional observational investigation covering patients admitted between December 2009 and September 2017. We established a scoring system; "ALSCORE" according to auditory, visual finding, biopsy, urinary, genetic findings and mutations of *COL4A3*, *COL4A4*, *COL4A5*. Also According to ACMG guidelines mutations were classified into groups (Group A, B, C,D ) according to their pathogenicity Variants and mutations were analyzed with up-to-date genetic databases. For clinical and genotype correlation analysis SPSS v11.0 was used. Statistical significance score was determined as  $p < 0.05$ . Chi-square, Spearman, Kruskal-Wallis, Mann-Whitney-U tests were used. **Findings:** In a total of 37 patients 40.5% were males and 59.5% were females. Mean age was 13.49±6.83 years, mean age at diagnosis was 10.55±8.2 years. Mean observation duration was 47.01±28.36 months. Diseased relative history was present at 62.2% of patients and consanguinity was present at 40.5%. Eighty eight percent of all variants were (n=16) located at *COL4A4*. Mean "ALSCORE" was 5.78±2.49 (max: 10, min: 2). ALSCORE levels of mutation carriers were significantly higher than those of variant carriers ( $p=0,002$ ,  $p<0,01$ ). Those who were only variant carriers also had lower ALSCORE than those who were carriers of both variant and mutation at the same time. ( $p=0,05$ ;  $p<0,05$ ). For Statistical Analysis NCSS (Number Cruncher Statistical System) 2007 (NCSS, LLC Kaysville, Utah, USA) programme was used. **Results:** Among all our patients *COL4A3* gene mutation was more frequent. The majority of patients with mutations had consanguineous marriage. Having two mutations at the same time had a higher impact on occurrence of visual findings at early ages. Patients with mutations had higher ALSCORE clinical scoring than those carrying mutation and variation at the same time. Most pathogenic mutations were accompanied with proteinuria. Macrohematuria was observed at younger ages.

**1016F**

**Systematic characterization of variants that affect RNA splicing to optimize assignment of precision therapies for cystic fibrosis.** A. Joynt<sup>1</sup>, T. Evans<sup>1</sup>, E. Davis<sup>1</sup>, M. Pellicore<sup>1</sup>, M. Atalar<sup>1</sup>, S. Han<sup>1</sup>, A. McCague<sup>1</sup>, Z. Lu<sup>1</sup>, N. West<sup>1</sup>, C. Merlo<sup>1</sup>, K. Raraigh<sup>1</sup>, P. Sosnay<sup>1</sup>, C.U. Cotton<sup>2</sup>, N. Sharma<sup>1</sup>, G.R. Cutting<sup>1</sup>. 1) Johns Hopkins University, Baltimore, MD; 2) Case Western Reserve University, Cleveland, OH.

Treatment of cystic fibrosis (CF) has been revolutionized by modulators that target CFTR protein. To maximize the number of individuals who can benefit, we determined the molecular consequences of 46 naturally occurring CF-causing variants (intronic=37 and missense=9) that were predicted to affect RNA splicing by CryptSplice and NNSplice or by their proximity to consensus splice sites. Expression mini-genes (EMGs) encompassing 20 of the 26 *CFTR* introns were used to experimentally determine variant effect upon RNA splicing and protein synthesis. CFTR function was evaluated by short circuit current measurement of CF bronchial epithelial cells that stably expressed variant EMGs. Five variants (intronic=3 and missense=2) had no detrimental effect on RNA splicing. The remaining 41 variants exhibited aberrant splicing resulting in either frameshifts (intronic=25 and missense=4) or in-frame deletions (intronic=13 and missense=5). Twenty variants generated more than one splice isoform. Importantly, 9/20 variants (intronic=8 and missense=1) generated reduced amounts of normal spliced transcript. Remarkably, 3 variants (intronic=2 and missense=1) used non-canonical GC as a splice donor site. Our observations using EMGs were corroborated by splicing patterns observed in primary nasal cells from CF individuals (n=5) harboring the same splicing variants. Immunoblotting revealed that the 41 splicing variants fell into three groups: Group A generated no protein due to introduction of a premature termination codon (PTC) (intronic=7), Group B had truncated protein due to an in-frame deletion or PTC at the 3' region of *CFTR* (intronic=19, missense=5), and Group C synthesized reduced amounts of full-length protein from normally spliced RNA isoforms (intronic=8, missense=1). Strikingly, splice variants at the 5' region of *CFTR* (intronic=6) produced truncated protein, likely due to use of an alternative translational start site. Ten variants that generated protein were selected to evaluate CFTR function and the effect of modulators. Four variants from group B synthesized stable truncated forms of CFTR that did not respond to modulators. However, all six variants selected from group C displayed residual CFTR function and responded to both classes of CFTR modulator. Variants that alter RNA splicing patterns can generate targetable protein thereby increasing the number of individuals who could receive CFTR modulator therapy.

**1017W**

**Natural genetic modifiers of *NGLY1* deficiency suggest a role for protein homeostasis in determining inter-individual outcomes.** D. Talsness, K. Owings, E. Coelho, K. Peralta, C.Y. Chow. Department of Human Genetics, University of Utah, Salt Lake City, UT.

Autosomal recessive loss-of-function mutations in *N-Glycanase 1 (NGLY1)* cause *NGLY1* deficiency, the only known disease of deglycosylation. *NGLY1* deficiency is a devastating, rare, neglected disease. Patients with *NGLY1* deficiency present with developmental delay, movement disorder, seizures, liver dysfunction, and alacrima. *NGLY1* is a conserved component of the endoplasmic reticulum associated degradation (ERAD) pathway. ERAD degrades misfolded proteins that accumulate in the lumen of the ER. *NGLY1* deglycosylates misfolded proteins as they are translocated from the ER lumen to the cytoplasm for degradation. Patients with *NGLY1* deficiency show a wide spectrum of severity. This is especially striking since all identified patients carry two null mutations. This phenotypic heterogeneity poses a great challenge to treating this disorder. To understand what may be underlying inter-individual differences in severity of *NGLY1* deficiency, we undertook a natural genetic variation screen. We developed a *Drosophila* model of *NGYL1* deficiency and crossed it into 200 strains from the *Drosophila* Genetic Reference Panel (DGRP), a collection of wild-derived *Drosophila* strains. We assessed the effect of natural genetic variation in modulating the phenotypic impact of loss of *NGLY1* activity by quantifying the number of mutant flies that survived to adulthood. Across the 200 strains, we found a very large phenotypic spectrum in survival in the absence of *NGLY1*. We found that some strains showed nearly 100% survival without *NGLY1* function and other strains were completely lethal without *NGLY1*. We performed an association analysis to identify natural polymorphisms that modify survival in flies lacking *NGLY1*. Modifier genes fall into diverse categories involved in protein homeostasis, including ERAD (*SEL1L*), ER Ca<sup>2+</sup> homeostasis (*TMTC1/2*), ER proteostasis (*ERMP1*), ubiquitination (*MYCBP2*), and vesicle trafficking (*RAB26*). We will present functional evidence, including tissue-specific studies, demonstrating how each modifier alters lethality associated with *NGLY1* deficiency in our *Drosophila* model. The genes identified from this study have excellent biological support and may serve as candidate modifiers of *NGLY1* deficiency. This study represents an important step to understanding the pathogenesis underlying *NGLY1* deficiency and provides a general framework for incorporating phenotypic variability, when developing personalized therapies for rare diseases.

## 1018T

**Genetic insight into Birt-Hogg-Dubé syndrome: A rare disease in India.** A. Ray<sup>1</sup>, S. Kundu<sup>2</sup>, S. Rajan<sup>3</sup>, S. Roy Chowdhury<sup>4</sup>, A. Bera<sup>5</sup>, U. Desai<sup>6</sup>, P. Prabhu-desai<sup>7</sup>, M. Kumar Sarma<sup>8</sup>, A. Kumar Prakash<sup>9</sup>, P. Singha<sup>3</sup>, A. De<sup>2</sup>, S. Mitra<sup>10</sup>, J. Madanmohan Joshi<sup>6</sup>, A. Jaiswal<sup>6</sup>, B. Roy<sup>1</sup>. 1) Human Genetics Unit, Indian Statistical Institute, Kolkata, West Bengal, India; 2) Department of Pulmonary Medicine, Chest, RG Kar Medical College & Hospital, Kolkata, India; 3) Chest Medicine, Bombay Hospital Institute of Medical Sciences, Mumbai, India; 4) Pulmonology, Apollo Gleneagles Hospital Limited, Kolkata, India; 5) Critical Care Medicine, Medica Superspeciality Hospital, Kolkata, India; 6) Department of Pulmonary Medicine, TNMC and BYL Nair Hospital, Mumbai, India; 7) Chest Medicine, Lilavati Hospital and Research Centre, Mumbai, India; 8) Alipurduar District Hospital, Alipurduar, India; 9) Department of Respiratory and Sleep Medicine, Medanta -the Medicity, Gurugram, India; 10) Department of Chest Medicine, Calcutta National Medical College, Kolkata, India.

**Background** Birt-Hogg-Dubé (BHDS) is a rare genetic condition manifesting in either or all of the three phenotypes - primary spontaneous pneumothorax (PSP), cutaneous fibrofolliculomas and kidney neoplasms. Familial PSP is mostly associated with inherited mutations in Folliculin (*FLCN*). Other similar pulmonary phenotypic disorders –LAMS, Homocystinuria, Marfan syndrome, alpha-1 antitrypsin deficiency, Ehlers-Danlos syndrome can sometime make a confounding diagnosis of BHDS making it important to distinguish BHDS from other PSP related phenotypes in the context of inherited mutations.

Most of the BHDS studies have been reported from Western countries with considerably fewer reports from Asia, including one study from India. Here, we are reporting mutations in *FLCN* and other PSP related genes in 86 individuals from 13 Indian families, having at least one BHDS patient in each family.

**Methods** Bidirectional Sanger DNA sequencing was performed to detect inherited mutation at *FLCN* from genomic DNA. Germline variations at *MTHFR* and *SERPINA1*, generally observed in Homocystinuria and alpha-1 antitrypsin deficiency respectively, were also evaluated. Sequence alignment software and protein prediction tools were used to detect the effect of mutations on protein structure. **Results** Sequencing data revealed a heterozygous C-deletion in poly-cytosine (C<sub>n</sub>) tract of exon 11(c.+1285) at *FLCN* in 19 individuals from 5 families, leading to a truncated protein. A family with a 41-yr-old female index patient (symptomatic), her mother and sister (both asymptomatic) were found to have a heterozygous 11-base deletion (c.+1150\_1160del11) in exon 10 of *FLCN*. This mutation has not, yet, been reported in any of BHDS patients from all over the world. Protein modelling predicted a stop codon (c.+1164) resulting in a truncated *FLCN* protein. No other pathogenic inherited mutations in *FLCN* were found in remaining 64 individuals from 7 families. Two deleterious SNPs - *rs1801133* and *rs762920973* were also found in *MTHFR* and *SERPINA1* respectively. Therefore, search for other structural mutations in *FLCN* and other PSP related genes are being carried out in these samples. **Conclusion** Apart from reported exon 11 *FLCN* mutation (c.+1285), a novel 11-nucleotide deletion mutation(c.+1150\_1160del11) in *FLCN* was also detected for the first time. Both the mutations are predicted to produce truncated *FLCN* protein. The truncated *FLCN* may play a role in deregulating metabolic pathways to generate the BHDS phenotype.

## 1019F

**Autosomal dominant visceral myopathy in connection with a *de novo* MYH11 truncating mutation.** A.C. Lionel<sup>1</sup>, J. Silver<sup>2</sup>, Y. Avitzur<sup>3</sup>, J. So<sup>1,2,4</sup>. 1) Department of Medicine, University of Toronto, Toronto, Ontario, Canada; 2) The Fred A. Litwin Family Centre in Genetic Medicine, University Health Network and Mount Sinai Hospital, Toronto, Ontario, Canada; 3) Division of Gastroenterology, Hepatology and Nutrition, The Hospital for Sick Children, University of Toronto, Toronto, Ontario, Canada; 4) Department of Laboratory Medicine and Pathobiology, University of Toronto, Toronto, Ontario, Canada. The disruption of *MYH11*, the gene encoding smooth muscle myosin heavy chain, results in a range of diverse clinical phenotypes. Heterozygous mutations, with suggestive evidence for a dominant negative mechanism of action, have been linked to familial thoracic aortic aneurysms and dissections, as well as patent ductus arteriosus. In contrast, autosomal recessive loss-of-function *MYH11* mutations have been reported in visceral myopathy, a rare inherited form of functional obstruction in the gastrointestinal and urinary tracts, also known as megacystis-microcolon-intestinal hypoperistalsis syndrome (MMIHS) or Berdon syndrome. We present a family with the first reported instance of autosomal dominant visceral myopathy connected to *MYH11*. The proband is a 32-year-old male with a history of congenital visceral myopathy and intermittent atonic bladder during childhood, with no history of cardiac issues and normal echocardiogram. He was dependent on total parenteral nutrition until successful cluster transplantation of stomach, small bowel, liver, and pancreas in young adulthood. Genetic testing revealed a *de novo* heterozygous frameshift deletion (c.5770\_5779del; p.Leu1924Serfs\*84) in *MYH11*, resulting in premature truncation of the coiled-coil domain. The pathogenic variant was subsequently also found in the proband's infant son with symptoms of visceral myopathy. Our findings expand the phenotypic spectrum of *MYH11* mutations and increase understanding of the genetic architecture of visceral myopathy. This will aid in genetic diagnosis and counseling related to this disorder.

## 1020W

**New digenic combinations with mutations of the genes associated with GnRH-dependent pubertal disorders contribute to variable phenotypes in idiopathic hypogonadotropic hypogonadism.** A. Gach<sup>1</sup>, I. Pinkier<sup>1</sup>, U. Wysocka<sup>1</sup>, K. Salacinska<sup>1</sup>, D. Salachna<sup>1</sup>, M. Szarras-Czapnik<sup>1</sup>, L. Rutkowska<sup>1</sup>, M. Rybak-Krzyszowska<sup>2</sup>, L. Jakubowski<sup>3</sup>. 1) Department of Genetics, Polish Mother's Memorial Hospital Research Institute, Lodz, Poland; 2) Department of Endocrinology and Diabetology, Children's Memorial Health Institute, Warsaw, Poland; 3) Department of Obstetrics and Perinatology, Jagiellonian University Medical Collage, Cracow, Poland.

**Introduction** Idiopathic hypogonadotropic hypogonadism (IHH) results from a dysfunction of the hypothalamic-pituitary-gonadal axis (HPG), which is essential for development and function of the reproductive system. IHH may be associated with anosmia/hyposmia (Kallmann syndrome, KS [MIM 308700]) or normal sense of smell. For many years IHH has been considered a monogenic disorder, with a single gene mutation conditioning up to 30% of cases. Numerous studies have proven that hypogonadotropic hypogonadism is not simply a monogenic Mendelian disease, but more than one gene may be involved in its pathogenesis in a single patient. **Objective** The aim was to explore digenic mutations spectrum in IHH/KS patients. **Material and methods** The study was carried out in the group of 32 patients with hypogonadotropic hypogonadism (HH) with or without anosmia using next generation sequencing (NGS) panel of 51 genes associated with HH. was performed on the MiniSeq platform with TrueSeq Custom Amplicon protocol for library preparation. Variant Studio Software was used for variant filtering and reporting. All disease-relevant and biologically significant variants were validated by Sanger sequencing. **Results** Of 32 IHH subjects five unrelated patients have been found to carry digenic mutations. Subject No 1 is a woman who presented to genetic counseling with primary amenorrhea, discrete features of dysmorphia and normosmia. She was identified with mutations in *CCDC141* (MIM 616031) and *POLR3B* (MIM 614366) genes. Subject No 2 is a woman with KS and anosmia, who was found to carry mutations in *SRA1* (MIM 603819) and *SEMA7A* (MIM 607961) genes. Subject No 3 is a man with micropenis, cryptorchidism and anosmia. Mutations in *CHD7* (MIM 608892) and *PROKR2* (MIM 607123) genes were reported. Subject No 4 and no 5 are men referred to genetic specialists due to clinical diagnosis of IHH. They were found to carry *SPRY4* (MIM 4607984)/*SEMA3A* (MIM 603961) and *STON1* (MIM 605357)/*SEMA3A* mutations respectively. Digenic combinations identified in this study have not been reported elsewhere. **Conclusion** The identification of 5 patients with IHH each harboring a unique combination of two rare variants in genes involved in GnRH neural migration, GnRH secretion or affecting pituitary gland function demonstrates the complexity of the genetic architecture of the disorder. In the era of personalized medicine understanding of full phenotypical spectrum of genotypes associated with IHH is increasingly important.

## 1021T

**Novel gene defect involved in the surfactant metabolism associated with canine lethal neonatal pulmonary alveolar proteinosis.** K.J. Dillard<sup>1,2,3,4</sup>, M. Ochs<sup>5</sup>, J. Niskanen<sup>1,2,3</sup>, M. Anttila<sup>4</sup>, M.K. Hytönen<sup>1,2,3</sup>, H. Lohi<sup>1,2,3</sup>. 1) Department of Veterinary Biosciences, University of Helsinki, Helsinki, Finland; 2) Molecular Neurology, Research Programs Unit, University of Helsinki, Helsinki, Finland; 3) The Folkhälsan Research Center, Helsinki, Finland; 4) Finnish Food Safety Authority - Evira, Pathology, Helsinki, Finland; 5) Institute of Functional and Applied Anatomy, Hannover Medical School, German Center for Lung Research (DZL), Hannover, Germany.

Pulmonary surfactant is produced by alveolar epithelial type II cells (PCII) and is a mixture of lipids and proteins with a property to reduce surface tension in the alveolus necessary for normal gas exchange in the lung. Proper lung surfactant metabolism is crucial for life and genetic disorders affecting this homeostasis are rare in human or any other species. Dog has emerged as an important natural model for human inherited diseases with clinicopathological and genetic similarities. We have studied here an extended family of dogs with neonatal mortality due to dyspnea from birth that generally leads to death in a few hours to days. Pathological examination of the affected puppies revealed a severe congenital pulmonary alveolar proteinosis resembling the group of human disorders of surfactant metabolism. Pedigree established around the affected dogs suggested an autosomal recessive inheritance. To identify the genetic cause, a combined approach of a genome wide association study (5 cases and 24 controls) and exome sequencing (2 cases and 2 controls) was utilized. GWAS using canine high density arrays revealed a disease associated ~3.9 Mb homozygous haplotype in chromosome 34 ( $P_{raw} = 7.161 \times 10^{-10}$ ,  $P_{Bonferroni} = 6.689 \times 10^{-6}$ ). Variant filtering in the identified locus with the assumption of a recessive inheritance revealed only three coding changes. Further analysis of these three variants in additional cases and controls in the breed (n=399), indicated a full segregation and penetrance of one of the variants with the disease. This variant is located in a functional candidate gene abundantly expressed in the lung and involved in surfactant metabolism. Our ongoing experiments aim to confirm the causality of this variant and the novel association of the gene with the disorders of surfactant metabolism.

The Height of an individual is a heritable and highly heterogeneous trait. So far, rare, low-frequency and common height-associated variants together explain about 27.4% of the heritability of height. Consistent with a model complex human trait, rare, large effect-size variants are important for growth development in individuals and are the underlying cause in monogenic forms of short stature. The missing causes in many patients represents an unmet problem for the evaluation of effective and disease-specific treatment. We established a clustered network of human growth and short stature genes to facilitate the characterization of novel candidate genes for short stature identified from WES in 254 unrelated families without known cause. Genes potentially involved in growth delay or growth regulation were selected from MedGen and OMIM. We performed enrichment analysis and clustering of terms from the Gene Ontology, UniProt, OMIM and KEGG in order to retrieve the biological framework of growth. The most significant cluster were related to Skeletal system development, Appendage development, Metabolic processes and Ciliopathy. Moreover, clusters were often related to central processes like chromatin binding or extracellular matrix formation. Based on the systematic characterization of WES variants in the 254 patients we classified 13 candidate genes as 1<sup>st</sup> level (highly confident) and 50 as 2<sup>nd</sup> level (confident) candidate genes. 6 of these 63 1<sup>st</sup> and 2<sup>nd</sup> level candidate genes (9.5 %) have previously been reported as candidate genes for short stature or syndromes including short stature (IFT81, ZBED4, AMMECR1, BRD4, FZD2, and LZTR1). Considering the enrichment cluster analysis 11 (85%) of the identified 1<sup>st</sup> level candidate genes (CPZ, EDEM3, FBRS, IFT81, KCND1, PLXNA3, RASA3, SLC7A8, UBR4, USP45, and ZFH3) are part of 21 defined clusters significantly enriched for growth (49 (98%) of the 2<sup>nd</sup> level candidate genes in 25 clusters). 2 (15%) of the identified 1<sup>st</sup> level candidate genes (LAMA5, MED24) and one of the 2<sup>nd</sup> level candidate genes (GREB1L) were not included in enriched clusters for growth indicating novel growth pathways. In conclusion, we build a map of enriched evolutionary functions and pathways for known growth retardation genes. We successfully applied this cluster to characterize 13 highly confident novel (50 confident) candidate genes for short stature.

**1023W**

**Prevalence and treatment of OI-related hearing loss with bisphosphonates.** E.M. Carter, C. Citron, S. Khan, K. Citron, C.L. Raggio. , Select a Country.

**PURPOSE:** Osteogenesis Imperfecta (OI) is a bone disorder that usually stems from dominant mutation in the type 1 collagen genes. The prevalence of hearing loss in OI varies from 50-92%. Bisphosphonates limit bone turnover and are used to treat OI. Recent research suggests bisphosphonates can halt the progression of OI-related hearing loss. **METHODS:** Retrospective review of 150 charts from individuals with a clinical diagnosis of OI identified 24 individuals (ages 2-66) with audiograms. Pure tone averages (PTA) of those with a single audiogram (N=17) were reviewed in the context of their age, OI type, and bisphosphonate treatment. PTA of individuals with more than one audiogram (N=7) were analyzed longitudinally with bisphosphonate treatment (hearing loss defined as  $\pm 10$ dB since previous audiogram). **RESULTS:** The majority of the population was female (N=21) with an average age of 30.08 $\pm$ 19.28 years. 24/150 individuals had an audiogram. 8/24 did not experience hearing loss, 2 of those took bisphosphonates. 16/24 individuals who had audiograms displayed hearing loss; 9 of those were treated with bisphosphonates. 8 individuals had OI Type I and hearing loss; 2 were treated with bisphosphonates, 6 never took bisphosphonates. 11/150 individuals were referred for ENT consultation but not given an audiogram. Left ear pure tone measurements at the 500 Hz level were the only significant difference between individuals treated with bisphosphonates and those who were not. Individuals with Types I, III, and IV OI significantly varied only in left ear pure tone measurements at 500 and 1000 Hz. There was no relationship between PTAs and age or years of bisphosphonate treatment. **CONCLUSION:** The comparisons made in this study suggest that bisphosphonate treatment in OI is equivocal in halting the progression of hearing loss. Because most individuals in this study did not have multiple audiograms, it is difficult to postulate whether bisphosphonate use impacts deterioration of hearing loss. These results also demonstrate the need for communication between specialists to optimize care for individuals with OI and raises questions about the lack of patient compliance in following physician recommendations. **SIGNIFICANCE:** Hearing loss may potentially be averted and/or the progression halted with bisphosphonate use. Emphasis needs to be placed on getting regular hearing tests so that proper treatment can be administered and its effects observed.

**1024T**

**Isolated brachymetatarsia due to a mutation in *TBX4*.** J. D'Alessandro, G. LaPorta. Podiatric Surgery, Lourdes Memorial Hospital, Binghamton, NY.

**Introduction** Brachymetatarsia is a disorder that causes premature closure of the physis associated with one or more metatarsal bones. The deformity can occur in isolation or with other comorbidities and has a predilection to the fourth metatarsal. Isolated Brachymetatarsia is rare and displays variable Mendelian patterns of inheritance. We performed whole exome sequencing (WES) in an affected Caucasian male presenting with isolated, idiopathic Brachymetatarsia and identified a pathogenic *de novo* variant in *TBX4*.

**Materials and Methods** -IRB approval and informed consent were obtained from Lourdes Memorial Hospital. -Genomic DNA from Proband and unaffected parents extracted from saliva. -Target capture on Agilent SureSelect V6.0. -Enriched library sequenced at Quick Biology. -Multiple filtering steps: Assuming a dominant inheritance pattern variants that were filtered out included: non-exonic, synonymous changes, or  $MAF > 0.01\%$  in 1000 genomes, ESP (n=6500), ExAC (n~62000), or gnomAD (n~123,000). -Prioritization steps based on: Evolutionary conservation (PhyloP), prediction of pathogenicity (PolyPhen2/SIFT), Biological/Clinical relevance (Pathways / interaction networks). -Sanger sequencing was used for validation in each member of the trio with primer pairs designed to the relevant region of *TBX4* (Reference sequence NM\_001321120.2). -Further exploration of this mutation and its clinical implications pending. **Main Findings** After WES in 3 samples and variant calling / filtering: -5 rare, nonsynonymous variants were retained, all with deleterious prediction by SIFT/PolyPhen. -the *TBX4* nonsense mutation chr17:59534035 NM\_018488.3:c.184C>T p.(Gln62Ter) is the most relevant as *TBX4* is linked to Ischiopatellar dysplasia (OMIM: 601719.0002), implying a role in lower extremity development. -This *TBX4* mutation is not documented in any public database and is thus considered to be very rare; its nonsense nature could greatly compromise the proteins structure-function relationship. **Conclusion** -This is the first documented report of Brachymetatarsia caused by a *de novo* mutation of *TBX4*. -The discovery of the 184C>T p.(Gln62Ter) mutation in *TBX4* therefore has important implications for disease screening, prognosis, and genetic counseling. .

**Childhood hypophosphatasia: Painful bone marrow edema mimicking chronic recurrent multifocal osteomyelitis improved after three months of asfotase alfa enzyme replacement therapy.** G.S. Gottesman<sup>1</sup>, D. Wenkert<sup>1</sup>, W.H. McAlister<sup>2</sup>, G. Khanna<sup>2</sup>, K. Mack<sup>1</sup>, S. Mumm<sup>1,3</sup>, M.P. Whyte<sup>1,3</sup>. 1) Center for Metabolic Bone Disease, Shriners Hospital for Children - St. Louis, Saint Louis, MO; 2) Mallinckrodt Institute of Radiology, Washington University School of Medicine, St. Louis, MO; 3) Division of Bone and Mineral Diseases, Washington University School of Medicine, St. Louis, MO.

Hypophosphatasia (HPP) is the inborn-error-of-metabolism that features hypophosphatasemia, tooth loss, and impaired skeletal mineralization with varying expressivity. In 2009, we reported an unrelated boy and girl with childhood HPP and recurrent periarticular soft tissue swelling and pain, primarily at the distal forearms and ankles. Radiographic, histopathologic, and MRI findings, including bone marrow edema, mimicked chronic recurrent multifocal osteomyelitis (CRMO). The pathogenesis remained unknown. Here, we report a teenage boy with childhood HPP and 7 episodes of recurrent wrist swelling and pain (5 episodes within the preceding 3 years). At age 9 years, he reported brief morning stiffness and intermittent leg pain treated with non-steroidal medications (NSAIDs). He had no fever, mucocutaneous or gastrointestinal symptoms. Each episode occurred with minor trauma causing rapid localized swelling and was associated with point tenderness. Conservative treatment with casting, for presumed Salter-Harris I growth plate fractures, improved the pain and swelling. He took NSAIDs for pain typically twice weekly. At 13 years of age, our review of the interval radiographs revealed slight worsening of the abnormalities typical of HPP at his wrists and knees. We then explored the most recent episode with an MRI of his forearms and hands, which showed metadiaphyseal signal increases consistent with CRMO. Additionally, functional testing confirmed new gross motor deficits consistent with childhood HPP. Mutational analysis of *ALPL* identified a novel heterozygous ~65 base pair deletion 5' of exon 4 that removed the splice site. With an evolving, worsening clinical status during his pubertal growth spurt, we started asfotase alfa enzyme replacement therapy (ERT). Three months later, pain had resolved (off NSAIDs), and follow-up MRI showed significant improvement of the metadiaphyseal bone edema (Figure). C-reactive protein and erythrocyte sedimentation rate, normal at baseline, remained normal. Procollagen type I amino-terminal peptide, elevated at baseline, fell 3.6-fold but was still elevated; collagen carboxy-terminal telopeptide also elevated at baseline, had normalized. Autoinflammatory mechanisms are considered an etiology for CRMO. Our patient's response to ERT alone suggests that CRMO-like lesions in HPP reflect a metabolic consequence of the alkaline phosphatase deficiency.

**1026W**

**Temporal growth trends in achondroplasia: Results from a multicenter achondroplasia registry.** S. Hashmi<sup>1</sup>, D. Rodriguez-Buritica<sup>1</sup>, E. Serna<sup>1</sup>, A. Alade<sup>2</sup>, J. Hoover-Fong<sup>2</sup>, M. Bober<sup>3</sup>, M. Little<sup>3</sup>, R. Pauli<sup>4</sup>, J. Legare<sup>4</sup>, P. Modaff<sup>4</sup>, C. Smid<sup>4</sup>, J. Hecht<sup>4</sup>. 1) McGovern Medical School at UTHealth, Houston, TX; 2) Greenberg Center for Skeletal Dysplasias, McKusick-Nathans Institute of Genetic Medicine, Johns Hopkins University, Baltimore, MD; 3) Al DuPont Hospital for Children, Jefferson University, Wilmington, DE; 4) University of Wisconsin School of Medicine and Public Health, Madison, WI.

**Objective:** Achondroplasia is the most common form of dwarfism occurring in 1/25,000 newborns. The natural history has been defined in a number of small studies that included limited number of individuals with achondroplasia. Therefore, the information about medical issues is sparse or imprecise leaving uncertainties about specific health recommendations. Weight in achondroplasia is a vexing problem for those with achondroplasia and for the providers who care for them, height velocity in achondroplasia is poorly defined and head circumference changes need better definition. The objective of this study is to utilize the recently created achondroplasia natural history database to evaluate temporal trends in height, weight and head circumference and to produce new growth charts. **Methods:** Approval was obtained by all institutional IRBs. A large multicenter achondroplasia registry using Research Electronic Data Capture (REDCap) system was created that included longitudinal patient data from Johns Hopkins University, Al duPont Hospital for Children, McGovern Medical School UTHealth, and the University of Wisconsin. All available demographic and medical data from 1957-2017 was abstracted and entered by study coordinators at each site and checked for consistency. Anthropomorphic data was compiled to calculate growth curves and growth velocities. **Results:** 1,377 patients in the registry yielded 15,734 data points for weight, 13,427 for height and 9951 for head circumference. Linear growth continued through 19.3 years and 21.7 years, with final adult heights of 127.3 cm (4'2") and 120.2 cm (3'11"), for males and females, respectively. There was no evidence of a pubertal growth acceleration for either males or females. The average adult weight in the study population was 59.4 kg (SD 16.6) and 58.4 kg (SD 17.4) and the average adult head circumference was 59.4 cm (SD 2.5) and 58.1 cm (SD 3.4), for males and females, respectively. **Conclusions:** The new growth charts are based on the largest number of measurements from patients with achondroplasia across age groups in the US. They allow greater precision in clinical follow-up of patients. They may also serve as baseline controls for comparison to subjects treated with novel pharmacologic, medical and surgical interventions, and other unstudied components.

**1027T**

**Application of noncontinuously binding (loop-out) oligonucleotide primers to avoid a polyT region in the untranslated region of SHOX gene exon 1.** M.A. Jama<sup>1</sup>, A. Milson<sup>1</sup>, K. Sumner<sup>1</sup>, G. Pont-Kingdon<sup>1</sup>, Y. Ji<sup>2,3</sup>. 1) 1ARUP Institute for Clinical and Experimental Pathology, Salt Lake City, Utah, Salt Lake City, UT. 500 Chipeta Way, Salt Lake City, UT 84108; 2) Department of Pathology, University of Utah, Salt Lake City, UT; 3) ARUP Laboratories, Salt Lake City.

Defects in the *SHOX* gene (short stature homeobox-containing gene), located in the pseudoautosomal region 1 (PAR1) of X and Y chromosomes, are associated with Léry-Weill, Langer syndrome, and idiopathic short stature. *SHOX* deficiency can be determined by MPLA analysis that detects ~80% pathogenic variants in patients, and DNA sequencing for sequence alteration in the remaining ~10-20% of patients. PCR primers were designed and M13 tails added to the 5'-end of the PCR primers to allow for touchdown PCR and Sanger sequencing using universal M13 sequencing primers. The noncoding region of exon 1, exons 2-5, and 6a were amplified. A highly polymorphic T (polyT) and a (GC)<sub>5-6</sub> regions were noted in the 5' untranslated region (UTR) of exon 1. A noncontinuous sequencing (loop-out) forward and reverse primers were therefore designed to obtain clean sequences for the detection of variants upstream and downstream of the polyT region. A forward sequencing primer was also designed upstream of the (GC)<sub>5-6</sub> region to achieve clean sequences only if the GC<sub>5-6</sub> region was polymorphic and heterozygous. Twelve DNA samples (10 wild-type and 2 Coriell samples with known *SHOX* mutations, NA20215 and NA20216) were amplified and sequenced with M13 primers and noncontinuous forward and reverse primers. DNA sequences with poor quality score around the polyT region were observed in all 12 samples with regular M13 sequencing primers, whereas clean DNA sequences were achieved from the same 12 PCR amplicons when the two loop-out primers were used. Only Sample #5 was noted to have the GC polymorphism and thus the upstream (GC)<sub>5-6</sub> forward primers were used to improve sequencing quality. Pathogenic variant and benign polymorphisms were previously reported in the 5'UTR of *SHOX* where both polyT and (GC)<sub>5-6</sub> tracks are technically challenging for optimal sequencing quality. Our study has demonstrated an easy solution for clinical laboratory by using a pair of noncontinuous loop-out primers. The (GC)<sub>5-6</sub> forward primers can be used only when a heterozygous (GC)<sub>5-6</sub> polymorphism is noted. This improved Sanger sequencing strategy can now be applied in the clinic lab to ensure the detection of sequence variants in up to 20% of patients who carry *SHOX* deficiency upon a negative *SHOX* MLPA result.

## 1028F

**Genotypic and phenotypic characterization of Chinese patients with osteogenesis imperfecta.** L. Li<sup>1</sup>, B. Mao<sup>1</sup>, S. Li<sup>1</sup>, J. Xiao<sup>1</sup>, H. Wang<sup>1</sup>, J. Zhang<sup>1</sup>, X. Ren<sup>2</sup>, Y. Wang<sup>3</sup>, Y. Wu<sup>1</sup>, C. Lu<sup>1</sup>, Y. You<sup>1</sup>, F. Zhao<sup>1</sup>, X. Geng<sup>1</sup>, C. Jiang<sup>1</sup>, Y. Ye<sup>1</sup>, T. Yang<sup>1</sup>, X. Zhao<sup>1</sup>, X. Zhang<sup>1</sup>. 1) Medical Genetics Dept, Institute of Basic Medical Sciences, Chinese Academy of Medical Sciences, Beijing, China; 2) Pediatric Orthopaedics Dept, the People's Hospital of Wuqing District, Tianjin; 3) Pediatric Orthopaedics Dept, Shandong Provincial Hospital Affiliated to Shandong University, Jinan.

Osteogenesis imperfecta (OI) is a clinically and genetically heterogeneous group of rare inherited connective tissue disorders, characterized by multiple fractures, deformity of the long bones, short statures and a variety of extraskeletal features. It is estimated that heterozygous mutations in genes encoding either the  $\alpha 1$  (*COL1A1*) or  $\alpha 2$  (*COL1A2*) chains of type I collagen cause 85–90% of OI cases with autosomal dominant (AD) inheritance. With the improvement of molecular diagnoses, at least 15 genes involved in bone mineralization (*IFITM5* and *SERPINF1*), collagen post-translational modification (*CRTAP*, *P3H1* and *PP1B*), processing and crosslinking (*SERPINH1*, *FKBP10*, *PLOD2* and *BMP1*), and osteoblast differentiation and function (*SP7*, *TMEM38B*, *WNT1*, *CREB3L1*, *SPARC* and *MBTPS2*) have been identified in OI patients. In the present study, we recruited the largest OI cohort in Asian populations, and performed clinical investigation and genetic analyses (whole exome sequencing and targeted sequencing) in 668 Chinese OI patients from 378 families. Finally, we identified 274 mutations (230 in type I collagen encoding genes and 44 in non-collagen genes), including 98 novel mutations, in 340 probands with a detection rate of 90%. Compared with 47 loss-of-function mutations detected in *COL1A1*, either a nonsense or a frameshift mutation was not found in *COL1A2* ( $P < 0.0001$ ). The major cause of autosomal recessive OI was biallelic mutations in *WNT1* (56%, 20/36). It is noteworthy that three genomic rearrangements, including one gross deletion and one gross duplication in *COL1A1* as well as one gross deletion in *FKBP10*, were detected in this study. Of ten individuals with N-terminal glycine substitutions in the  $\alpha 1$  (I) chain, none exhibited hearing loss, suggesting a potential genotype–phenotype correlation. The findings in this study expanded the mutation spectrum and identified potential novel correlations between genotype and phenotype in Chinese OI patients.

## 1029W

**Vertebral segmentation defect and hemivertebra due to rare autosomal biallelic *FBN2* mutations in a Chinese congenital scoliosis cohort.** M. Lin<sup>1,2</sup>, Y. Chen<sup>1,2</sup>, W. Chen<sup>1,2</sup>, Y. Niu<sup>3</sup>, X. Li<sup>3</sup>, Z. Wu<sup>3,4,5</sup>, N. Wu<sup>1,3,4,5</sup>, J. Lin<sup>1,2,4</sup>, Y. Ye<sup>1,4,5</sup>. 1) Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, B, Beijing, Beijing, China; 2) Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing 100730, China; 3) Beijing Key Laboratory for Genetic Research of Skeletal Deformity, Beijing 100730, China; 4) Department of Central Laboratory, Peking Union Medical College Hospital, Peking Union Medical College and Chinese Academy of Medical Sciences, Beijing 100730, China; 5) Medical Research Center of Orthopedics, Chinese Academy of Medical Sciences, Beijing 100730, China.

**Background** Congenital scoliosis (CS) is a common disorder with an incidence of around 0.5–1 in 1000 live births. The genetic basis of sporadic CS is still unclear. *FBN2* gene which lies in 5q23.3 region has been suggested as a candidate gene for CS. Diseases associated with *FBN2* include Arthrogyposis, Distal, Type 9 (DA9; MIM: # 121050) and Macular Degeneration, Early-Onset (EOMD; MIM: # 616118). *Fbn2* mouse models indicated skeleton phenotypes involving congenital kyphoscoliosis and vertebral segmentation defect in MGI. Previous report indicated that partial fusion of C2–C3 vertebral bodies could be characteristics of DA9. Moreover, congenital kyphoscoliosis was shown in about 45% in DA9 according to *FBN2* implicated in OMIM. **Methods** We consecutively enrolled 500 individuals with sporadic CS via Deciphering Disorders Involving Scoliosis and Comorbidities (DISCO) study (<http://www.discostudy.org/>) in Peking Union Medical College Hospital (PUMCH) from October 2010 to November 2017, 110 of which have familial samples. WES was performed on the patients and available family members. Variant calling and annotation was executed by an in-house developed analytic pipeline (PUMch Pipeline, PUMP), followed by data interpretation and reporting according to ACMG guidelines. **Results** We identified rare autosomal biallelic *FBN2* missense mutations (c.1180C>T(p.Arg394Cys) and c.6073G>A(p.Gly2025Ser)) in one sporadic CS case of XH483 by WES. XH483 is characterized by vertebral segmentation defect of T10–T11 and T11 hemivertebra. According to ACMG guidelines, this variant of Arg394Cys should be classified as VUS because the only support of potential pathogenicity comes from its complete absence in our in-house controls, MAF in ExAC (0.000016) and in silico prediction (PolyPhen (0.999), SIFT (0.16), and CADD (26.3)). Arg394 is in the TGFBP #01 domain and highly conserved. Moreover, the variant of Gly2025Ser was recurrent in 3 unrelated CS patients and two unaffected controls. We consider this variant was a risk allele due to the low MAF in ExAC (0.000074) and in silico prediction (PolyPhen (1), SIFT (0.19), and CADD (35)). Gly2025 is in the cb EGF-like #31 domain and highly conserved. Thus, the biallelic *FBN2* mutations were putatively deleterious. **Conclusions** Our findings indicated that biallelic *FBN2* missense mutations might contribute to CS, which also raises the possibility that some CS cases may be due to a primary pathogenetic mechanism involving the recessive *FBN2* variants.

**Bruck syndrome variant lacking congenital contractures due to novel compound heterozygous *PLOD2* mutations.** S. Mumm<sup>1,2</sup>, G.S. Gottesman<sup>2</sup>, P.M. Campeau<sup>3</sup>, A. Nenninger<sup>2</sup>, M. Huskey<sup>4</sup>, V.N. Bijanki<sup>2</sup>, D.J. Veis<sup>1,2</sup>, A. Barnes<sup>5</sup>, J.C. Marini<sup>6</sup>, D. Wenkert<sup>2</sup>, W.H. McAlister<sup>2</sup>, M.P. Whyte<sup>1,2</sup>. 1) Division of Bone and Mineral Diseases, Department of Internal Medicine, Washington University School of Medicine, St. Louis, MO; 2) Center for Metabolic Bone Disease and Molecular Research, Shriners Hospital for Children; 3) Department of Pediatrics, University of Montreal; 4) National Institute of Child Health and Human Development, NIH; 5) Mallinckrodt Institute of Radiology, Washington University School of Medicine at St. Louis Children's Hospital.

A 10-year-old girl was referred for an unidentified skeletal dysplasia featuring osteopenia with poorly-healing fragility fractures, short stature, Wormian bones in her skull, cleft soft palate and uvula, congenital fusion of cervical vertebrae, bell-shaped thorax, progressive scoliosis, restrictive and reactive pulmonary disease, blue sclera, and other dysmorphic features. Previously, chromosome 22q11 deletion analysis for velocardiofacial syndrome and *COL1A1* and *COL1A2* sequencing were negative. Iliac crest biopsy revealed low trabecular connectivity, abundant osteoid, and active bone formation featuring widely-spaced tetracycline labels consistent with osteogenesis imperfecta (OI). Alendronate treatment improved her bone density. Copy number microarray excluded a contiguous gene syndrome. Sanger sequencing of *LRP5*, *PP1B*, *FKBP10*, and *IFITM5* was negative. Instead, exome sequencing revealed two novel missense variants in *PLOD2* (exon 8, c.797G>T, p.Gly266Val; exon 12, c.1280A>G, p.Asn427Ser) which encodes procollagen-lysine, 2-oxoglutarate 5-dioxygenase 2 (lysyl hydroxylase 2, LH2). In ExAC, absence (Asn427Ser) and low frequency (Gly266Val, 0.0000419) implicated both as mutations. The father carried the exon 8 mutation whereas the mother and sister carried the exon 12 defect, and all were well. Autosomal recessive (AR) *PLOD2* mutations cause Bruck syndrome 2 (OMIM #609220) reported in at least 20 cases/15 families as a rare OI featuring congenital contractures of large joints, typically with pterygia, a feature not seen in our patient. Defective LH2 causes under-hydroxylated type I collagen telopeptides compromising crosslinking. Most *PLOD2* missense mutations causing Bruck syndrome 2 are located in exons 17-19 (of 20 total) encoding the C-terminal domain having LH activity, but others are truncating defects (frameshift, splice site mutations) found throughout the gene. AR *PLOD2* mutations causing mild or moderate OI without congenital contractures have been reported in only three reports. Our patient represents the fourth such patient. Her *PLOD2* missense mutations are in the central domain of unknown function, and one (Gly266Val) is the most N-terminal missense defect to date. Hence, our patient's novel *PLOD2* mutations underlie a distinctive skeletal phenotype. Atypical Bruck syndrome should be considered as a possibility in *COL1A1* and *COL1A2*-negative OI cases.

**1031F**

**Loss of function variants in *KDM4C* in Ollier disease: A methylation-dependent mechanism for tumor development.** S. Robbins<sup>1,2</sup>, C. Halde-Engler<sup>3</sup>, A. Dowiak<sup>4</sup>, E. Cirulli<sup>5</sup>, G. Semenza<sup>6,7</sup>, D. Gorkin<sup>4</sup>, D. Valle<sup>6</sup>, N.L.M. Sobreira<sup>1,6</sup>. 1) McKusick-Nathans Institute of Genetic Medicine, Johns Hopkins School of Medicine, Baltimore, MD., USA; 2) Predoctoral Training Program in Human Genetics, Johns Hopkins School of Medicine, Baltimore, MD., USA; 3) Fullerton Genetics Center, Mission Health, Asheville, NC., USA; 4) USCD Center for Epigenomics, University of California San Diego, San Diego, CA., USA; 5) Duke University School of Medicine, Durham, NC., USA; 6) Department of Pediatrics, Johns Hopkins School of Medicine, Baltimore, MD., USA; 7) Institute for Cell Engineering, Johns Hopkins School of Medicine, Baltimore, MD, USA.

Ollier disease (OD) is a rare disorder characterized by the development of multiple enchondromas which can cause skeletal deformity and fractures. Maffucci syndrome (MS) is a related disorder characterized by enchondromas and vascular anomalies. Patients with OD or MS are also at increased risk for cancer, mainly chondrosarcomas and gliomas. Amary et al., (2011) and Pansuriya et al., (2011) identified specific somatic mutations in *IDH1* or *IDH2* in 80% of enchondromas, vascular anomalies, and chondrosarcomas isolated from patients with OD and MS. *IDH1* and *IDH2* catalyze the oxidative decarboxylation of isocitrate to  $\alpha$ -ketoglutarate ( $\alpha$ -KG). Specific gain of function variants found in patients with OD and MS convert  $\alpha$ -KG to 2-hydroxyglutarate, hypothesized to be an oncogenic metabolite. We present a 16-year-old boy with hypotonia, mild learning disability, dysphagia, vocal cord dysfunction, short stature, and multiple enchondromas in his hands and feet first diagnosed at 3 years of age. We performed Sanger sequencing on DNA isolated from an enchondroma and found no variants in *IDH1* or *IDH2*. However, whole exome sequencing of his leukocyte DNA revealed compound heterozygous missense variants in *KDM4C*, [c.11A>G, p.Tyr4Cys];[c.2320G>A, p.Ala774Thr], each inherited from one of his parents. *KDM4C*-Tyr4Cys (gnomAD MAF = 1.1e-5) disrupts a conserved tyrosine and is highly deleterious by GERP and SIFT; *KDM4C*-Ala774Thr (gnomAD MAF = 1.4e-5) is deleterious by SIFT and PolyPhen2. *KDM4C* encodes JMJD2C, an  $\alpha$ -KG dependent histone demethylase that acts as a co-activator of HIF1A, and like HIF1A, JMJD2C levels increase in response to hypoxia (Luo et al., 2012). By immunoblot analysis of extracts of fibroblasts cultured under normoxia from our patient, we found reduced levels of JMJD2C (0.62 fold of control). After 48 hours of culture under hypoxic conditions, JMJD2C levels in control fibroblasts increased 2.4-fold, while levels in our patient fibroblasts increased only 1.2-fold, or 0.32-fold of control. Currently, we are performing ChIP-seq to determine the effect of these loss of function *KDM4C* variants on the H3K9me3 and H3K36me3 demethylase activity of JMJD2C. To further explore the effects of these *KDM4C* variants on the expression of downstream genes, we are performing qPCR and RNA-seq. Our results implicate *KDM4C* in the development of enchondromas and other features in our patient and uncover a possible mechanism for the association of *IDH1/IDH2* with cancer.

**1032W****An unknown problem in a well-known disorder: OI fractures show delayed healing and increased possibility of re-fracture in murine models.**

J. Zieba, E. Munivez, M.M. Jiang, B.H. Lee. Baylor College of Medicine, Houston, TX.

Osteogenesis Imperfecta (OI) is the most common genetic bone dysplasia that is phenotypically and genetically complex. It is characterized by bone deformities and fractures caused by low bone mass and impaired bone quality. Roughly 85-90% of cases are dominantly inherited and result from mutations in genes encoding type I collagen (*COL1A1* and *COL1A2*), the major protein of the bone matrix. 10-15% of OI cases are recessively inherited and the majority result from mutations in members of the prolyl-3-hydroxylation complex including Cartilage Associated Protein (CRTAP). OI patients are at an increased risk of fracture throughout their lifetimes and anecdotal evidence suggests successful fracture recovery. However, non-union has been reported in 24% of fractures and 52% of osteotomies and many stabilization techniques result in additional surgery due to re-fracture. Additionally, re-fractures typically go unreported making the frequency of re-fractures in OI patients unknown. Thus, there is an unmet need to better understand the mechanisms by which OI affects fracture healing. It is our hypothesis that OI fractures undergo suboptimal healing and that this process results in ultimately weaker bone leading to the increased possibility of re-fracture. Using an open tibial fracture model, we show a decrease in callus size in both *Col1a1*<sup>G6100A</sup> and *Crtap*<sup>-/-</sup> OI mouse models post-fracture indicating delayed healing and decreased callus cell proliferation. Additionally, fracture calluses in both models exhibited a significant decrease in polar moment of inertia (PMOI) indicating a decrease in resistance to torsional stress supporting a potential functional deficit in newly healed bone. This data provides valuable insight into the effect of the ECM on fracture healing, a poorly understood mechanism. Most importantly, we performed biomechanical testing via three-point-bending of fully healed *Crtap*<sup>-/-</sup> tibia to determine the mechanical strength of the fracture site. In wild type bone, the healed fracture site resulted in stronger bone when compared to the unfractured tibia. However, *Crtap*<sup>-/-</sup> healed fractured tibia are mechanically weaker than the contralateral unfractured bone. This implies the possibility that OI fractures do not heal properly and may be a prime location for re-fracture. These data may support aggressive prevention of primary fractures as well as a need for therapies during fracture healing to decrease incidence of refracture and deformity in OI patients.

**1033T****Whole exome sequencing identifies known and likely pathogenic variants in a Turkish tooth agenesis cohort.**

Tooth agenesis (TA), described as the failure of development of one or more permanent teeth, is a common craniofacial abnormality observed in different world populations. The genetic etiology of TA is heterogeneous; more than a dozen genes have been associated with nonsyndromic TA, while more than 80 genes for syndromic forms have been described. In this study, we applied whole exome sequencing to identify potential pathogenic variants for TA in 15 multiplex Turkish families affected with TA. Parental consanguinity was reported in 13 pedigrees. Array-based genotyping and linkage analysis were also employed to localize regions segregating with TA. Sanger sequencing and segregation analysis were performed for all variants of interest. Of these 15 families, six were characterized by syndromic TA, and potentially pathogenic variants identified in six genes. In particular, variants in *KREMEN1* (c.146C>G:p.T49R and c.773\_778del:p.F258\_P259del) were identified in two families, respectively; variants in *BCOR* (c.1651G>A:p.D551N) and *WNT10A* (c.682T>A:p.F228I) were identified in one family that had a dual molecular diagnosis; and variants in *TSPEAR* (c.[1726C>T; 1728delC]:p.V576Lfs\*38), *ANTXR1* (c.1312C>T:p.R438C), and *LAMB3* (c.547C>T:p.R183C) are each identified in one family. Nine families were characterized by nonsyndromic TA, and putative deleterious variants were identified in six genes. Variants in *WNT10A* (c.697G>T:p.E233\*, c.682T>A:p.F228I, and c.433G>A:p.V145M) were identified in six families, one of whom had a dual molecular diagnosis including a variant in *LAMA3* (c.1097G>A:p.R366H); variants in *LRP6* (c.3607+3\_6del) and *TSPEAR* (c.1877T>C:p.F626S) were identified each in one family; and variants in *DKK1* (c.548-4G>T), *COL17A1* (c.3277+3G>C), and *LAMA3* (c.2798G>T:p.G933V) segregated with TA in one family, suggesting potential oligogenic inheritance. In conclusion, we identified variants in four WNT signaling pathway genes (*WNT10A*, *LRP6*, *KREMEN1*, *DKK1*), consistent with the role of this pathway in tooth development. The genotype-phenotype relationships described in the present study further represent an expansion of the clinical spectrum associated with *ANTXR1*, *BCOR*, *COL17A1*, *LAMA3*, *LAMB3*, and *TSPEAR*. Our data also support potential multilocus genomic variation, or mutational burden, in three families, underscoring the underlying genetic complexity in this common complex trait.

**Patient with skeletal dysplasia, importance of medical criteria in *RUNX2* spectrum.** *J. Rojas*<sup>1,2</sup>, *A. Paredes*<sup>1,2</sup>. 1) Instituto de Genética Humana, Pontificia Universidad Javeriana, Bogotá D.C., Colombia; 2) Clínicos programas de atención integral S.A.S.

*RUNX2 (CBFA1)* is a master regulatory gene in bone formation. Mutations in this gene have been described in patients with cleidocranial dysplasia (CCD [MIM 119600]) and metaphyseal dysplasia-maxillary hypoplasia-brachydacty syndrome (MDMHB [MIM 156510]), which is a rare autosomal dominant genetic disease, characterized by the triad of hypoplastic or aplastic clavicles, persistence of wide-open fontanels and sutures and multiple dental abnormalities. In general, skeletal abnormalities include short stature, scoliosis, genu valgum, pes planus, a wide pubic symphysis, dysplastic scapulae, and coxa vara. Nevertheless, the range of clinical manifestations can be very broad, where mild cases as isolated dental anomalies, may be underdiagnosed. We present a male patient of 8-years-old with short stature, disproportionate, dental anomalies, frontal bossing, midface hypoplasia, chest with pectus excavatum, scoliosis, genu valgum. The patient was previously studied by another genetics, whom consider a skeletal dysplasia and request a skeletal dysplasia panel of 59 genes, which report a variant of uncertain clinical significance in the *DYM* gene, however the phenotype of the patient does not correspond to that described the literature for diseases associated with mutations in this gene. We extend the molecular study for skeletal dysplasia, which reports the variant c.884C>T (p.Pro295Leu), classified as VUS in the *RUNX2* gene. The *RUNX2* gene (6p21) is a member of the RUNX family of transcription factors, which encodes a nuclear protein essential for osteoblastic differentiation and skeletal morphogenesis. The variant found in the patient, was neither in ExAC nor 1000 genomes, the deletion in this position results in CCD (HGMD CD992745). Currently some genotype-phenotype correlations have been established for dental manifestations, it is essential to identify characteristics that allow limiting the etiological suspicion, to perform the molecular diagnostic confirmation supported by the patient's phenotype. As we know more about the variability of expression of a disease, a whole clinical spectrum is recognized, as is the case of CCD Spectrum Disorder, in which a patient may have isolated dental anomalies, milder cases, skeletal compromise, such as aplasia of the clavicles and anomalies in the closure of cranial sutures, in typical cases. This is where the experience and semiology of the clinician impacts on the direction of molecular studies and the correct diagnosis. .

**1035W**

**Bruck syndrome, a clinical case presentation and literature review.** *L. Mora*<sup>1,2,3</sup>, *A. Paredes*<sup>1,2</sup>. 1) Pontificia Universidad Javeriana, Bogotá D.C., Colombia; 2) Instituto de Genética Humana; 3) Meintegral S.A.S.

Introduction: Bruck's syndrome (BRKS1 [MIM 259450]) was first described by Bruck et al. in 1897. It is a monogenic disease with autosomal recessive inheritance mechanism, characterized by the association of osteogenesis imperfecta and congenital joint contractures. There are two genes associated with this disease, which allow its classification. Its clinical manifestations include short stature, osteoporosis, wormian bones, scoliosis secondary to alterations in the vertebrae, bone fragility and progressive joint contractures associated with multiple pterygium. Case report: We present the case of a 26-month-old female patient, daughter of non-consanguineous parents who cursed with fractures in-uterus, later associated with joint contractures. Taking into account the physical examination findings, we decided to enlarge the skeletal dysplasia panel, where the homozygous pathogenic variant c.612C>G, p.(Tyr204\*) in the *FKBP10* gene was reported. Discussion: Bruck syndrome is classified into 2 types, according to the gene involved. Type 1, the mutation is found in the *FKBP10* gene (17q215), in type 2 in the *POLD2* gene (3q24), which codes for telopeptide lysyl hydroxylase. Mutations in these genes cause deficiency of the bone-specific lysyl telopeptide hydroxylase enzyme, which generates an aberrant cross-linking of type I collagen. Also, pathogenic variants in *FKBP10* are associated with osteogenesis imperfecta type XI and Bruck syndrome, which can be differentiated from each other by means of the physical examination, like in this case. Due to unknown prevalence of Bruck syndrome and low knowledge we bring this case report. Conclusion: Although skeletal dysplasia is a large and heterogeneous group of diseases, it is essential to identify characteristics that limit diagnostic suspicion; as in the case presented, where the clinical concept of the doctor regarding the recognition of the association between pathological fractures and congenital joint contractures associated with pterygium, was essential to define the molecular test and diagnostic confirmation of Bruck syndrome.

**A novel mutation in *NBAS* causes SOPH syndrome.** G.F. Godínez-Zamora<sup>1,2</sup>, P. Baeza-Capetillo<sup>1</sup>, A. Villaseñor-Domínguez<sup>1</sup>, A. Reyes-de-la-Rosa<sup>1</sup>, C. Armijos-Torres<sup>1</sup>, C. García-Delgado<sup>1</sup>, V. Morán-Barroso<sup>1</sup>, J. Aguirre-Hernández<sup>1</sup>. 1) Laboratory of Genomics, Genetics and Bioinformatics, Hospital Infantil de México. México city; 2) Universidad Nacional Autónoma de México,.

**Background:** SOPH syndrome (OMIM 614800) is a disease characterized by short stature, optic nerve atrophy and Pelger-Huet anomaly. This disease was initially described in Siberian Yakut people, where most of the cases have been found. A small number of patients have been found in Europe, and none in other regions across the world. This disease is characterised by global developmental delay, bone chronological age delay, compression of the medullar channel and metabolic alterations. The syndrome shows phenotypic variability, with some patients, but not all, having liver failure. The gene underlying this syndrome is *NBAS*, which codes for a protein that is part of the syntaxin 18 sub complex that plays a role in retrograde transport from the endoplasmic reticulum to the Golgi apparatus. Alterations in *NBAS* have been shown to alter protein recycling and lead to defects in protein glycosylation. Here we describe a girl presenting short stature, bilateral optic atrophy and other multisystem features; global developmental delay, bone chronological age delay, compression of the medullar channel C7 to T5 and facial features suggestive of SOPH syndrome. **Materials and methods:** Whole exome sequencing was performed in the proband and her parents. After read alignment and variant calling, variants were filtered by depth, consequence, segregation, and frequency in public databases, as well as in a local database. Remaining variants were prioritised with the software Exomiser. **Results:** Whole exome sequencing data of the patient and her parents showed that the proband was homozygous for a novel transversion in the acceptor splice site immediately before exon 15 of *NBAS* (ENST00000281513.5:c.1342-1G>C hg19 2:15614449 C>G). Both parents were found to be carriers of this variant. **Conclusions:** SOPH is a very rare disease, previously known only from Siberia and a very small number of European patients. Here, a novel splice site mutation is reported in a very young female patient, from a small population in southern Mexico, presenting phenotypic features of SOPH.

**Molecular and clinical characterization of Turkish patients with Steel syndrome.** J.M. Fatih<sup>1</sup>, G. Yesil<sup>2</sup>, D. Pehlivan<sup>1,3</sup>, Y. Bayram<sup>4</sup>, Z.C. Akdemir<sup>1</sup>, Y. Sahin<sup>5</sup>, E. Karaca<sup>1</sup>, S.N. Jhangian<sup>6</sup>, D.M. Muzny<sup>6</sup>, R.A. Gibbs<sup>1,6</sup>, J.E. Posey<sup>1</sup>, J.R. Lupski<sup>1,7,8</sup>, Baylor-Hopkins Center for Mendelian Genomics. 1) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; 2) Department of Medical Genetics, Bezmi Alem Vakif University Faculty of Medicine, Istanbul, Turkey; 3) Section of Neurology, Department of Pediatrics, Baylor College of Medicine, Houston, Texas; 4) Department of Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, New York; 5) Department of Medical Genetics, Necip Fazil City Hospital, Kahramanmaraş, Turkey; 6) Human Genome Sequencing Center, Baylor College of Medicine, Houston, Texas; 7) Department of Pediatrics, Baylor College of Medicine, Houston, Texas; 8) Texas Children's Hospital, Houston, Texas.

Steel syndrome (STLS) is an autosomal recessive disorder associated with osteochondrodysplasia, a rare form of skeletal dysplasia described in the Puerto Rican population with clinical manifestations that include dislocated hips and radial heads, short stature, scoliosis, carpal coalition, characteristic facies, cervical spine anomalies, and pes cavus. Clinical findings are limited to the skeletal system. We previously identified (Gonzaga-Jauregui, *et al.* (2015) *Eur J Hum Genet* 23: 342-346) a homozygous *COL27A1* variant (c.2089G>C; p.Gly697Arg) and provided evidence for a Puerto Rican founder allele. Since then, two distinct homozygous pathogenic variants have been reported in families from India and the UAE. We studied three unrelated Turkish families with reported parental consanguinity. We applied whole-exome sequencing (WES) in two patients from different families with a clinical diagnosis of an uncertain skeletal dysplasia. Due to a clinical diagnosis of STLS in the third proband, they were sent directly for Sanger sequencing of *COL27A1*. Clinical evaluation revealed distinctive craniofacial features in addition to rhizomelic shortening of the upper limbs, bowing of the femurs, pes calcanovalgus, and joint laxity. WES revealed a homozygous *COL27A1* missense variant (c.2683G>A; p.Gly895Arg) in patient BAB5133 and a homozygous *COL27A1* frameshift deletion (c.4976\_4980delGAGGA; p.Gly1660Aspfs\*3) in patient BAB8900. The third patient, BAB10793, who was clinically diagnosed with Steel syndrome, underwent Sanger sequencing and was found to have a homozygous 11bp *COL27A1* deletion involving the intron1/exon2 boundary causing c.63-5\_68delTCTAGGGGGTT; p.22\_23delGlyPhe. For the families with available data, the *COL27A1* gene mapped within large segments of absence of heterozygosity (AOH), of 9.2Mb for BAB5133 and 3.68Mb for BAB8900, suggesting identity by descent and consistent with the reported parental consanguinity. Our findings demonstrated that STLS is a clinically recognizable disorder with distinctive facial dysmorphic features and we further delineate the skeletal findings of this syndrome. Additionally, we expanded the mutational spectrum of *COL27A1* variants and further confirm the gene-disease association in STLS.

Congenital scoliosis (CS) is a rare and severe malformation with a prevalence of ~0.5-1%. Genetic underpinnings have been implicated in CS pathogenesis. We previously reported that compound inheritance of a rare null mutation and a hypomorphic common variant haplotype of *TBX6* could explain ~11% of CS cases. Here, we elucidate the role of missense mutations of *TBX6* in CS pathogenesis and further investigate the genetic underpinnings, disease biology and etiology of CS. We enrolled patients clinically diagnosed with CS in Peking Union Medical College Hospital between October 2010 and November 2017 as part of the Deciphering Disorders Involving Scoliosis and COMorbidities (DISCO) study. The CS diagnosis was confirmed with radiological imaging and patients with additional syndromic features were excluded. We performed whole exome sequencing for the entire cohort (N = 499) and identified 10 missense mutations of *TBX6* in 16 patients (16/499, 3.2%). Among them, four patients present as CS with hemi/wedge-vertebrae, three with segmentation defects and ten with hemi-/wedge-vertebrae combined with segmentation defects in thoracic or lumbar vertebrae. Five mutations were not present in ExAC, 1000 Genomes, ESP6500 databases, and our in-house database. CADD score showed three mutations (c.424G>T, c.440A>T and c.929C>T) were damaging/likely damaging (CADD = 21, 16.01 and 20.6, respectively), and two (c.1184G>A and c.1300C>T) as tolerated (CADD = 8.97, 11.06, respectively). The remaining five mutations were rarely present with frequency < 0.001 in ExAC, all absent in 1000 Genomes, < 0.005 in ESP6500, and 1, 7, 3, 0, 0 in 998 subjects respectively in our in-house database. CADD showed four mutations (c.356G>A, c.434C>T, c.499C>T and c.700G>C) as damaging/likely damaging (CADD = 34, 16.65, 20.9 and 19.27), and one (c.1112C>T) as tolerated (CADD = 11.36). We further investigated the transcriptional activity of *TBX6* mutations using a dual luciferase reporter assay. Interestingly, we identified two mutations (c.356G>A and c.424G>T) with significantly decreased luciferase activity compared to the wild-type. In addition, we identified the hypomorphic haplotype 'T-C-A' (the co-occurrence of three common SNPs, rs2289292-rs3809624-rs3809627) in *trans* in 9 out of the 16 subjects. Our findings indicate that the likely gene disrupting missense mutations of *TBX6* could contribute to the etiology of CS, thus expanding the mutational spectrum of *TBX6* associated congenital scoliosis (TACS).

## 1039T

**Combining large-scale in vitro functional testing with protein stability simulations to develop new insights into hypophosphatasia genotype/phenotype correlation.** G. del Angel<sup>1</sup>, E. Mornet<sup>2</sup>, J. Reynders<sup>1</sup>. 1) Alexion Pharmaceuticals Inc., Lexington, MA; 2) Laboratoire de génétique constitutionnelle prénatale et postnatale. Centre Hospitalier de Versailles. Le Chesnay, France.

Hypophosphatasia (HPP) is a rare, systemic, inherited metabolic disorder that can involve bone, muscle, kidney and other organs. The disease is characterized by low alkaline phosphatase (ALP) enzymatic activity and is typically caused by mutations in the tissue non-specific alkaline phosphatase gene (*ALPL*, OMIM:171760). It has been previously shown that clinical presentation severity correlates with mutant protein *in vitro* enzymatic activity and with the strength of dominant-negative effects (Zurutuza 1999; Lia-Baldini 2001). Our study had two aims: first, to expand our understanding of *ALPL* genotype/phenotype relation by characterizing *in vitro* a larger portion of population variants, and to use this *in vitro* data to develop methods to predict variant enzymatic activity level. We first tested 62 *ALPL* missense mutations for residual enzymatic activity and dominant negative effect using site-directed mutagenesis and transient co-transfections of WT/mutant plasmids into MDCK cells. Twenty-nine of these mutations had been previously characterized and were used to validate the assay. The remaining 33 missense variants had not been previously characterized *in vitro*, and 24 of them would be marked as Variants of Unknown Significance (VUS) according to ACMG guidelines. Of these 33, 15 showed low residual enzymatic activity and 2 showed dominant negative effects, thereby increasing their likelihood of pathogenicity. Once combined with previously reported results, this dataset of 128 *in vitro*-tested variants, which encompasses all *ALPL* missense variants with gnomAD carrier frequencies above 1/10,000 (Lek 2016), was used to develop and validate a new algorithm that predicts low enzymatic activity for *ALPL* missense variants. We first measure effects of amino-acid changes on ALP dimer thermodynamic equilibrium by using free energy perturbation methods (Steinbrecher 2017), and we predict low enzymatic activity based on changes in protein structure stability, affinity and metal cross-link presence, yielding prediction accuracy, as measured by the area under the receiver operating curve (AUC), of 0.78. We then use *in-silico* scores like Polyphen-2 (Adzhubei 2010) as additional inputs to the model to improve performance with an AUC metric of 0.87, compared with an AUC of 0.83 for Polyphen-2 alone. This model can be used to score novel *ALPL* variants, and may help get new insights into HPP genotype/phenotype correlation. .

## 1040F

**Multilocus genomic variants may explain the clinical heterogeneity of patients with KBG syndrome.** C. Zhang<sup>1</sup>, J.F. Mazzeu<sup>2,3</sup>, S.V. Braz<sup>2</sup>, B.M. Ferreira<sup>2</sup>, A.C. Acevedo-Poppe<sup>2</sup>, Z.C. Akdemir<sup>1</sup>, S.N. Jhangiani<sup>1</sup>, J.E. Posey<sup>1</sup>, D.M. Muzny<sup>4</sup>, R.A. Gibbs<sup>5</sup>, C.M.B. Carvalho<sup>1</sup>, J.R. Lupski<sup>1,4,5,6</sup>. 1) Department of Molecular and Human Genetics, BCM, Houston, TX; 2) University of Brasilia, Brasilia, Brazil; 3) Robinow Syndrome Foundation, Anoka, MN; 4) Human Genome Sequencing Center, BCM, Houston, TX; 5) Department of Pediatrics, BCM, Houston, TX; 6) Texas Children's Hospital, Houston, TX.

KBG syndrome (MIM:148050) is an autosomal dominant disorder characterized by macrodontia of the upper central incisors, distinctive craniofacial findings, skeletal anomalies, and neurodevelopmental involvement including developmental delay and intellectual disability (DD/ID). Diagnosis can be challenging due to extensive phenotypic variability and overlap with other neurodevelopmental conditions. In addition, many of the features, including intellectual disability, can be mild, and none are pathognomonic for diagnosis. Heterozygous variants in *ANKRD11* leading to haploinsufficiency are the cause of KBG syndrome with more than 60 mutations identified. We hypothesize that some of the clinical heterogeneity observed in patients with a diagnosis of KBG syndrome can be partially explained by multiple genetic variants in addition to mutations in *ANKRD11*. To test this hypothesis, we studied two patients with KBG-like phenotypes by SNP array and whole exome sequencing (WES). Both of these patients have *de novo* indel variants affecting exon 9 of 13 exons in *ANKRD11*. In addition, we also identified a hemizygous likely pathogenic variant in *MED12* in the first patient. This rare variant is a conserved missense at position c.3571G>A; p.Asp1191Asn. Missense variants in *MED12* have been implicated in three distinct X-linked intellectual disability syndromes with distinctive clinical features, phenotypes that largely overlap with KBG syndrome. Thus, some distinct phenotypes such as speech problems and upslanted palpebral fissures are more likely caused by the variant in *MED12*. Wide fontanel, short stature, anteverted nares, long philtrum and cryptorchidism, are more likely caused by the truncated variant in *ANKRD11*. Other overlapping phenotypes like high forehead and intellectual disability may be associated with either of these two variants. For the second patient, we identified a 18Mb AOH region at position 14q21.1q23.1 (g.41435763-59516209). Some distinct phenotypes, such as high forehead, upturned nose, anteverted nares, long philtrum, and 5th finger clinodactyly are more likely to be caused by truncated variant in *ANKRD11*. Other phenotypes, like development delay and intellectual disability may be associated with either the variant in *ANKRD11* or maternal/paternal AOH on chromosome 14. In summary, our data provide evidence that clinical phenotypic variability of KBG syndrome may result from multilocus genomic variation in some patients.

## 1041W

**A missense mutation of *COL2A1* gene in an achondrogenesis type II neonate (Case report).** C.H. Lee<sup>1,2</sup>, Y.N. Yang<sup>1,2,3</sup>, P.J. Ko<sup>2,4</sup>, M.L. Yeh<sup>2,4</sup>, L.M. Chen<sup>1,2</sup>, Y.T. Su<sup>1,2</sup>, N.C. Lee<sup>5,6</sup>. 1) Department of Pediatrics, E-DA Hospital, Kaohsiung, Taiwan; 2) School of Medicine, I-Shou University, Kaohsiung, Taiwan; 3) Graduate Institute of Medicine, College of Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan; 4) Division of Pediatric Surgery, Department of Surgery, E-DA Hospital, Kaohsiung, Taiwan; 5) Department of Medical Genetics, National Taiwan University Hospital, Taipei, Taiwan; 6) Department of Pediatrics, National Taiwan University Hospital, Taipei, Taiwan.

**Introduction:** Achondrogenesis type II (OMIM #200610) was a rare lethal skeletal disorder which affected cartilage and bone development. The major clinical characteristics were extremely short trunk and limbs, a narrow chest with short ribs, and underdeveloped lung. Achondrogenesis type II was an autosomal dominant inheritance and caused by *de novo* mutation in the collagen type II-1 *COL2A1* gene. This gene made a protein that formed type II collagen which was essential for the normal development of bones and other connective tissues. **Case presentation:** This male neonate was born at 40 weeks and 2 days of gestation age via vaginal delivery and his parents were without consanguinity or know medical problems. After birth, he was admitted to neonatal intensive care unit due to severe tachypnea, dyspnea, and substernal retraction. The physical examination showed body length 38cm (<3 percentile), body weight 2755gm (3-15% percentile), head circumference 36cm (85-97 percentile), arm span 36cm, pseudo low-set ears, mid-facial hypoplasia, anteverted nostrils, cleft palate, micrognathia, short neck, narrow chest cavity with bulging of anterior chest, prominent abdomen, bilateral simian crease, clinodactyly of bilateral 5th fingers, and bilateral clubfoot. Radiographs revealed short ribs, short and broad long bones, and a lack of ossification in the spine and pelvis. **Method and result:** Whole exome sequencing was performed for skeletal dysplasia survey. The heterozygote missense mutation c.1529G>A (p.Gly510Asp) was identified in exon 24 of *COL2A1* gene which was also confirmed by Sanger sequencing. According to Leiden Open Variation Database (LOVD-COL2A1 2015 update) and clinical features, this case was accord with achondrogenesis type II. **Conclusions:** To our knowledge, this case was the third time this mutation was reported in achondrogenesis type II. Through whole exome sequencing, the patient could gain a rapid, accurate, and cost-efficient diagnosis. In clinical, it was much important for appropriate medical care, identifying potential treatment, prognosis of the disorder, genetic counseling, and access to support groups.

**Chondrodysplasia Punctata (CDPX1) presenting with respiratory distress.** *G.E. Tiller<sup>1</sup>, D.D. Tieu<sup>2</sup>, E.H. Rhee<sup>3</sup>.* 1) Genetics, Kaiser Permanente, Los Angeles, CA; 2) Head and Neck Surgery, Kaiser Permanente, Los Angeles, CA; 3) Pediatrics, Kaiser Permanente, Los Angeles, CA.

X-linked recessive chondrodysplasia punctata (type 1; CDPX1) is a rare skeletal dysplasia presenting with mild dysmorphic features, epiphyseal +/- soft tissue stippling, and brachytelephalangy (shortened distal phalanges). We describe a term male infant with CDPX1 who presented with mild dysmorphic features and respiratory distress. He exhibited mild hypertelorism, epicanthal folds, small nose with flat nasal bridge, retrognathia, and malar hypoplasia. The patient developed stridor and respiratory distress in the first 12 hours of life. He was transferred to our NICU and underwent supraglottoplasty for shortened aryepiglottic folds; no tracheal stenosis was evident during direct laryngoscopy. Due to persistent stridor and increased work of breathing, a tracheostomy was performed at one month of life, which relieved his symptoms. Imaging studies revealed C3-C4 fusion, brachytelephalangy, as well as stippling of proximal femurs, ankles, and posterior thoracolumbar spinal elements. No cervical spinal stenosis nor CNS anomalies were noted. Microarray revealed no deletions or duplications, but sequencing of the ARSE gene revealed a Gly141Glu substitution. Glycine 141 is highly evolutionarily conserved, and predictive software suggests that the amino acid substitution is deleterious. This case serves to illustrate additional airway and cervical spinal anomalies that can be seen in CDPX1, as well as identifying an additional novel missense variant in ARSE.

**Identification of a diagnostic fusion transcript in a patient with multiple exostoses clinically negative for EXT variants.** *G.R. Oliver<sup>1</sup>, P. Blackburn<sup>1</sup>, F. Pinto e Vairo<sup>1</sup>, M.S. Ellingson<sup>2</sup>, D. Babovic-Duksanovic<sup>1</sup>, E.W. Klee<sup>1</sup>.* 1) Center for Individualized Medicine, Mayo Clinic, Rochester, MN; 2) Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN.

Hereditary Multiple Exostoses (HME) are cartilaginous outgrowths inherited in an Autosomal Dominant fashion. Mutations in *EXT1* and *EXT2* are usually causative with 70-75% of cases due to protein truncating point mutations and 10% caused by deletions involving single or multiple exons. Some have suggested the remaining cases may be due to mutation at novel loci, while others have highlighted the role of mosaic mutations in *EXT1* and *EXT2*. We describe the case of a nine-year-old male born to healthy parents of mixed European descent. At age 4 months, the patient was referred to Clinical Genomics for failure to thrive. At 10 months, he was diagnosed with global developmental delay, short stature, dysmorphisms, and with multiple exostoses that have worsened at 6 years of age. Focal epilepsy was diagnosed at 2 years. The patient had a normal karyotype, and array genomic comparative hybridization (aCGH) revealed a de novo interstitial deletion of chromosome 16p13.3 spanning approximately 219 kilobases and encompassing 11 known genes unrelated to patient's phenotype. Multiplex ligation-dependent probe amplification (MLPA) and direct sequencing of all coding exons of *EXT1* was negative for mutations. Whole Exome Sequencing revealed a heterozygous, maternally inherited splice mutation in *DCX* (c.809-1G>A). This mutation was deemed diagnostic of the patient's neurological phenotype but exostoses remained unexplained. RNA sequencing revealed a candidate intrachromosomal *SAMD12-EXT1* fusion transcript. Subsequent reinspection of clinical aCGH identified a region of low probe intensity potentially indicative of a sub-calling threshold chromosomal loss between *SAMD12* exon 1 and *EXT1* exon 1. Re-analysis with a second array of higher probe density reinforced these findings and the event was categorized as a likely mosaic deletion resulting in gene fusion and *EXT1* loss of function. The event was deemed diagnostic of the multiple exostoses. This case corroborates previously published work describing the need to consider mosaic loss in cases of *EXT* mutation-negative HME patients. Furthermore the findings highlight the value of extended investigation in the resolution of undiagnosed cases and exemplify an emerging reality in genetic analysis whereby traditional approaches may benefit from novel analyses and hypothesis-building to maximize diagnostic yield.

## 1044W

**KIAA1217: Evidence for a novel candidate gene associated with cervical segmentation defects.** N. AIDhaheer<sup>1</sup>, N. Wu<sup>2</sup>, S. Zhao<sup>2</sup>, Z. Wu<sup>2</sup>, R. Blank<sup>3</sup>, C. Raggio<sup>4</sup>, M. Halanski<sup>5</sup>, K. Noonan<sup>5</sup>, B. Nemeth<sup>5</sup>, S. Sund<sup>5</sup>, N. Sobreira<sup>1</sup>, P. Giampietro<sup>6</sup>. 1) McKusick Nathans Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, MD, United States; 2) Peking Union Medical College Hospital, China; 3) Medical College of Wisconsin, Milwaukee, WI; 4) Hospital for Special Surgery, NY; 5) University of Wisconsin-Madison, WI; 6) Drexel University College of Medicine, Philadelphia, PA.

**Background:** Cervical segmentation defects (CSD) are caused by alterations in somitogenesis, which may occur in association with other renal, cardiac, or spinal cord birth defects (30-60% of cases), and are associated with disabling pain from myelopathy and disc disease. The genetic etiology of most CSD disorders remains unknown and its identification may aid in the development of novel treatment and prevention strategies. **Methods:** We performed whole exome sequencing (WES) on a cohort of eight unrelated probands with CSD and a constellation of additional anomalies affecting their cardiac, CNS, and musculoskeletal systems. Using PhenoDB analysis tool, heterozygous and homozygous, rare (MAF<1%) and functional (missense, nonsense, splicing and indels) variants in each proband were selected. These genes and variants were evaluated for their ClinVar, HGMD, OMIM, GWAS, mouse model phenotypes and other annotations to identify the best candidate variants in each proband. Genes that were mutated in 3 or more probands were also selected. **Results:** We identified rare heterozygous variants in *KIAA1217* in 3 unrelated probands. In a separate cohort of 35 patients with CSD from DISCO (Deciphering Disorders Involving Scoliosis & COmorbidities) study, we identified compound heterozygous variants in a single proband and heterozygous variants in 5 probands. In total, we identified 10 variants in 9 patients, 3 of which have not been described in gnomAD and one is a stopgain variant. Collectively, patients had cervical segmentation abnormalities, cardiac and central nervous system abnormalities. **Discussion:** *KIAA1217* is involved in embryonic skeletal development (The Gene Ontology project). It is also found to be required for normal intervertebral disc development and GWAS studies identified its association with lumbar disc herniation. Mice homozygous for a gene-trapped allele, display malformations of the notochord and caudal vertebrae and may exhibit caudal tail kinks. DECIPHER describes a patient with a 10.44 Mb (97 genes) *de novo*, heterozygous deletion affecting *KIAA1217* in a proband with hemivertebrae, abnormality of the pinna, hypoplasia of the radius, low-set ears, and renal agenesis. **Conclusion:** Based on our findings and on what is known about the biology of this gene, we suggest that *KIAA1217* pathogenic variants can cause autosomal dominant CSD with or without cardiac and CNS anomalies.

## 1045T

**Diagnostic yield and clinical relevance of exome screening in patients with early-onset scoliosis (EOS).** S. Zhao<sup>1,2</sup>, W. Chen<sup>1,2,3,4</sup>, Z. Yan<sup>1,2,3</sup>, W. Wu<sup>1,2,4,9</sup>, *Deciphering Disorders Involving Scoliosis and COmorbidities (DISCO) study.* 1) Department of Orthopedic Surgery, Peking Union Medical College Hospital, Peking Union Medical College and Chinese Academy of Medical Sciences, Beijing 100730, China; 2) Beijing Key Laboratory for Genetic Research of Skeletal Deformity, Beijing 100730, China; 3) Graduate School of Peking Union Medical College, Beijing 100005, China; 4) Department of Molecular and Human Genetics, Baylor College of Medicine; Houston, TX 77030, USA; 5) Obstetrics and Gynecology Hospital, State Key Laboratory of Genetic Engineering at School of Life Sciences, Institute of Reproduction and Development, Fudan University, Shanghai 200433, China; 6) Key Laboratory of Reproduction Regulation of NHFPC, Collaborative Innovation Center of Genetics and Development, Fudan University, Shanghai 200433, China; 7) Shanghai Key Laboratory of Female Reproductive Endocrine Related Diseases, Shanghai 200433, China; 8) Baylor Genetics Laboratory, Houston, TX 77021, USA; 9) Medical Research Center of Orthopedics, Chinese Academy of Medical Sciences, Beijing 100730, China; 10) Department of Central Laboratory, Peking Union Medical College Hospital, Peking Union Medical College and Chinese Academy of Medical Sciences, Beijing 100730, China; 11) Departments of Pediatrics, Baylor College of Medicine, Houston, TX 77030, USA; 12) Texas Children's Hospital, Houston, TX 77030, USA.

Scoliosis, defined as a lateral spine curvature more than 10°, is a descriptive clinical diagnosis rather than an etiological diagnosis. The age of onset of scoliosis is a key factor in determining the therapeutic strategy. Early onset scoliosis (EOS), onset age before 10, conveys significant health risk to affected children. The etiology of EOS includes vertebral anomalies (CS I, vertebral malformation; CS II, segmentation defect; CS III, mixed condition), neuromuscular defects, and various syndromes, presenting a complex phenotypic context. Although genetic factors are believed to underlie these conditions, genetic testing is not routinely ordered for children with EOS. To investigate the molecular diagnosis rate by whole exome sequencing (WES) among EOS and its associated syndromes, and the prevalence of clinical actionable variants including both primary and incidental findings, we consecutively recruited 500 patients with EOS in Peking Union Medical College Hospital as part of the Deciphering Disorders Involving Scoliosis and COmorbidities (DISCO) study (<http://www.discostudy.org/>), 110 of whom have familial samples. WES was performed on the patients and available family members. Variant calling and annotation was executed by an in-house developed analytic pipeline, followed by data interpretation and reporting according to ACMG guidelines. A total of 106 (21.2%) EOS patients received a molecular diagnosis, including 56 (11.2%) *TBX6*-associated scoliosis (TACS) patients and 50 (10.0%) patients with reported pathogenic variants. The diagnostic rate varies between scoliotic subgroups: 62/126 (49.2%) in CS I, 8/45 (18%) in CS II, 21/289 (7.3%) in CS III, 3/4 in Neurofibromatosis, 3/10 in neuromuscular scoliosis, 3/3 in osteogenesis imperfecta, 3/3 in achondroplasia, and 3/20 in idiopathic EOS. In 106 patients with molecular diagnoses, 19 (18%) yielded findings of significant clinical relevance, defined by preventive surgical measures (*PLOD1*, *RYR1*, *COL5A2*), multi-system symptomatic treatment (*EBP*, *MYH7*, *JAG1*, *PTPN11*), and targeted treatment (*COL1A1*, *NF1*). In conclusion, WES allows the identification of molecular etiology in 21.2% patients with EOS, and detection of clinically actionable mutations emphasizes the necessity of genetic testing for EOS patients.

**1046F**

**Structural alteration of glycosaminoglycan side chains and spatial disorganization of collagen networks in the skin of patients with musculocontractural Ehlers-Danlos syndrome caused by CHST14/D4ST1 deficiency.** T. Koshō<sup>1,2</sup>, T. Hirose<sup>3</sup>, N. Takahashi<sup>3</sup>, P. Tangkawattana<sup>4</sup>, J. Minaguchi<sup>3</sup>, S. Mizumoto<sup>5</sup>, S. Yamada<sup>5</sup>, N. Miyake<sup>6</sup>, A. Hatamochi<sup>7</sup>, J. Nakayama<sup>8</sup>, T. Yamaguchi<sup>1,2</sup>, K. Takehana<sup>3</sup>. 1) Medical Genetics, Shinshu University School of Medicine, Matsumoto, Japan; 2) Center for Medical Genetics, Shinshu University Hospital, Matsumoto, Japan; 3) Laboratory of Microanatomy, School of Veterinary Medicine, Rakuno Gakuen University, Ebetsu, Hokkaido, Japan; 4) Department of Veterinary Anatomy, Faculty of Veterinary Medicine, Khon Kaen University, Khon Kaen, Thailand; 5) Department of Pathobiochemistry, Faculty of Pharmacy, Meijo University, Nagoya, Japan; 6) Department of Human Genetics, Yokohama City University Graduate School of Medicine, Yokohama, Japan; 7) Department of Dermatology, Dokkyo Medical University, Mibu, Japan; 8) Department of Molecular Pathology, Shinshu University Graduate School of Medicine, Matsumoto, Japan.

Musculocontractural Ehlers-Danlos syndrome (EDS) due to CHST14/D4ST1 deficiency (mcEDS-CHST14) is a recently delineated type of EDS caused by biallelic loss-of-function mutations in *CHST14*, resulting in depletion of dermatan sulfate (DS). Clinical characteristics of mcEDS-CHST14 consist of multiple malformations and progressive fragility-related manifestations including skin hyperextensibility and fragility. Skin fragility is postulated to result from impaired assembly of collagen fibrils caused by alteration of glycosaminoglycan (GAG) chain of decorin-proteoglycan (PG) from DS to chondroitin sulfate (CS). This systemic investigation of skin pathology of patients with mcEDS-CHST14 includes immunostaining of decorin and transmission electron microscopy-based cupromeronic blue staining to visualize GAG chains. Collagen fibrils were dispersed in the affected papillary to reticular dermis in contrast to regularly and tightly assembled in the controls; and also appeared to have perpendicular arrangement to the affected epidermis in contrast to the parallel arrangement along with the control epidermis. Affected GAG chains were shown to be linear stretching from the outer surface of collagen fibrils, in contrast to those of the controls showing to be curved attaching onto the outer surface of collagen fibrils. Decorin-PG appeared as filamentous forms in the affected skin, whereas thick bundles intermingled with collagen fibers in the controls. This is the first observation of compositional alteration, from DS to CS, of the GAG side chains to cause structural alteration of GAG side chains, which results in spatial disorganization of collagen networks, presumably disrupting recently uncovered ring-mesh structure of GAG side chains surrounding collagen fibrils. McEDS-CHST14 is a critical model to delineate importance of DS as GAG side chains of decorin-PG assembling collagen fibrils in the maintenance of connective tissues.

**1047W**

**A unique COL1A2 mutation in a teenage male with patellar dislocations.** E.M. Pereira, E. Guzman. New York-Presbyterian, Morgan Stanley Children's Hospital, Columbia University Medical Center, Department of Pediatrics, Division of Clinical Genetics, NY, NY.

Our patient presented to clinical genetics to rule out a connective tissue disorder. This 16-year-old male is the product of a non-consanguineous union between parents of Dominican descent. After an unremarkable prenatal course, he was noted to have bilateral congenital hip dislocations which resolved over time. At 3 years of age he sustained a femur fracture after an accidental trauma which required a spica cast for 3 months. As a teenage he suffered a left knee injury and subsequently had 4 patellar dislocations (one spontaneously). After corrective surgery at 15 years old there have been no recurrences. The patient had a normal echocardiogram. An ophthalmologic exam was scheduled. Developmentally, the patient had a history of speech delay and early intervention services were in place till he was 5 years old; currently he is in regular education. His family history is significant for a mother, maternal half-brother, and paternal half-sister with minor flexibility but no dislocations. The patient's physical exam did not reveal skin hyperextensibility. There was atrophic scarring around his left knee at the surgical site. He had grey tinged sclerae but otherwise unremarkable features. His Beighton score was 0, but there was mild joint hypermobility. Given his neonatal history and subtle physical findings, chromosomes, microarray, and a collagenopathy panel were sent. Results were positive for a likely pathogenic *COL1A2* variant: c.398G>T giving p.Gly133Val which affects the highly conserved glycine residue important in fibrillary collagen stability. *COL1A2* related disorders have been associated with phenotypes ranging from autosomal dominant forms of osteogenesis imperfecta and 2 forms of Ehlers-Danlos syndrome (cardiac valvular and arthrochalasia type). Though he does have grey tinged sclerae and had a femur fracture at a young age, he has been playing competitive high contact sports in high school and has not sustained further fractures. His normal echocardiogram rules out Ehlers-Danlos syndrome, cardiac valvular type. He does have a history of congenital bilateral hip dislocation, but does not meet clinical criteria for Ehlers-Danlos syndrome, arthrochalasia type (aEDS). Additionally, patients with aEDS have a mutation in exon 6 of *COL1A1* or *COL1A2* while our patient's variant is in exon 9. Lifestyle changes may be warranted given this *COL1A2* variant, but more studies (including familial variant testing) would be important for further classification.

**1048T**

**Homozygous mutation in *PLOD3*, encoding lysyl hydroxylase 3, causes recessive dystrophic epidermolysis bullosa with abnormal anchoring fibrils and deficiency in type VII collagen.** H. Vahidnezhad<sup>1,5</sup>, L. Youssefian<sup>1</sup>, AH. Saeidianan<sup>1</sup>, A. Touati<sup>1</sup>, S. Pajouhanfar<sup>1</sup>, S. Aristodemou<sup>2</sup>, L. Liu<sup>2</sup>, T. Baghdad<sup>3</sup>, A. Kariminejad<sup>4</sup>, S. Zeinali<sup>5</sup>, JA. McGrath<sup>6</sup>, J. Uitto<sup>1</sup>. 1) Department of Dermatology and Cutaneous Biology, Sidney Kimmel Medical College, Thomas Jefferson University, Philadelphia, PA, USA; 2) Viapath, St Thomas' Hospital, London, UK; 3) Department of Orthopedic Surgery, Imam Khomeini Hospital, Tehran University of Medical Sciences, Tehran, Iran; 4) Kariminejad-Najmabadi Pathology & Genetics Center, Tehran, Iran; 5) Molecular Medicine Department, Biotechnology Research Center, Pasteur Institute of Iran, Tehran, Iran; 6) Department of Medical and Molecular Genetics, St. John's Institute of Dermatology, King's College London (Guy's Campus), London, UK.

Epidermolysis bullosa (EB), a group of heritable skin fragility disorders, manifests with blistering and erosions leading to ulcers with poor healing tendency. As many as 20 different genes have so far been associated with different forms of EB. Tissue separation in the dystrophic EB (DEB) which is characteristically caused by mutations in *COL7A1* is below the lamina densa within the upper papillary dermis at the level of anchoring fibrils. Anchoring fibrils, which consist of type VII collagen, can be reduced in number, morphologically altered or entirely absent in DEB as a result of mutations in *COL7A1*. In this study, 363 distinct consanguineous EB families were examined by whole exome sequencing and genome-wide homozygosity mapping. A pathogenic homozygous mutation in the *PLOD3* was detected in a patient with clinical impression of mild DEB and multiple joint contractures. Immunofluorescence microscopy and Western blot showed complete absence of *PLOD3* in the patient. Interestingly, skin immunostaining with different antibodies against proteins of basement membrane zone showed markedly attenuated amounts of type VII collagen. Residual VII collagen was present both in the roof and the floor of the blister. In addition, the level of cleavage was shown to be below the lamina densa by transmission electron microscopy. Furthermore, only a few, thin wisp-like structures with no clearly discernable anchoring fibrils were present. Also, several fibroblasts were present close to the dermal-epidermal junction embedded within densely packed individual collagen bundles, and these cells displayed dilated endoplasmic reticulum and prominent vesicles close to the cell membrane. The latter findings are consistent with fibrotic reaction, a feature of DEB. In summary, our study demonstrated the consequences of homozygous *PLOD3* mutation in a patient with skin fragility with DEB-like phenotype with sub-lamina densa blistering, and perturbation of anchoring fibrils with deficiency in type VII collagen. In addition, there was evidence of fibrosis in the upper papillary dermis, features of DEB. Collectively, these findings suggest a novel gene harboring mutations in the mild dystrophic forms of EB, and suggest an additional mutant gene associated with skin fragility disorders in the spectrum of EB.

**Reduced elastin deposition in a *PI4K2A*-related cutis laxa patient.** E.C. Lawrence<sup>1</sup>, E. Morava<sup>2,3</sup>, F. Liu<sup>1</sup>, M. Mohamed<sup>4</sup>, M.G. Waugh<sup>5</sup>, R.A. Wevers<sup>1</sup>, Z. Urban<sup>1</sup>. 1) Human Genetics, University of Pittsburgh, Pittsburgh, PA; 2) Haywards Genetics Center, Tulane University, New Orleans, LA; 3) Department of Pediatrics, University Medical Centre Leuven, Belgium; 4) Translational Metabolic Laboratory, Department of Laboratory Medicine, Radboud University Nijmegen Medical Center, the Netherlands; 5) Lipid and Membrane Biology Group, University College London, UK.

A recent whole exome sequencing study identified a recessive p.R275W mutation in the phosphatidylinositol 4-kinase type 2  $\alpha$  (*PI4K2A*) gene in an individual with cutis laxa, choreoathetoid movement disorder, dysmorphic features and intellectual disability. This mutation reduced *PI4K2A* activity to 22.5% of normal. The goal of this study is to identify the molecular mechanisms that may connect this gene mutation to the disease phenotype by examining elastic fiber biosynthesis and signalling pathways influenced by phosphatidylinositides. We Sanger sequenced an additional 115 probands with Cutis laxa of unknown genetic origin on the 9 coding exons of *PI4K2A*. Two additional probands had amino acid mutations, one mutation also likely to decrease enzyme activity (p.R328Q) and another (p.L262F) found in a water molecule-mediated hydrogen bond. The original patient and 3 control skin fibroblasts lines were grown to harvest RNA and protein for assays. By immunostaining, *PI4K2A* was localized to EEA1-positive endosomal compartments and was absent in the Golgi apparatus and lysosomes in both patient and control cells. The staining with the EEA1 and *PI4K2A* also showed colocalization in both patient and control samples showing that the mutation did not alter the localization of the *PI4K2A*. Quantitative RT-PCR detected increased expression of *ELN*, decreased expression of *FN1* and *FBLN4* and normal expression of *FBLN5*, *LOX* and *LOXL1*. Immunostaining showed largely normal levels and distribution of elastin, but diminished fibrillin-1 microfibrils. Colorimetric FASTIN assays demonstrated significant reduction of insoluble elastin in patient cells. In response to WNT3A, none of the cells showed a significant stabilization of beta catenin. Whereas normal cells responded by a robust increase in AKT phosphorylation to WNT3A treatment, the mutant cells did not. AKT phosphorylation, however, was increased the same way in patient and control cells in response to insulin. The p.R275W mutation does not interfere with the correct localization of *PI4K2A*, and likely acts through a change in enzyme activity. Impaired elastin deposition in mutant cells is associated with decreased fibrillin microfibril density. It remains to be determined whether the apparent loss of responsiveness to WNT3A in mutant cells contributes to the observed alterations in elastic fiber production and we are working on the additional amino acid changes to determine how they are involved in the disease phenotype.

### 1050W

**A pathogenic deletion of the *VPS33B* gene leading to a case of attenuated arthrogryposis-renal dysfunction-cholestasis (ARC) syndrome.** S.S. Rabin-Havt<sup>1</sup>, K. Gallagher<sup>2</sup>, P. Levy<sup>2</sup>, S. Klugman<sup>1</sup>, D.H. Lee<sup>2</sup>, R. Marion<sup>2</sup>. 1) Dept of Obstetrics & Gynecology and Women's Health, Montefiore Medical Center/ Albert Einstein College of Medicine, Bronx, NY; 2) Department of Pediatrics, Montefiore Medical Center/ Albert Einstein College of Medicine; 3) Department of Medicine, Montefiore Medical Center/ Albert Einstein College of Medicine.

**Introduction:** The increasing clinical use of exome sequencing (ES) is providing a window into the phenotypic spectrum of known syndromes. The *VPS33B* gene plays a crucial role in intracellular trafficking (Zhou & Zhang, 2014). Variants can disrupt epidermal barrier formation (Gruber et al., 2017) and have been implicated in arthrogryposis-renal dysfunction-cholestasis syndrome (MIM 208085) and, rarely, autosomal recessive keratoderma-ichthyosis-deafness syndrome (ARKID). ARC syndrome, an autosomal recessive disorder typically fatal in infancy, presents with arthrogryposis, renal tubular acidosis, and cholestatic jaundice often accompanied by ichthyosis, platelet dysfunction, brain and cardiac anomalies, and deafness (Zhou & Zhang, 2014). Rare cases of attenuated ARC syndrome, presenting later and with milder symptoms who have survived into childhood have been described (Smith et al., 2012). A 2017 paper reported on 3 patients with ARKID who presented with palmoplantar keratoderma (PPK), ichthyosis, sensorineural deafness, and variable associated symptoms (Gruber et al., 2017). **Case:** We report on an 11-year-old female who was referred to Dermatology-Genetics clinic. She presented with pruritic ichthyosis (since 6 months of age), bilateral hearing loss (since 2 years of age), severe intellectual disability, and failure to thrive. Pregnancy, birth, and family history were unremarkable and there was no reported consanguinity. Exam revealed proportional growth delay, microcephaly, rocker bottom feet, severe PPK, and ichthyosis. **Results:** Chromosomal microarray and connexin deafness panel were negative. ES revealed two variants of the *VPS33B* gene: the first, a partial gene deletion that includes the starting codon (a new pathogenic variant), the second, c.1225+5G>C, a previously described likely pathogenic variant predicted to cause abnormal gene splicing (previously reported in patients with attenuated ARC syndrome). After the diagnosis of *VPS33B*-related disorder was made, she was found to have elevated aminotransferase and renal tubular acidosis. **Conclusion:** This rare presentation of attenuated ARC syndrome with phenotypic overlap with ARKID syndrome suggests that these conditions represent a phenotypic spectrum. Diagnosis by ES led to presymptomatic identification of hepatic and renal involvement, and ES will continue to elucidate natural history and improve management. We propose renaming this clinical spectrum *VPS33B*-Related Disorder.

### 1051T

**Probing a novel familial giant lipomatosis syndrome with genetics.** J. de Vegvar<sup>1</sup>, V. Aggarwal<sup>1</sup>, D. Goldstein<sup>1</sup>, K. Anyane-Yeboah<sup>1</sup>, H. Depaz<sup>2</sup>, N. Jouayed<sup>2</sup>, F. Figurasin<sup>2</sup>, R. Enghal<sup>2</sup>. 1) Columbia University, New York, NY; 2) Harlem Hospital, New York, NY.

**Abstract: Introduction:** Lipomas are slow-growing adipose tumors that occur more frequently in mature adults aged 40 to 60 years old. Most lipomas are small and weigh only several grams. A giant lipoma is defined as at least 10 cm in one dimension and weighs at least 100 grams. Cases of giant lipomas have been reported, but a clinical syndrome of a solitary giant encapsulated lipoma with a strong familial component has not yet been described.

**Goals and hypothesis:** We studied a 42-year-old man born in St. Croix with macrocephaly, intellectual disability and a giant lipoma. This same condition has been traced through three generations of the patient's family including his grandmother, two aunts, uncle and cousin. We hypothesized that this condition is caused by an unknown hereditary factor. **Methods:** We employed whole exome sequencing of the proband to determine the disease causing variant.

**Results:** A number of rare variants with significance were found. **Conclusion:** This case shows that solitary giant lipomas can present with a genetic family history. In this case, the pattern of inheritance fits an autosomal dominant model because it is three generations, and affects males and females equally. The presence of macrocephaly and intellectual disability in the affected individuals suggests that this is likely to be syndromic rather than an isolated condition. The results also show that there are many genetic conditions with unknown molecular basis, even with exome testing. Whole genome sequencing is now being used to identify the disease causing variant.

**1052F****Exome sequencing identifies semidominant inheritance of a new *GNMB* mutation in an extended pedigree with amyloidosis cutis dyschromica.**

McGrath<sup>1</sup>. 1) St John's Institute of Dermatology, School of Basic and Medical Biosciences, King's College London, London SE1 9RT, United Kingdom; 2) As'ad Al-Hamad Dermatology Center, Al-Sabah Hospital, Kuwait City 13001, Kuwait; 3) Department of Dermatology, National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan 70101, Taiwan; 4) International Research Center of Wound Repair and Regeneration (iWRR) National Cheng Kung University, Tainan 70101, Taiwan; 5) Dermatopathology Laboratory, Viapath, St Thomas' Hospital, London SE1 7EH, United Kingdom; 6) National diagnostic EB laboratory, Laboratory, Viapath, St Thomas' Hospital, London SE1 7EH, United Kingdom; 7) Department of Genetics, School of Basic and Medical Biosciences, King's College London, Guy's Hospital, London SE1 9RT, United Kingdom.

Amyloidosis cutis dyschromica (ACD) is an autosomal recessive disorder characterized by prepubertal onset of reticular hyperpigmentation with hypopigmented spots, and amyloid deposition in the upper dermis. Recently, bi-allelic mutations in *GNMB* (encoding a glycoprotein involved in melanosome maturation) have been described. We undertook whole-exome sequencing in three affected individuals with ACD from an extended consanguineous Bedouin pedigree with nine affected members. Focusing on homozygous protein altering variants with a frequency <0.01, we identified a single previously unreported splicing variant (c.700+5G>T) in *GNMB*. Co-segregation analysis showed homozygosity for this variant in all affected individuals but also revealed two individuals (the mother and one offspring) who were heterozygous and who had a milder/intermediate skin phenotype (less hyperpigmentation, fewer areas of hypopigmentation). We confirmed the splicing defect by reversion-transcription, with loss of the canonical donor splice site and use of a cryptic one, and introduction of a new premature stop codon. Moreover, qPCR in RNA from whole skin biopsies in three individuals with different genotypes of the *GNMB* mutation, showed approximately 35% reduction in *GNMB* expression in a heterozygous affected member, and almost no expression in a homozygous individual when compared to a wild-type unaffected family member. Immunofluorescence analysis showed markedly reduced *GNMB* in homozygote skin, patchy reduction in melanocyte numbers and basal keratinocyte melanin, as well as positive amyloid labelling in the papillary dermis. Electron microscopy in homozygote skin revealed numerous dermal colloid bodies (dead basal keratinocytes). In contrast, heterozygote skin showed a slight reduction in the number of melanocytes and reduced melanin but no amyloid deposition or colloid bodies. In summary, these data expand the spectrum of mode of inheritance in ACD, highlighting semidominant inheritance rather than just autosomal recessive transmission, and identify a new mutation in *GNMB*.

**1053W****A novel KIT mutation in a family with expanded syndrome of Piebaldism.**

S. Majid<sup>1</sup>, I. Hamadah<sup>2</sup>, M. Chisti<sup>2</sup>, M. Haider<sup>2</sup>, H. Dosssari<sup>1</sup>, R. Humaidan<sup>1</sup>, B. Meyer<sup>1</sup>. 1) King Faisal Specialist Hospital & Research Center, Riyadh, Saudi Arabia; 2) Department of Dermatology, King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia.

Mutations in the KIT gene have been associated rare autosomal dominant genodermatosis characterized by depigmentation of skin and white forelocks. KIT gene which encodes the cell surface transmembrane tyrosine kinase receptor for KIT ligand represents critical factor for melanoblast migration, proliferation, differentiation, survival and a decrease in melanogenesis. We screened a family of four affected's consistent with autosomal dominant pattern of inheritance using Next Generation Sequencing in a comprehensive gene panel incorporating 194 dermatological genes. While our patients presented with classical phenotype of piebaldism, additional features in the form of sensorineural deafness and heterochromia iridis were observed in some patients. Our results from next generation sequencing derm panel suggests novel missense mutation in the tyrosine kinase domain of the KIT gene, responsible for the severe form of piebaldism in our patients. Our findings expand the mutation spectrum of KIT-associated piebaldism disorders and highlight the clinical utility of next generation sequencing derm panel for the diagnosis in patients with suspected genodermatosis.

**Analysis options for human whole genome sequencing.** T. Stokowy<sup>1,2,3</sup>, A. Supernat<sup>4</sup>, O.V. Vidarsson<sup>5</sup>, R. Holdhus<sup>1</sup>, T. Fiskerstrand<sup>6</sup>, G. Houge<sup>6</sup>, V.M. Steen<sup>1,2,3</sup>. 1) Department of Clinical Science, University of Bergen, Bergen, Hordaland, Norway; 2) NORMENT & K.J. Jebsen Centre for Psychosis Research, Department of Clinical Science, University of Bergen, Norway; 3) Dr. E. Martens Research Group for Biological Psychiatry, Department of Medical Genetics, Haukeland University Hospital, Bergen, Norway; 4) Laboratory of Cell Biology, Intercollegiate Faculty of Biotechnology, University of Gdańsk and Medical University of Gdańsk, Poland; 5) Computational Biology Unit, Institute of Informatics, University of Bergen, Norway; 6) Department of Medical Genetics, Haukeland University Hospital, Bergen, Norway.

Testing of patients with hereditary disorders is in progress of shifting from single gene assays to gene panel sequencing, whole-exome sequencing (WES) and whole-genome sequencing (WGS). Therefore, we decided to summarize analysis options for human whole genome sequencing from a clinical perspective. As the first step, we performed a comprehensive literature search and review of 512 articles related to WGS applications. Subsequently, we tested DeepVariant, a new TensorFlow machine learning-based variant caller, and compared to GATK 4.0 and SpeedSeq, using 30X WGS data of the well-known NA12878 DNA reference sample. According to our comparison, DeepVariant reached the highest F-Score (i.e. harmonic mean of recall and precision) both for SNVs and indels (0.98 and 0.94 respectively). Performance of SNV calling using the three mentioned tools was comparable (GATK and SpeedSeq reached lower F-Scores, however still equal to 0.98 after rounding to two decimal places). On the other hand, DeepVariant was more precise in indel calling (GATK and SpeedSeq reached F-Scores 0.90 and 0.84, respectively). We concluded that the DeepVariant tool has great potential and usefulness for medical genetics. We used methods mentioned above to disclose causes of three monogenic disorders: keratolytic winter erythema (CTSB, duplication of enhancer), severe Penttinen syndrome (PDGFRFB, de novo substitution) and immunodeficiency syndrome (IL, deletion). The functional data which support our findings (RNA-Seq, epigenetics and successful drug testing in patient-derived cell lines) will be presented during the meeting.

**1055F**

**Novel *Dsg1* mutation in focal palmoplantar keratoderma.** T. Nomura<sup>1</sup>, M. Takeda<sup>1</sup>, T. Miyauchi<sup>1</sup>, S. Suzuki<sup>1</sup>, J.T. Peh<sup>1</sup>, T. Uesugi<sup>2</sup>, H. Shimizu<sup>1</sup>. 1) Department of Dermatology, Hokkaido University Graduate School of Medicine, Sapporo, Japan; 2) Uesugi Dermatology Clinic, Sapporo, Japan.

Inherited palmoplantar keratodermas (PPKs) are clinically and genetically heterogeneous genodermatoses, characterized by hyperkeratosis of the palms and soles. Based on the distribution pattern of hyperkeratotic lesions, PPKs are clinically classified into four types; diffuse, striate, focal, and punctate. To date, more than 20 genes have been reported to be responsible for PPKs. Although the majority of heterozygous mutations in the gene encoding desmoglein 1 (*DSG1*), a key molecule for epidermal adhesion and differentiation, cause striate PPK, mutations causing haploinsufficiency of *DSG1* have also been identified in one and three families with diffuse and focal PPKs, respectively. Here we report a Japanese family with focal PPK caused by a *DSG1* mutation. 10-year-old dizygotic twins presented with focal skin thickening of the palms and soles that had appeared since their birth. Palmoplantar skin of their father and paternal grandfather was similarly affected. None of the affected individuals showed a striate pattern of hyperkeratosis on their palmoplantar regions. Histology of the affected plantar skin showed marked hyperkeratosis, parakeratosis, highly eosinophilic cytoplasm of keratinocytes, and widen intercellular spaces and disadhesion of keratinocytes. Sanger sequencing revealed that the patients are heterozygous for a previously unreported nonsense mutation in *DSG1*, whereas their unaffected mother is wild-type for the mutation. These findings collectively led us to diagnose the patients as having focal PPK due to a *DSG1* mutation. In conclusion, this study further highlights the clinical heterogeneity of *DSG1*-associated PPKs. Although mutation analysis of *DSG1* has been performed primarily for striate PPK, our results suggest that *DSG1* screening should also be considered routinely in focal PPK.

## 1056W

**Genetic heterogeneity in Osteogenesis Imperfecta, NGS based study.**

K. Sałacińska<sup>1</sup>, L. Rutkowska<sup>1</sup>, I. Pinkier<sup>1</sup>, D. Salachna<sup>1</sup>, A. Rusinska<sup>2</sup>, E. Jakubowska-Pietkiewicz<sup>2</sup>, A. Jamsheer<sup>3</sup>, M. Rybak-Krzyszowska<sup>4</sup>, L. Jakubowski<sup>1</sup>, A. Gach<sup>1</sup>. 1) Department of Genetics, Polish Mother's Memorial Hospital Research Institute, Lodz, Poland; 2) Department of Propaedeutics of Paediatrics and Metabolic Diseases, University Teaching Hospital, Lodz, Poland; 3) Department of Medical Genetics, University of Medical Science, Poznan, Poland; 4) Department of Obstetrics and Perinatology, Jagiellonian University Medical College, Cracow, Poland.

**Introduction**Osteogenesis Imperfecta (MIM 166200) is a rare genetic disorder of connective tissue characterized by numerous bone fractures, gray or blue sclera, tooth abnormalities, short stature and skeletal deformity. The diversity of clinical features and its severity varies between patients, even within a single family, ranging from severe perinatal lethal to a mild form. It is estimated that about 1500 different mutations in only 2 genes linked to proper protein structure and amount of collagen type I are responsible for about 90% of OI cases. Remaining 10% is caused by mutations of numerous genes directly influencing collagen type I protein biosynthesis or related molecular pathways. The aim of this project was to determine genetic heterogeneity versus clinical variability observed in patients affected by OI.**Material and methods**Next Generation Sequencing technique using custom panel dedicated for re-sequencing of 34 genes with confirmed and probable significance in pathogenesis of OI was performed. The study included 102 patients, aged 1-44 years, presenting a broad spectrum of clinical manifestation. Twenty-five of them were familial cases. Based on bioinformatic analysis, selected variants were verified with Sanger sequencing in a group of 69 patients.**Results**We have identified *COL1A1* (MIM 120150) mutations in 40 patients, *COL1A2* (MIM 120160) in 23 patients and mutations in 3 non-collagenous genes in 6 patients. In one patient pathogenic variants in both collagen type 1 genes were identified. A total of 36 different mutations in *COL1A1* and 20 in *COL1A2* were found. Respectively 14 and 11 have not been reported in dedicated Osteogenesis Imperfecta Variant Database. A novel identified variant in *COL1A2* occurred in two family members and two nonconsanguineous patients. In a 25-year old patient with moderate form of OI we identified novel compound heterozygous mutations in a *BMP1* gene (MIM 112264). Both *BMP1* mutations affect highly conserved residues across distant species localized in CUB1 domain.**Discussion**Obtained results extend variant spectrum of *COL1A1* and *COL1A2* mutations. Phenotype variability between patients within the same type of OI or possessing the same mutation is observed both inter- and intrafamilial. Thus far, mutations in *BMP1* gene have been identified within metalloprotease, CUB2 and CUB3 domains, signal peptide, 3'UTR sequence but not in CUB1 domain. Our study broadens insights into genotype-phenotype correlation in OI.

## 1057T

**MALTA (MYH9 Associated eLasTin Aggregation) syndrome: Germline variants in MYH9 cause rare sweat duct proliferations and irregular elastin aggregations.**

Ha<sup>5</sup>, J. Schaller<sup>6</sup>, D. Adams<sup>7</sup>, E. Rytina<sup>8</sup>, M. van SteENSEL<sup>9,10</sup>, M. Tischkowitz<sup>1</sup>. 1) University of Cambridge, Cambridge, United Kingdom; 2) Department of Dermatology, Venerology and Allergology, University Hospital, Leipzig, Germany; 3) Center for Genomics and Transcriptomics and Praxis für Humangenetik Tübingen, Tübingen, Germany; 4) East Anglian Medical Genetics Service, Cambridge University Hospitals National Health Service Foundation Trust, Cambridge Biomedical Campus, Hills Road, Cambridge, Cambridgeshire, CB2 0QQ, UK; 5) Department of Dermatology, Addenbrooke's Hospital, Cambridge, Cambridgeshire, CB2 0QQ, UK; 6) Dermatopathologie Duisburg, Duisburg, Germany; 7) Experimental Cancer Genetics, Wellcome Trust Sanger Institute, Hinxton, Cambridge, Cambridgeshire, CB10 1SA, UK; 8) Department of Histopathology, Addenbrooke's Hospital, Cambridge, Cambridgeshire, CB2 0QQ, UK; 9) Skin Research Institute of Singapore, Singapore; 10) Lee Kong Chian School of Medicine, Nanyang Technological University, Singapore.

**Background:** In the present study we investigate several patients with an irregular distribution of elastin fibres and benign sweat duct proliferations who were initially diagnosed with Rombo and Nicolau-Balus syndrome. Analysis of the germline mutations within these individuals provides evidence that these disorders represent a single entity, characterised by variants in non-muscle myosin gene *MYH9* [MIM: 160775]. Pathogenic variants in *MYH9* have been previously described in patients with thrombocytopaenia and giant platelets. **Methods:** DNA was extracted from blood of six affected individuals from three families with a history of sweat duct proliferations. Whole exome sequencing was performed across these individuals to identify rare, protein-affecting variants that co-segregate in affected individuals. The *MYH9* gene, which contained variants in these three families, was Sanger sequenced in a further two affected families. The functional impact of identified variants on known binding sites was analysed *in silico* using 3D protein modelling and the conservation of affected amino acids was assessed across different myosin classes. **Results:** Predicted protein-affecting variants in *MYH9* were identified in all tested sweat duct proliferation syndrome families, co-segregating with the phenotype. None of the affected individuals presented with any phenotypic features of the previously described *MYH9*-related platelet disorder (MRPD). Four out of the five identified variants were located within the myosin head ATP binding pocket. The amino acids modified by these variants are conserved across eight different classes of myosin. **Discussion:** We provide evidence that sweat duct proliferations with abnormal elastin aggregations are associated with germline pathogenic variants in *MYH9*. We therefore suggest the name MALTA (MYH9 Associated eLasTin Aggregation) syndrome to reflect this underlying genetic basis. The identified *MYH9* variants are located in different gene regions and appear to have a different effect on myosin function to those previously associated with *MYH9*-related platelet disorder (MRPD). Understanding the genetic basis of MALTA syndrome will aid the diagnosis and management of this disease by providing a way of differentiating its associated skin lesions from histopathologically similar but clinically aggressive sweat duct tumours. Importantly, our findings point to a novel disease mechanism for non-muscle myosins in tumorigenesis and skin diseases.

**1058F****Characterization of vascular phenotypic variability in a non-isogenic mouse model for Marfan syndrome.** *I.G. Gyuricza<sup>1</sup>, R.B. Souza<sup>1</sup>, G.R. Fernandes<sup>1</sup>, L.E. Farinha-Arcieri<sup>1</sup>, I.H.J. Koh<sup>2</sup>, L.V. Pereira<sup>1</sup>.*

1) Department of Genetics and Evolutionary Biology, University of São Paulo, São Paulo, Brazil; 2) Department of Surgery, Paulista School of Medicine, Federal University of São Paulo, São Paulo, Brazil.

Marfan syndrome (MFS) is autosomal dominant connective tissue disorder caused by mutations in *FBN1* gene, which encodes the extracellular matrix protein Fibrillin-1. The main manifestations of MFS include the skeletal and cardiovascular tissues, the latter being the leading cause of mortality. Despite its complete penetrance, there is a wide inter and intra familial clinical variability among patients, which makes the prognosis more difficult and suggest the existence of modifier genes. Based on that, our group created a new MFS mice strain by crossing C57BL/6 mice heterozygous for *Fbn1* mutation ( $mg\Delta^{loxprneo}$ ) and 129/Sv wild type (WT) mice, generating a model with higher genetic and phenotypic variability. The main objective of this study was to characterize the vascular phenotypic variability in the mixed B6/129  $mg\Delta^{loxprneo}$  model. We analyzed histological aorta sections from  $mg\Delta^{loxprneo}$  and WT mice, and measured a set of features such as: medial and adventitia aortic wall thickness, number of vascular smooth muscle cells (VSMC) and elastic fibers integrity. Using Principal Component Analysis (PCA), we could observe that  $mg\Delta^{loxprneo}$  and WT mice presented wide phenotypic variability, and the main aortic feature that distinguishes MFS from WT mice is the elastic fibers integrity. Despite the fact that all the  $mg\Delta^{loxprneo}$  mice showed reduced elastic fibers integrity, those with thicker medial and adventitia aortic wall, as well as higher number of VSMCs, did not develop aneurysms. These results suggest that the adaptive events of aortic wall might be important for the maintenance of vascular function and that genes involved in these pathways should be further analyzed as potential protective genes. In conclusion, the B6/129  $mg\Delta^{loxprneo}$  strain models the clinical variability of MFS and can be useful for identifying the molecular and physiological mechanisms underlying cardiovascular diseases. In addition, the identification of these mechanisms can improve the patient's prognosis and support the development of new therapeutic targets.

**1059W****A somatic activating NRAS mutation associated with kaposiform lymphangiomatosis.** *S.F. Barclay<sup>1</sup>, K.W. Inman<sup>2</sup>, V.L. Luks<sup>2</sup>, J.B. McIntyre<sup>3</sup>, A. Al-Ibraheemi<sup>2,7</sup>, A.R. Perez-Atayde<sup>2</sup>, S.J. Fishman<sup>4,7</sup>, A.I. Alomari<sup>5,7</sup>, G. Chaudry<sup>6,7</sup>, C.C. Trenor, III<sup>6,7</sup>, D. Adams<sup>6,7</sup>, H.P.W. Kozakewich<sup>2,7</sup>, K.C. Kurek<sup>1</sup>.*

1) Departments of Pathology & Laboratory Medicine and Medical Genetics, Alberta Children's Hospital Research Institute and Cumming School of Medicine, University of Calgary, Calgary, AB; 2) Department of Pathology, Boston Children's Hospital, Boston, MA; 3) Translational Laboratory, Tom Baker Cancer Centre, Department of Oncology, Cumming School of Medicine, University of Calgary, Calgary, AB; 4) Department of Surgery, Boston Children's Hospital, Boston, MA; 5) Division of Interventional Radiology, Boston Children's Hospital, Boston, MA; 6) Department of Hematology/Oncology, Boston Children's Hospital, Boston, MA; 7) Vascular Anomalies Center, Boston Children's Hospital, Boston, MA.

Kaposiform lymphangiomatosis (KLA) is a rare, aggressive, and systemic disorder of lymphatic proliferation, occurring primarily in children with rare reports in adults. Even with multimodal treatments, KLA has a poor prognosis and high mortality rate secondary to coagulopathy, effusions and systemic involvement. We hypothesized that, as has recently been found for other vascular anomalies, KLA may be caused by somatic mosaic mutations during vascular development. To explore this hypothesis, we performed exome sequencing of tumour samples from five individuals with KLA, along with samples from uninvolved control tissue in three of the five. We identified a somatic activating *NRAS* (c.182A>G, p.Q61R) mutation in four of the five KLA tumour samples, at levels ranging from 3-14%, that was absent from the control tissues. We subsequently used digital PCR (dPCR) to validate the exome findings and to screen four additional KLA samples. In total we identified the *NRAS* p.Q61R mutation in lesional tissue from 8/9 KLA individuals. The *NRAS* p.Q61R mutation is a known 'hotspot' mutation, frequently identified in several types of human cancer, especially melanoma. It results in a constitutively active *NRAS* protein, leading to unchecked cellular growth and proliferation. KLA therefore joins a growing group of vascular malformations and tumours caused by somatic activating mutations in the RAS/PI3K/mTOR signalling pathways. This discovery will expand treatment options for these high risk patients as there is potential for use of targeted RAS pathway inhibitors.

**1060T****Novel ABCA12 mutations in Japanese patients with harlequin ichthyosis.**

M. Takeda<sup>1</sup>, T. Nomura<sup>1</sup>, S. Suzuki<sup>1</sup>, T. Miyauchi<sup>1</sup>, Y. Fujita<sup>1</sup>, N. Tabata<sup>2</sup>, M. Akiyama<sup>3</sup>, H. Shimizu<sup>1</sup>. 1) Department of Dermatology, Hokkaido University Graduate School of Medicine, Sapporo, Hokkaido, Japan; 2) Department of Dermatology, Japanese Red Cross Sendai Hospital, Sendai, Miyagi, Japan; 3) Department of Dermatology, Nagoya University Graduate School of Medicine, Nagoya, Aichi, Japan.

Harlequin ichthyosis (HI) is the most severe form of autosomal recessive congenital ichthyosis and has a high mortality rate. HI is clinically characterized by thick plate-like scales with deep fissures, severe ectropion, eclabium, rudimentary ears, excessive loss of body fluids, hypohidrosis, hyper/hypothermia, respiratory distress, infection, and growth retardation. Loss-of-function mutations in the gene encoding adenosine triphosphate-binding cassette subfamily A member 12 (ABCA12), a lipid transporter that is crucial for epidermal barrier formation, have been identified as the genetic cause of the disease. In this study, we genetically analyzed two HI siblings from a Japanese family. Two girls of the ages of 2 years and 1 year who presented with generalized erythroderma and marked scales were referred to us for genetic testing. Although they showed typical HI phenotypes at their birth, oral etretinate had alleviated the severity of their skin symptoms. Whole-exome and Sanger sequencing revealed them to be compound heterozygous for previously unreported two mutations (c.2122-1G>A and c.4663\_4677del) in ABCA12, whereas the father and mother are heterozygous for the former and the latter mutation, respectively. cDNA sequencing analysis demonstrated that the splice-site mutation c.2122-1G>A yields a single aberrant splice variant, r.2122\_2332del (p.Ala708Hisfs\*19). The deletion mutation c.4663\_4677del results in the absence of 5 amino acids within the first ATP-binding cassette (p.Leu1555\_Gly1559del). The deleted amino acids are conserved among species, suggesting the importance of these amino acid residues in ABCA12 lipid transporter activity. In summary, this study further expands our understanding of genotype-phenotype correlations in HI and highlights the importance of the early introduction of oral retinoids in the management of HI.

**1061F****Intranasal desmopressin treatment for massive subcutaneous hematoma in five patients with musculocontractural Ehlers-Danlos syndrome.**

N. Fujita<sup>1,3</sup>, M. Ishikawa<sup>1</sup>, E. Kise<sup>1</sup>, T. Yamaguchi<sup>1,2</sup>, T. Yoshinaga<sup>1</sup>, T. Takano<sup>1,2</sup>, T. Kosho<sup>1,2</sup>. 1) Center for Medical Genetics, Center for Medical Genetics, Matsumoto, Japan; 2) Department of Medical Genetics, Shinshu University School of Medicine, Matsumoto, Japan; 3) Problem-Solving Oriented Training Program for Advanced Medical Personnel: NGSD (Next Generation Super Doctor) Project, Matsumoto, Japan.

Musculocontractural Ehlers-Danlos syndrome (mcEDS) is a rare subtype of Ehlers-Danlos syndrome (EDS) caused by impaired synthesis of dermatan sulfate. Massive subcutaneous hematoma is one of the most serious complications in mcEDS, occurring with mild traumas, spreading with severe pain, and sometimes resulting in hemorrhagic shock. Intranasal desmopressin treatment is used for patients with mild hemophilia and von Willebrand disease through increased activities in factor VIII and von Willebrand factor. According to several reports describing the usefulness of intravenous or intranasal desmopressin in patients with various types of EDS (Stine and Becton, *J Pediatr Hematol/Oncol* 19: 156–158, 1997; Mast et al., *Br J Haematol* 144: 230–233, 2008), we tried the treatment for a patient with mcEDS suffering from recurrent massive subcutaneous hematoma (Kosho et al., *Am J Med Genet A* 138A: 282–287, 2005; Kosho et al., *Am J Med Genet A*, 152A: 1333–1346, 2010). In this report, we described safety and efficacy of intranasal desmopressin treatment (150µg/episode) for a total of five patients (1 male, 4 females; the mean age 18.2 years) receiving the treatment to date in Shinshu University Hospital. Clinical information was retrospectively reviewed from medical records of these patients. The mean age of the first episode of massive subcutaneous hematoma was 8 years (range, 4 to 15). Most episodes were associated with obvious triggers (falling down, fighting). Hematoma developed at the legs in all and at the heads in four. Surgical drainage was required in three and blood transfusion in two. Elevated activities of factor VIII and von Willebrand factor were measured in all after administration of intranasal desmopressin. Four continue the treatment without adverse effects, whereas one child discontinued it because of numbness in the arms. Except for extraordinary situations such as a traffic accident, no patients developed severer episodes requiring surgical drainage or transfusion under the treatment. Most realized that the treatment suppressed growth of hematoma and shortened the suffering time. In view of these findings, intranasal desmopressin treatment on patients with mcEDS would be safe at least in adolescent or adult patients and effective in preventing massive subcutaneous hematoma.

Duchenne muscular dystrophy (DMD) is a relatively common X linked recessive progressive muscle dystrophy affecting approximately 1 in 5000 male births. Most mutations are new in the family due to a high rate of de novo mutations in DMD. Typically, diagnosis is established at age 3-5, and with progressive loss of muscle function, loss of ambulation occurs around age 10-13 years. There are a wide range of mutations in the DMD locus, and a portion of disease variability is accounted for by variations in dystrophin expression, and is linked to specific mutation type. Thus, Comprehensive DNA diagnostics are standard for providing prognostic information. Further, novel genetic treatments require specific knowledge of mutation type. However, even with intense molecular diagnostics, there remain patients without a clear DNA mutation. Here we explore the use of RNA\_SEQ from muscle tissue to clarify mutational consequence for rare mutations in DMD and to identify otherwise cryptic intronic DNA mutations. Further, we explore unusual DMD patients with out of frame mutations and a high rate of revertant fibers where dystrophin is demonstrated to be restored in the muscle membrane, and explore the molecular mechanisms responsible. We argue that muscle biopsy should remain a commonly performed test in Duchenne/Becker muscular dystrophy.

**1063T**

**EPG5 variants with modest functional impact result in an ameliorated and primarily neurological phenotype in a 3-year old patient with Vici syndrome.** *M.S. Kane*<sup>1</sup>, *J. Zhao*<sup>1</sup>, *J.A. Muskett*<sup>1</sup>, *A. Diplock*<sup>2</sup>, *S. Srivastava*<sup>2</sup>, *N. Hauser*<sup>1</sup>, *J.F. Deeken*<sup>1,3</sup>, *J.E. Niederhuber*<sup>1,4</sup>, *W.E. Smith*<sup>5</sup>, *D. Ebrahimi-Fakhari*<sup>1</sup>, *T. Vilboux*<sup>1</sup>. 1) Inova Translational Medicine Institute, Inova Health System, Falls Church, VA; 2) Department of Neurology, Boston Children's Hospital, Harvard Medical School, Boston, MA; 3) Department of Medicine, Virginia Commonwealth University, Richmond, VA; 4) Department of Oncology and Surgery, Johns Hopkins University School of Medicine, Baltimore, MD; 5) Department of Pediatrics, The Barbara Bush Children's Hospital, Maine Medical Center, Portland, ME.

Congenital disorders of autophagy are an emerging class of multisystem disorders with significant neurological involvement. *EPG5*-associated Vici syndrome is a prototypical congenital disorder of autophagy and presents with the cardinal features of agenesis of the corpus callosum, bilateral cataracts, hypertrophic and/or dilated cardiomyopathy, combined immunodeficiency, and skin, hair, and retinal hypopigmentation in the majority of cases. The vast majority of *EPG5* variants leading to Vici syndrome are null alleles with only a few missense variants reported to date. We have previously reported a missense variant in *EPG5* that leads to aberrant splicing with a high percentage of the resulting transcripts encoding premature termination codons. Here we report on a 3-year old patient with a molecular diagnosis of Vici syndrome attributed to compound heterozygous *EPG5* variants [NM\_020964.2:c.772G>T, p.Glu258\* and NM\_020964.2:c.5943-9\_5943-5del]. The clinical presentation of this patient deviates notably from the classical Vici phenotype with a lack of hypopigmentation, cataracts, immunodeficiency, cardiomyopathy or failure to thrive. Neurological manifestations, however, are consistent within the known spectrum of Vici syndrome and are significant for early-onset global developmental delay and post-natal microcephaly with a thin corpus callosum. Based on the ameliorated and primarily neurological phenotype, we hypothesized that the functional impact of the *EPG5* variants present would be milder with a higher amount of residual *EPG5* expression. Analyses of *EPG5* mRNA in the patient and his parents were performed to examine expression level and splicing; mRNA from a healthy donor and a patient with classic Vici syndrome were also included. Despite the nonsense mutation, *EPG5* mRNA levels were modestly decreased in the patient and half the transcripts were properly spliced. In contrast, we observed a 50% reduction in mRNA expression in classic Vici syndrome and proper splicing in only 30% of the residual mRNA. These results support a model of disease severity which correlates to the dosage of wild-type *EPG5* expression.

**Search for molecular biomarkers of spinal muscular atrophy.** *M.A. Maretina*<sup>1,2</sup>, *N.A. Tsyganova*<sup>2</sup>, *A.A. Egorova*<sup>1</sup>, *T.E. Ivashchenko*<sup>1</sup>, *V.S. Baranov*<sup>1,2</sup>, *A.V. Kiselev*<sup>1</sup>. 1) D.O. Ott Research Institute of Obstetrics, Gynecology and Reproductology, Saint-Petersburg, Russian Federation; 2) Saint-Petersburg State University, Saint-Petersburg, Russian Federation.

Spinal muscular atrophy (SMA) is a severe autosomal recessive neuromuscular disorder caused by mutations within the *SMN1* gene. This gene has a nearly identical centromeric copy – the *SMN2* gene – that produces low amount of full-length *SMN* (*FL-SMN*) transcripts. The majority of transcripts produced by the *SMN2* gene lack exon 7 ( $\Delta 7$ -*SMN*) and encode non-functional protein. Correction of *SMN2* gene splicing is one of the most promising SMA therapeutic strategies. Development of new therapies for SMA requires reliable biomarker whose score significantly differs between patients, carriers and healthy individuals and a precise technique for detection of this biomarker. Several potential biomarkers of SMA have been examined in this work: a percentage of *FL-SMN* transcripts from total *SMN* transcripts; a ratio of *FL-SMN* to  $\Delta 7$ -*SMN* transcripts and a level of SMN protein relative to overall proteins level. Such methods as real-time quantitative RT-PCR, semiquantitative RT-PCR and quantitative fluorescent RT-PCR have been compared for most accurate determination of *SMN* transcripts level, while SMN protein level has been determined by means of ELISA. The analysis has been performed on blood cell samples obtained from SMA patients, SMA carriers and healthy individuals. Percentage of *FL-SMN* transcripts detected by means of semiquantitative RT-PCR and quantitative fluorescent RT-PCR has been shown to differ significantly between three examined groups. In order to further evaluate developed biomarkers SMA patient-derived fibroblasts have been transfected with several antisense oligonucleotides (ASO) able to correct *SMN2* exon 7 splicing. Significant increase in percentage of *FL-SMN* transcripts have been observed in SMA fibroblasts treated with ASO compared to intact cells. These data indicate that percentage of *FL-SMN* transcripts can serve as a suitable biomarker for SMA treatment efficacy determination. This work was supported by Russian Foundation for Basic Research grant 18-315-00258 mol\_a. Marianna Maretina is supported by President of Russian Federation scholarship (SP-822.2018.4).

**1065W**

**A rare variant in *ABCC1* is associated with altered APP processing in a familial case of late-onset Alzheimer's disease.** *W.M. Jepsen*<sup>1</sup>, *M. De Both*<sup>1</sup>, *A.L. Siniard*<sup>1</sup>, *A. Henderson-Smith*<sup>1</sup>, *K. Ramsey*<sup>2</sup>, *R. Caselli*<sup>3</sup>, *G. Serrano*<sup>4</sup>, *T.G. Beach*<sup>4</sup>, *M.J. Huettelman*<sup>1</sup>. 1) Neurogenomics, Translational Genomics Research Institute, Phoenix, AZ; 2) Center for Rare Childhood Disorders, TGen, Phoenix, AZ; 3) Mayo Clinic, Phoenix, AZ; 4) Banner Sun Health Research Institute, Sun City, AZ.

The study of germline mutations in familial, early-onset Alzheimer's disease (AD) has been invaluable in unraveling the molecular pathways of AD, yet no effective therapy exists to halt or reverse the disease at any age of onset. Other than mutations in the *TREM2* locus, little is known about the genetics of heritable late-onset AD (LOAD). By identifying rare mutations in familial LOAD cases, it may be possible to identify novel, targetable pathways to alter disease progression. We analyzed a familial case of late-onset AD – in which 6 of 10 siblings were diagnosed with AD – and have identified a rare, germline mutation in *ABCC1* (chr16:16216007 A>G, p.Y1189C) found in 3 affected females, but not in 2 unaffected siblings. Genetic material for the remaining 5 siblings was unavailable. Previous studies have shown *Abcc1* double K/O significantly decreases Abeta clearance across the BBB in an AD mouse model, and that an amino acid change at our position of interest (p.Y1189) alters the substrate specificity of the human protein. Here, we show that *ABCC1*(WT) overexpression significantly decreases Abeta1-40 and 1-42 levels in BE(2)-m17 cells in culture, with a reduced effect in the Y1189C mutant line. We also show that our *ABCC1* cell lines are differentially affected by both thiethylperezine (TEP, an *ABCC1*-transport activator) and Reversan (an *ABCC1* inhibitor). 25uM TEP decreases extracellular levels of Abeta1-40 in both *ABCC1* cell lines, but Abeta1-42 only decreases in the WT line. 0.75uM Reversan resulted in cellular detachment of the *ABCC1*(WT) line with no effect on the empty vector or Y1189C line, suggesting that *ABCC1* may influence extracellular matrix proteolysis, and that this effect is dramatically reduced in the Y1189C mutant. RNA-seq of the cell lines revealed that mRNA levels of *TIMP3*, a membrane metalloprotease inhibitor, was significantly reduced in the *ABCC1*(WT) cell line versus the control line, with a smaller effect in the Y1189C line. The mutation also resulted in a higher ratio of extracellular Abeta to soluble APPalpha. This suggests that the mutant skews APP processing towards the beta-secretase pathway, or specifically hinders Abeta transport. Taken together, our data show that the Y1189C mutation likely increases the amyloid burden in our AD family, and to our knowledge, this is the first germline mutation in *ABCC1* to ever be associated with human disease, and only the second identification of a late-onset familial Alzheimer's disease gene.

**Strikingly high frequency of p.R132X variant identified in *MMACHC* gene of Indian children presenting with late-onset cobalamin C defect.** S.V. Attri<sup>1</sup>, R. Kaur<sup>1</sup>, A.G. Saini<sup>1</sup>, N. Sankhyan<sup>1</sup>, M. Faruq<sup>2</sup>, A. Patial<sup>1</sup>, S. Singh<sup>1</sup>. 1) Pediatrics, Postgraduate Institute of Medical Education & Research (PGIMER), Chandigarh, India; 2) Genomics and Molecular Medicine Unit, Institute of Genomics and Integrative Biology (IGIB), New Delhi, India.

**Introduction:** Cobalamin C (CblC) defect is the most common inborn error of cobalamin metabolism caused by defects in *MMACHC* gene leading to impaired conversion of dietary vitamin B<sub>12</sub> into methylcobalamin and adenosylcobalamin. Variants in *MMACHC* cause the accumulation of methylmalonic acid and homocysteine and decreased methionine synthesis. **Objective:** To identify disease-causing variants in *MMACHC* gene in children with Cbl defect. **Methods:** A total of 18 children diagnosed with Cbl defect on the basis of elevated plasma and urine homocysteine, urine methylmalonic acid, propionylcarnitine (C3) and low methionine were enrolled. Only the exonic regions of *MMACHC* gene were screened for the pathogenic variants by Sanger sequencing. **Results:** Out of 18 children with suspected cbl defect, 13 were found to have CblC (*MMACHC*) defect. Median (IQR) age at the enrolment was 11 years (6-18). Male to female ratio was 10:3. The spectrum of clinical features included gait disturbances (11/13), intellectual disability (10/13), global developmental delay (8/13), speech issues (8/13), behavior problems (7/13), acute encephalopathy (6/13), seizures (5/13) and megaloblastic anemia (4/13). Vitamin B<sub>12</sub> and folate levels were normal in all the cases. The median (IQR) plasma total homocysteine was 111 µmol/L (81-135), urine homocysteine 6.0 mmol/mol Cr (4.7-38.5), methionine 8.22 µmol/L (6.9-10) and urine MMA was 813 mmol/mol Cr (89-1640). The mean (range) C3 level was 4.7 µmol/L (1.0-9.1). The consanguinity was present in 3 families. Remarkably, sequencing of *MMACHC* revealed 12/13 (92%) cases with homozygous pathogenic p.R132X (c.394C>T) and one with homozygous pathogenic p.L116P (c.347T>C) variant. Parents and some of the siblings were found to have this variant in heterozygous state. Stable mRNA is expected to be produced from *MMACHC* harboring p.R132X variant since it is located within 50 nt of penultimate exon-exon junction. **Conclusion:** Our study presents the largest clinical series of children with late-onset CblC defect from India. Finding of common homozygous p.R132X variant in 92% children from unrelated families suggests founder effect. Association of p.R132X variant with late-onset disease suggests that stable mRNA is generated from *MMACHC* resulting in residual function protein. Such premature termination generating variants could be ideal target to prioritize readthrough therapies in individualized fashion to treat basic defect in Cbl defects and other Mendelian disorders.

**Spectrum of *CBS* gene variants in Indian children with classical homocystinuria: A study from tertiary care hospital.** R. Kaur<sup>1</sup>, S.V. Attri<sup>1</sup>, A.G. Saini<sup>1</sup>, N. Sankhyan<sup>1</sup>, M. Faruq<sup>2</sup>, V.L. Ramprasad<sup>3</sup>, S. Sharda<sup>3</sup>, A. Patial<sup>1</sup>, S. Singh<sup>1</sup>. 1) Department of Pediatrics, Postgraduate Institute of Medical Education and Research (PGIMER), Chandigarh, India; 2) Genomics and Molecular Medicine Unit, Institute of Genomics and Integrative Biology (IGIB), New Delhi, India; 3) MedGenome Labs Ltd., Bengaluru, Karnataka, India.

**Introduction:** Classical homocystinuria, characterized by elevated levels of homocysteine in blood and urine can be caused by pathogenic variants in *CBS* gene, the most common cause responsible for isolated homocystinuria. **Objectives:** Characterization of children with classical homocystinuria through clinical, biochemical and genetic assessment. **Methods:** A total of 17 children with urine homocysteine ≥4 mmol/mol Creatinine on two or more occasions, high or normal methionine, and normal methylmalonic acid with strong clinical symptoms of classical homocystinuria; were enrolled from Neurology and Genetic units of Advanced Pediatrics Centre, PGIMER, Chandigarh. Written informed consent was obtained in all the cases. Plasma total homocysteine was analyzed in all the cases. The coding regions of *CBS* gene were amplified through PCR and screened for variants through Sanger sequencing. **Results:** Out of 17 suspected cases, genetic testing for *CBS* gene confirmed the diagnosis in 14 cases. Median age at enrolment was 9 years (Interquartile range, IQR= 6-11 years). Male to female ratio was 4:3. Ten children were on treatment at the time of enrolment. The clinical features in the children with confirmed diagnosis included vision issues (12/14), lens subluxation/dislocation (11/14), intellectual disability (9/14), developmental delay (8/14), skeletal abnormalities (8/14), behaviour problems (6/14), spontaneous thrombosis (3/14), stroke (3/14) and seizures (2/14). One family had two affected individuals and consanguinity was reported in four families. The median (IQR) plasma total homocysteine was 117.72 µmol/litre (54-145), mean (range) urine homocysteine was 46.8 mmol/mol Creatinine (18-84), median (IQR) methionine was 33.7 µmol/litre (16.4-229). Fifteen different pathogenic/ likely pathogenic variants were found in 14 cases and 12/15 variants were in highly conserved catalytic domain of CBS enzyme. Five out of 14 variants were novel (three frameshift deletions, one nonsense, one splice site variant) and were predicted to be deleterious by Mutation Taster software. Thirteen cases were found to be either homozygous or compound heterozygous for potentially pathogenic variants; however one case was found to have pathogenic variant in one allele only. **Conclusion:** In this series, varied genotypes observed in *CBS* gene resulted in classical homocystinuria with broad clinical heterogeneity in children from India.

**The molecular profile of degenerative cerebellar ataxias and some unique, novel genotypes from India: A journey from short PCR to NGS based diagnostics over last decade.** S. Aggarwal<sup>1,2</sup>, S. Balakrishnan<sup>1</sup>, M. Muthu Lakshmi<sup>2</sup>, A. Das Bhowmik<sup>2</sup>, V. Venugopal<sup>2</sup>, A.K. Meena<sup>3</sup>, K. Rukmini

Mridula<sup>3</sup>, P. Ranganath<sup>1,2</sup>, A. Dala<sup>1,2</sup>. 1) Department of Medical Genetics, Nizam's Institute of Medical Sciences, Hyderabad, India; 2) Diagnostics Division, Centre for DNA fingerprinting & Diagnostics, Hyderabad, India; 3) Department of Neurology, Nizam's Institute of Medical Sciences, Hyderabad, India.

This study reports the molecular profile of patients presenting with degenerative cerebellar ataxia at a tertiary Medical Genetics facility in South India over last ten years. The study is retrospective from 2008-2016 and prospective from 2017 onwards. Patients satisfying inclusion criteria were recruited and triaged for molecular testing on basis of clinical presentation, pedigree information, neuroimaging and other ancillary laboratory findings. Molecular testing involved short PCR for Spinocerebellar ataxia(SCA) type 1,2,3,6,7 and TP-PCR for Friedreich ataxia(FA) in the retrospective cohort. The prospective cohort in addition underwent second tier testing for SCA 8,12,17,36 by short PCR and selected cases with autosomal recessive pattern or syndromic/complex presentations were evaluated using phenotype guided tests or Next generation sequencing. 165/557(30%) patients tested positive for SCA 1,2,3 with equal prevalence of the three subtypes. 452 patients underwent testing for SCA6 & 7, leading to a diagnosis of SCA7 in six, and SCA6 in one. None of the 29 individuals tested for SCA 8,12,17 and 36 had a positive result. 106/379(28%) individuals tested positive for Friedreich ataxia, indicating FA to be the single most common diagnosis in our cohort. Phenotype based targeted testing yielded a diagnosis of SCA 34 in one patient and Huntington disease in another. One patient each homozygous for SCA 1 and 3 were found and one individual with FA due to homozygous deletion of *FXN* was identified in the cohort. Targeted exome sequencing interrogating the known disease causing OMIM genes yielded final diagnosis in 6/7 patients, including 3 cases of ataxia with oculomotor apraxia, and one each of SCA 23,29 and Dystroglycanopathy. WES revealed a putative pathogenic variant in *PCDH12* gene in two sibs with a complex phenotype of cerebellar ataxia, dystonia and exudative retinopathy. To conclude, FA and SCA 1,2,3 account for a significant proportion of the degenerative cerebellar ataxias in our cohort, while the other SCAs are extremely rare. NGS based testing in selected cases showed a high diagnostic yield and revealed a putative novel gene for ataxia-dystonia-retinopathy phenotype in one sibpair. This data provides interesting clues for designing a diagnostic algorithm suited for our population.

**A biallelic frameshift variant in a novel gene results in ataxia and dysarthria in humans.** F. Aslam, S. Naz. School of Biological Sciences, University of the Punjab, Lahore, Punjab, Pakistan.

Hereditary ataxias are a heterogeneous group of disorders that are characterized by uncoordinated body movements. Ataxias may be manifested with gait abnormalities, dysarthria, apraxia, dysphagia and other pyramidal and extrapyramidal signs. More than forty genes have been implicated in the etiology of recessively inherited ataxias and others remain to be discovered. We recruited a consanguineous Pakistani family with two affected siblings. Patients suffered from a movement disorder but had no specific diagnosis for their disorder. We performed clinical assessments and molecular analyses which included magnetic resonance imaging and whole-exome sequencing to delineate the underlying pathology of the disorder. Whole-exome sequencing data were evaluated for all homozygous exonic and splice-site variants which were predicted to be pathogenic and had a frequency of less than 0.01 in public databases. Segregation analyses were performed for the variants by Sanger sequencing. Effect of variant on RNA expression was evaluated by gene specific PCR on an oligo dT primed cDNA library which was constructed from patient RNA, extracted from blood. Clinical evaluations of the patients revealed that both affected individuals suffered from abnormalities of gait, limb incoordination and dysarthria. These conditions were consistent with a diagnosis of ataxia. Magnetic resonance imaging conducted for the oldest affected individual did not reveal brain abnormalities. Whole-exome data analyses identified a frameshift variant of a gene which has not been previously associated with a human disorder though knockout of its orthologous gene is known to cause movement related phenotypes in mice. Patients were homozygous for the variant, obligate carriers were heterozygous and an unaffected sibling did not have the variant. The variant was absent in all public databases and from the DNA of ethnically matched controls. cDNA analysis demonstrated that the mutant RNA escapes nonsense mediated decay, at least in blood. If the mutant mRNA is translated, half of the important functional domains of the protein will be missing. Our work has identified a gene which encodes a protein participating in a conserved molecular pathway in both mice and humans. This study is funded by HEC 2877, Pakistan.

Cerebellar atrophy is a key neuroradiological finding usually associated with cerebellar ataxia and cognitive development defect in children. Unlike the adult forms, early onset cerebellar atrophies are classically described as mostly autosomal recessive conditions and the exact contribution of de novo mutations to this phenotype has not been assessed. In contrast, recent studies pinpoint the high prevalence of pathogenic de novo mutations in other developmental disorders such as intellectual disability, autism spectrum disorders and epilepsy. Here, we investigated a cohort of 47 patients with early onset cerebellar atrophy and/or hypoplasia using a custom gene panel as well as whole exome sequencing. De novo mutations were identified in 35% of patients while 27% had mutations inherited in an autosomal recessive manner. Understanding if these de novo events act through a loss or a gain of function effect is critical for treatment considerations. To gain a better insight into the disease mechanisms causing these cerebellar defects, we focused on *CACNA1G*, a gene not yet associated with the early-onset form. This gene encodes the Cav3.1 subunit of T-type calcium channels highly expressed in Purkinje neurons and deep cerebellar nuclei. In total, we identified four patients with de novo *CACNA1G* mutations. They all display severe motor and cognitive impairment, cerebellar atrophy as well as variable features such as facial dysmorphisms, digital anomalies, microcephaly and epilepsy. Three subjects share a recurrent c.2881G>A/p.Ala961Thr variant while the fourth patient has the c.4591A>G/p. Met1531Val variant. Both mutations drastically impaired channel inactivation properties with significantly slower kinetics (5 times) and negatively shifted potential for half-inactivation (> 10 mV). In addition, these two mutations increase neuronal firing in a cerebellar nuclear neuron model and promote a larger window current fully inhibited by TTA-P2, a selective T-type channel blocker. This study highlights the prevalence of de novo mutations in early-onset cerebellar atrophy and demonstrates that Ala961Thr and Met1531Val are gain of function mutations. Moreover, it reveals that aberrant activity of Cav3.1 channels can markedly alter brain development and suggests that this condition could be amenable to treatment.

Episodic ataxias (EA) are a heterogeneous group of inherited neurological disorders characterized by recurrent attacks of ataxia. Eight forms have been described to date based on causal genes, presumed gene loci or clinical characteristics. Mutations in *KCNA1* (EA1) and *CACNA1A* (EA2) account for the majority of EA cases worldwide. All forms described to date follow a dominant mode of transmission with variable penetrance. We recruited a large French Canadian cohort of 65 undetermined EA cases belonging to 37 families, expecting that because of their common origin some would share the same founder mutation. We excluded families with mutations in known EA genes. We characterized the clinical phenotypes of EA, including the age at onset (AAO) of first episodes, AAO of the progressive ataxia and SARA scores. All affected patients had recurrent attacks of ataxia, often triggered by physical activity or alcohol. Variable penetrance was observed in all families. The mean AAO was 54.4 years (30-72) for the first episodes and 60 years (45-72) for the progressive ataxia. Ataxia was mild to moderate with a mean SARA score of 8.9/40 (1-18). We established that 50% of affected patients have diminished vibration sense in their lower extremities. Brain MRI showed moderate cerebellar atrophy in permanently ataxic cases. In the largest studied family, we observed ataxia with mean AAO of 56.4 years (40-64) for first episodes and 59.5 years (45-67) for progressive ataxia, but with major variability in the severity and duration of symptoms (mean SARA score: 6/40 (0-18)). To uncover the genetic cause(s) of disease, we first performed whole exome sequencing (WES) in the three largest families, which failed to identify potentially pathogenic variants that co-segregated with the disease. This led to whole genome sequencing (WGS) in two affected cases in each of the three families, which again did not share any rare variant. To prioritize the thousands of variants identified within families, we launched linkage analysis using SNP genotyping in the largest family (9 affected and 11 unaffected) in the hope to uncover a locus that will allow targeted analysis of the WGS data sets. In conclusion, this new French Canadian cohort of late-onset exercise-induced EA illustrates that WES and WGS alone may not be sufficient to uncover mutations for clinically variable autosomal dominant conditions.

**107 Tunisian patients with autosomal recessive ataxia: A clinical and genetic study.** M. Hammer<sup>1</sup>, H. Nehdi<sup>2</sup>, G. El Euch Fayache<sup>2</sup>, J. Ding<sup>1</sup>, JR. Gibbs<sup>1</sup>, R. Amouri<sup>2</sup>, F. Hentati<sup>2</sup>, A. Singleton<sup>1</sup>. 1) National Institutes of Health, Bethesda, MD; 2) National Institute of Neurology, Tunis, Tunisia.

**Background** Autosomal recessive cerebellar ataxia (ARCA) comprises an extensive group of heterogeneous neurological disorders where balance is lost without muscle weakness. Whole exome sequencing presented a significant impact in the identification of disease causing genes driving the number to over 50. **Objective** We aim at identifying the genetic origin of ARCA in a cohort of 107 Tunisian patients. **Methods** This study comprised 79 patients belonging to 32 families with autosomal recessive pattern of inheritance and 28 patients with no family history. The strategy consisted in: 1) Performing a TP-PCR to screen for GAA trinucleotide repeat in *FXN* responsible for Friedreich ataxia 2) Screening with direct sequencing for the frame-shift deletion (c.744delA) in *TTPA* associated with ataxia with vitamin E deficiency and for the mutations reported in Tunisia at the time of the study in *APTX*, *SETX* and *SACS* genes, respectively responsible for ataxia with oculomotor apraxia type 1, ataxia with oculomotor apraxia type 2 and ataxia of Charlevoix-Saguenay 4) Whole exome sequencing for the remaining cases. **Results** The (GAA)<sub>n</sub> expansion in *FXN* was present at the homozygous state in 7/107 patients. Only two siblings (2/107) were found to be homozygous for the c.744delA mutation in *TTPA*. Screening for mutations reported in Tunisia in *APTX*, *SETX* and *SACS* revealed two mutations in each gene in a total of 16/107 patients. Exome sequencing allowed the identification of two known *SETX* mutations not previously reported in Tunisia as well as known mutations in other genes associated with ARCA and spastic paraplegia (*SLC25A46*, *APOB*, *SPG20* and *SPG11*) in 13/107 affected individuals. Novel probably disease-causing variants were also found in common ARCA genes (*SACS*, *SETX*, *GRM1*, *ADCK3*, etc.) and in genes associated with different autosomal recessive disorders where ataxia is only a clinical feature (*POLR3A*/ Hypomyelinating leukodystrophy 7, *KCNJ10*/ SeSAME syndrome, *PEX16*/ Zellweger syndrome). Most importantly, strong novel candidate genes were identified such as *MAP1A* and *CHD6* which lead to an ataxic phenotype in homozygous mutated mice. **Conclusion** We used different techniques to investigate the genetic origin of ataxia in a cohort of 107 patients but only found the probable disease-causing mutation in 72 individuals. Whole genome sequencing might be the next step to take in hope to unravel the genetic cause of ataxia in the remaining cases.

**Next-generation sequence enabled diagnosis of family aggregated ataxia in an endogamic Colombian population.** J.A. Tejada Moreno<sup>1</sup>, C.A. Villegas Lanau<sup>1,2</sup>, L. Madrigal Zapata<sup>2</sup>, A.Y. Baena<sup>2</sup>, O. Campo Nieto<sup>1</sup>, L. Rishishwar<sup>3,4</sup>, E.T. Norris<sup>3,4,5</sup>, A.T. Chande<sup>3,4,5</sup>, I.K. Jordan<sup>3,4,5</sup>, G. Bedoya Berrio<sup>2</sup>. 1) Molecular Genetics Research Group, University of Antioquia. Medellin, Colombia; 2) Neurosciences Research Group, University of Antioquia. Medellin, Colombia; 3) IHRC-Georgia Tech Applied Bioinformatics Laboratory, Atlanta, Georgia, USA; 4) PanAmerican Bioinformatics Institute, Cali, Valle del Cauca, Colombia; 5) School of Biological Sciences, Georgia Institute of Technology, Atlanta, Georgia, USA.

Neurodegenerative diseases are a class of severe pathologies, including dementia and numerous movement disorders. Diagnosing many of these disorders is a complex and resource-intensive process and can involve multiple invasive procedures. Furthermore, clinical tests of this kind often do not result in any conclusive diagnosis. This is an even bigger challenge in a limited resource environment such as Colombia. Numerous recent studies have shown the advantages of adopting next-generation sequencing (NGS) based diagnostic assays for quicker and more precise diagnosis of patients with previously inconclusive diagnoses. Our group is developing approaches for NGS enabled diagnosis of neurodegenerative diseases in the Colombian population of Antioquia. Historically, the population of Antioquia has shown high levels of endogamy and corollary high prevalence of autosomal recessive diseases. Here, we discuss our efforts to apply NGS based diagnosis to autosomal ataxia (AA) in five multigenerational families from Antioquia. Standard clinical and neurodevelopmental tests performed on the probands from these families have not been sufficient alone for unambiguous diagnoses. In an effort to yield more precise diagnoses for these patients, we used whole exome sequencing (WES) of the AA probands and two immediate family members (parent(s) and/or sibling). We evaluated 367 autosomal recessive and 118 autosomal dominant AA candidate genes compiled from the literature for potential AA causal single nucleotide variants. Family pedigrees were first evaluated to characterize AA cases as autosomal recessive or dominant, and WES variants were screened accordingly by comparing affected and unaffected family members. We also used a number of additional variant filters following the American College of Medical Genetics and Genomics guidelines. Potential causal variants were considered in the context of the clinical, pathophysiological and neuropsychological characteristics of these patients in order to converge on the best NGS enabled diagnosis for each patient. While further work is needed to establish the mode of action of the putative causal variants, we have shown the viability and power of NGS based tests in Colombia for neurodegenerative disease diagnosis.

**Hotspot variants in the *GRIK2* kainate receptor gene are causative for neurodevelopmental disorders with diverse phenotypes.** G. T. Swanson<sup>1</sup>, J.R. Stolz<sup>2</sup>, G.L. Carvill<sup>3</sup>, B. Keren<sup>3</sup>, C. Mignot<sup>3</sup>, P.R. Mark<sup>4</sup>. 1) Pharmacology, Northwestern University Feinberg School of Medicine, Chicago, IL; 2) Neurology, Northwestern University Feinberg School of Medicine, Chicago, IL; 3) Département de Génétique, Hôpital Pitié-Salpêtrière, Paris, France; 4) Spectrum Health Medical Genetics, Grand Rapids, MI.

Ionotropic glutamate receptors (iGluRs) are critical signaling molecules in the central and peripheral nervous systems, and missense variants in genes encoding several iGluR subunits have been shown to cause autism and related neurodevelopmental disorders (NDDs). We recently reported the first missense variant (p.A657T) in a gene encoding a kainate receptor (KAR) subunit subtype of the iGluRs, *GRIK2* (Glutamate receptor, ionotropic, kainate 2; GluK2 protein) (Guzmán et al., *Neurol. Genet.*, 2017). This *de novo* variant was determined to be causative for a non-syndromic NDD with intellectual disability, speech deficits and ataxia as primary clinical features. The p.A657T substitution occurs in the pore-forming third membrane (M3) domain, which has been characterized as a “hotspot” of NDD-causing mutations in other iGluR subunit genes. The biophysical properties of GluK2(A657T) subunit-containing receptors were different from wildtype GluK2 in several substantive ways that included a greatly enhanced sensitivity to glutamate, slowed decay kinetics and destabilization of the desensitized state of the receptor. This study prompted us to determine if pathogenic variants in the same hotspot region of *GRIK2* or other KAR subunit genes were implicated in NDDs more broadly. In this report, we will present clinical data from two additional children with *de novo GRIK2* variants that occur in the exon encoding the M3 and the adjacent linker between M3 and the S2 segment of the ligand-binding domain (M3-S2 linker). These children had highly divergent NDD phenotypes: severe pediatric epilepsy [GluK2(p.T660K) variant] and autism [GluK2(p.I668T) variant]. Introduction of the analogous mutations into the GluK2 subunit also had varied effects on the expression and biophysical properties of the receptors. GluK2(T660K) receptors were very similar to GluK2(A657T) in their slowed decay kinetics and destabilized desensitized states, whereas GluK2(I668T) had profoundly reduced peak amplitudes and rapid desensitization. These data demonstrate that variants in the *GRIK2* KAR subunit gene in the M3/M3-S2 hotspot region alter channel function and can be causative for a spectrum of NDDs, including intellectual disability, autism, epilepsy and movement disorders such as ataxia. KAR subunit genes should therefore be added to the growing list of synaptic signaling molecules whose disruption can cause NDDs of variable presentation.

**1075T**

**Functional characterization of biallelic *SZT2* variants in a patient with seizures and brain abnormalities.** J. Calhoun<sup>1</sup>, I. Bellinski<sup>1</sup>, L. Kinsley<sup>1</sup>, M.C. Schultz<sup>2</sup>, A. Ramamurthy<sup>2</sup>, E. Bryant<sup>2</sup>, J. O'Connor<sup>2</sup>, J. Millichap<sup>2</sup>, E. Gerard<sup>1</sup>, G. Carvill<sup>1</sup>. 1) Northwestern University Feinberg School of Medicine, Chicago, IL; 2) Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL.

Compound heterozygous *SZT2* variants were first implicated in autosomal recessive epileptic encephalopathy with recurrent seizures, developmental delay, macrocephaly, and corpus callosum abnormalities. *SZT2* encodes a large gene product with no discernible structural similarities to other known proteins. Due to this lack of overt functional protein architecture, the function of *SZT2* in the cell remained elusive for several years; though a *Szt2* mouse model was originally reported to modify seizure susceptibility. Recently *SZT2* was shown to form part of the KICSTOR complex responsible for recruiting the GATOR complex to the lysosome where it acts as a negative regulator of mTORC1 (mechanistic target of rapamycin complex 1) in the context of amino acid deprivation. We identified a proband with compound heterozygous *SZT2* missense variants of unknown significance (VUS) in a patient with adult-onset epilepsy, macrocephaly, and MRI abnormalities. While the majority of published patients are reported with truncating variants, suggesting complete loss of function for *SZT2*, the patient described here carried missense variants in an uncharacterized portion of *SZT2*. We hypothesized that these missense variants may be full or partial loss-of-function *SZT2* variants and may lead to a milder phenotype than the null allele which is associated with early onset epilepsy with poor outcome. We examined whether primary dermal fibroblasts from the proband displayed altered regulation of mTOR activity in response to amino acid deprivation. Primary dermal fibroblasts from the proband display robust mTORC signaling by enhanced phosphorylation of S6K upon amino acid deprivation, consistent with a defect in the amino acid response. These results are consistent with diminished or lost *SZT2* function leading to breakdown of amino acid sensing in knockout models of *SZT2*. We are developing a cellular platform to functionally test individual *SZT2* variants which will allow us to characterize previously reported and novel *SZT2* missense variants. Analysis of additional variants provide an opportunity to define the functional domains of *SZT2*, understand how mTORC is recruited to the lysosome, unravel potential genotype-phenotype correlations and identify novel therapeutic targets.

**An intronic repeat expansion in familial ALS.** *M.M. Course<sup>1</sup>, K. Gudsnuk<sup>1</sup>, K. Winston<sup>1</sup>, N. Desai<sup>1</sup>, J. Ross<sup>2</sup>, P.A. Dion<sup>2</sup>, G.A. Rouleau<sup>2</sup>, P.N. Valdmanis<sup>1</sup>.* 1) Division of Medical Genetics, Department of Medicine, University of Washington, Seattle, WA, USA; 2) Montreal Neurological Institute, McGill University, Montreal, QC, Canada.

Amyotrophic lateral sclerosis (ALS) is a devastating neurodegenerative disease, characterized by rapidly progressive muscle weakness and early death. No effective treatments are available, and our understanding of the disease remains nascent. Our lab seeks to uncover genetic mutations underlying the 40-50% of familial ALS cases with no identified causes. By applying linkage analysis to a large family with ALS, we identified a haplotype that segregates with the disease. While the family already carries a pathogenic variant in *FUS* known to cause ALS, this mutation cannot fully explain the penetrance of the phenotype. It is fully explained, though, once coupled with our disease haplotype. The haplotype region includes an intronic, human-specific tandem repeat expansion in the gene *WDR7*, which exhibits greater repeat copy length in patients with ALS as compared to unaffected individuals, both within our family and in 350 sporadic ALS patient samples as compared to 270 control samples from the Coriell Institute. We therefore hypothesize that this expansion is a genetic cause or modifier of ALS. So far we have observed that this repeat can expand up to 5520 bp, while the ancestral copy is only 105 bp. By sequencing 144 multiplexed patient samples using long-read PacBio sequencing, we were able to obtain the exact number of repeats in each allele, as well as the exact sequence of each repeat copy. The repeat also boasts a unique hairpin structure, which we have confirmed forms microRNAs. These microRNAs, in turn, are predicted to target gene products involved in ALS pathobiology, and we are now working to understand the mechanism by which this repeat expansion leads to ALS.

**Coexistence of schwannomatosis and glioblastoma in two families.** *C. Deiller<sup>1,2</sup>, C. Goizet<sup>1</sup>, C. Zordan<sup>1</sup>, J. Tinat<sup>1</sup>, H. Loiseau<sup>3</sup>, T. Fabre<sup>4</sup>, C. Delleci<sup>5</sup>, J. Cohen<sup>6</sup>, M. Vidaud<sup>6,7</sup>, B. Parfait<sup>6,7</sup>, J. Van-Gils<sup>1</sup>.* 1) CHU Bordeaux, Service de Génétique Médicale, Bordeaux, France; 2) Laboratoire MRGM, INSERM U1211, Univ. Bordeaux, Bordeaux, France; 3) CHU Bordeaux, Service de neurochirurgie, Bordeaux, France; 4) CHU Bordeaux, Service d'orthopédie, Bordeaux, France; 5) CHU Bordeaux, Service de Médecine Physique et Réadaptation, Bordeaux, France; 6) Service de Génétique et Biologie Moléculaires, Hôpital Cochin, Assistance Publique-Hôpitaux de Paris, Paris, France; 7) EA7331, Université Paris Descartes, Sorbonne Paris Cité, Faculté de Pharmacie de Paris, Paris, France.

Schwannomatosis is a rare affection predisposing to multiple peripheral neurologic tumors. Approximately, one third of patients with schwannomatosis are carriers of a germline mutation in *LZTR1* (Leucin Zipper Transcription Regulator 1). Tumorigenesis in schwannomatosis responds to a somatic 5-hit/3-step mechanism resulting in a loss of function (LOF) of *LZTR1* and the contiguous genes of locus 22q11.2q12.2. Effectively, *LZTR1* is mapped on 22q11.2 and centromeric to *SMARCB1* also implicated in the determinism of schwannomatosis and *NF2*, responsible for neurofibromatosis type 2. The 5-hit/3-step consists in germline LOF of *LZTR1* first allele followed by two somatic events: a loss of heterozygosity of the locus 22q11.2q12.2 with the deletion of *LZTR1*, *SMARCB1* and *NF2*, and mutation of the remaining allele of *NF2*. On a somatic point of view, *LZTR1* mutations are known to drive with a significant frequency glioblastoma (GB) development. Pathophysiology of GB also requires biallelic loss of function of *LZTR1*. We report here two families in which segregate both multiple schwannomas and GB. In each family, we describe a proband with schwannomatosis due to a germline heterozygous *LZTR1* mutation, and a relative deceased from an apparently isolated GB. Molecular analysis of GB sample from the affected relative showed the presence of the familial mutation. These observations suggest a potential link between schwannomatosis and the GB development.

**1078T**

**Huntington disease in Africa: Emerging genetic and phenotypic differences.** A. Krause<sup>1</sup>, D.G. Anderson<sup>1</sup>, J. Levesley<sup>1</sup>, F. Baine-Savanhu<sup>1</sup>, M. Ciosi<sup>2</sup>, D. Monckton<sup>2</sup>, R. Margolis<sup>3</sup>. 1) Human Genetics, National Health Laboratory Service and University of the Witwatersrand, Johannesburg, Gauteng, South Africa; 2) Institute of Molecular, Cell and Systems Biology, University of Glasgow, Glasgow, Scotland; 3) Departments of Psychiatry and Neurology, Program in Cellular and Molecular Medicine, Johns Hopkins University School of Medicine, Baltimore, MD, USA.

Huntington disease (HD) is an inherited, progressive neurodegenerative disease. Most patients with an HD phenotype have a trinucleotide repeat expansion in the *HTT* gene. However, an HD phenocopy (HDL2) due to a trinucleotide expansion in the *JPH3* gene, accounts for 30% of confirmed HD diagnoses among black South Africans, with the highest number of cases reported number worldwide. Although the clinical phenotype of HDL2 is reported to be broadly similar to HD, some differences have been proposed, based on case studies. We report preliminary findings of a cross-sectional study to characterize the clinical phenotype of HDL2 from a neurological, neuropsychological, haematological and radiological perspective; and to compare it to HD. The eyes signs were indistinguishable in a comparison of 13 HD and 9 HDL2 patients, suggesting that oculomotor signs are not a feature that distinguishes HDL2 from HD as initially proposed. There was no significant difference in the total score between the two diseases or in any sub-score parameters of ocular pursuit, saccade initiation or saccade velocity. Early reports suggested that the presence of acanthocytes in the peripheral blood smear might distinguish patients with HDL2 from those with HD. No acanthocytes were seen in 12 South African cases studied. In MRI studies, using semiautomated volumetric analysis and morphometry, the pattern of volume loss was similar in HDL2 and HD but tended to be greater in the HDL2 group. Significantly more thalamic volume loss was seen in HDL2 relative to HD and controls when controlled for age, repeat length and disease duration. HD in African patients has molecular differences from HD in European patients - *HTT* expansions occur on different haplotype backgrounds. Further, the CAG/CCG repeat tract in *HTT* shows significantly higher sequence diversity among Africans. The most common disease allele in African ancestry HD patients has an atypical structure compared to European patients. A unique *cis*-acting modifier, the CCGCCA cassette, appears to reduce the average age of diagnosis in African ancestry HD patients by 6.6 years. Studies of HD and HDL2 in Africa provide novel insights into the clinical spectrum of Huntington disease and provide unique insights into the pathophysiology of the disease. Further novel molecular insights are being gained from studies of the genetic diversity of this monogenic disease in Africa.

**1079F**

Bauer<sup>1</sup>. 1) Centogene AG, Rostock, Germany; 2) Istanbul University, Istanbul Medical Faculty, Medical Genetics Department, Istanbul, Turkey; 3) Division of Genetics and Metabolic Medicine, Department of Pediatrics, Prince Sultan Military Medical City Riyadh, Saudi Arabia; 4) Department of Anatomy and Cell Biology, College of Medicine, Alfaisal University, Riyadh, Saudi Arabia; 5) Pediatrics Department, Prince Sultan Military Medical City, Riyadh, Saudi Arabia; 6) GENDIA, Genetic Diagnostic Network, Belgium; 7) First Department of Pediatrics, "Aghia Sophia" Children's Hospital, University of Athens, Greece; 8) MBBS, Salmaniya Medial Complex, Ministry of Health, Manama, Kingdom Of Bahrain; 9) Albrecht-Kossel-Institute for Neuroregeneration, Medical University Rostock, Rostock, Germany.

The nuclear activating signal cointegrator 1 (ASC-1) complex has been suggested to participate in RNA processing events and in transcriptional coactivation, but specific downstream targets remain elusive. It is composed of the four subunits ASC-1 (encoded by *TRIP4*), ASC1 (*ASCC1*), ASC2 (*ASCC2*) and ASC3 (*ASCC3*). Homozygous variants in *TRIP4* (n=4 families) and in *ASCC1* (n=4 families) were recently associated with severe neuromuscular phenotypes. Upon whole exome sequencing (WES) of a clinically heterogeneous patient cohort, we identified the *TRIP4* variants c.512G>A (p.Cys171Tyr) and c.1678+1\_1678+2insC as well as the *ASCC1* variants c.626+1G>A and c.897G>A (p.Trp299\*) in homozygosity in one individual each; Sanger sequencing confirmed these WES-derived findings. The two patients with homozygous *TRIP4* variants (currently aged 7 months and 14 years, respectively) shared muscular hypotonia, joint contractures, scoliosis, microretrognathia and high palate; bone fractures were not observed. The homozygous *ASCC1* variants were identified in an aborted fetus and in an infant that died at 27 days of age from massive pleural effusion. Both were characterized by decreased fetal movements, thin ribs, and fractures of long bones (humeri and femora). The apparent differences in severity were followed up by a meta-analysis of all cases known to date (n=12 for *TRIP4* vs. n=11 for *ASCC1*). This revealed that variants in *ASCC1* are more often associated with congenital bone fractures (p=0.011, two-sided Fisher's exact test) and with perinatal death (p=0.003). We also noticed that all known pathogenic *ASCC1* variants are predicted to entail complete absence of the *ASCC1* protein, while this was not true for any of the pathogenic *TRIP4* variants (presence of ASC-1 protein species with (i) a single amino acid exchange, (ii) an internal in-frame deletion, or (iii) an altered C-terminus). Our findings broaden the mutational spectrum for ASC-1 complex-related disease, and suggest that the degree of severity depends on the mutated subunit and/or the mutational consequences. We are currently following up on genetic findings for *ASCC2* and *ASCC3* to see whether variants in these two genes can be incorporated into the above concept.

**1080W**

**Loss-of-function variants in the gene *IRF2BPL* are associated with neurological phenotypes.** L.D.M. Pena<sup>1</sup>, P.C. Marcogliese<sup>2</sup>, R.C. Spillmann<sup>1</sup>, N. Stong<sup>3</sup>, J.A. Rosenfeld<sup>2</sup>, M.K. Koenig<sup>4</sup>, D. Ortiz<sup>5</sup>, K. Riley<sup>1</sup>, G. Mirzaa<sup>6,9</sup>, D. Hemelsoet<sup>7</sup>, S. Bellen<sup>2,10,11,12</sup>, *UD-ProZA Members, UDN Members.* 1) Division of Medical Genetics, Department of Pediatrics, Duke University School of Medicine, Durham, North Carolina; 2) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, Texas; 3) Institute for Genomic Medicine, Columbia University, New York, New York; 4) Division of Child & Adolescent Neurology, Department of Pediatrics, University of Texas Health Sciences Center, Houston, Texas; 5) Children's Hospital of Pittsburgh, University of Pittsburgh, Pittsburgh, Pennsylvania; 6) Center for Integrative Brain Research, Seattle Children's Research Institute; 7) Department of Medical Genetics, Ghent University Hospital, Ghent, Belgium; 8) Department of Human Genetics, David Geffen School of Medicine, University of California - Los Angeles, Los Angeles, California; 9) Department of Pediatrics, University of Washington, Seattle, Washington; 10) Howard Hughes Medical Institute, Houston Texas; 11) Program in Developmental Biology, Baylor College of Medicine, Houston, Texas; 12) Jan and Dan Duncan Neurological Research Institute, Texas Children's Hospital, Houston, Texas; 13) Department of Neuroscience, Baylor College of Medicine, Houston, Texas.

The Interferon Regulatory Factor 2 Binding Protein-Like (*IRF2BPL*) is a single-exon gene with unknown function or disease association in humans. We report seven individuals with neurodevelopmental phenotypes and heterozygous variants in *IRF2BPL* identified by exome sequencing. Current age ranges between 2-43 years, and 5/7 had normal early childhood development. The five cases with nonsense variants had neurological regression that started with deterioration of gait and loss of intentional movements during childhood. Subsequently they developed dysarthria, loss of speech, dysphagia, spasticity, incontinence, and a progressive movement disorder. Although brain MRI was normal in childhood, the two oldest cases had diffuse cerebral atrophy. All had abnormal EEGs and eventually developed epilepsy. The two cases with missense variants had a generally milder course with epilepsy and developmental delay, but no developmental regression or a movement disorder. The variants are *de novo* for all who had parental testing. *IRF2BPL* is a very intolerant gene with an RVIS score of 9.3%, a pLI score of 0.97, and constraint to missense variants ( $z = 4.73$ ). All variants were absent from the gnomAD and ExAC databases. The CADD score for all variants is over 34, among the most deleterious. The DOMINO tool yielded a high score that predicts that monoallelic variants in *IRF2BPL* would very likely cause disease. The fly homolog of *IRF2BPL* is the uncharacterized conserved gene *pits*. *Pits* is robustly expressed in the nucleus of neurons. Complete loss of *pits* is lethal early in development. Partial knock-down with RNA interference in neurons leads to neurodegeneration, revealing requirement for this gene in proper neuronal function and maintenance. The nonsense variants in *IRF2BPL* identified in patients behave as severe loss-of-function alleles in flies, while ectopic expression of the missense variants leads to a range of phenotypes. We present a new, undiagnosed neurological phenotype with variants in *IRF2BPL*. The bioinformatics signature of the gene and variants supports pathogenicity. Modeling in the fruit fly revealed that *pits* is important for development and neuronal integrity over time, and showed that the nonsense variants are strong loss-of-function. Additional model organism work is ongoing to clarify gene function and inform the clinical phenotype.

Multilocus pathogenic rare variation refers to the presence of pathogenic variant alleles in two or more disease-causing genes. Recent studies from our lab (Karaca *et al*, Genet Med. 2018) have shown that multilocus variation can explain some cases of apparent phenotypic expansion, with an overall rate of multiple molecular diagnoses in 12% of molecularly diagnosed neurodevelopmental cases (13/108 families), including 42% (8/19) of cases with apparent phenotypic expansion. In this study, we have performed whole exome sequencing (WES) and analysis on an additional 47 families with neurodevelopmental disorders (NDDs). Our preliminary analyses have identified two families with multilocus variation presenting with homozygous rare variants in genes linked to both autosomal recessive (AR) and autosomal dominant (AD) diseases. The first case (BH8450-1) has likely pathogenic variants in two known disease-causing genes, *RTN2* (AD, MIM#604805) and *PNKP* (AR, MIM#613402) in the same AOH (absence of heterozygosity) region of ~ 21Mb on Chr19. The second case (BH8426-1) has a likely pathogenic variant in *WDR81* (AR, MIM#610185) and a homozygous missense variant in *TUBB6* (c.736C>A, p.L246I) which has been recently linked to disease (AD, MIM#617732). In both cases, we see examples of AR inheritance in AD described diseases. The overall rate of molecular diagnoses, i.e. cases for which WES was diagnostic, for our NDD cohort is 69% (121/175 families). Of these, the overall rate of multiple molecular diagnoses in our molecularly diagnosed NDD cohort is 12.4% (15/121 families), which is higher than that observed in an outbred clinical cohort as reported by Posey *et al*, NEJM 2017 (4.9%, 101/2076 families,  $p=0.003$ ). Of the 15 families with multiple molecular diagnoses in our NDD cohort, 13 families were identified to have dual molecular diagnoses and 6/13 families showed an AR+AR inheritance model. Higher rates of presumed identity-by-descent as evidenced by AOH in this cohort aided in the identification of homozygous variants that are potentially pathogenic. Additional studies including segregation, functional analyses, and sequencing of additional families with NDDs are being carried out. Development of tools to utilize structured phenotype ontologies to determine the relative contributions to phenotype of each identified molecular diagnosis will further assist in identifying multilocus variation.

**1082F****Genetic background of unexplained full-term cerebral palsy: Genomic analysis identifies candidate pathogenic variants in 9 of 17 patients.**

Y. Takezawa<sup>1</sup>, A. Kikuchi<sup>1</sup>, K. Haginoya<sup>1,2,3</sup>, T. Niihori<sup>4</sup>, Y. Numata-Uematsu<sup>1,3</sup>, T. Inui<sup>2,3</sup>, S. Yamamura-Suzuki<sup>2</sup>, T. Miyabayashi<sup>2</sup>, M. Anza<sup>2,3</sup>, S. Suzuki-Muromoto<sup>2</sup>, Y. Okubo<sup>2,3</sup>, W. Endo<sup>2,3</sup>, N. Togashi<sup>2</sup>, Y. Kobayashi<sup>2</sup>, A. Onuma<sup>2</sup>, R. Funayama<sup>2</sup>, M. Shiota<sup>2</sup>, K. Nakayama<sup>2</sup>, Y. Aoki<sup>4</sup>, S. Kure<sup>1</sup>. 1) Department of Pediatrics, Tohoku University School of Medicine, Sendai, Japan; 2) Department of Pediatric Neurology, Miyagi Children's Hospital, Sendai, Japan; 3) Department of Pediatric Neurology, Takuto Rehabilitation Center for Children, Sendai, Japan; 4) Department of Medical Genetics, Tohoku University School of Medicine, Sendai, Japan; 5) Division of Cell Proliferation, United Centers for Advanced Research and Translational Medicine, Tohoku University Graduate School of Medicine, Sendai, Japan; 6) Division of Interdisciplinary Medical Sciences, United Centers for Advanced Research and Translational Medicine, Tohoku University Graduate School of Medicine, Sendai, Japan.

**Background and Objective:** Cerebral palsy is a common, heterogeneous neurodevelopmental disorder that causes movement and postural disabilities. Recent studies have suggested cerebral palsy have more genetic abnormalities than expected. We hypothesized that two simple criteria, i.e., full-term births and nonspecific brain MRI findings, are keys to detecting pathogenic variants in cerebral palsy cases due to the following: (i) preterm infants are susceptible to multiple environmental factors and therefore demonstrate an increased risk of cerebral palsy and (ii) brain MRI assessment is essential for excluding environmental causes and other particular disorders. **Methods:** A total of 107 patients—all full-term-births—without specific findings on brain MRI were identified among 897 patients diagnosed with cerebral palsy who were followed at our center. DNA samples were available for 17 of the 107 cases for trio whole-exome sequencing and array comparative genomic hybridization. We prioritized variants in genes known to be relevant in neurodevelopmental diseases and evaluated their pathogenicity according to the American College of Medical Genetics guidelines. **Results:** Pathogenic/likely pathogenic candidate variants were identified in 9 of 17 cases (52.9%) within eight genes: CTNNA1, CYP2U1, SPAST, GNAO1, CACNA1A, AMPD2, STXB1, and SCN2A. Five identified variants had previously been reported. No pathogenic copy number variations were identified. The AMPD2 missense variant and the splice-site variants in CTNNA1 and AMPD2 were validated by *in vitro* functional experiments. **Conclusion:** Our study showed the possibility that a subset of CP patients categorized by two simple criteria (full-term births and nonspecific brain MRI findings) include pathogenic/likely pathogenic variants despite several limitations. Further genetic investigations of larger cohorts of CP patients are required to help support our results or identify other CP subsets that may likely include genetic abnormalities. This could eventually aid the further characterization of the molecular mechanisms of CP and optimizing its therapeutic interventions.

**1083W****AMPD2-related pontocerebellar hypoplasia type 9: A report of 12 new Egyptian families and further delineation of the spectrum.** M.S. Zaki<sup>1</sup>, M.S. Abdel-Hamid<sup>2</sup>, M.Y. Issa<sup>1</sup>, H.M. Elbendary<sup>2</sup>, G.M.H. Abdel-Salam<sup>1</sup>.

1) Clinical Genetics Department, Human Genetics and Genome Research Division, National Research Centre, Cairo, Egypt; 2) Medical Molecular Genetics Department, Human Genetics and Genome Research Division, National Research Centre, Cairo, Egypt; 3) Child Health Department, Medical Research Division, National Research Centre, Cairo, Egypt.

Pontocerebellar hypoplasia (PCH) is a rare inherited heterogeneous group of disorders with a progressive neurodegeneration of prenatal onset. Currently, there are 11 partially overlapping clinical subtypes with 15 known causative genes. PCH type 9 is an autosomal recessive disorder characterized by severe microcephaly, severe psychomotor delay, spasticity, intractable seizures. The brain MRI shows hypogenesis of the corpus callosum, cerebellar hypoplasia, ventral pontine degeneration, figure 8 shape of hypoplastic midbrain and variable degrees of cortical atrophy. Herein, we report 13 patients from 12 unrelated Egyptian families with PCH9. They were 7 males and 6 females, their aged from 3 months to 2 6/12y and parental consanguinity was recorded in all families. Patients were assigned as candidates for target *AMPD2* gene sequencing based on clinical and neuro-radiological presentation. All had progressive microcephaly, severe global developmental delay, spasticity, intractable generalized and myoclonic seizures and the specific neuroimaging findings including variable degrees of the cerebellum and brain stem hypoplasia, hypogenesis of corpus callosum and cortical atrophic changes. Mutational analysis of *AMPD2* gene identified 8 novel mutations and 4 previously reported in the literature. This study emphasizes the importance of clinico-radiological characterization of PCH9 linked to *AMPD2* gene and further expand the mutational spectrum. To our knowledge, this is the largest reported series of PCH9 from the same ethnic group.

**1084T**

**Opposite functional consequences of a novel de novo variant in the voltage-sensing domain of Kv1.2 (KCNA2) in a case of infantile epilepsy.** M. Kaneko<sup>1</sup>, A. Pantazis<sup>2</sup>, G. Raca<sup>1,3</sup>, W. Mitchell<sup>4,5</sup>, R. Olcese<sup>2,6</sup>, S. Saitta<sup>1,3</sup>. 1) Center for Personalized Medicine, Children's Hospital Los Angeles, Los Angeles, CA; 2) Department of Anesthesiology & Perioperative Medicine, University of California Los Angeles, Los Angeles, CA; 3) Department of Pathology, Keck School of Medicine at University of Southern California, Los Angeles, CA; 4) Department of Neurology, Children's Hospital Los Angeles, Los Angeles, CA; 5) Department of Pediatrics, Keck School of Medicine at University of Southern California, Los Angeles, CA; 6) Department of Physiology, University of California Los Angeles, Los Angeles, CA.

Using an exome-based panel of 166 epilepsy genes, we found a heterozygous *de novo* c.906T>G missense change in *KCNA2*, in a female infant with onset of generalized seizures at age 5 months. Clusters of seizures were provoked by fever or overheating, overlapping with a Dravet phenotype. *KCNA2* encodes the Kv1.2 voltage-gated potassium channel, expressed in the nervous system. This p.Phe302Leu change in the S4 segment of Kv1.2's voltage-sensing domain (VSD) was not previously reported in either general population (gnomAD) or in clinical variant (ClinVar) databases. Amino-acid sequences of the S4 segment are identical from human through *Drosophila* and 6 heterozygous pathogenic variants in S4 have been reported, with varied patient phenotypes from infantile epileptic encephalopathy to spastic paraplegia. The functional effects of S4 variants range from loss of function, gain of function, or combined loss and gain of function. Genotype-phenotype correlation and molecular mechanisms underlying the functional effects of *KCNA2* variants are still poorly understood. We characterized the functional consequences of p.Phe302Leu (F302L) using the highly conserved rat Kv1.2 homolog expressed in *Xenopus* oocytes by cut-open oocyte voltage clamp and voltage-clamp fluorometry. Channels with F302L activated faster and at more negative membrane potentials, a gain-of-function effect. Co-expressing wild-type and F302L subunits (1:1) to simulate heterozygous expression resulted in left-shifted conductance suggesting a dominant effect. Voltage-clamp fluorometry showed that VSDs from F302L channels also activated at more negative potentials and F302L stabilized the active state of Kv1.2, facilitating channel opening at more hyperpolarized potentials. Studies of the slow-inactivation process during prolonged depolarization showed that F302L inactivates at more hyperpolarized potentials with a loss-of-function effect. Our data indicate that the functional consequences of F302L may depend on neuronal excitability: in slow-firing neurons a gain-of-function effect on channel activation would predominate suppressing excitability, while in fast-firing neurons, increased Kv1.2 inactivation would favor excitability. As new variants are identified, biophysical assays are useful adjuncts to test the effects on an affected protein. Knowledge of the functional consequences of a variant can help identify specific treatments personalized to a patient's genotype.

**1085F**

**The usefulness of additional clinical evaluation in patients with complex genetic testing results.** E.R. Elias<sup>1</sup>, K. Chatfield<sup>2</sup>. 1) Pediatrics and Genetics, Children's Hospital Colorado, Aurora; 2) Pediatric Cardiology, Children's Hospital Colorado, Aurora.

**Introduction:** Testing with Next Generation Sequencing panels have established new diagnoses for complex patients. Interpreting rare variants or VOUS's can be difficult, however, and guidelines are often unclear regarding further workup. A case is reported of a patient with several unrelated genetic abnormalities, demonstrating the value of additional evaluation in clarifying the significance of variant findings. **Case History:** This 9 yr old boy has a history of pontocerebellar hypoplasia, partial agenesis of the corpus callosum (molar tooth sign), strabismus, amblyopia, and a feeding disorder. He has severe intellectual disability. On physical exam he is thin, and microcephalic. He has dysmorphic features including dysplastic pinnae, and esotropia. His orthopedic deformities include windswept lower extremities and a moderate scoliosis. **Genetic testing** demonstrated a **TUBA1A (c.1169G>A, p.Arg390His) pathogenic variant**. He also has a variant of uncertain significance in **FLNA, (c.3814C>T p.Arg1272Cys)**. This variant is predicted to impact secondary protein structure. Lastly, he is heterozygous for a duplication within 9q34.3. The duplicated region involves exons 1-3 of the **INPP5E gene**. **Discussion:** The TUBA1A gene encodes the tubulin alpha 1A protein, which is involved in neuronal migration and brain development. Variants in TUBA1A are associated with brain malformations involving the corpus callosum, brainstem and cerebellum. Patients present with microcephaly, intellectual disability, and epilepsy. An EEG was moderately abnormal, although this patient does not have clinical seizures. Mutations of X-linked FLNA encoding Filamin A, have been found in a broad spectrum of phenotypes. As aortic abnormalities may be seen in patients with FLNA mutations, an echocardiogram was done, which demonstrated mild dilation of the aortic root, with an hour-glass appearance of the aortic root/ ascending aorta. The INPP5E gene encodes inositol polyphosphate-5-phosphatase. Pathogenic variants in INPP5E cause autosomal recessive Joubert syndrome. This child has a Molar Tooth sign on MRI, but the significance of a duplication of part of the INPP5E gene is not clear. It is comforting for the family to have a partial explanation for his phenotype. Furthermore, test results led to additional evaluations showing cardiac and EEG abnormalities, which require future medical oversight. Additional testing of multiple genetic findings has led to an improvement in this patient's care.

**1086W****Genetic investigation of Nemaline myopathy in Middle Eastern patients.**

*A. Haghighi<sup>1</sup>, Y. Nilipour<sup>2</sup>, S. Nafissi<sup>3</sup>, A. Haghighi<sup>4</sup>, R.J. Desnick<sup>5</sup>, R. Kornreich<sup>5</sup>.*  
 1) Harvard Medical School, Boston, MA; 2) Department of Pathology, Pediatric Pathology Research Center, Mofid Children Hospital; 3) Tehran University of Medical Sciences; 4) Toronto General Hospital, University of Toronto; 5) Department of Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York.

Nemaline myopathy is a rare genetic muscular disease clinically characterized by muscle weakness and hypotonia, with nemaline rods in skeletal muscle fibers. Nemaline myopathy is both genetically and phenotypically heterogeneous disease, for which a number of disease genes have been identified. We investigated the clinical features and genetic cause of nemaline myopathy in pathologically diagnosed patients from Middle Eastern families. Half of the families were consanguineous (first-cousins). We applied a targeted next-generation sequencing (NGS) myopathy panel to identify single nucleotide variants (SNVs), insertions/deletions, and copy number variations in these patients. In addition, we reviewed the previously reported cases with the identified variants and attempted to suggest genotype–phenotype correlations. Sequence analysis revealed rare homozygous SNVs in NEB (in 66% of families) and ACTA1 (in 34% of families). Segregation analysis showed that the other affected family members were homozygous for the identified variants, whereas parents were heterozygous and healthy siblings were either heterozygous or wild type. All NEB variants were predicted to cause loss of function of the gene products, whereas the ACTA1 variants were missense. Five of the identified disease-causing variants were novel. These results suggest a) NEB and ACTA1 to be the most prevalent cause of nemaline myopathy in Middle Eastern patients, and b) targeted NGS panel is a rapid and cost-effective approach to analyze the molecular basis of nemaline myopathy.

**1087T****Whole exome sequencing identifies novel mutation in ChAT gene for a lethal perinatal presentation of hydrops and arthrogryposis multiplex congenita.** *D. Khattar, N. Smith, R. Hopkin.* CCHMC, Cincinnati, OH.

Arthrogryposis refers to multiple congenital contractures consequent of decreased intrauterine fetal movement. Etiology includes genetic causes such as chromosomal or single gene disorders as well as non-genetic causes including teratogen exposures and intrauterine space constraints. The cause remains unknown in more than half of the cases. Accurate diagnosis can aid in prognosis, risk assessment for future pregnancies and evaluation for preimplantation genetic diagnosis and counseling. We describe a case with recurrent pregnancy losses complicated by hydrops and arthrogryposis. Proband was a 36-year old previously healthy woman who was being evaluated for an abnormal second trimester ultrasound with fetal joint contractures, skin and scalp edema, bilateral pleural effusion and abdominal ascites. Her obstetric history was significant for one healthy live term birth, one first-trimester loss, and two mid-trimester losses which included a 26-week singleton neonate with hydrops and arthrogryposis and 22 week triplets, where baby B was affected with a similar presentation. No drug exposures, infections, or illness were identified. First trimester screening was normal. Amniocentesis was performed and alpha-fetoprotein level, chromosomes and microarray were sent, all of which returned normal. At 22 weeks gestation, the pregnancy was complicated by PPROM with subsequent neonatal demise. Postnatal evaluation and tissue culture of facia lata was performed. Whole exome sequencing was done as a trio with parental samples. Compound heterozygous mutations were identified in the ChAT gene, one maternally inherited (c.1663G>T) and the other was paternally inherited (c.1811T>A), consistent with a diagnosis of presynaptic congenital myasthenic syndrome (CMS). These variants occurred at a highly conserved nucleotide and were predicted to be deleterious by multiple software programs including PolyPhen, SIFT and MutationTaster. Conclusion: Biallelic mutations in ChAT result in a deficiency of choline acetyltransferase which impairs presynaptic neuromuscular transmission. It is characterized by variable presentation of apnea, hypotonia and respiratory distress with an onset anytime from birth to childhood. To our knowledge, this is the first description of a case of severe perinatal CMS presenting as fetal losses with hydrops and arthrogryposis. Future directions include investigating potential treatment options including cholinergic agonists in the perinatal period.

**Expanding the phenotype of chromosome 17q21.31 duplication syndrome: Severe epilepsy and self-injuring behavior as prominent features.** C.M. Lourenco<sup>1</sup>, Y.B.S. Valeta<sup>1</sup>, L. El-Kadre<sup>1</sup>, R. Calvo<sup>1</sup>, R. Bogas<sup>1</sup>, D. Sas<sup>2</sup>, L. Lima<sup>2</sup>. 1) Clinical Genetics, Centro Universitario Estacio de Ribeirao Preto, Ribeirao Preto, Sao Paulo, SAO PAULO, Brazil; 2) Genotyping - Diagnósticos Genéticos, Botucatu, Sao Paulo, Brazil.

**Background:** 17q21.31 microdeletion syndrome (Koolen-de Vries syndrome), is a rare copy number variants associated in humans with intellectual disability, friendly behavior, congenital malformations. Recently, a novel microduplication syndrome involving the reciprocal 17q21.31 was described and **to date only 10 cases were reported**. is not so well characterized. Here we describe the 11th patient with 17q21.31 duplication in a Brazilian family. **Methods/Results:** Clinical features and genetic data are reported, and compared with previously reported patients with 17q21.31 microduplication. It was possible to show that duplication arose de novo. Intellectual skills showed moderate mental retardation with progressive cognitive decline not reported/described in other patients so far. Patient showed poor social interaction, self-mutilating behavior and refractory epilepsy, besides relationship difficulties, reminiscent of autistic spectrum disorders. **Conclusion:** Patient clinical characterization helps to further delineate and expand the clinical spectrum of 17q21.31 microduplication syndrome; progressive cognitive decline was not previously described and can be related to the recent findings showing 17q21.31 duplication as the genetic basis of a novel entity marked by prominent tauopathy, leading to early-onset dementia with an Alzheimer disease clinical phenotype.

**1089W**

**Prodromal Parkinson's disease in patients with 22q11.2 microdeletion syndrome: Preliminary results.** G.M. Repetto<sup>1</sup>, P. Chana<sup>2,3</sup>, T. Cordova<sup>4</sup>, A. Cuiza<sup>4</sup>, R. Fritsch<sup>5</sup>, C. Jurí<sup>6</sup>, V. Kramer<sup>7</sup>, A. Ocampo<sup>4</sup>, C. Ornstein<sup>5</sup>, K. Villanueva<sup>4</sup>. 1) Universidad del Desarrollo, Santiago, Chile; 2) Centro de Trastornos del Movimiento, Santiago, Chile; 3) Dept of Neurology, Universidad de Santiago, Chile; 4) Instituto de Ciencias Biomedicas, Universidad de Chile; 5) Dept of Psychiatry, Facultad de Medicina, Universidad de Chile; 6) Dept of Neurology, Facultad de Medicina, P. Universidad Catolica de Chile; 7) Positron-Med, Santiago, Chile.

Parkinson's disease (PD) is the second most common neurodegenerative disorder. The classical motor symptoms are preceded by non-motor, prodromal manifestations by a decade; prodromes include anosmia, autonomic dysfunction and REM-sleep behavior disorder (RBD). Chromosome 22q11.2 microdeletion syndrome (22q11DS) was recently recognized as a cause of PD, particularly of early onset (<45 years of age). The aim of this study is to assess the presence of prodromal and motor PD findings in adults with 22q11DS, using the International Parkinson and Movement Disorder (MDS) research criteria, namely: motor testing with UPDRS scale, autonomic symptoms with COMPASS-21 scale, olfactory function with "Sniffin' Sticks", RBD-13 screening questionnaire, one full-night domiciliary video-polysomnographic (v-PSG) record and PET-CT with the presynaptic dopamine transporter (DAT) tracer <sup>18</sup>F-PR04-MZ. Data on clinical and molecular manifestations of 22q11DS, a cognitive evaluation using WISC-IV and a clinical psychiatric and MINI interview, including use of antipsychotic medications was obtained. We report the results on the first 12 participants: 6 males and 6 females, median age 29.5 years (range 18-49 years), none had PD. Data were available on deletion size for 9 patients, 6 had the common LCR-AD 3Mb deletion, and 3 had an AB 1.5Mb deletion. Ten had a history of repaired open (1) or submucous (9) cleft palate. Full-scale IQ median was 74 (range 56-87). Three patients had psychosis; two were receiving aripiprazole and one, clozapine. UPDRS score average was 10 (range 1-16, normal 0); three patients had olfactory scores in the anosmia range, none had orthostatic hypotension. Home v-PSG performed in 7 participants, showed no objective sign of REM-sleep without atonia or behavioral RBD. PET-CT results showed increased, symmetric <sup>18</sup>F-PR04-MZ DAT signaling compared to age and gender-matched controls (130% of controls in the caudate nucleus, 115% in putamen). These initial results suggest the presence of anosmia and motor disturbances. The observed increase in dopamine signaling on PET-CT may be related to haploinsufficiency of COMT, located within the deletion region and involved in dopamine metabolism. Caution should be taken when analyzing these results, due to the limited sample size and the lack of validated screening tools for patients with cognitive deficits. Funded by Fondecyt-Chile #1171014 and Fundacion Puelma.

*PLP1* is a disease-causing gene in which variation can result in X-linked Pelizaeus–Merzbacher disease (PMD, MIM# 312080) or Spastic Paraplegia type 2 (SPG2, MIM# 312920). Pathogenic variation in *PLP1* includes point mutations, whole-gene duplications and deletions. The frequency, as well as phenotypic effect of each of these lesions, vary extensively within same-sex individuals as well as affected males and females owing to X-chromosome inactivation (XCI) in the latter. Microdeletions involving *PLP1* are the rarest form of all lesions (<10% of phenotypic cases) and have been associated with a complicated form of SPG2. We describe the genomic features of 7 novel *PLP1*-deletion events and expand on the clinical picture associated with large genomic deletions encompassing this gene. Three of the reported cases elucidate a severe infantile-onset neurological phenotype that is specific in its presentation to female cases. The minimal region of overlap between deletion events identified in similarly manifesting female cases was investigated for potential modifier regions. Moreover, the size of the deletion appears to play a role in early-onset penetrance of disease in the majority of female cases. XCI testing was performed revealing random patterns in blood, with the exception of the largest-deletion case in which skewed inactivation (>90%) of the deletion-bearing paternal X-chromosome was confirmed. Two of the described deletions are unique in their genetic content as one is a hemizygous deletion spanning more genes in addition to *PLP1* than has been observed in reported males thus far, and another is a heterozygous deletion encompassing an additional disease-causing gene, *PIH1D3*, in an affected female. Breakpoint-junction sequencing and examination of genomic architecture via a novel approach of identifying low copy repeats (LCRs) and repetitive elements revealed an overrepresentation of deletion breakpoints that lie within these classes of repeat structures/genome architectures, specifically LCRs. Although previous studies suggested a mechanism of non-homologous end joining, genomic characteristics of the majority of these *PLP1* deletions reveal microhomology at the breakpoints, as observed for *PLP1* copy-number gain events, and suggest the potential involvement of replicative mechanisms and template switching in their formation.

**The morbidity of neurofibromatosis 1: Rates and nature of hospitalizations in a population-based cohort in Denmark.** J.J. Mulvihill<sup>1</sup>, L. Kenborg<sup>2</sup>, A.K. Duun-Heniksen<sup>2</sup>, V.M. Riccardi<sup>3</sup>, K. Rugbjerg<sup>2</sup>, C. Pedersen<sup>2</sup>, K. Doser<sup>2</sup>, A. Kroyer<sup>2</sup>, P.E. Bidstrup<sup>2</sup>, S.O. Dalton<sup>2</sup>, C. Johansen<sup>2</sup>, K.K. Andersen<sup>2</sup>, J.R. Ostergaard<sup>4</sup>, H. Hove<sup>5</sup>, S.A. Sorensen<sup>6</sup>, J.F. Winther<sup>2,7</sup>. 1) Pediatrics, University of Oklahoma, Oklahoma City, OK; 2) Danish Cancer Society Research Center, Copenhagen, DK; 3) The Neurofibromatosis Institute, La Crescenta, CA; 4) Pediatrics, Centre for Rare Diseases, Aarhus University Hospital, Aarhus, DK; 5) Clinical Genetics, Rigshospitalet University Hospital, Copenhagen, DK; 6) Neurogenetics, Institute of Cellular and Molecular Medicine, The Panum Institute, University of Copenhagen, Copenhagen, DK; 7) Clinical Medicine, Aarhus University, Aarhus, DK.

Neurofibromatosis 1 (NF1) is a Mendelian disorder with increased mortality, predisposition to certain cancers, neurocognitive and neurologic manifestations, and, according to case series, occasional manifestations in nearly every organ system. To quantitate the disease burden to assay the full morbidity, we analysed the rates and nature of hospitalizations for individuals NF1 in all of Denmark. We matched all 2,515 persons with NF1 in the Danish National Patient Register (DNPR) (1977–2013) and two national Centres for Rare Diseases (1995–2013) to 24,629 general population comparisons from the Danish Civil Registration System. International Classification of Diseases versions 8 and 10 identified patients and allowed careful exclusion of neurofibromatosis 2, but gene testing was not systemically done. Based on hospital discharge diagnoses from the DNPR, hospitalization rates for non-psychiatric diagnoses were used to calculate a rate ratio (RR) and an absolute excess risk (AER). In Cox proportional hazard models, a hazard ratio (HR) was estimated for 12 main diagnostic groups according to age and cancer status. The RR for a first hospital admission among NF1 persons in 146 selected diagnostic categories was 1.81 (95% confidence interval 1.73–1.90), in another words, nearly double rate in the general population. The overall AER of 304 per 10,000 person-years (95% CI, 274–334) was high in all 12 diagnostic groups; 64% of the excess was accounted for by just five groups [benign neoplasms (14%), malignant neoplasms (14%), disorders of the central nervous system and sense organs (13%), the respiratory (11%) and the digestive systems (11%)]. An increased HR for any hospitalization was observed for all age groups, with or without an associated cancer, and highest for children. Individuals with NF1 spent twice as many days in hospital as did the general population, with an overall mean of 9.5 versus 4 hospitalizations by age 60 years; children under 10 years averaged 3.5 hospitalizations compared to 1 in the population. In this population-based, nation-wide cohort, NF1 persons had an overall greater likelihood of hospitalization, with more frequent and longer hospitalizations involving problems in every organ system, and the highest burden in children.

**1092W**

**Disease-associated sites in *PCDH19* cluster in between cadherin domains depleted from the general population.** A. Rochtus<sup>1</sup>, S. Iqbal<sup>2,3</sup>, E. Pérez-Palma<sup>4</sup>, L. Smith<sup>1</sup>, D. La<sup>2,3,4,5</sup>, A. Poduri<sup>1</sup>. 1) Epilepsy Genetics Program, Department of Neurology, Boston Children's Hospital and Harvard Medical School, Boston, MA; 2) Stanley Center for Psychiatric Research, Broad Institute of MIT and Harvard, Cambridge, MA; 3) Analytic and Translational Genetics Unit, Massachusetts General Hospital, Boston, MA; 4) Cologne Center for Genomics, University of Cologne, Cologne, Germany; 5) Cleveland Clinic, Cleveland, OH.

**Rationale:** Protocadherin-19 (*PCDH19*) encodes a transmembrane protein with six cadherin domains, which creates an extensive adhesive interface. Over 100 pathogenic variants have been identified in patients with a female-restricted form of infantile-onset epilepsy. In contrast to typical X-linked diseases, hemizygous males are spared. Our aim was to characterize structural determinants associated with *PCDH19*-related epilepsy variants. **Methods:** Variants were ascertained from the literature with the search parameters "PCDH19" AND "Epilepsy" (PubMed). Subsequently, we assembled a 3-dimensional structural model of the *PCDH19* protein, mapped all reported missense *PCDH19* variants on the model, and compared the spatial distribution of patients' variants to those reported in the population database (gnomAD). Furthermore, we determined whether the patient variants affect buried amino acids or amino acids at the surface. Finally, we performed an enrichment analysis comparing amino acid positions with patient vs. population missense variants with respect to the predicted functional domains of the protein model, such as the calcium-binding sites. **Results:** We mapped 106 missense variants reported in literature to 77 locations on the 3-dimensional protein model. We show that the missense patient variants are present in distinct regions from population variants ( $p < 0.0001$ , Fisher's exact test). Moreover, 47/77 (61%) of the missense patient variants are enriched in regions where control individuals from gnomAD show a paucity of variants ( $p < 0.0001$ , Fisher's exact test). Among those variants, 62% (29/47) are enriched in calcium binding sites in between the cadherin domains ( $p = 0.038$ , Fisher's exact test). **Conclusions:** Mapping all known disease-associated variants on a computationally derived structural model of *PCDH19* reveals that missense variants in *PCDH19*-related epilepsy cluster at regions distinct from those where general population variants are located, specifically, between the cadherin domains at the adhesive interface of the protein. The present results provide further support to the idea that it is the abnormal binding of these cadherin domains between cells that mediate at least some of the neurological dysfunction seen in patients. We thus demonstrate that mapping genetic variants onto a 3-dimensional protein structure can facilitate variant interpretation and also provide molecular insight into the pathogenesis of disease.

**Genetic analysis of SMN in SMA pedigrees.** F. Song, YY. Cao, YJ. Qu, JL. Bai, MM. Cheng. Capital Institute of Pediatrics, Beijing, China.

Spinal muscular atrophy (SMA) pathogenic gene, *SMN1* and modified gene, *SMN2* co-locate at 5q13. This region is complex and many repeats are there, easily leading to deletion or gene conversion. *SMN1* homozygous deletion and compound heterozygous mutation can lead to SMA. Currently the SMA genetic studies focused on disease population, but no family studies were reported. In this study, we aim to identify the distribution of *SMN* in SMA pedigrees. One hundred and fifty-three SMA pedigrees, which were got the genetic diagnosis from the department of genetics in Capital Institute of Pediatrics, were recruited. Multiplex Ligation-dependent Probe Amplification (MLPA) was used to analyze copy numbers of the *SMN1* and *SMN2*. The gene conversion was determined by the copy numbers of exon 7 and exon 8 of *SMN1* and *SMN2*. In 153 SMA pedigrees, 146 (95.4%) probands were homozygous deletion of *SMN1*, and 7 (4.6%) probands carried *SMN1* compound heterozygous mutations. Both parents with *SMN1* heterozygous deletion were found in 128 families (Classic deletion), while only one parent with *SMN1* heterozygous deletion were found in 18 families (2+0), whose children were all *SMN1* homozygous deletion. Moreover, in 7 pedigrees with *SMN1* compound heterozygous mutations, both parents carried *SMN1* heterozygous deletions and gene variations, respectively. Conversion analysis showed that in 21/128 (16.4%) pedigrees, at least one family member had SMN conversion; three families (3/18, 16.7%) had SMN conversion in 18 pedigree with 2+0 type; no SMN conversion were found in 7 pedigree with *SMN1* compound heterozygous mutations. Therefore, 15.7% (24/153) of SMA pedigrees had SMN conversion. Moreover, among 306 SMA carriers from 153 SMA pedigrees, there were 25 cases (2+0 and point variant) could not be detected by MLPA, leading to false negative rate of 8.9% (25/306). Therefore, individuals with type of 2+0 and point variant of *SMN* should be considered in SMA carrier screening; on the other hand, SMN conversion is still a factor of SMA, which is not be ignored. **Acknowledgments** This study was supported by the National Key Research and Development Program of China (2016YFC0901505), National Natural Science Foundation of China (81500979, 81501850), the Natural Science Foundation of Beijing Municipality (5163028, 7172039), CAMS Initiative for Innovative Medicine (CAMS-I2M), Central research institutes of basic research and public service special operations (2016ZX310182-6).

**Variant pathogenicity evaluation through the community-driven Inherited Neuropathy Variant Browser.** *D. Bis<sup>1</sup>, C. Saghira<sup>1</sup>, D. Stanek<sup>2</sup>, A. Strickland<sup>3</sup>, D.N. Herrmann<sup>3</sup>, M.M. Reilly<sup>4</sup>, S.S. Scherer<sup>5</sup>, M.E. Shy<sup>6</sup>, S. Zuchner<sup>1</sup>*. 1) Department of Human Genetics and Hussman Institute of Human Genomics, University of Miami, Miami, USA; 2) DNA Laboratory, Department of Paediatric Neurology, 2nd Faculty of Medicine, Charles University in Prague and University Hospital Motol, Prague, Czech Republic; 3) Department of Neurology, University of Rochester, Rochester, New York, USA; 4) MRC Centre for Neuromuscular Diseases, UCL Institute of Neurology, Queen Square, London, UK; 5) Department of Neurology, University of Pennsylvania, Philadelphia, Pennsylvania, USA; 6) Department of Neurology, University of Iowa, Iowa City, Iowa, USA.

Charcot-Marie-Tooth disease (CMT) is an umbrella term for inherited neuropathies affecting an estimated 1 in 2500 people. Over 120 CMT and related genes have been identified and clinical gene panels often contain more than 100 genes. Such a large genomic space will invariably yield variants of uncertain clinical significance (VUS) in nearly any person tested. This rise in number of VUS creates major challenges for genetic counseling. Additionally, fewer individual variants in known genes are being published as the academic merit is decreasing, and most testing now happens in clinical laboratories, which typically do not correlate their variants with clinical phenotypes. For CMT, we aim to encourage and facilitate the global capture of variant data to gain a large collection of alleles in CMT genes, ideally in conjunction with phenotypic information. The Inherited Neuropathy Variant Browser provides user-friendly open access to currently reported variation in CMT genes. Geneticists, physicians, and genetic counselors can enter variants detected by clinical tests or in research studies in addition to genetic variation gathered from published literature, which are then submitted to ClinVar bi-annually. Active participation of the broader CMT community will provide an advance over existing resources for interpretation of CMT genetic variation.

**Improvements in arginase 1 deficiency-related disease manifestations following plasma arginine reduction with pegzilarginase: Early phase 2 results.** *R.T. Zori<sup>1</sup>, G.A. Diaz<sup>2</sup>, J.L. Merritt II<sup>3</sup>, A. Schulze<sup>4</sup>, G.M. Enns<sup>5</sup>, M.C. McNutt<sup>6</sup>, E.L. Teles<sup>7</sup>, K.C. Patki<sup>8</sup>, J.E. Wooldridge<sup>9</sup>, S.P. Batzios<sup>9</sup>*. 1) University of Florida, Gainesville, FL, USA; 2) Icahn School of Medicine at Mt. Sinai, NY, USA; 3) University of Washington, Seattle, WA, USA; 4) University of Toronto and The Hospital for Sick Children, Toronto, ON, Canada; 5) Stanford University, Stanford, CA, USA; 6) UT Southwestern Medical Center, Dallas, TX, USA; 7) Centro Hospitalar de São João, Porto, Portugal; 8) Aeglea BioTherapeutics, Austin, TX, USA; 9) Great Ormond Street Hospital NHS Trust, London, UK.

**Background:** Arginase 1 Deficiency (ARG1-D) is a rare, progressive, autosomal recessive disease characterized by hyperargininemia that causes spasticity, impaired mobility, and developmental delay, typically presenting in early childhood. Current methods to reduce plasma arginine are inadequate and problematic. Pegzilarginase is a pegylated, cobalt-substituted human arginase 1 that has been shown to lower plasma arginine in patients with ARG1-D. **Methods:** Data are from an ongoing Phase 1/2 clinical trial and Phase 2 Open Label Extension study of intravenously (IV) administered pegzilarginase in patients with ARG1-D. In addition to evaluations of safety, pharmacokinetics and effects on plasma arginine and related guanidino compounds (GCs), clinical outcomes assessments were incorporated at baseline and follow-up, including 6-minute walk test (6MWT), Berg Balance Scale (BBS), and Gross Motor Function Measure (GMFM-66). Safety assessments include physical examinations, laboratory tests, anti-drug antibody (ADA) evaluations and ECGs. **Results:** All enrolled patients had disease manifestations including hyperargininemia, neuromotor, and neurocognitive deficits. IV pegzilarginase, added to standard disease management, rapidly lowered plasma arginine into the normal range in all patients and was well tolerated except for a single infusion associated reaction in one patient. This infusion reaction was managed with dose interruption, medication, and a slower infusion rate without further adverse events. Sustained reductions in arginine, GCs, and improvements in several clinical tests of neuromotor function were observed in the first two patients during repeat-dose treatment. Dietary protein intake also increased in these two patients. **Discussion:** These data from the Phase 1/2 clinical trial and Phase 2 Open Label Extension study demonstrated the first evidence of clinically relevant treatment effects in neuromotor function with pegzilarginase beyond what can be achieved with standard disease management. Pegzilarginase produced marked and sustained reduction of plasma arginine and GCs in patients with ARG1-D. Additional insights are expected from recently enrolled adult and pediatric patients, as well as from longer term dosing in previously enrolled patients. .

**Introduction:** Epilepsy with migrating focal seizures in infancy (EMFSI) is a severe epileptic syndrome characterized by focal seizures beginning in the first months of life, migrating from one cortical region to another, highly pharmac-resistant, and associated with a severe cognitive outcome. In about 50% of patients, EMFSI is due to de novo KCNT1 gain-of-function mutations. In a few patients, EMFSI is linked to mutations in different genes (SCN1A, SMC1A, GABRB3, SCN8A, SCN2A, QARS, SLC25A22, SLC12A5, TBC1D24, PLCB1) according to de novo or autosomal recessive inheritance models. **Methods:** We reviewed clinical and molecular data of 26 new patients with EMFSI. We analyzed KCNT1 by Sanger sequencing and performed targeted next generation sequencing (NGS) analysis in patients without KCNT1 mutations. **Results:** We identified a causal mutation in 23/26 patients (88%). Fourteen patients (54%) carried missense KCNT1 mutations. The majority of KCNT1 mutations lies on already known hotspots. All occurred de novo, except for p.Arg398Gln which was inherited from a father affected by autosomal dominant nocturnal frontal lobe epilepsy (ADNFLE) and present in two paternal uncles, one being asymptomatic and the other having presented a single tonic-clonic seizure. In 9 patients (35%), mutations were identified in different genes: PIGA (n:2), SCN8A (n:2), KCNA1 (n:1), KCNC1 (n:1), CHRNA2 (n:1), ALDH7A1 (n:1), QARS (n:1). PIGA mutations were associated with cerebellar atrophy and with a better response of seizures to ketogenic diet; QARS mutations with a severe ponto-cerebellar hypoplasia. **Conclusions:** We confirm in a new large cohort that KCNT1 mutations are the major cause of EMFSI, with mutations in 54% of patients. The majority of KCNT1 mutations lies on specific hotspots. No genotype-phenotype correlation is possible, since a same mutation can be linked to a spectrum of conditions ranging from EMFSI to asymptomatic carrier, even in the same family. Moreover, these results underline that EMFSI is a genetically heterogeneous condition since we identified pathogenic variants affecting different genes in 35% of patients. In particular, we described for the first time PIGA, KCNA1, KCNC1, CHRNA2, and ALDH7A1 mutations in EMFSI. These results underline that targeted NGS is an appropriated strategy in patients with EMFSI. Moreover, they have relevant implication for antiepileptic treatment and genetic counseling.

**A novel variation in X-linked inherited IQSEC2 from a three-generation Korean family with Lennox-Gastaut syndrome and mental retardation.** M. Choi<sup>1,2</sup>, J. Min<sup>1</sup>, J. Lee<sup>1</sup>, S. Jun<sup>1</sup>, Y. Lee<sup>1</sup>, J. Yoon<sup>1</sup>, S. Jeon<sup>1</sup>, I. Byeon<sup>3</sup>, J. Kang<sup>3</sup>, J. Yang<sup>1</sup>, N. Kim<sup>1,2</sup>. 1) Genomics Structure Research Center, Korea Research Institute of Bioscience and Biotechnology, Daejeon, South Korea; 2) Department of Functional Genomics, Korea University of Science and Technology (UST), Daejeon, 34141, Republic of Korea; 3) Department of Pediatrics and Medical science, Chungnam National University Hospital, College of Medicine, Chungnam National University, Daejeon, 35015, Republic of Korea; 4) Korean BioInformation Center (KOBIC), Korea Research Institute of Bioscience and Biotechnology (KRIBB), Daejeon, 34141, Republic of Korea.

Lennox-Gastaut syndrome (LGS [MIM 606369]) is a childhood onset epilepsy that makes up 10% of childhood epilepsies. Of LGS patients, 80% also have intellectual disability. To identify causative genes related to LGS, we collected data from a three-generation Korean family with LGS, in which one family members had LGS, two had mental retardation, and two were normal. LGS patients have features such as generalized slow spike and wave discharges in electroencephalography, multiple types of seizures, and developmental delay. Analyses of whole-exome data from the family revealed a mutation of guanine to adenine on nucleotide 1048 of *IQSEC2* [MIM 300522] (c.1048G>A). This variation changes a non-polar hydrophobic alanine residue to a polar uncharged threonine at residue 350 (p.A350T). This variation is within highly evolutionarily conserved IQ-like motif, indicating decrease of calmodulin-binding capacity or AMPA transmission. The hemizygous variation in the male proband was a maternally inherited X-linked variation from heterozygosity in the maternal grandmother and mother. These findings indicate that the variation of X-linked *IQSEC2* triggers both LGS and mental retardation dependent on sex and variation type. We first report a novel variation of X-linked inherited *IQSEC2* for LGS and mental retardation that could be a useful marker to diagnose LGS and mental retardation.

**Exome sequencing identifies molecular diagnosis in children with drug-resistant epilepsy that associates with risk of sudden death.** *B. Chung, M. Tsang.* The University of Hong Kong, Hong Kong, NA, China.

**Objective:** Sudden unexpected death in epilepsy (SUDEP) is relatively uncommon in children but the risk increases and persists into adulthood. This life-threatening condition is strongly related to drug-resistant epilepsy. We aim to identify the underlying genetic causes of a children cohort with drug-resistant epilepsy, and whether the findings can provide information to stratify the risk of sudden death. **Methods:** We include subjects with drug-resistant epilepsy with onset before 18 years old managed in the Department of Paediatrics & Adolescent Medicine, the University of Hong Kong. Clinical chromosomal microarray (CMA) and then whole exome sequencing (WES) was performed using genomic DNA from the subjects. In the first-tier analysis of the exome data, we aimed to identify disease-causing mutations in 546 genes known to cause epilepsy. For negative cases, we proceeded to exome-wide analysis. Rare coding variants were interrogated for pathogenicity based on the American College of Medical Genetics and Genomics (ACMG) guideline. **Results:** We recruited 50 subjects (male=22). We identified six pathogenic or likely pathogenic mutations, giving a diagnostic yield of 12% (6/50). Mutations were found in six different genes: *SCN8A*, *SCN1A*, *MECP2*, *CDKL5*, *DEPDC5*, and *CHD2*. The *CDKL5* variant was found to be a mosaic mutation. One variant of unknown significance (VUS) in *KCNT1* was found in a subject with compatible clinical features. Four variants were *de novo*, and three variants were inherited from father. Interestingly, an incidental finding of pathogenic *SCN5A* mutation contributed to Brugada syndrome, was also noted in the subject with *SCN1A* mutation. **Significance:** Genetic diagnosis can help to consolidate the clinical diagnosis, to facilitate phenotypic expansion, and to influence management options for seizure control in our patients. Importantly, in our study, a significant portion of the genetic findings are known to be associated with an increased risk of SUDEP. Since the genetic variants can be inherited, the risk of SUDEP can go beyond the patients to family members without epilepsy but carry the variants. This information is important for the comprehensive genetic counselling of these families.

**1099T**

**A candidate gene for progressive myoclonic epilepsy in a Malian family.**

Landouré<sup>1,2,4</sup>, The H3Africa Consortium.* 1) Service de Neurologie, CHU du Point G, Bamako, Mali; 2) Faculté de Médecine et d'Odontostomatologie, USTTB, Bamako, Mali; 3) Service de Neurologie, CHU de Gabriel Touré, Bamako, Mali; 4) Neurogenetics Branch, NINDS, NIH, Bethesda, MD; 5) Institut d'Ophtalmologie Tropicale de l'Afrique, Bamako, Mali; 6) Service d'ORL, CHU de Gabriel Touré, Bamako, Mali.

**Introduction:** Progressive myoclonic epilepsy (PME) is a group of disorders characterized by seizures and other neurological and non-neurological features. Several genes and loci have been associated to the disease; however, reports in sub-Saharan Africa are rare. **Objectives:** Characterize patients with PME, and identify the underlying genetic defect. **Methods:** After consent, patients went through a thorough clinical examination. Electroencephalography (EEG), brain imaging and blood chemistries were done to consolidate our diagnosis. DNA was extracted for genetic analysis. **Results:** We identified a consanguineous family in which three siblings presented symptoms consistent with PME at around age 7. Symptoms started with hand tremor followed by jerk movement and difficulty with walking. Symptoms worsened overtime, and in addition they presented problems with speech and progressive cognitive decline. Neurological examination found cerebellar ataxia, and hearing and visual impairment. EEG showed generalized spike-waves and slow basal rhythm and photosensitivity in both patients, and brain imaging was consistent with cerebellar atrophy. In addition, unusual features including extrapyramidal symptoms were noticed. Epilepsy gene panel testing (126 genes + mtDNA) was negative. Exome sequencing in two affected individuals has showed three variants in three different genes. These variants are not present in SNP databases including dbSNP, Exac and 1000Genomes. None of these genes have been previously involved in any disease, and two of them are highly expressed in the brain. Of latter, one has a role in the axonal function while SNPs in the other were associated with neurodegenerative disorders. In addition, the mutated residues were conserved through a wide range of species. **Conclusion:** Our findings suggest two novel candidate genes causing PME. Further studies are underway to evaluate these variants in extended family members and the Malian population to select the putative variant that will be studied in cell culture.

**1100F****Pyridoxal phosphate-dependent neonatal epileptic encephalopathy:**

**Clinical case.** T.V. Kozhanova<sup>1,2</sup>, S.S. Zhilina<sup>1,2</sup>, T.V. Mescheryakova<sup>1</sup>, E.G. Luk'yanova<sup>1</sup>, K.V. Osipova<sup>1</sup>, S.O. Ayvazyan<sup>1</sup>, A.G. Prityko<sup>1,2</sup>. 1) St.Luka Scientific and Practical Center of Specialized Medical Care for Children, Department of Health, Moscow; 2) Pirogov Russian National Research Medical University, Moscow, Russia.

Pyridoxine-dependent epilepsy (OMIM # 266100) is severe epileptic encephalopathy with an autosomal recessive type of inheritance, characterized by neonatal seizures resistant to traditional antiepileptic therapy, and a therapeutic response to the administration of pharmacological doses of vitamin B6. Pyridoxine-dependent epilepsy is caused by homozygous or compound heterozygous mutations in *ALDH7A1* gene. *ALDH7A1* gene is mapped on chromosome 5q31 and consists of 18 coding regions (exons). The article presents a clinical case of a patient with severe infantile generalized idiopathic epilepsy with status seizures, muscular dystonia syndrome and developmental delay. The observation included phenotypic analysis: the nature of seizures, cognitive and behavioral disorders, video electroencephalography, magnetic resonance imaging of the brain, features of the perinatal period, and targeted exome sequencing of the genes associated with epileptic encephalopathy (NGS). The previously not described nucleotide heterozygous variants in the *ALDH7A1* gene, which led to stop codon in the 82 position of the protein (p.Arg82Ter) and amino acid substitution in the 399 position of the protein (p.Glu399Gln) were detected by NGS. This clinical observation demonstrates the importance of DNA diagnostics by using targeted exome sequencing to find molecular defects, especially in severe neonatal drug-resistant seizures. The patient should be given therapeutic doses of vitamin B6 for relief of seizures in the case of determining mutations in the *ALDH7A1* gene.

Epileptic encephalopathies are severe brain disorders that result in developmental delay and sometimes early death. To date, more than a hundred genes have been implicated, many of which encode ion channels. Here, we report a *de novo* variant (c.2791T>C; p.W931R) in exon 20 of *ATP1A1* in a girl with treatment refractory epilepsy and profound hypo-magnesemia who died at 10 months from a respiratory infection. *ATP1A1* encodes the ubiquitous alpha 1 subunit of Na<sup>+</sup>/K<sup>+</sup>-ATPase, the ion pump that creates the sodium and potassium gradients across the cell membrane and is responsible for generating the membrane potential. It uses more than 50% of brain's energy consumption. No previous links between *ATP1A1* variants and epilepsy have been described. However, mutations have been identified in the Na<sup>+</sup>/K<sup>+</sup>-ATPase alpha3 subunit (*ATP1A3*) in two children with catastrophic early life epilepsy. In the affected child, autopsy revealed a partial loss of primarily hippocampal neurons and by high resolution confocal microscopy on the autopsy material indicates that ATP1A1 was still expressed in the membrane of the remaining hippocampal neurons. Next, we showed that expression of the W931R alpha 1 in HEK cells led to significantly decreased viability of the cells. Since W931 is located in a trans-membrane region, we then used molecular dynamics simulations to characterize possible differences in interactions to non-specific bulk lipids. In this way, W931R alpha1 was found to induce asymmetric protein-lipid interactions and to accumulate water in pockets between the mutant residue and the sodium-binding sites. The findings indicate that the mutant alpha1 disturbs the hydrophobic core of the membrane and is less favorably anchored to its lipid environment. Finally, imaging of fluorescently tagged wild type and W931R alpha1, expressed in cultured hippocampal neurons and HEK cells, show that W931R Na<sup>+</sup>/K<sup>+</sup>-ATPase is, to a lesser extent than wild type Na<sup>+</sup>/K<sup>+</sup>-ATPase, inserted into the membrane. Taken together, these findings are likely to be the cause of impaired control of membrane potential and neuronal activity. In summary, our data indicate that a unique *de novo* variant in *ATP1A1* is the likely cause of catastrophic early life epilepsy. The exchange of a non-polar hydrophobic residue to an arginine residue in a trans-membrane region may represent a novel disease-causing mechanism in the field of ion pumps and channels.

## 1102T

**Towards the elucidation of the genetic architecture of autosomal dominant lateral temporal epilepsy.** C. Nobile<sup>1</sup>, E. Dazzo<sup>1</sup>, A. Giallonardo<sup>2</sup>, C. Di Bonaventura<sup>2</sup>, P. Pulitano<sup>3</sup>, O. Mecarelli<sup>4</sup>, A. Gambardella<sup>4</sup>, P. Striano<sup>5</sup>, R. Michelucci<sup>6</sup>. *Genetics Commission Italian League Against Epilepsy.* 1) CNR-Neuroscience institute, Padova, Italy; 2) Department of Neurological Sciences, University of Rome "Sapienza," Roma, Italy; 3) Department of Neurology and Psychiatry, University of Rome "Sapienza", Roma, Italy; 4) Institute of Neurology, University Magna Graecia, Catanzaro, Italy; 5) Muscular and Neurodegenerative Disease Unit, Institute "G. Gaslini," University of Genoa, Genova, Italy; 6) IRCCS-Institute of Neurological Sciences, Bellaria Hospital, Bologna, Italy.

Autosomal dominant lateral temporal epilepsy (ADLTE [MIM 600512]) is a genetically heterogeneous focal epilepsy characterized by auditory seizures. Disease-causing mutations have been discovered in three genes, *LG11* (MIM 604619), *RELN* (MIM 600514), and *MICAL-1* (MIM 607129), which altogether account for the disorder in 50-60% of ADLTE families. To fully elucidate the genetic architecture of ADLTE, we investigated eight well-studied ADLTE families without mutations in known genes by combining genome-wide single nucleotide polymorphism-array linkage analysis and whole exome sequencing. Filtering exome-derived rare variants included localization to positive linkage peaks in the corresponding families, gnomAD frequency < 0.001, and gene residual variation intolerance score < 50%. A relatively short list of candidate genes was finally evaluated based on their expression pattern, function, and implication in other epileptic or neurodevelopmental disorders in each affected family. Using this approach, we identified several potentially pathogenic variants that might be implicated in ADLTE. Studies of their functional effects and of additional families will reveal which of them is actually implicated in the aetiology of ADLTE, improving our knowledge of the genetic basis of ADLTE.

Patterson<sup>1,2</sup>, J.N. Bailey<sup>1,10</sup>, A.V. Delgado-Escueta<sup>1,2</sup>. 1) Epilepsy Genetics/Genomics Lab, VAGLHS, Los Angeles, CA; 2) Department of Neurology, David Geffen School of Medicine at University of California, Los Angeles, CA; 3) Instituto de Neurología y Neurocirugía "Manuel Velasco Suarez", Mexico City, Mexico; 4) Facultad de Ciencias de la Salud, Universidad Tecnológica Centroamericana UNITEC, Tegucigalpa, Honduras; 5) Chapman University, Irvine, CA; 6) General Hospital of Mexico, Mexico City, Mexico; 7) Universidad Nacional Autónoma de Honduras, Tegucigalpa, Honduras; 8) Universidad Federal de Sao Paulo (UNIFESP-EPM), Sao Paulo, Brazil; 9) Hospital de Especialidades Nuestra Señora Reina de la Paz, San Miguel, El Salvador; 10) Epidemiology, Fielding School of Public Health, University of California, Los Angeles, CA.

To investigate disease mechanisms in Juvenile Myoclonic Epilepsy, we have studied autophagy for a rare variant found in a 37-member, four-generation Mexican family, who have 6 epilepsy affected members (five with Childhood Absence Epilepsy (CAE) with eyelid myoclonias evolving to JME, one with absence-tonic-clonic grand mal only) and two with only EEG spike waves. An extremely rare variant (R638W, frequency 0.00000921 at ExAC browser) in *IPO8* (*RANBP8*) on 12p11.21, identified by whole exome sequencing, cosegregated with all eight clinical and EEG affected members. R638W variant encodes *Importin 8*, a member of the *Importin β* family. R638W is absent in 777 controls matched for ethnicity/ancestral origin. Five other rare missense mutations of *IPO8*, one rare 5'UTR SNP and one novel 3' UTR deletion of transcript variant2 of *IPO8* is present in nine out of 295 families with CAE/JME. *Importin 8* reportedly transports the transcription factor (TFEB) for autophagy genes to nuclei. Therefore, we have assessed expression levels of TFEB and autophagy related gene products using western blotting. HEK 293 cells were transiently transfected with plasmids carrying mutated human full length *IPO8*. R638W increased the expression of Calcineurin (P=0.006) in the cytoplasm, the nuclear translocation of TFEB, the total expression of TFEB, and the autophagy marker, LC3B (P=0.049) at 10 min after administration of hydrogen peroxide (160uM) and amino acid starvation by EBSS medium. We conclude *IPO8* regulates autophagy and the upregulated autophagy could be involved in photosensitivity and seizure induction during awakening seizures.

**1104W****Novel variants causing inherited leukodystrophies in Sudanese families.**

M. Amin<sup>1</sup>, I. Dorboz<sup>2</sup>, I. Mohamed<sup>1</sup>, A. Hamed<sup>1</sup>, M. Elaseed<sup>1</sup>, A. Yahia<sup>1</sup>, A. Babai<sup>1</sup>, E. Badi<sup>1</sup>, M. Hasan<sup>1</sup>, E. Emad<sup>1</sup>, S. Samaan<sup>2</sup>, L. Elsayed<sup>1</sup>, A. Ahmed<sup>1</sup>, O. Boespflug-Tanguy<sup>2</sup>. 1) Faculty of Medicine, University of Khartoum, Khartoum, Sudan; 2) Neuropediatrics and metabolic disorders unit, Hospital Robert Debre, Paris, France.

**Background:** Leukodystrophies are a group of heritable metabolic disorders resulting from defective myelination of the central nervous system. There are currently dozens known different types of leukodystrophies, all with distinct clinical and radiological characteristics. However, the genetics of leukodystrophies remain unknown in many parts of the world especially in Sub-Saharan Africa. **Methods:** In this study, we recruited three consanguineous families from Sudan: one with Metachromatic leukodystrophy (MLD) and two with Megalencephalic leukodystrophy with sub-cortical cysts (MLC) with typical clinical and radiological signs. Genomic DNA was extracted and screened for mutations in all leukodystrophy causing genes. **Results:** Three novel variants were discovered: one (c.380G>C, p.Arg127Pro) in *PSAP* gene causing MLD, and two variants (c.831\_838DUPATATCTGT, p.Ser280Tyrfs\*8 and c.971T>G, p.Ile324Ser) in *MLC1* gene in the two families with MLC. The segregation pattern was consistent with autosomal recessive inheritance. The pathogenicity of these variants was predicted using bioinformatics tools. **Conclusion:** This is the first study to underlie the genetics of leukodystrophy in Sudan. However, more families are needed to establish the whole spectrum of genetic variations causing inherited leukodystrophies in Sudanese families.

**1105T****Effects of long-term eteplirsen treatment on upper limb function in patients with Duchenne muscular dystrophy: Findings of two phase 2 clinical trials.**

L.N. Alfano<sup>1</sup>, K. Berry<sup>1</sup>, J.R. Mendell<sup>1</sup>, H. Eliopoulos<sup>2</sup>, L. Han<sup>2</sup>, L.P. Lowes<sup>1</sup>. 1) Nationwide Children's Hospital, Columbus, OH; 2) Sarepta Therapeutics, Inc., Cambridge, MA.

**Introduction:** Duchenne muscular dystrophy (DMD) is a progressive, degenerative neuromuscular disease caused by gene mutations that result in the absence or deficiency of dystrophin protein, which causes muscle deterioration and the loss of upper limb function, negatively impacting quality of life. Eteplirsen (Exondys 51; Sarepta Therapeutics, Inc., Cambridge, MA), the first treatment approved for DMD, is indicated for treatment of patients with DMD amenable to exon 51 skipping. **Methods:** We evaluated long-term upper limb function outcomes in patients aged 7-13 years with DMD amenable to exon 51 skipping who participated in 2 consecutive clinical trials of eteplirsen. In Study 201, a 28-week trial, patients were randomized to receive once-weekly intravenous infusions of eteplirsen (30 mg/kg or 50 mg/kg) or placebo for 24 weeks. At Week 25, all patients received open-label eteplirsen through Week 28. In Study 202, an open-label extension trial, all patients received once-weekly eteplirsen at the same dose as in Study 201 through 240 weeks. Upper limb function tests included the 9-Hole Peg Test (seconds) and a maximum voluntary isometric contraction test with a quantitative movement assessment system to assess hand grip and elbow extension and flexion (kg). **Results:** Study 201 enrolled 12 patients who received once-weekly eteplirsen (30 mg/kg, n=4; 50 mg/kg, n=4) or placebo (n=4); all patients completed extension Study 202. Following the confirmation of dystrophin production, all patients showed relative stability or minimal decline of upper limb function on all measures assessed through week 240. Specifically, mean values at Week 240 for functional assessments of the dominant hand/arm were 22.0 seconds (9-Hole Peg Test), 7.68 kg (hand grip strength), 2.62 kg (elbow extension), and 1.53 kg (elbow flexion). **Conclusion:** Based on published data from healthy reference individuals, the mean 9-Hole Peg Test completion time of 19.9 seconds for boys aged 8-9 years decreases steadily with age to 18.0 seconds for boys aged 14-15 years. As expected, mean completion times are lower in natural history studies of patients with DMD and typically decrease with age and disease progression. In the current report, patients treated with eteplirsen for up to 240 weeks had a mean 9-Hole Peg Test completion time of 22.0 seconds. Based on these and other functional assessments, eteplirsen may slow the deterioration of upper arm function in patients with DMD amenable to exon 51 skipping.

**1106F****CRISPR/Cas9 preclinical studies in patient-derived *FOXP1* mutated cells.**

S. Croci<sup>1</sup>, S. Daga<sup>1</sup>, F.C. Lorenzetti<sup>1</sup>, F.T. Papa<sup>1</sup>, F. Donati<sup>2</sup>, C. Lo Rizzo<sup>3</sup>, D. Lopercolo<sup>1,2</sup>, M. Doria<sup>4</sup>, A. Auricchio<sup>4</sup>, S. Conticello<sup>3</sup>, A. Renieri<sup>1,2</sup>, I. Meloni<sup>1</sup>. 1) Medical Genetics Laboratory, University of Siena, Siena, Italy; 2) Genetica Medica, Azienda Ospedaliera Universitaria Senese, Siena, Italy; 3) Molecular Mechanisms of Oncogenesis, ITT Core Research Laboratory (CRL), Firenze, Italy; 4) TIGEM (Telethon Institute of Genetics and Medicine), Napoli, Italy.

We first identified *FOXP1* gene as associated to disease in humans (Ariani F et al Am J Hum Genet 2008): the congenital variant of Rett syndrome, characterized by early developmental delay, seizures, lack of speech and inability to control body movements. A therapy for this devastating disorder is still lacking. We present here a successful example of transformative gene-based medicines using CRISPR/Cas9 gene editing technology and our previously established cellular model (Patriarchi T et al 2016 Eur J Hum Genet). We have engineered a two-plasmid system to correct specific *FOXP1* mutations, namely c.688C>T - p.Arg230Cys and c.765G>A - p.Trp255\*. Plasmid constructs have been designed and produced for both mutations. Specific sgRNAs and donor DNAs have been selected and cloned into an appropriate plasmid with an mCherry/GFP reporter system. Cas9 flanked by mutation-specific sgRNA recognition sequences for auto-cleaving has been cloned in a second plasmid. Fibroblasts transfected with both constructs showed that cells correctly acquire them and produce Cas9. Since intravenous administration of AAV9 particles has been recently used in a phase I clinical trial for gene replacement delivery in patients affected by Spinal Muscular Atrophy type 1, with no relevant adverse effects, we decided to use the same delivery system. Cell types relevant to the project (fibroblasts, iPSCs, iPSC-derived neuronal precursors and neurons) have been infected with AAVs to select the most appropriate serotype. AAV9 infection in terminally differentiated iPSC-derived neurons demonstrated that these cells can be efficiently co-infected. Finally, mCherry+/GFP+ cells isolated by Fluorescent Activated Cell Sorting and analyzed by Next Generation Sequencing demonstrated high efficiency of gene editing. Further steps will include the ongoing mouse model and patient recruitment. Since the identification of *FOXP1* we have been following 16 *FOXP1*-mutated patients. Five families have already expressed their willingness to participate to the proposed research study and are eager to be involved in clinical trials. They include 2 male and 3 female patients with an age range 3-30 yrs (mean age of 12 yrs). The grant "a glimpse of hope for *FOXP1*" from Blackswan Foundation is acknowledged.

**1107W****Exploring the potential of CRISPR/Cas9 for the treatment of Pelizaeus-Merzbacher disease.** E. Maino<sup>1,2</sup>, E. Hyatt<sup>1</sup>, E.A. Ivakine<sup>1</sup>, R.D. Cohn<sup>1,2,3</sup>.

1) Program in Genetics and Genome Biology, The Hospital for Sick Children, Toronto, Canada; 2) Department of Molecular Genetics, University of Toronto, Canada; 3) Department of Pediatrics, University of Toronto and The Hospital for Sick Children, Toronto, Canada.

Pelizaeus Merzbacher Disease (PMD) is an X-linked pediatric leukodystrophy that leads to limited quality of life and premature death of affected children. Currently, there is no curative treatment and patient care is restricted to symptom management. PMD is caused by mutations in the *PLP1* gene, which codes for Proteolipid Protein 1, one of the main components of myelin. Mutations in *PLP1* result in impaired myelination of the nervous system which ultimately leads to the onset of the typical PMD symptoms, such as locomotor disabilities and cognitive impairment. Duplications of the X chromosome region containing the *PLP1* gene account for 70% of PMD cases. Here, we propose to develop a clinically relevant CRISPR/Cas9-based genome editing strategy to correct the duplication mutation and to ameliorate the disease phenotypes in a PMD mouse model which has a *P1p1* duplication. First, we characterized this model and we confirmed the presence of dysmyelination and neurological deficits. To remove the *P1p1* duplication we employed a single gRNA-CRISPR/Cas9 approach developed by our group. In proof-of-principle experiments, I validated the single gRNA strategy *in vitro*, using primary cells derived from the PMD mice and *in vivo*, through localized administration of the CRISPR/Cas9 components. Data obtained from these experiments suggest the successful removal of the duplicated region. The preliminary results deriving from this project emphasize the potential of CRISPR/Cas9-based therapies as a future treatment for PMD patients and open a potentially new avenue for the treatment of genetic disorders caused by genomic duplications. .

**Research genomics expands the genetic etiology and phenotypic spectrum of rare pediatric conditions.** D.C. Koboldt<sup>1</sup>, T. Mihalic Mosher<sup>1</sup>, B.J. Kelly<sup>1</sup>, P. Martin<sup>2</sup>, S.E. Hickey<sup>2</sup>, K.L. McBride<sup>2</sup>, P. White<sup>1</sup>, R.K. Wilson<sup>1</sup>. 1) Institute for Genomic Medicine, Nationwide Children's Hospital, Columbus, Ohio, USA; 2) Division of Molecular & Human Genetics, Nationwide Children's Hospital, Columbus, Ohio, USA; 3) The Research Institute at Nationwide Children's Hospital, Columbus, Ohio, USA.

Children with rare inherited conditions are increasingly referred for clinical exome sequencing, which yields a positive finding in only ~25-35% of them. For the remaining undiagnosed cases, research sequencing of the proband and available family members has the potential to uncover new genetic etiologies of disease. Our institute has enrolled more than 40 families suffering rare inherited conditions into a research genomics protocol. Using predominantly whole genome sequencing of multiple family members, we have identified likely causal variants in 30% of cases and strong candidate variants in another 20%. Here, we describe three unpublished cases whose underlying etiology or phenotypic association challenges the current knowledge of genotype-phenotype relationships. First, we found that a 6-year-old male with congenital contractures and severe muscular atrophy harbored a *de novo* inframendel indel in *BICD2*, a gene in which missense mutations cause a milder form of muscular atrophy restricted to the lower extremities. We established the pathogenicity after meeting the author of a poster at ASHG 2017 describing the same mutation in a 12-year-old female with nearly identical features. Second, whole-genome sequencing uncovered a *de novo* 182-kb inversion disrupting *SGCE* in a male with myoclonic dystonia who was negative for clinical testing. Orthogonal validation assays confirmed the variant's *de novo* status and its breakpoint in the third intron. This finding not only provides a molecular diagnosis to this patient, but also demonstrates the power of WGS to detect pathogenic variants missed by conventional testing. Third, we enrolled a family with multiple pregnancy losses and a child born with severe skeletal dysplasia who died on the first day of life. Sequencing the proband, a fetal demise, and both parents revealed compound heterozygous variants in the gene for galactosyltransferase-I (*B4GALT7*; associated with the spondylodysplastic form of Ehlers-Danlos syndrome). One (p.R270C) was a known pathogenic variant but the other (p.Q133R) had never been reported. Enzymatic activity assays demonstrated that while p.R270C reduces B4GALT7 activity, the novel p.Q133R variant abrogates it entirely, which likely explains the lethal disease manifestation in the family we studied. Taken together, these case studies demonstrate the power of research genomics to provide long-sought molecular diagnoses and further delineate the phenotypic spectrum of rare inherited conditions.

Le Deist<sup>1</sup>, M. Thompson<sup>2</sup>, T. Kinoshita<sup>2</sup>, P.M. Campeau<sup>1</sup>. 1) CHU Sainte-Justine, Montreal, Quebec, Canada; 2) Research Institute for Microbial Diseases, Osaka University, Osaka 565-0871, Japan; 3) Department of Pediatrics, University of California, San Diego, California, USA, 92093; 4) Department of Molecular & Human Genetics, Baylor College of Medicine, Houston, TX, USA, 77030; 5) University of Rochester Medical Center, NY, USA, 14642; 6) Greenwood Genetic Center, Greenwood, SC, USA 29646; 7) NewYork-Presbyterian Morgan Stanley Children's Hospital, New York, NY 10032; 8) Rady Children's Hospital-San Diego, San Diego, CA, USA 92123; 9) University of Texas, Southwestern Medical Center, Dallas, Texas; 10) Illumina Inc, San Diego, CA 92121, USA.

Inherited GPI deficiencies (IGD) are a subset of congenital disorders of glycosylation that are increasingly recognized due to advances in whole exome (WES)/whole genome (WGS) sequencing. IGDs cause a series of overlapping phenotypes consisting of seizures, dysmorphic features, multiple congenital malformations, and severe intellectual disability. We present a study of six individuals from three unrelated families in which WES or WGS identified biallelic phosphatidylinositol glycan class S (*PIGS*) biosynthesis gene mutations. Phenotypes included severe global developmental delay, seizures (partly responding to pyridoxine), hypotonia, weakness, ataxia, and dysmorphic facial features. Two of them have compound heterozygous variants (NM\_033198.3) c.108G>A, p.Trp36\* and c.101T>C, p.Leu34Pro, and two siblings of another family were homozygous for a deletion and insertion leading to p.Thr439\_Lys-451delinsArgLeuLeu. The third family had two fetuses with multiple joint contractures consistent with fetal akinesia. They were compound heterozygous for c.923A>G, p.Glu308Gly, and c.468+1G>C, a splicing mutation. Flow cytometry analyses demonstrated that the individuals with *PIGS* mutations show a GPI-AP deficiency profile. Expression of the p.Trp36\* mutation in *PIGS*-deficient HEK293 cells revealed only partial restoration of cell surface GPI-APs. In terms of both biochemistry and phenotype, loss of function of *PIGS* shares features with *PIGT* deficiency and other IGDs. This study contributes to the understanding of the GPI-AP biosynthesis pathway by describing the consequences of *PIGS* disruption in human and extending the family of IGD.

**Clinical whole genome sequencing (WGS): A precision genomic approach to solving “diagnostic odysseys”.** S.P. Shankar<sup>1</sup>, V. Wheelock<sup>2</sup>, V.T. Triano<sup>3</sup>, A. Moshiri<sup>4</sup>, M. Hegde<sup>4</sup>, K.A. Rauen<sup>1</sup>. 1) Pediatrics, UC Davis, Sacramento, CA; 2) Ophthalmology, UC Davis, Sacramento, CA; 3) Neurology, UC Davis, Sacramento, CA; 4) Perkin Elmer, USA.

The cost of WGS is rapidly declining allowing its use in clinics. We report whole genome sequencing results in 2 male siblings from the UC Davis Precision Genomics Clinic that identified their underlying genetic disorder. The siblings aged 38 and 35 years, presented in early childhood with bilateral sensorineural hearing loss, normal motor and cognitive development until ~14 years of age when they developed progressive tremors, dystonic movements and ataxia. They also have dental enamel issues, and adult onset retinal dystrophy. Significant exam findings include normal cognition, dysarthria, amelogenesis imperfecta, gaze abnormalities, and severe ataxia. Brain MRI revealed pontocerebellar atrophy and signal changes in basal ganglia. Their symptoms are responsive to DOPA and deep brain stimulation (DBS). Extensive work up including muscle biopsy and extensive genetic testing including Fragile X, SCAs 1, 2, 3, 6, 17, Friedreich ataxia, and mitochondrial genes that were negative. Given the clinical presentation, our differential diagnosis was autosomal recessive, peroxisomal disorders caused by *PEX1* or *PEX6* genes respectively or progressive parkinsonian tremor, dystonia and ataxia and hearing loss caused by *ATP1A3* gene with other cause for retinal phenotype. WGS revealed an extremely rare missense variant R867W in cis with a 4-bp deletion (c.\*442\_445delTAAA) in the 3-prime UTR of the *PEX6* gene in both siblings, inherited from father, who was homozygous for the 4-bp deletion in the 3-prime UTR. A recent study by Falkenberg KD et al reported on allelic expression imbalance in *PEX6*, with overrepresentation of a pathogenic *PEX6* variant, than wild-type, when in cis with this same 3-prime UTR deletion. Mother had 2 wild type alleles and no 4-bp deletion in the 3-prime UTR. This finding confirms our clinical suspicion of a peroxisomal biogenesis disorder spectrum and is the underlying genetic etiology for the siblings. Further functional studies are planned to corroborate these findings further. As the cost WGS decreases further, the advantages of WGS with option of providing pharmaco-genomic data, copy number variations and covering noncoding regions along with better coverage of coding regions will make this a “one test” of the future allowing for personalizing treatments, providing better prognosis and counseling for individuals with genetic disorders.

**Relaxation of selective constraints on mitochondrial genome correlates with progression of Huntington’s disease.** Y. Wang<sup>1</sup>, X. Guo<sup>1</sup>, M. Orth<sup>2</sup>, Z. Gu<sup>1</sup>. 1) Division of Nutritional Sciences, Cornell University, Ithaca, NY; 2) Department of Neurology, Ulm University, Ulm, Germany.

Mitochondrial dynamics and function may be impaired in the brain and peripheral tissues in Huntington’s disease (HD). A genome-wide association study revealed an association of genetic variants in loci relevant for mitochondrial homeostasis with CAG independent motor age-at-onset. It suggests the effectiveness of mitochondrial quality control which ensures the maintenance of mitochondrial homeostasis such as mitochondrial DNA (mtDNA) quality may be compromised in HD. Expansion of mtDNA mutations in somatic tissues can cause mitochondrial dysfunction in age-related diseases including neurodegeneration. However, it has not been studied in the context of HD. Here, we applied a targeted sequencing approach to evaluate mtDNA mutation spectra in HD lymphoblast and longitudinal blood samples collected in the European Huntington’s Disease Network’s REGISTRY cohort. We achieved deep sequencing coverage on mtDNA (median depth: ~3600X in lymphoblast and 6100X in blood). Despite similar incidence and variant allele fraction (VAF) distribution for the overall mtDNA mutations in lymphoblasts between 1549 HD patients and 182 unaffected controls, we found increased VAFs for predicted pathogenic mtDNA mutations in HD lymphoblasts. Accordingly, the variant dosage as the sum of VAFs for predicted pathogenic mutations was elevated in HD patients compared to controls by > 70% (0.11 vs 0.06), which was also higher in HD patients in middle-late stages compared to that in patients in prodromal-early stages of the disease (0.13 vs 0.10;  $P < 0.006$ ). We further found that the expansion of VAFs of pre-existing predicted pathogenic mutations in the baseline blood of 181 HD patients was correlated with the degree of disease stage change and the exacerbation of clinical symptoms during a median follow-up of 6 years. Our results point to the expansion of pathogenic mtDNA mutations in the hematopoietic system as a molecular feature of HD progression, supporting the role of defective mitochondrial quality control in HD pathogenesis. In sum, our targeted mtDNA sequencing approach provides insights into the molecular basis of the progressive decline of mitochondrial function in HD and a potential biomarker for HD progression using mtDNA in peripheral tissues.

**1112F****A new case of an intermediate phenotype along the spectrum of**

**ATP1A3-related neurological disorders.** L. Fernandez<sup>1,2</sup>, J. Kohler<sup>1,2</sup>, D. Zastrow<sup>1,2</sup>, D. Bonner<sup>1,2</sup>, C. McCormack<sup>1,2</sup>, M. Wheeler<sup>1,2</sup>. 1) Stanford Center for Undiagnosed Diseases, Stanford University, Stanford, CA; 2) Division of Cardiovascular Medicine, Stanford University, Stanford, CA; 3) NIH Undiagnosed Diseases Network, Common Fund, Office of the Director and the National Human Genome Research Institute, National Institutes of Health, Bethesda, MD; 4) Baylor Miraca Genetics Laboratories, Houston, TX; 5) Department of Neurology, Stanford University School of Medicine, Stanford, CA; 6) Department of Genetics, Stanford School of Medicine, Stanford, CA; 7) Department of Pediatrics, Stanford University School of Medicine, Stanford, CA; 8) Lucille Packard Children's Hospital Stanford, Stanford, CA.

The *ATP1A3* gene encodes the alpha-3 catalytic subunit of the Na<sup>+</sup>/K<sup>+</sup>-ATPase ion pump, critical for the maintenance of the electrochemical gradient of the plasma membrane. It is expressed in the central nervous system and is fundamental for neuronal homeostasis and synaptic transmission. *ATP1A3*-related neurologic disorders represent a clinical continuum in which at least three distinct phenotypes have been described: Rapid-onset Dystonia-Parkinsonism (RDP); Alternating Hemiplegia of Childhood (ACH); and, Cerebellar ataxia, areflexia, pes cavus, optic atrophy, and sensorineural hearing loss (CAPOS) syndrome. Some affected individuals have intermediate phenotypes that do not fit well into one of these major phenotypes. We report on an 8 year-old Hispanic male with a history of developmental delay, ataxia, chorea, epilepsy, hypotonia, and hyporeflexia. Trio whole exome sequencing performed through the Undiagnosed Diseases Network identified a *de novo*, pathogenic variant in the *ATP1A3* gene: heterozygous c.2267G>A (p.R756H). This mutation was first reported in severe early onset RDP phenotype, and has been also associated with a familial childhood-onset progressive cerebellar syndrome, and intermediate phenotypes. Six patients with *ATP1A3* mutations at residue 756, including four with R756H, were recently reported with a distinct phenotype characterized by fever-induced paroxysmal weakness and encephalopathy (FIPWE). Our patient's clinical features overlap those reported with *ATP1A3*-related conditions; shared features include ataxia, hyporeflexia and hypotonia. However, our patient lacks the characteristic features of AHC, RDP, CAPOS syndrome, as well as, FIPWE. Recent reports of atypical presentations related to *ATP1A3* associate residue 756 with diverse emerging phenotypes including ataxia as a predominant feature. This case report contributes to the understanding of the genotype-phenotype correlations of *ATP1A3*. Further identification and characterization of patients with intermediate phenotypes will be essential to understand the molecular mechanisms underlying the pathogenesis of *ATP1A3* mutations.

May<sup>7</sup>, A.J. Campbell<sup>8</sup>, D. Lal<sup>2,3,8,10</sup>, M.J. Daly<sup>1,2,6,11</sup>. 1) Analytic and Translational Genetics Unit, Massachusetts General Hospital, Boston, MA, USA; 2) Broad Institute, Stanley Center for Psychiatric Research, Cambridge, MA, USA; 3) Cologne Center for Genomics (CCG), University of Cologne, Germany; 4) MRC London Institute of Medical Sciences, National Heart and Lung Institute, Imperial College London, London, UK; 5) The Danish Epilepsy Center, Dianalund, DK; 6) Institute for Molecular Medicine Finland (FIMM), University of Helsinki, Helsinki, Finland; 7) Luxembourg Centre for Systems Biomedicine, Esch-sur-Alzette, University of Luxembourg, Luxembourg; 8) Genomic Medicine Institute, Lerner Research Institute Cleveland Clinic, OH, US; 9) Psychiatric & Neurodevelopmental Genetics Unit, Department of Psychiatry, Massachusetts General Hospital, Boston, MA, USA; 10) Epilepsy Center, Neurological Institute, Cleveland Clinic, Cleveland, US; 11) Program in Medical and Population Genetics, Broad Institute of MIT & Harvard, Cambridge, Massachusetts, USA; 12) Institute for Regional Health Services, University of Southern Denmark, Odense, Denmark.

Malfuncions of multiple voltage-gated sodium (Na.s encoded by *SCNxA* genes) and calcium channels (Ca.s encoded by *CACNA1x* genes) have been associated with severe neurological, psychiatric, cardiological and other diseases. Most of those diseases are a consequence of either a gain or loss of ion channel function (GOF or LOF, respectively). Individual variants' functional effects are currently assayed in costly, difficult-to-interpret electrophysiological experiments. We thus developed a computational method that predicts LOF/GOF/neutral effects of missense variants. From the scientific literature, we determine whether genetic variants contribute to a given disease via GOF or LOF of the respective ion channel. For example, in *SCN1A*, which is associated with Dravet syndrome, the majority of electrophysiologically tested patients variants are LOF, so we assume, that variants in *SCN1A* lead to Dravet syndrome via a LOF mechanism. In this fashion, we categorized missense variants in fourteen different diseases of three *CACNA1x* (*CACNA1A/E/S*) and six *SCNxA* (*SCN1/2/4/5/8/9A*) genes into putative LOF or GOF. Mapped onto the gene family protein sequence alignment, we find significant clusters of published and unpublished inferred 537 LOF or 349 GOF missense variants, suggesting similar pathomechanisms across these ion channels. We identify >20 sequence-based and structure-based features that are associated with either LOF or GOF variants. Harnessing these observed correlations between protein features and functional impact across the gene family, we develop a machine learning method to: 1) Predict the functional impact (LOF/GOF/neutral) of genetic variants. The most important features include GOF/LOF/neutral variant density in other protein family members, gene family specific conservation and protein secondary structure. Excitingly, our model can predict LOF/GOF consequence of 91 published electrophysiologically characterized variants (ROC=0.75, AUC=0.65). 2) Predict overall pathogenicity in > 2000 cases and 2000 controls better than standard variant prediction tools CADD, Polyphen or MPC. We thus introduce the first computational prediction method of functional LOF/GOF/neutral variant effects in an important protein family and a strategy that can be applied to other gene families. While gaining insight into shared pathomechanisms in this gene family, our work should improve gene discovery and enhance personalized medicine.

Hereditary Spastic Paraplegias (HSPs) are rare (1-5 : 100 000) neurological disorders caused by the progressive distal degeneration of the corticospinal tracts. Among the 79 loci and 65 Spastic Paraplegia Genes (SPGs) involved in HSPs, mutations in *SPAST*, encoding spastin and responsible for Spastic paraplegia 4 (SPG4), are the most frequent cause of both familial and sporadic HSP. SPG4 is characterized by a clinically pure phenotype, predominantly affecting corticospinal tracts and posterior columns of the spinal cord, and rarely associated with additional neurological signs. We analysed a cohort comprising 842 SPG4-HSP patients in order to assess genotype-phenotype correlations and possibly explain the extreme age at onset variability, typical of SPG4-HSP affected patients. Age of onset (n=547) followed a bimodal distribution, characterized by a first peak extending from birth to the first decade and a second one comprised between the third and fifth decades. The underlying cause of the observed bimodal trend, missing in previous reports, was identified when considering the nature of *SPAST* pathogenic mutations. SPG4-HSP causative mutations resulted mostly located in spastin AAA cassette (75%, 201/268), therefore impairing its microtubules severing activity and leading predominantly to a loss of function mechanism. The comparison of age at onset between missense and truncating mutation carriers revealed a significant lower age at onset in the former group when compared to the latter (23 ± 19.7, n = 180 versus 33.4 ± 16.7, n = 245; Mann-Whitney test, p < 0.0001). This observation not only gives an explanation to SPG4-HSP age at onset bimodal trend, but allows to establish for the first time a genotype-phenotype correlation that links the mutation nature and the disorder age of onset. The sex of the individual appeared as a second factor influencing our cohort's age at onset. When focusing on 84 pedigrees, intrafamilial correlation of age at onset resulted highly significant in same-sex sib-pairs, especially among brothers (r=0.58, n = 34, p = 0.0002). Moreover, disorder penetrance resulted being lower in women (0.86 versus 0.92 in men, p = 0.03). Altogether, these results show that SPG4-HSP age at onset is strongly influenced by mutation nature and sex linked-factors. The presence of still unidentified genetic and environmental modifiers should definitely be investigated to fully understand the observed variability.

**NEDDFL syndrome due to an apparently balanced translocation t(1,17)**

**(q24.3;q24.2) disrupting BPTF in a 35-year-old man.** P. Stankiewicz<sup>1,2</sup>, N. Tommerup<sup>3</sup>, B. Panasiuk<sup>4</sup>, L. Cooper<sup>5</sup>, S.E. Scherer<sup>6</sup>, J. Borys<sup>6</sup>, B. Kosztyla Chojna<sup>7</sup>, R. Skowronski<sup>8</sup>, A.T. Midro<sup>4</sup>. 1) Dept of Molecular & Human Genetics, Baylor College of Medicine, Houston, TX; 2) Baylor Genetics, Houston, TX; 3) Wilhelm Johannsen Centre for Functional Genome Research Department of Cellular and Molecular Medicine (ICMM), University of Copenhagen, Denmark; 4) Department of Clinical Genetics, Bialystok, Poland; 5) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX; 6) Clinic of Maxillo-Facial Surgery; 7) Department of Phonoaudiology and Logopedics; 8) Department of Orthopaedics and Traumatology, Medical University, Bialystok, Poland.

Neurodevelopmental disorder with dysmorphic facies and distal limb anomalies (NEDDFL, OMIM 617755) was recently shown to result from haploinsufficiency of *BPTF* encoding the largest subunit of a nucleosome remodeling factor (NURF), a member of ISWI chromatin remodeling complex. We observed similar phenotypic features in a 35-year-old male with a *de novo* apparently balanced chromosomal translocation t(1;17)(q24.3;q24.2), reported in 1993 with Russell-Silver syndrome (PMID:8403458). FISH with BAC and fosmid clones and WGS revealed that the 17q24.2 breakpoint maps at chr17:65,944,420-65,955,659 (hg19) and disrupts the dosage sensitive *BPTF* (pLI=1.00). The 1q24.3 breakpoint was mapped at chr1:172,228,441-17,234,934 (hg19) disrupting the brain specific gene *DNM3* predicted to tolerate loss-of-function (pLI=0.03). No non-polymorphic CNVs were identified by CMA. Phenotypic analyses performed according to the Munich Dysmorphismology Database (MDDb) methodology revealed short stature, hemihypotrophy, microcephaly, triangular shape of asymmetric face, prominent forehead, hypertelorism, protruding eyeballs, broad palpebral fissures, long eye lashes, long nasal bridge, short philtrum, thin lips, and microretrogenia. Limb anomalies include bilateral 5th finger clinodactyly, short phalanges, and broad big first toes. Intellectual disability, speech delay, vision problems, muscle hypotonia, and the defect of phonemic audition have improved over the course of 24 years of observations. Our results expand the clinical spectrum of human disorders caused by ablation of chromatin remodeling complexes.

**Predictive modeling implicates threonyl-tRNA synthetase (*TARS*) in axonal peripheral neuropathy.** R. Meyer<sup>1</sup>, Y. Park<sup>1</sup>, M. Meisler<sup>1</sup>, A. Beg<sup>2</sup>, A. Antonellis<sup>1</sup>. 1) Department of Human Genetics, University of Michigan, Ann Arbor, MI 48109, USA; 2) Department of Pharmacology, University of Michigan, Ann Arbor, MI 48109, USA.

Aminoacyl-tRNA synthetases (ARSs) charge tRNA molecules with cognate amino acids, a critical step in translating the genetic code. Mutations in five genes encoding an ARS cause autosomal dominant, axonal peripheral neuropathy, which is characterized by impaired motor and sensory function in the distal extremities. Neuropathy-associated ARS mutations decrease enzyme function in biochemical and yeast complementation assays, and are dominantly toxic when modeled in *C. elegans*. These functional studies provide important evidence for determining the pathogenicity of newly identified mutations in patient populations, suggesting that such models have considerable predictive power. Here, we use the above model systems to determine if mutations in any ARS gene can cause peripheral neuropathy, beginning with threonyl-tRNA synthetase (*TARS*), which has not been associated with any human disease. Like the five ARS enzymes previously implicated in peripheral neuropathy, *TARS* is homodimeric and charges tRNA in the cytoplasm, making it a strong candidate for testing our predictive models. We first performed a loss-of-function screen in yeast by testing 10 *TARS* missense mutations that affect highly conserved amino-acid residues in critical regions of the enzyme. Three mutations (N412Y, R433H, and G541R) reduce or ablate yeast cell growth, indicating impaired enzyme function. We then used CRISPR/Cas9 mutagenesis to model the loss-of-function *TARS* mutations in the *C. elegans* ortholog *tars-1* and tested each variant for dominant toxicity. From these assays, we identified one *TARS* variant (G541R) that is loss-of-function in yeast and dominantly toxic in worm. These findings make G541R *TARS* similar to *HARS* and *AARS* variants that are implicated in neuropathy. Toward assessing G541R *TARS* for a role in peripheral neuropathy, we generated and validated a knock-in mouse strain for this variant. Here, I will present our unpublished computational, yeast, *C. elegans*, and mouse data indicating that certain human *TARS* mutations can cause axonal peripheral neuropathy. I will also present our efforts to directly link *TARS* to human disease by testing six *TARS* variants found in patient populations. This work provides a framework for using functional assays to proactively identify novel ARS loci and alleles that contribute to axonal peripheral neuropathy.

**Accurate molecular detection and functional validation of PI3K-AKT-MTOR pathway in focal malformations of cortical development: Novel genetic insights.** G. Ruggeri<sup>1</sup>, L.L. Gonzalez<sup>2</sup>, A.E. Timms<sup>3</sup>, A. Piacitelli<sup>4</sup>, W.B. Dobyns<sup>1,2</sup>, P. Filomena<sup>1</sup>, J.G. Ojemann<sup>5</sup>, E.J. Novotny<sup>6</sup>, S. Poliachik<sup>7</sup>, R.F. Hevner<sup>8</sup>, R.P. Kapur<sup>9</sup>, G.M. Mirzaa<sup>1,2</sup>. 1) Center for integrative Brain Research, Seattle Children's Research Institute, Seattle, WA; 2) Seattle Children's Hospital, Division of Genetic Medicine, Department of Pediatrics, University of Washington, Seattle, WA; 3) Center for Developmental Biology and Regenerative Medicine, Seattle Children's Research Institute, Seattle, WA; 4) Broad Institute of MIT and Harvard, Boston, MA, USA; 5) Department of Neurosurgery, Seattle Children's Hospital, Seattle, WA, USA; 6) Department of Neurology, Seattle Children's Hospital, Seattle, WA, USA; 7) Department of Radiology, Seattle Children's Hospital, Seattle, WA, USA; 8) Department of Pathology, University of California San Diego, CA, USA; 9) Department of Pathology, Seattle Children's Hospital, Seattle, WA, USA.

Focal malformations of cortical development (FMCD) constitute a spectrum of developmental brain disorders associated with brain overgrowth, cellular dysplasia, and co-morbidities such as intractable epilepsy, autism and intellectual disability. Constitutional and mosaic mutations of the PI3K-AKT-MTOR pathway genes have been identified in this spectrum. Identifying the underlying molecular etiology in these disorders has significant benefits for patients and their families, including informed genetic counseling and personalized therapeutic interventions. Widely used diagnostic methods, such as standard-depth whole exome sequencing, are not sensitive enough to detect mosaic mutations common among FMCD patients. These methods are also not suitable for screening limited amounts of surgically resected FMCD brain tissue due to their high DNA input requirements. Ultimately, more optimal molecular diagnostic methods and high throughput pre-clinical models are necessary to identify and study the effects of FMCD-related mutations on brain development. To address these challenges for characterizing FMCD, we utilized digital droplet PCR (ddPCR) as a new and sensitive tool for screening common mutations in the PI3K-AKT-MTOR pathway. We screened a cohort of 54 families (110 samples), including 50 singletons and 4 trios for 8 of the most common FMCD-associated mutations: *PIK3CA* (E545K, E542K, H1047R, H1047L), *AKT3* (E17K), and *MTOR* (S2215Y, S2215F). Of 54 patients, we identified mosaic mutations in 9 individuals (27 samples; 16.7%) in *PIK3CA* (N=7), *AKT3* (N=1), and *MTOR* (N=1). Mutation-positive samples ranged in alternate allele frequencies (AAF) from 0.3% to 25.6% across several tissues. To understand the functional consequences of these mutations on early fore-brain development, we generated 7 fibroblast patient-derived induced pluripotent stem cell (iPSC) lines by transcriptional reprogramming and differentiated them into 2D neuronal cultures. Our results suggest that targeted molecular analysis for the common PI3K-AKT-MTOR pathway mutations by ddPCR is an effective molecular diagnostic approach for FMCD. Given the high sensitivity and low DNA input requirements for this assay, ddPCR may also be an effective molecular tool for other mosaic disorders with a narrow mutational spectrum. Finally, our iPSC lines provide a valuable model for dissecting the functional consequences of these mutations and future drug screens using PI3K-AKT-MTOR pathway inhibitors.

Hypomyelinating leukodystrophies form a large and heterogeneous group among inherited white matter disorders. Clinical presentations include nystagmus, developmental delay, hypotonia, ataxia, spasticity and intellectual disability. Using trio genome and exome sequencing, we identified four unrelated individuals that each harbor one of three novel heterozygous missense variants in *TMEM63A*. None of the variants are present in GnomAD or dbSNP, all are predicted damaging and encode highly conserved amino acids that reside either within or directly adjacent to transmembrane helices. The variants were confirmed to have arisen *de novo* in three of the four individuals. Each of the affected individuals presented in infancy with congenital nystagmus, motor delay and deficient myelination, prompting the diagnosis of Pelizaeus-Merzbacher or Pelizaeus-Merzbacher-like disease. Unexpectedly, the clinical evolution of all four individuals has been surprisingly favorable, with resolution of nystagmus and near-normalization of neurological signs and developmental progression. In the three individuals with follow-up imaging after four years of age, the myelin deficit had almost completely resolved. The fourth individual also displayed a substantial improvement of myelination when last imaged at 31 months of age. *TMEM63A* encodes an osmosensitive calcium-permeable cation channel that has not previously been associated with disease. The function of *TMEM63A* has not been well characterized. It is highly expressed in oligodendrocytes and has been shown to be enriched in lysosomal membranes. These findings add *TMEM63A* to the list of genes related to myelin disorders and represent a novel phenotype of an infantile disorder with transient hypomyelination, providing important prognostic information for affected families.

**A novel de novo frameshift mutation in *KAT6A* identified by whole exome sequencing.** A. Alkhateeb. Jordan University of Science and Technology, Irbid, Jordan.

Intellectual disability is a common condition with multiple etiologies. The identified genes of monogenic forms have increased steadily in recent years due to the implementation of next generation sequencing. Here, we describe a two-year old happy boy with global developmental delay and intellectual disability. The child had feeding difficulties since birth. He had delayed motor skills and muscular hypotonia. Upon brain MRI, diffuse white matter loss and thinning of the corpus callosum were found. Chromosome karyotyping and array CGH were normal. Whole exome sequencing revealed a novel de novo frameshift mutation c.3390delA (p.Lys1130Asnfs\*4) in *KAT6A* gene (NM\_006766.4). The heterozygous mutation was confirmed by Sanger sequencing in patient and its absence in parents. *KAT6A* gene, coding a histone acetyltransferase has been recently found to be associated with a neurodevelopmental disorder (OMIM: #616268, autosomal dominant mental retardation 32). Features of this specific disorder are nonspecific which makes it difficult to characterize the condition based on the clinical symptoms alone, thus, our findings confirm the utility of whole exome sequencing to quickly and reliably identify the etiology of such conditions.

Yokochi<sup>8,9</sup>, K. Aiba<sup>9</sup>, J. Tohyama<sup>6</sup>, C. Ohba<sup>10</sup>, S. Miyatake<sup>10</sup>, N. Miyake<sup>10</sup>, K. Ogata<sup>4</sup>, A. Fukuda<sup>2</sup>, N. Matsumoto<sup>10</sup>.* 1) Dept Biochem, Hamamatsu Ika Daigaku, Hamamatsu, Shizuoka, Japan; 2) Dept Neurophysiology, Hamamatsu Ika Daigaku, Hamamatsu, Shizuoka, Japan; 3) Dept Pediatrics, Showa Univ Sch Med, Japan; 4) Dept Biochem, Grad Sch Med, Yokohama City Univ, Japan; 5) Dept Pediatric Neurol, Pediatric Medical Care Center, Osaka City General Hospital, Japan; 6) Dept Pediatrics, Epilepsy Center, Nishi-Niigata Chuo National Hospital, Japan; 7) Dept Neurology, Gunma Children's Medical Center, Japan; 8) Dept Pediatric Neurol, Seirei-Mikatahara General Hospital, Japan; 9) Dept Pediatrics, Toyohashi Municipal Hospital, Japan; 10) Dept Human Gen, Grad Sch Med, Yokohama City Univ, Japan.

$\alpha$  (*CAMK2A*) and  $\beta$  (*CAMK2B*) isoforms of Calcium/calmodulin-dependent protein kinase II (CaMKII) play a pivotal role in neuronal plasticity and learning and memory processes in the brain. By whole exome sequencing, we identified *de novo* *CAMK2A* and *CAMK2B* variants in three and two individuals with neurodevelopmental phenotypes, respectively. Intellectual disability and developmental delay were common to all individuals, and were profound in four individuals. Seizures were also accompanied in three individuals with *CAMK2A* variants. Five variants include one splice site variant and four missense variants at evolutionarily conserved amino acids. Using a minigene splicing assay, we demonstrated that the splice site variant caused skipping of exon 11 leading to an in-frame deletion of the regulatory segment of CaMKII $\alpha$ . By mapping the variant sites on the crystal structures of human CaMKII $\alpha$ , all the four missense variants are predicted to impair the interaction between the kinase domain and the regulatory segment responsible for the autoinhibition of its kinase activity. The Thr286/Thr287 phosphorylation as a result of release from autoinhibition was increased in three mutants when the mutants were stably expressed in Neuro-2a neuroblastoma cells. Expression of a CaMKII $\alpha$  mutant (P212Q) in primary hippocampal neurons significantly increased A-type K<sup>+</sup> currents, which facilitated spike repolarization of single action potentials. Knock-in mice of *Camk2b*<sup>P213L</sup>/*P213L* showed ataxic gait and beam walking test revealed impairment of fine motor coordination and balance. Our data highlight the importance of CaMKII $\alpha$  and CaMKII $\beta$  and their autoinhibitory regulation in human brain function.

**1121F**

**Background:** Niemann Pick Type C (NPC) is a rare genetic, lysosomal storage disorder caused by mutations of the NPC protein. Systemic and neurological symptoms are heterogeneous progressive and lead to death. A prospective **observational study** in NPC patients was initiated leading into a **randomized placebo-controlled double-blind interventional trial with a heat shock protein (HSP) amplifier; arimoclolol**. HSP is known to improve the folding of NPC1 protein and improve lysosomal function. **Methods:** Patients, 2 to 18 years of age, diagnosed with NPC, who had at least one neurological symptom and preserved ability to walk with assistance were eligible. Patients were maintained on standard therapy. Assessments were conducted at baseline and minimally at 6 months to observe the natural disease course before patients rolled into the 2:1 randomized placebo-controlled interventional trial receiving a daily dose of up to 600 mg arimoclolol or placebo orally for 12 months. The key assessments performed were: a 5-domain NPC-severity score (ambulation, cognition, fine motor skills, speech and swallowing), global clinical impression score (CGI-I), safety and samplings for biomarkers. **Results:** In the observational study, 36 patients with a mean age of 9.86 years (SD4.61) were enrolled across 12 sites in 7 European countries. 27 patients continued in the interventional trial and an additional 25 patients were enrolled from the same sites along with additional 2 sites in the US. Data on disease progression showed a mean increase of 1.4 (SD=2.9) on the 5-domain NPC-CSS corresponding to a mean rate of change of 0.75/6 months (SD=1.58). The 5-domain NPC-CSS is an abbreviated score of the NPC-CSS. A novel glycosphingolipid species was discovered as potential biomarker and a dramatically decreased level of HSP70 in white blood cells were observed. The trial is completed and currently, data is being processed. The results at 12-months on the safety and efficacy of arimoclolol will be reported for the rate of progression and for a responder analysis of the proportion of patients who stabilize or improve by CGI-I compared to placebo. **Conclusions:** Progression rates in the cohort from the observational study were shown to be comparable to previously reported studies. These clinical findings as well as the biomarker data will support the interpretation of this Phase II/III intervention trial results that will show if orally administered arimoclolol can safely alter the disease course.

**1122W**

**Inherited peripheral neuropathies: Analysis of *PDXK* gene identifies a new treatable disorder.** V. Chelban<sup>1,2</sup>, J. Vandrovcova<sup>2</sup>, M. Wilson<sup>3</sup>, S. Efthymiou<sup>2</sup>, E. Zamba<sup>4</sup>, Papanicolaou<sup>4</sup>, N. Wood<sup>2</sup>, P. Mills<sup>3</sup>, P. Clayton<sup>3</sup>, H. Houlden<sup>2</sup>, SYNAPSE Study Group. 1) Department of Neurology and Neurosurgery, Institute of Emergency Medicine, Chisinau, Moldova; 2) 1Department of Molecular Neuroscience, Institute of Neurology, University College London, London, UK; 3) Genetics and Genomic Medicine, GOS Institute of Child Health, University College London, London, UK; 4) The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus.

Peripheral neuropathies are amongst the most common neurological conditions worldwide affecting over 20 million people. Until now, no disease-modifying treatment has been established in these conditions. This is unsurprising since 40% of patients with primary peripheral neuropathies have no disease-causing mutation identified. We performed a combination of whole genome sequencing, homozygosity mapping and segregation analysis for novel disease-causing gene discovery in patients with severe peripheral neuropathy. Pathogenicity was confirmed via enzymatic assays and mass spectroscopy on recombinant protein and patient-derived fibroblasts, plasma and erythrocytes. We used circular dichroism to show secondary structure changes and isothermal titration calorimetry to investigate the impact of mutation on the ATP binding. We report that biallelic mutations in human *PDXK* are associated with primary axonal peripheral neuropathy and optic atrophy, characterised by blindness and severe, muscle weakness and wasting, leading to patients becoming wheelchair-bound. Pyridoxal kinase (*PDXK*) is involved in converting vitamin B<sub>6</sub> to its active form, pyridoxal 5'-phosphate (PLP). We show that *PDXK* mutations lead to pathology via decreased plasma PLP concentrations. Our functional studies revealed conformational rearrangement in the mutant enzyme around the kinase ATP binding pocket with impaired *PDXK* ability to bind ATP and reduced erythrocyte *PDXK* activity. We show that both the human clinical picture and biochemical profile in *PDXK* mutations are rescued by PLP supplementation. Patients regained their ability to walk independently. Furthermore, treatment led to normalisation of plasma PLP levels, correlated with reduction of neurofilament light chain concentrations, a biomarker of axonal breakdown. In conclusion, biallelic mutations in human *PDXK* are associated with a novel disorder leading to a treatable primary axonal peripheral neuropathy and optic atrophy. As B<sub>6</sub> is a cofactor for more than 70 enzymes representing diverse, essential biological pathways it can be linked to diseases through a wide-range of processes involved in the vitamin B<sub>6</sub> pathway, these findings have direct implications for neuropathies of different aetiology characterised by reduction of PLP levels. Collectively, these data establish the importance of the vitamin B<sub>6</sub> pathway for normal neurological function in both central and peripheral nervous systems and thus identifies PLP as a therapeutic target.

**1123T**

**Molecular analysis and functional characterization of mutations in Niemann-Pick disease type A and type B in Indian patients.** D. Deshpande<sup>1</sup>, S. Gupta<sup>1</sup>, P. Ranganath<sup>1,2</sup>, J. Seth<sup>3</sup>, M. Kabra<sup>4</sup>, N. Gupta<sup>4</sup>, KM. Girisha<sup>5</sup>, S. Phadke<sup>6</sup>, C. Datar<sup>7</sup>, A. Dalal<sup>1,2</sup>. 1) Center for DNA fingerprinting and Diagnostics, Hyderabad, (TS), India; 2) Nizam's Institute of Medical Sciences, Hyderabad, (TS) India; 3) Foundation for Research in Genetics and Endocrinology (FRIGE), Ahmedabad, Gujrat, India; 4) All India Institute of Medical Sciences, New Delhi, India; 5) Kasturba Medical College, Manipal, Karnataka, India; 6) Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, (UP) India; 7) Sahyadri Medical Genetics and tissue culturing facility, Pune (MH), India.

Niemann-Pick disease (NPD) is a rare Mendelian - autosomal recessive - lysosomal storage disease, characterized by accumulation of sphingomyelin inside the lysosomes. Mutations in (Sphingomyelin-phosphodiesterase-1) *SMPD1* gene, encoding enzyme Acid sphingomyelinase (ASM), Cause Type A or Type B NPD. Inability of mutated ASM to cleave sphingomyelin, results in lysosomal accumulation causing cell death. The severity of NPD depends on type of mutation and its location in *SMPD1* domains. In this study, patients with NPD were recruited based on clinical evaluation by geneticist and enzyme assay results, after due informed consent from parents and approval from institutional ethical committee. After DNA isolation, all 6 exons with flanking intronic regions were sequenced. Identified variants were verified by checking in 1000G, ExAC, dbSNP databases for polymorphisms and in HGMD and Clinvar databases for known pathogenic variants. Variants were then subjected to various mutation prediction software e.g. Polyphen2, SIFT, and Hansa, CADD etc. Variants predicted as disease causing and absent in above databases (novel variants) were selected for functional characterization. We found total 81 mutations in 138 patients, including 46 Novel mutations out of which, 31 missense, 1 nonsense and 14 frameshift) The PDB structure of *SMPD1* enzyme shows a Saposin domain which plays crucial role in recruiting sphingomyelin to lysosomal membrane and the phosphodiesterase domain 3 (catalytic domain) which cleaves the lipid. We further characterized missense mutations in these regions e.g. c.314T>C, c.647T>G, c.1783C>G, c.1028G>C, c.1429C>A using Molecular Dynamic Simulations. Till now, 10 missense mutations have been analysed and *in vitro* functional characterisation for the same is being done. The change in an amino acid can alter or destabilize the enzyme structure or substrate interactions. Mutation at position c.1783C>G makes enzyme structure unstable whereas c.1048G>C makes the structure rigid. This may result in no substrate binding at all or too tight substrate binding, respectively. Knowledge regarding pattern of mutations in different populations helps to discern demography and pathophysiology of the disease. We have been successful in establishing mutation spectrum for Indian patients. The present study has aided in accurate prenatal diagnosis and proved helpful for genetic counselling.

**1124F**

**Clinical features of arginase 1 deficiency: Review of literature case series.** G.A. Diaz<sup>1</sup>, N. Longo<sup>2</sup>, A. Schulze<sup>3</sup>, G. Bubb<sup>4</sup>, S. Eckert<sup>4</sup>, K.C. Patki<sup>4</sup>, J.E. Wooldridge<sup>4</sup>, J.L. Merritt II<sup>5</sup>. 1) Icahn School of Medicine at Mt. Sinai, New York City, NY; 2) University of Utah, Salt Lake City UT, USA; 3) University of Toronto and The Hospital for Sick Children, Toronto, ON, Canada; 4) Aeglea BioTherapeutics, Austin, TX, USA; 5) University of Washington, Seattle, WA, USA.

**Background:** Arginase 1 Deficiency (ARG1-D) is a rare, progressive, autosomal recessive disease caused by deficiency of a key arginine metabolizing enzyme. The high plasma arginine level is believed to be the key driver of spasticity, developmental delay and seizures that develop in early childhood and progress over time. **Methods:** We identified more than 100 unique, historical ARG1-D cases in the literature to develop a more systematic understanding of the clinical presentation, disease progression, and impact of available management on both arginine levels and disease manifestations. **Results:** Initial review of 3 largest series comprised of 85 unique ARG1-D patients was completed. At publication, mean age of living patients was 16.1 years (range 1–37; median 13); 11 patients were deceased with mean age at death of 13.9 years (range 0.13 – 45; median 12). Mean age at presentation was 2.1 years (range 0–6; median 1.9), and mean age at diagnosis was 6.9 years (range 0–27; median 5). The primary disease manifestation was spasticity, with lower limb (LL) and upper limb (UL) spasticity reported in 66% and 31% of cases respectively. In all but 2 cases with UL spasticity LL spasticity was also seen. Abnormal gait/ataxia was reported in 21% and 10% were non-ambulatory. Cognitive impairment was reported in 74% and was moderate or severe in 40%. Seizures were reported in 66% of patients, 58% had periodic vomiting, and 22% had growth retardation. A protein-restricted diet was used in 89% of patients and 58% received nitrogen scavengers. Transaminases >ULN (upper limit of normal) were reported in 39% of cases and 35% had liver pathology. Mean plasma arginine was 634 $\mu$ M (range 96–1756), mean serum  $\alpha$ -keto- $\delta$ -guanidinovaleric acid was 5.72 $\mu$ M (ULN 0.25) and mean serum argininic acid was 3.37 $\mu$ M (ULN 0.115), mean plasma guanidinoacetate was 4.74 $\mu$ M (ref range: 0.8–2.6). Plasma ammonia > ULN was reported in 93% cases and 57% had a least one value >100 $\mu$ M. Percentages were based on publication report; therefore, actual incidence could be higher. **Discussion:** This analysis demonstrates the significant morbidity in patients with ARG1-D, including evidence of premature death. Despite symptoms in early childhood, diagnosis is often delayed. Plasma arginine remains markedly elevated despite standard disease management, including dietary protein restriction, with evidence of continued disease progression. This analysis supports the development of much needed new therapies in ARG1-D.

**Oral plasmalogen precursor, PPI-1040, improves plasmalogen levels and hyperactivity in a Pex7 deficient mouse model of Rhizomelic Chondrodysplasia Punctata type 1 (RCDP1).** W. Fallatah<sup>1,2</sup>, T. Smith<sup>3</sup>, W. Cui<sup>1</sup>, D. Jayasinghe<sup>3</sup>, E. Di Pietro<sup>1</sup>, S. Ritchie<sup>3</sup>, N. Braverman<sup>1</sup>. 1) Department of Human Genetics, McGill University, Research Institute of the MUHC, Montreal, Canada; 2) Department of Medical Genetics, King Abdul-Aziz University, Jeddah, Saudi Arabia; 3) Med-Life Discoveries LP, Saskatoon SK, Canada.

**Background:** RCDP1 is a peroxisome biogenesis disorder distinguished by congenital cataracts, a characteristic skeletal dysplasia and neurological impairment. This results in profound psychomotor and growth retardation, and early demise. RCDP1 is caused by defects in the peroxisome receptor, PEX7, resulting in negligible biosynthesis of plasmalogen phospholipids (PL). Disease severity directly correlates to residual PL levels. In fact, patients with milder forms of RCDP have residual erythrocyte PLs that are around 34% of controls. Currently, there is no disease modifying therapy for RCDP. We generated novel hypomorphic Pex7 deficient mice (B6;129S6-Pex7<sup>tm2.38Rev</sup>, referred here as Pex7<sup>HypoNull</sup>) with 90% survival, resembling mild RCDP. The total PL levels were decreased to 20% of Pex7<sup>WT/WT</sup> (WT) in plasma, erythrocytes. PL levels were 17% of WT in brain, and 26–40% in liver, small intestine and skeletal muscle. Our Pex7<sup>HypoNull</sup> mice exhibit a hyperactive behavior in the open field environment. These data establish useful biochemical and behavioral endpoints for preclinical trials. **Aim:** To evaluate the therapeutic response of Pex7<sup>HypoNull</sup> mice to oral PL precursor supplementations PPI-1011, sn1-1-0-alkyl[C16:0], sn2-DHA, sn3-lipoic acid and PPI-1040, sn1-1-0-alkenyl[C16:0], sn2-DHA, sn3-cyclic phosphoethanolamine (PE). **Method:** 3 cohorts of adult male and female Pex7<sup>HypoNull</sup> mice received oral gavage with PPI-1011, PPI-1040 or vehicle control at 50 mg/kg for 4 weeks (5x/week). The study included a matched cohort of untreated WT. The open field test was performed at baseline and after treatment. Tissues were collected for PL analysis by LC/MSMS. **Results:** In PPI-1040 treated Pex7<sup>HypoNull</sup> mice, total C16:0 PE and target C16:0/DHA PL levels increased in plasma to 81% and 72% of WT, in erythrocytes to 28% and 38% of WT, in liver, small intestine, and skeletal muscle to 52–60% and 60–65% of WT, respectively; there was no increase in PLs in brain. Interestingly, PPI-1040 treated Pex7<sup>HypoNull</sup> mice showed significant improvement of the hyperactivity phenotype compared to vehicle treated Pex7<sup>HypoNull</sup> controls. Although PPI-1011 did not improve PL levels or hyperactivity, PPI-1040 is a promising therapy for RCDP. Recovery of the behavioral phenotype could be secondary to changes in brain neurochemistry not apparent by analysis of PL levels in the whole brain, or secondary to the documented PL increase in peripheral tissues.

## 1126T

**Expansions of intronic TTTCA and TTTTA repeats in three genes cause benign adult familial myoclonic epilepsy.** H. Ishiura<sup>1</sup>, K. Doi<sup>2</sup>, J. Mitsui<sup>3</sup>, J. [Background] Benign adult familial myoclonic epilepsy (BAFME) is an autosomal dominant disorder characterized by infrequent epilepsy and myoclonic tremor. The causative genes for BAFME have not been identified. [Methods] Fifty three families including 93 patients were enrolled. We performed SNP typing-based linkage analysis and whole genome sequence and RNA-seq analyses employing HiSeq2500. To search for expanded tandem repeats, we applied TRhist (*Bioinformatics* 2014). [Results] Parametric linkage analysis of four families revealed a linkage to 8q24, which has been shown as a candidate region of BAFME in Japanese families. We found conserved haplotypes among the six families, which enabled us to narrow the candidate region to 134 kb. An intensive search of the whole genome sequence data revealed TTTCA and TTTTA repeat expansions in intron 4 of *SAMD12*, which were found exclusively in the patients in the 50 families. In a family, a different repeat configuration in *SAMD12* was revealed that also included TTTCA repeat expansions. RNA foci consisting of UUUCA repeats, but not of UUUUA repeats, were observed in neurons of the autopsied brains. RNA-seq analysis of brain revealed increased coverages in introns upstream of the mutation, suggesting abortive transcription. Applying TRhist to RNA-seq data, we found short reads filled with [UUUCA]<sub>exp</sub> in autopsied brains with BAFME. In addition, reads filled with altered repeat motifs ([CUUCA]<sub>exp</sub> and [GUUCA]<sub>exp</sub>) were also found in autopsied brains, raising the possibility of modification of RNA sequences. No ubiquitinated inclusions were found in autopsied brains. In the two families with the clinical diagnosis of BAFME, we did not detect expanded TTTCA and TTTTA repeats in *SAMD12*. Hypothesizing that the same repeat motifs in other genes might be involved in the two families, we searched for accumulated short reads filled with TTTCA and TTTTA repeats employing TRhist, and identified repeat expansion mutations in introns of *TNRC6A* in a family and of *RAPGEF2* in the other family. [Discussion] The findings that the same expanded repeat motifs in the three independent genes lead to BAFME phenotypes emphasize the role of TTTCA repeat expansions in BAFME, presumably through RNA-mediated toxicity, which was further supported by the presence of RNA foci without ubiquitinated inclusions. The search for RNA binding proteins that specifically bind to the expanded repeat motifs is underway.

## 1127F

**A novel disease gene *DTMPK* identified in 2 siblings with mitochondrial DNA depletion syndrome.** C. Lam<sup>1</sup>, W.L. Yeung<sup>2</sup>. 1) Pathology, The University of Hong Kong, Hong Kong, China; 2) Department of Pediatrics and Adolescent Medicine, Alice Ho Miu Ling Nethersole Hospital, Hong Kong, China.

We described 2 brothers, aged 1 and 6 years, with microcephaly, hypotonia and severe intellectual disability (ID) and they shared common biochemical abnormalities including high serum lactate, pyruvate and alanine. The younger brother is now 12 months old (m.o.), who was a full term baby with low birth weight of 2.46 kg. The baby was noted to have congenital microcephaly, hypotonia and global delay at 6 m.o. He suffered from status epilepticus associated with febrile illness at 7 m.o. and subsequently had developmental regression, hypertonia, cortical blindness and dysphagia. CT brain showed no focal lesion while MRI brain revealed bilateral symmetric restricted diffusion at caudate heads, basal ganglia, thalami, corona radiata, cerebellar dentate nuclei and crus cerebri. Repeated MRI brain at 10 m.o. showed marked cerebral atrophy with bilateral subdural haemorrhagic effusion, and lactate peak in MR spectroscopy. At age of 12 m.o., he had no head control and was unable to roll over or reached out for objects. His 6-year-old elder brother also has congenital microcephaly (head circumference: 31 cm) and low birth weight of 2.1 kg. He also presented with hypotonia, global developmental delay and severe ID. He can now walk independently and speak few single words. His vision and hearing are normal and has no seizure attack all along. His serum lactate fluctuated from 2.0 - 3.5 mmol/L with slight elevation of alanine. MRI brain was unremarkable. His head circumference remained static in the past 3 years and is now 5 cm below the 3<sup>rd</sup> percentile. The 2 siblings were recruited to our Undiagnosed Diseases Program for whole exome sequencing (WES) analysis after informed consents. Two variants in the *DTYMK* gene were identified. The first variant is a frameshift mutation NM\_012145.3:c.287\_320del (p.Asp96Valfs\*8) and the second one is a novel missense mutation c.295G>A (p.Ala99Thr). Segregation study showed the two variants were *in trans*. Deoxythymidylate kinase (thymidylate kinase), *DTYMK* is an essential gene in both *de novo* and salvage pyrimidine deoxyribonucleotide biosynthetic pathway. Knockdown of *DTYMK* gene would lead to reduced dTDP levels in the mitochondria. This suggests the vital role of *DTYMK* in mitochondria and explain the clinical and biochemical features seen in the siblings. Our novel findings suggested *DTYMK* is a new mitochondrial disease gene and should be included in the future gene panel analysis for mitochondrial DNA depletion syndrome.

## 1128W

**Defining the natural history of cognition in type 3 Gaucher disease.** A.M. Steward<sup>1</sup>, E.A. Wiggs<sup>1</sup>, T. Lindstrom<sup>1,2</sup>, S. Ukwuanji<sup>3</sup>, T. Roshan-Lal<sup>1</sup>, E. Ryan<sup>1</sup>, G. Lopez<sup>1</sup>, R. Schiffman<sup>4</sup>, E. Sidransky<sup>1</sup>. 1) NIH, Bethesda, MD; 2) University of Miami, Miami, FL; 3) Emory University, Atlanta, GA; 4) Baylor Research Institute, Dallas, TX.

Gaucher disease (GD) is an autosomal recessive disorder caused by mutations in the *GBA1* gene, leading to deficiency of the lysosomal enzyme glucocerebrosidase and subsequent buildup of substrate. Type 3 GD is characterized by varying degrees of chronic neurological involvement. The most common neurological feature is horizontal supranuclear gaze palsy, though manifestations range from intellectual delay to progressive myoclonic epilepsy, among others. No correlations exist between degree of neurologic involvement and *GBA1* genotype. Currently-approved therapies for GD do not affect neurological manifestations. We aimed to characterize the natural history of cognition in 33 individuals with type 3 GD who completed neuropsychological evaluations at the National Institutes of Health Clinical Center between 1982 and 2017. Individuals were evaluated between 1 and 18 times, using age-appropriate Wechsler Intelligence Scales over 1 to 20 years. Mean verbal, performance, and full-scale intelligence quotients (IQs) were 86.2, 79.3, and 81.0, respectively. Variation in all IQ domains was not linear with time, excluding regression and MANOVA as reliable statistical methods. The coefficient of variation (CV, standard deviation/mean) was used to characterize variation for each individual. Mean (sd) verbal, performance, and full-scale CVs were 0.08 (0.05), 0.09 (0.06), and 0.07 (0.05), respectively. Mixed effects regressions were used to determine if IQ was associated with clinical features, such as splenectomy and behavioral characteristics, among others. Models were optimized using backward step reduced fit with Satterthwaite degrees of freedom. Subject ID was included as a random effect to account for internal correlation of an individual's IQ scores. Splenectomy and autism were associated with verbal IQ; splenectomy, behavioral issues, ataxia, myoclonus, ADD/ADHD, and having an individualized education plan (IEP) were associated with performance IQ; splenectomy and behavioral issues were associated with full-scale IQ. These results indicate that IQ in type 3 GD varies over time, with no clear trajectory and average variation of roughly 2-13%. Changes outside this range should prompt evaluation of specific clinical features associated with that IQ domain. Finally, to use IQ as a clinical trial efficacy measure, multiple evaluations prior to intervention are needed to establish a reliable mean IQ and determine whether IQ changes can be attributed to that intervention.

## 1129T

**Replication of MIR149 association with onset age and severity of CMT1A in a European population.** F. Tao<sup>1</sup>, G. Beecham<sup>1</sup>, A. Rebelo<sup>1</sup>, S. Blanton<sup>1</sup>, L. Besta Neurological Institute, 20133 Milan, Italy; 15) Department of Neurology, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA 19104, USA; 16) MRC Centre for Neuromuscular Diseases, UCL Institute of Neurology, Queen Square, London WC1N 3BG, UK.

Charcot-Marie-Tooth disease type 1A (CMT1A) is the most common form of inherited peripheral neuropathies. The genetic basis of CMT1A is a 1.5-Mb duplication on chromosome 17p11.2, which includes the causative gene *Peripheral Myelin Protein 22 (PMP22)*. In search for modifier genes and alleles, a common SNP rs2292832 in microRNA 149 (MIR149) was recently reported to be significantly associated with age at onset (AAO) and severity of CMT1A in an Asian population. However, the SNP has not been studied in other populations. In this study, we aimed to examine the association of rs2292832 with AAO and severity of CMT1A in a European population. The study included 644 CMT1A patients of European ancestry, which was confirmed by principal component analysis (PCA) using patients' genotyping data. Three clinical outcomes were tested: self-reported AAO of difficulty walking, CMT neuropathy score (CMTNS), and median motor nerve conduction velocity (MNCV). The analysis was performed using linear regression in PLINK. However, we did not observe any significant association of rs2292832 with the three phenotypes ( $P = 0.1061$  for AAO,  $P = 0.2444$  for CMTNS,  $P = 0.3180$  for MNCV). We then divided the cases into early-onset group (AAO < 20 years) and late-onset group (AAO  $\geq$  20 years), and performed the association analysis using chi-square test. No significant difference was identified in allele frequencies between early and late-onset individuals ( $P = 0.2580$ , OR = 1.271). We also tested for disease severity as a binary outcome of severe cases (CMTNS > 10, MNCV  $\leq$  20) and mild cases (CMTNS  $\leq$  10, MNCV > 20). The analysis did not identify any significant association ( $P = 0.6884$ , OR = 0.9290 for CMTNS,  $P = 0.7593$ , OR = 0.9382 for MNCV). In conclusion, our study did not replicate the association of the MIR149 SNP in an independent European population. Since the minor allele frequency of rs2292832 differ among populations ( $T = 0.637$  in East Asians and  $T = 0.282$  in Europeans reported from 1000 Genomes), it is possible that the effect of rs2292832 is ethnic-specific. Additional studies in other populations are required to further validate the role of MIR149 in CMT1A.

**Identification of pathogenic variants of DMD gene in Indian Backers Muscular Dystrophy: A comparison to the DMD spectrum.** A. Anand<sup>1</sup>, R. Tyagi<sup>1</sup>, K. Sharma<sup>1</sup>, C. Thakur<sup>1</sup>, S. Kumar<sup>1</sup>, A. Dala<sup>2</sup>, M. Faruq<sup>3</sup>, M. Mohanty<sup>4</sup>. 1) Neuroscience Research Lab, Department of Neurology, Post Graduate Institute of Medical Education and Research, Chandigarh, India; 2) Diagnostics Division, Center for DNA fingerprinting and Diagnostics, Hyderabad, India; 3) Genomics and Molecular Medicine Unit, Institute of Genomics and Integrative Biology, New Delhi, India; 4) Department of Neurosurgery, Postgraduate Institute of Medical Education and Research, Chandigarh, India.

**Introduction:** DMD is a widely studied gene responsible for a fatal inherited disorder Duchenne Muscular Dystrophy (DMD) and its milder variant Backers Muscular Dystrophy (BMD). DMD and BMD phenotypes are results of preservation of Open Reading Frame due to variation. Increased number of sporadic cases and the emergence of novel therapeutic approaches including exon skipping necessitates repurposing identification and characterization of pathogenic variants in DMD and BMD. **Methods:** A total of 100 DMD and 21 BMD subjects were recruited as per guidelines outlined by Institute Ethics Committee. Variations were detected by Multiplex Ligation-dependent Probe Amplification (MLPA) followed by capillary electrophoresis in the sequencing platform. Coafflyser.Net was used to obtain the relative ratios based on which type of variation is detected. Ratios between .70-1.30 were considered to show normal dosage quotient, 0.00 as deletion and 1.5-2.0 as duplication.

**Results:** Out of 21 BMD subjects 14/21 (66.66 %) showed deletion/duplication. Among these 11/14 (78.57 %) showed deletion between the hot spot region (Exon 45-55). 3/14 (21.42 %) showed deletion in the proximal region of the DMD gene. Deletion/Duplications were not detected in 33.33 % BMD cases. In contrast to BMD subjects, 80 % DMD subjects revealed deletion or duplication. 45/80 (56.25 %) variations in DMD cases, were amenable to Exon 51 skipping for the restoration of open reading frame and its conversion to BMD like phenotype. Skipping can potentially impact Central nervous system specific Dp160, Dp71, Dp40 isoforms leading to improved quality of life.

**Conclusion:** Spectrum of DMD pathogenic variants reveals an increased shift in the deletion/duplication profile. This data can be not only utilized to develop database but also for exon skipping interventions based on single exon or multi-exon administration of PMOs.

**1131W**

**Wide range of phenotypic variability caused by missense variants in NARS2 gene.** L. Kalfon<sup>1</sup>, S. Ben Harouch<sup>1,2</sup>, H. Ladany<sup>1,2</sup>, H. Mandel<sup>1</sup>, T.C. Fallik-Zaccari<sup>1,2</sup>. 1) Institute of Human Genetics, Galilee Medical Center, Nahariya, Israel; 2) The Azrieli Faculty of Medicine, Bar Ilan, Safed, Israel.

Combined oxidative phosphorylation deficiency-24 is an autosomal recessive mitochondrial disorder with a wide phenotypic variability. The disease is caused by bi allelic variants in the NARS2 gene, encoding for the Mt-Asparaginyl-tRNA Synthetase. The protein belongs to a class of enzymes called aminoacyl tRNA synthetase (aaRS) that charge tRNAs with their cognate amino acids. Mt-aaRSs are synthesized in the cytosol and are imported to the mitochondria, taking a vital role in the mitochondrial translation machinery. In the current study we describe three patients originating from two unrelated families. Two affected siblings are from a consanguineous Muslim family. The older sister (18 years), presented with congenital sensorineural hearing loss, recurring seizures (from age 5 years) followed by profound developmental delay and regression. Her brother (age 3 years), has shown earlier and more severe clinical manifestation (onset of intractable seizures at 6 months) and developmental regression. Trio exome sequencing identified a homozygous missense variant in the NARS2 gene (c.434T>G). Sanger sequencing and RFLP confirmed the variant segregation in the family in an autosomal recessive manner. The third proband is the youngest offspring in a consanguineous Druze family, who presented seizures (at age of 5 months), sensorineural hearing loss, truncal hypotonia and developmental regression. The proband deceased at 6 months of age. Trio exome sequencing revealed a novel homozygous missense variant in NARS2 (c.500A>G) predicted to be deleterious. The two variants reported here are in proximity to a dimerization motif and the catalytic site, and therefore may affect the dimerization and thus the function of Mt-Asparaginyl-tRNA Synthetase. To the best of our knowledge, 12 missense variants in the NARS2 gene were reported to date, associated with hearing loss, mitochondrial respiratory chain deficiency, microcephaly and Leigh syndrome. Our patients provide evidence for inter and intra familial phenotypic variability and expand the phenotypes associated with pathogenic genetic variants in NARS2 gene.

**Peripheral neuropathies: Application of targeted next generation sequencing for Lithuanian patients cohort.** *B. Burnyte*<sup>1,2</sup>, *L. Ambrozaityte*<sup>1,2</sup>, *K. Grigalioniene*<sup>1,2</sup>, *A. Morkuniene*<sup>1,2</sup>, *K. Baronas*<sup>1,2</sup>, *V. Kucinskas*<sup>1,2</sup>, *A. Utkus*<sup>1,2</sup>. 1) Inst of Biomed Sciences, Fac of Med, VU, Vilnius, Lithuania; 2) VUHSK, Vilnius, Lithuania.

Hereditary peripheral neuropathies (HPN) are an etiologically heterogeneous group of neurodegenerative disorders of the peripheral motor, sensory, and autonomic nerves. Molecular diagnosis of HPN is often very challenging. There is a considerable overlap of phenotypes, and variants in one gene can cause different entities. In this study, we have customised a panel of 150 HPN associated genes for next-generation sequencing (NGS). A cohort of 34 patients with a yet molecularly undiagnosed HPN with or without additional features were included in this study. The sequencing data was filtered for the variants meeting the set of quality requirements, having a population frequency less than 1% and coverage of at least 20x. Pathogenic or likely pathogenic variants in genes known to cause HPN were identified in 29% (10/34) of the patients. Five patients (15%) harbored novel pathogenic variants in HPN associated genes *AARS*, *MARS*, *DCTN1*, *GBN4* or *LITAF*. One patient (3%) with intellectual disability and axonal neuropathy had novel variant in *ATAD3A* gene. Additionally, two patients (6%) had variants in a novel candidate HPN gene *ARHGEF10*. Previously reported biallelic pathogenic variants were identified for four patients (12%); three of those in *HINT1* gene. Digenic inheritance was identified in one patient with heterozygous variants in *GNB4* and *DNM2* genes, where *GNB4* gene variant was novel. In a few patients variants of unknown significance were detected highlighting the dilemma in prioritizing them due to insufficient *in silico* predictions and other prognostic scores. In 56% of the cases further molecular studies were recommended (WES or WGS) for identifying new genes implicated in the pathogenesis of HPN. Therefore, application of the targeted gene panel for HPN can significantly enhance the effectiveness of genetic diagnosis. Identification of new pathogenic variation and characterization of associated phenotypes advances the knowledge of the pathogenesis of peripheral neuropathies.

Parkinson disease (PD) is the most common neurodegenerative movement disorder. PD is pathologically characterized by the loss of dopaminergic neurons in the substantia nigra, spreading to other brain areas, and  $\alpha$ -synuclein (encoded by *SNCA*) protein aggregates. Increasing evidence supports an extensive and complex genetic contribution to PD. Previous genome-wide association studies (GWAS) have shed light on the genetic basis of risk for this disease. However, the genetic determinants of PD age of onset are largely unknown. Here we performed an age of onset GWAS based on 28,568 PD cases. We estimated that the heritability of PD age of onset due to common genetic variation was  $\sim 0.11$ , lower than the overall heritability of risk for PD ( $\sim 0.27$ ). We found two genome-wide significant association signals, *SNCA* and *TMEM175*, both of which are known PD risk loci. In addition, we identified that *GBA* coding variant carriers have a lower age of onset compared to non-carriers. Notably, *SNCA*, *TMEM175*, and *GBA* have all been shown to directly influence alpha-synuclein aggregation. Similar trends were seen for other loci implicated in alpha-synuclein aggregation pathways (e.g. *SCARB2*, *BAG3*) although not reaching genome-wide significance. Interestingly, other well-established PD risk loci such as *STK39*, *MAPT* and *RAB7L1* (PARK16) did not show a significant effect on age of onset of PD, implying different mechanisms for disease. Overall, the significantly associated variability is centered on the gene encoding alpha-synuclein and on variability in several other lysosomal proteins that have been shown to directly influence alpha-synuclein aggregation or clearance. These results highlight that therapies that target alpha-synuclein aggregation are more likely to be disease-modifying than therapies targeting other pathways.

**Leveraging consanguinity in essential tremor families from Turkey to identify candidate genes.** L. Clark<sup>1,2</sup>, D. Robakis<sup>3</sup>, A. Tekinay<sup>4</sup>, C. Akbostancı<sup>5</sup>, F.N. Durmaz-Celik<sup>6</sup>, T. Ozcelik<sup>7</sup>. 1) Department of Pathology and Cell Biology, College of Physicians and Surgeons, Columbia University Irving Medical Center, New York, NY, 10032, USA; 2) Taub Institute for Research on Alzheimer's Disease and the Aging Brain, College of Physicians and Surgeons, Columbia University, New York, NY, 10032, USA; 3) Department of Neurology, Yale School of Medicine, Yale University, New Haven, CT, USA; 4) Institute of Materials Science and Nanotechnology, Bilkent University, Ankara, Turkey; 5) Faculty of Medicine, Department of Neurology, Ankara University, Ankara, Turkey; 6) Faculty of Medicine, Department of Neurology, Osmangazi University, Eskisehir, Turkey; 7) Department of Molecular Biology and Genetics, Bilkent University, Ankara, Turkey.

**Background:** Genetic analyses of consanguineous families or populations with endogamy is a powerful approach for gene identification and can help to unravel the underlying genetic defects in diseases that are genetically heterogeneous. Essential Tremor (ET), a disease whose hallmark feature is action tremor (i.e. tremor occurring during voluntary movements), is the most common cause of tremor in humans. Prevalence increases with age reaching ~20% during the ninth decade of life in the US. In Turkey, prevalence estimates are very similar to US estimates with the prevalence of ET in Mersin province, Turkey estimated to be 4% in individuals aged >40 years. **Objectives:** Here we have leveraged consanguinity and population endogamy in a unique cohort of ET families collected throughout Turkey at Bilkent University to identify candidate genes. **Methods:** As of 2018, the Turkish ET family study at Bilkent University consists of 160 ET families (443 collected samples), of which 51% are consanguineous or endogamous. Detailed clinical assessment of these families was performed and six families were selected for whole genome sequencing and genetic analyses. An integrated analyses including homozygosity mapping and WGS analyses (SNV/indel and CNV/SV) was performed. **Results:** We have identified a number of interesting candidate genes in these ET families which are currently being validated by functional studies. In one family with ET and parkinsonism, we identified compound heterozygosity for two heterozygous missense variants, predicted to be pathogenic by *in silico* tools and that are rare in populations databases (GnomAD), in the vacuolar protein sorting 13A gene (*VPS13A*) that co-segregated with the ET and parkinsonism phenotype. Homozygous or compound heterozygous mutations in *VPS13A* cause Chorea-acanthocytosis (ChAc, OMIM#200150), a rare autosomal recessive inherited syndrome characterized by a hyperkinetic movement disorder, progressive neurodegeneration and red cell acanthocytosis. ChAc can also manifest clinically as chorea, tremor, parkinsonism, dystonia, cognitive impairment, seizures and psychosis. **Conclusion:** Here, we show the utility of genetic studies in consanguineous pedigrees for genetically heterogeneous diseases such as ET. The candidate genes that we have identified may represent novel genetic causes of ET and represent possible gene targets for therapeutic intervention. This study is funded by the National Institutes of Health, R21 NS098930 (Clark).

## 1135T

**Whole genome sequencing of a large Lewy Body dementia and Frontotemporal dementia cohort for genetic discovery: A public resource for the research community.** C.L. Dalgard<sup>1</sup>, C. Viollet<sup>2</sup>, E. McGrath-Martinez<sup>2</sup>, C. Alba<sup>2</sup>, M. Sabir<sup>3</sup>, S. Ahmed<sup>4</sup>, Y. Abramzon<sup>4</sup>, R. Ferrari<sup>5</sup>, J. Hardy<sup>6</sup>, A. Chio<sup>7</sup>, O.A. Ross<sup>7</sup>, M.D. Wilkerson<sup>1</sup>, R. Gibbs<sup>4</sup>, A. Singleton<sup>4</sup>, B.J. Traynor<sup>4</sup>, S.W. Scholz<sup>2</sup>. 1) Anatomy, Physiology & Genetics, Uniformed Services University of the Health Sciences, Bethesda, MD, USA; 2) The American Genome Center, Uniformed Services University of the Health Sciences, Bethesda, MD, USA; 3) Neurodegenerative Diseases Research Unit, National Institute of Neurological Disorders and Stroke, National Institute of Health, Bethesda, MD, USA; 4) Laboratory of Neurogenetics, National Institute of Aging, National Institute of Health, Bethesda, MD, USA; 5) Department of Molecular Neuroscience, Institute of Neurology, University College London, London, UK; 6) Department of Neuroscience, University of Turin, Turin, Italy; 7) Department of Neuroscience, Mayo Clinic, Jacksonville, FL, USA.

Lewy body dementia (LBD) and frontotemporal dementia (FTD) are common complex neurodegenerative diseases with multifactorial etiologies. Familial cases of LBD and FTD suggest genetic predisposition for these diseases. Advances in whole genome sequencing technologies and computational resources have led us to initiate a genomic profiling study for large cohorts of LBD and FTD patients to identify new genetic risk loci associated with dementia and provide raw data to publicly accessible repositories upon production. Here, we report a summary for whole genome sequencing of 6,761 samples at a mean depth of 35.5x [range: 23.8-42.5x], including 2,112 LBD cases, 2,592 FTD cases and 2,057 matched controls. We also describe detailed demographics of control subjects with matched age greater than 60 years, neurological assessments, and/or histopathological negative features after autopsy examination within this resource for multiple potential study designs and analyses by the research community. Whole genome sequencing was completed by PCR-free DNA library preparation from mechanically sheared 1 microgram gDNA input, followed by single library, single lane clustering on the Illumina cBot2 and paired-end 150bp sequencing on the Illumina HiSeq X platform. Sample-level data was analyzed on the seqEngine pipeline using the HAS2 package with Isaac Aligner and Strelka Germline Variant Caller for alignment and variant calling. Analysis metrics for within- and cross-sample contamination, heterozygous/homozygous SNV ratio, sex chromosome SNV ratio and counts, identity by descent replicate assessment were applied for quality control sample-level filter, with a dropout rate of 1.67%. Sequencing results were clustered using 54 quality metrics to identify and correct technical bias in relationship with sample assembly site, library preparation date, sequencing data and additional processing factors, yielding negligible observed batch effects. Rare variation (MAF < 0.05) burden across cohorts from this workflow is ~9,000 mean variants per 0.5mb window, including ~120 mean exonic rare variants per 0.5mb window. Raw sequencing data will be assembled on a cloud storage instance for replicate primary and secondary analysis in advance of rapid sharing to dbGaP and other public repositories. We anticipate that access and analysis of this resource, in combination with additional data resources will accelerate the pace of genetic discovery within the dementia research field.

**1136F**

**Two Japanese familial cases of C9ALS/FTD complex in Fukuoka prefecture, Northern Kyushu Island, Japan.** *H. Furuya<sup>1</sup>, A. Watanabe<sup>2</sup>, N. Fujii<sup>2</sup>.* 1) Department of Neurology, Kochi Medical School, Kochi, Japan, Kochi, Japan; 2) Department of Neurology, Neuro-Muscular Center, NHO Omuta Hospital, Omuta, Fukuoka, Japan.

Amyotrophic Lateral Sclerosis (ALS) caused by expansion of (GGGGCC) repeats in *C9orf72(C9)* gene is extremely rare in Asian ethnic group including Japanese and its prevalence is almost 1/20 to 1/40 compared with caucasian. We had two familial Japanese C9ALS/FTD cases in Fukuoka prefecture, Northern Kyushu, Japan. Case 1. 56 years old male. He suffered character change and troubles in carrying his work three months before. Cerebral MRI image showed mild frontal lobe atrophy and cerebral blood flow SPECT revealed decreased cerebral blood flow in frontal area. After 1.5 years of onset, he showed dysphagia, muscle atrophy, weakness in extremities and bilateral pyramidal tract signs. He had under the control of mechanical ventilator due to severe respiratory failure. He died with empyema after 8 years from onset. Fronto-temporal cerebral atrophy progressed constant and he had diagnosed as bvFTD/ALS complexes. Gene analysis revealed expansion of repeats in *C9*. Case 2. 63 years old right-handed male noticed progressive motor aphasia and dementia. He was diagnosed as transcortical motor aphasia at age 64 and showed no neurological abnormality such as muscle weakness, parkinsonism or pyramidal tract sign except configuration apraxia. He had three sisters and one brother. His second sister died with early onset dementia and third sister suffered primary progressive dementia and epilepsy, his elderly brother suffered FTD with parkinsonism. All these members possessed expansion of repeats in *C9*. In Japan, C9ALS is rare, but it exists at a certain rate. Clinical phenotype differs in each cases.

**1137W**

**Reduced penetrance of *SOD1* p.Ala90Val mutation in Finnish ALS patients.** *L. Kuuluvainen<sup>1,2</sup>, K. Kaivola<sup>3</sup>, S. Mönkäre<sup>2,4</sup>, H. Laaksovirta<sup>3,5</sup>, M. Jokela<sup>6,7</sup>, S. Penttilä<sup>8</sup>, B. Udd<sup>6</sup>, M. Valori<sup>3</sup>, P. Pasanen<sup>4,8</sup>, A. Paetau<sup>9</sup>, J. Schleutker<sup>4,8</sup>, M. Pöyhönen<sup>1,2</sup>, L. Myllykangas<sup>2</sup>, P.J. Tienari<sup>3,5</sup>.* 1) Department of Clinical Genetics, Helsinki University Central Hospital, Helsinki, Finland; 2) Department of Medical Genetics, University of Helsinki, Helsinki, Finland; 3) Molecular Neurology, Research Programs Unit, University of Helsinki, Helsinki, Finland; 4) Turku University Hospital, Laboratory Division, Genetics and Saske, Department of Medical Genetics, Turku, Finland; 5) Department of Neurology, Helsinki University Hospital, Helsinki, Finland; 6) Neuromuscular Research Center, Tampere University Hospital and University of Tampere, Tampere, Finland; 7) Division of Clinical Neurosciences, Turku University Hospital and University of Turku, Turku, Finland; 8) Institute of Biomedicine, University of Turku, Turku, Finland; 9) Department of Pathology, University of Helsinki, Helsinki, Finland.

Superoxide dismutase 1 (*SOD1*) mutations are the second most common cause of familial amyotrophic lateral sclerosis (FALS) accounting for approximately 15-20% of FALS and approximately 1-2% of sporadic ALS. We examined the clinical and neuropathological phenotype of an ALS patient with the *SOD1* mutation c.269C>T, p.Ala90Val and analyzed its frequency and carriers' clinical characteristics in two ALS cohorts from Finland. The index patient was screened for mutations using whole exome sequencing. Two ALS cohorts were studied, Helsinki cohort (n=300) with whole genome sequencing data and Turku cohort (n=153) from samples sent to a diagnostic laboratory for *SOD1* sequencing. The mutation carriers' clinical data was examined from patient records. Allele-sharing analysis was conducted using single nucleotide polymorphism markers. Eight patients (1.8%) were found to carry the *SOD1* p.Ala90Val heterozygous mutation. Common clinical features included a long disease course and sensory neuropathy. Neuropathologically changes consistent with motor neuron disease without TDP43 pathology were observed. Allele-sharing analysis suggested a common founder. None of the patients had family history of ALS. All patients had additional potentially contributing variants in other genes. Lack of family history and finding other potentially contributing variants suggests the importance of oligogenic mechanisms for disease penetrance.

**1138T**

**Sequencing of the *GFAP* canonical transcript may not be suitable for the diagnosis of adult-onset Alexander disease.** *F. Vairo<sup>1</sup>, N. Bertsch<sup>2</sup>, E. Klee<sup>3</sup>, R. Gavrilova<sup>4</sup>.* 1) Center for Individualized Medicine, Mayo Clinic, Rochester, MN., USA; Department of Health Sciences Research, Mayo Clinic, Rochester, MN, USA; 2) Department of Clinical Genomics, Mayo Clinic, Rochester, MN, USA; 3) Center for Individualized Medicine, Mayo Clinic, Rochester, MN, USA; Department of Health Sciences Research, Mayo Clinic, Rochester, MN, USA; Department of Clinical Genomics, Mayo Clinic, Rochester, MN, USA; Department of Biomedical Informatics, Mayo Clinic, Rochester, MN, USA; 4) Center for Individualized Medicine, Mayo Clinic, Rochester, MN, USA; Department of Clinical Genomics, Mayo Clinic, Rochester, MN, USA; Department of Neurology, Mayo Clinic, Rochester, MN, USA.

Alexander disease (AD) is an autosomal dominant progressive leukoencephalopathy caused by heterozygous mutation in the glial fibrillary acidic protein (*GFAP*) gene. Based on the age at presentation, onset of symptoms can range from infancy to adulthood, with the infantile form being most common and the adult onset form accounting for one third of cases. The adult form is characterized by variable symptoms, most commonly bulbar, but also may present with pyramidal, cerebellar, dysautonomia, sleep disturbance, and seizures. The diagnosis is typically confirmed via Sanger sequencing of the *GFAP* gene, as 98% of the individuals have detectable single nucleotide or small indels pathogenic variants. Here, we report on an adult-onset case with radiographic features and positive pathological findings in an affected family member suggestive of Alexander disease, who had negative *GFAP* Sanger sequencing in a clinical/CLIA laboratory.

**1139F**

**Whole exome analyses discover risk factors for familial dystonia.** *R. Yadav<sup>1,2,3</sup>, C.T. Russo<sup>2</sup>, S. Bressman<sup>4</sup>, R. Rachel Saunders-Pullman<sup>4</sup>, K. Simon-yan<sup>5</sup>, M. Hutchinson<sup>6</sup>, A. Lang<sup>7</sup>, N. Sharma<sup>2</sup>, M.E. Talkowski<sup>1,2,3</sup>, L.J. Ozelius<sup>2</sup>.* 1) ) Center for Genomic Medicine, Massachusetts General Hospital, Boston, MA, USA; 2) Department of Neurology, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA; 3) Program in Medical and Population Genetics and Stanley Center for Psychiatric Research, Broad Institute, Cambridge, MA, USA; 4) Department of Neurology, Mount Sinai Beth Israel Medical Center, New York, NY, USA; 5) Department of Otolaryngology, Massachusetts Eye and Ear Infirmary, Boston, MA, USA; 6) Department of Neurology, St Vincent's University Hospital Dublin, Dublin, Ireland; 7) Division of Neurology, Toronto Western Hospital, Toronto, ON, Canada.

Dystonia is a heterogeneous group of neurological movement disorders characterized by sustained or intermittent muscle contractions causing abnormal, often repetitive, movements and/or postures. Both body regions affected and age of onset vary among the dystonia types. There is a significant genetic contribution to many forms of dystonia, though incomplete penetrance is a prominent feature that often confounds gene discovery efforts, particularly when using population-based references. Here, we sought to explore differences in coding variant burden between familial and sporadic forms of dystonia. We sequenced 554 individuals affected with various forms of dystonia of unknown etiology, as well as 49 unaffected family members. Sporadic cases represented 335 samples while 219 cases had a family history (FH) of dystonia. The FH cohort consisted of individuals from 39 multiplex pedigrees with two or more affected individuals sequenced. All variants were called using GATK haplotyp caller and Scalpel, followed by variant annotation and comparison of rare variants filtered by minor allele frequency < 0.001 in gnomAD, CADD score >20 and missense z-score >3.09 or if the variation is found in a gene with pLI score >0.9. Here we focus on the variant burden in FH positive (FH+) dystonia (219 cases, inclusive of 86 cases from 39 multiplex pedigrees). We observed pathogenic variants that segregated with dystonia in two genes, *ATP1A3* and *TUBB4A*, thus explaining 5% of FH+ dystonia in 39 multiplex families; no other known pathogenic variants were detected. In the remaining FH+ cases (n=133), multiple rare and predicted deleterious variants were observed in *previously defined* dystonia genes: *ATP1A3*, *ANO3*, *COL6A3*, *SGCE*, *TH*, *THAP1*, *CIZ1*, *PRRT2*, *PRKRA*, *TOR1* and *KMT2B*, accounting for an additional 17.7% of genetic risk of dystonia. In *ATP1A3*, R756H and T613M have both been previously identified as pathogenic and segregated with disease in the families. The *TUBB4A* variant (Q424H) segregated in a family with 5 affected members with isolated dystonia. *ANO3* variants S95L and V568D both segregated with disease. No other family members were available for testing the variants in *SGCE*, *THAP1*, *CIZ1* and *TOR1A* while segregation analysis in not-sequenced family members is in progress for variants in *PRRT2* and *KMT2B*. Genome wide association analysis for predicted deleterious variants in sporadic dystonia are ongoing with ancestry-matched controls from large population-based cohorts.

Shukla<sup>1</sup>.* 1) Department of Medical Genetics, Kasturba Medical College, Manipal Academy of Higher Education, Manipal, India; 2) Department of Paediatrics, Kasturba Medical College, Manipal Academy of Higher Education, Manipal, India; 3) Department of Paediatric Genetics, Amrita Institute of Medical Sciences, Kochi, India; 4) Division of Genetics, Mazumdar Shaw Medical Center, Narayana Health City, Bangalore, India; 5) Department of Paediatrics, Lady Hardinge Medical College, New Delhi, India; 6) Institute of Medical Genetics and Genomics, Sir Ganga Ram Hospital, New Delhi, India; 7) Department of Neurology, Kasturba Medical College, Mangalore, Manipal Academy of Higher Education, Manipal, India; 8) Department of Paediatrics, Postgraduate Institute of Medical Education and Research, Chandigarh, India; 9) Department of Paediatrics, Kasturba Medical College, Mangalore, Manipal Academy of Higher Education, Manipal, India; 10) Jaslok Hospital and Research Centre, Mumbai, India; 11) Department of Paediatrics, Indiana Hospital and Heart Institute, Mangalore, India; 12) First neuro hospital, Mangalore, India; 13) Department of Paediatrics, K.S.Hegde Hospital, NITTE University, Mangalore, India; 14) Department of Paediatrics, Manipal Hospitals, Bangalore, India; 15) Department of Paediatrics, Jawaharlal Nehru Medical College, Belgaum, India; 16) Department of Neonatology, Kasturba Medical College, Manipal Academy of Higher Education, Manipal, India.

Inherited white matter disorders can be subdivided into leukodystrophies and genetic leukoencephalopathies. Leukodystrophies involve primary defect in myelination whereas genetic leukoencephalopathies are caused due to secondary involvement of myelin. At present, variations in approximately 150 genes are known to cause inherited white matter disorders. Owing to the phenotypic and genetic heterogeneity of these conditions whole exome sequencing (WES) was employed as first line genetic testing. We recruited sixty-one individuals from fifty-six families with clinical and radiological profile suggestive of an inherited white matter disorder. Of these, thirty-eight were males and twenty-four were females. The age range was from new born to twenty-five years. Nine families (16.07%) presented with hypomyelination while other white matter pathologies were noted in the forty-seven remaining families (83.93%). WES was performed for index patients of fifty-two families and trio (index patient and parents) was performed for four families. Overall, final diagnosis was established for forty families (71.42%). A total of 38 pathogenic variants were identified in this study, of which 25 (65.78%) variants are novel. Four families (10%) were diagnosed with leukodystrophies and thirty-six families (90%) were diagnosed with genetic leukoencephalopathies. Among the genetic leukoencephalopathies were inborn errors of metabolism (n=17, 47.23%), mitochondrial encephalopathies (n=7, 19.45%), congenital muscular dystrophies (n=3, 8.34%) and other neurodegenerative disorders (n=9, 25%). Three novel leukoencephalopathies were identified along with the causative genes, *ISCA1*, *AIMP2* and *TFIP11*. Extremely rare conditions namely ribose 5-phosphate isomerase deficiency (MIM #608611), leukodystrophy, progressive, early childhood-onset (MIM #617762) and epileptic encephalopathy, early infantile, 35 (MIM #616647) were identified. Founder effect was noted on three instances including Multiple mitochondrial dysfunctions syndrome 5 (MIM# 617613), Aicardi-Goutieres syndrome 3 (MIM# 610329) and Maple syrup urine disease, type 1A (MIM# 248600). This is an ongoing study with the aim of further delineation of phenotypes and molecular mechanisms of inherited white matter abnormalities in the underrepresented Indian population. The study would help in definitive genetic counseling and prenatal diagnosis as a direct benefit for families with inherited white matter disorders.

**1141T****Proband-only exome sequencing in small families with late onset hereditary neuropathy.**

*M.K. Ndugga-Kabuye<sup>1</sup>, D.H. Chen<sup>2</sup>, K.G. Gwathmey<sup>3</sup>, M.O. Dorschner<sup>4</sup>, J. Wolff<sup>1</sup>, T.D. Bird<sup>1,2</sup>, W.H. Raskind<sup>1</sup>.* 1) Division of Medical Genetics, University of Washington, Seattle, WA; 2) Department of Neurology, University of Washington, Seattle, WA; 3) Department of Neurology, University of Virginia, Charlottesville, VA; 4) Center for Precision Diagnostics, University of Washington, Seattle, WA.

**Introduction:** The primary hereditary neuropathies demonstrate wide clinical and genetic heterogeneity with more than 100 genes implicated thus far. They include Charcot Marie Tooth (CMT) and the hereditary sensory and autonomic neuropathies (HSAN/HSN). Many patients remain undiagnosed even after molecular diagnostic testing for the most common etiologies. **Methods & Results:** We performed proband-only exome sequencing in three adults from three unrelated families with a clinical diagnosis of axonal neuropathy with symptom onset after the age of 50yo. All three individuals had prior negative multi-gene testing for neuropathy. We identified three novel variants in genes that are rare causes of autosomal dominant forms of hereditary neuropathy; *MARS* (p.Gly570Glu), *SPTLC1* (p.Gln47fs) and *ATL3* (c.510+1G>T). The *MARS* (p.Gly570Glu) variant had a CADD score of 27.3, a GERP score of 5.66 and was not present in gnomAD or ClinVar. The *SPTLC1* frameshift variant (p.Gln47fs) had an allele frequency of 1.792E-5 in gnomAD and is not in ClinVar. Through ClinVar we identified an additional affected patient with a *SPTLC1* (p.Leu344fs) frameshift variant and an axonal neuropathy with symptom onset after 50yo. The *ATL3* (c.510+1G>T) variant had a CADD score of 24.2, a GERP score of 5.14 and is not present in gnomAD or ClinVar. We confirmed all three candidate variants via Sanger sequencing. **Discussion:** *SPTLC1* encodes serine palmitoyltransferase 1, and is implicated in HSN1A (MIM # 162400). Our finding of two frameshift variants in *SPTLC1* lead us to propose that loss of function/haploinsufficiency can be a mechanism of disease in HSN1A. *ATL3* encodes GTPase Atlantin-3 and is implicated in HSN1F (MIM # 61563). The two previously implicated variants in HSN1F were missense variants. Splice site variants have not been reported in HSN1F. *MARS* encodes methionyl-tRNA synthetase and is implicated in CMT2U, (MIM # 616280). The three previously described pathogenic variants in *MARS* have also been missense variants. **Conclusions:** In four families with primary hereditary neuropathy with symptom onset after the age of 50 we report the first splice site variant in *ATL3* (c.510+1G>T), the first two frameshift variants in *SPTLC1* (p.Gln47fs & p.Leu344fs), and the fourth pathogenic variant in *MARS* (p.Gly570Glu). Proband-only exome sequencing can be an effective molecular diagnostic modality in late onset primary hereditary neuropathy.

**1142F**

**6-year-old girl with autism and *de novo* missense variant in *NECTIN3*.** J. Pappas<sup>1</sup>, R. Rabin<sup>1</sup>, R. Person<sup>2</sup>, J. Juusola<sup>2</sup>. 1) NYU School of Medicine, New York, NY; 2) GeneDx, Gaithersburg, MD.

The association of autism with *de novo* pathogenic variants has been established in hundreds of genes (Basu SN et al., 2009). We present a 6-year-old girl with autism and *de novo* missense variant in *NECTIN3* (previously known as *PVRL3*), a gene that has never been associated with autism in the medical literature. Our case was born full term 3 kg weight and 48 cm length to 21 year old primigravida without any complications. She was developing typically until about 30 months when her speech and social development arrested. Neurodevelopmental assessment diagnosed autism. Brain MRI, EEG and ophthalmology evaluations were normal. The parents were not consanguineous and they had four typically developing children after our patient. The clinical examination of our case at age 6 revealed no apparent malformations, growth at about the 20<sup>th</sup> centile for all anthropometrics and impulsive behaviors with loss of personal space and inappropriate laughter. Chromosome analysis, SNP microarray analysis using the Affymetrix Cytoscan HD platform and DNA methylation test for Angelman was reported normal. Trio exome sequencing analysis revealed the p.Arg503Gly (AGG>GGG): c.1507 A>G *de novo* novel variant in exon 6 in the *NECTIN3* (NM\_015480.2). This variant is not observed in gnomAD (Lek et al., 2016). It is a non-conservative amino acid substitution, likely to impact secondary protein structure as these residues differ in polarity, charge and size. In-silico analyses, including protein predictors and evolutionary conservation, support that this variant does not alter protein structure/function (MutationTaster, Schwarz JM et al., 2014). Our case introduces a possible association of *NECTIN3* and autism. The possible association is supported by the localization of *NECTIN3* in synapses. *NECTIN3* is an immunoglobulin-like protein that connects with afadin to actin cytoskeleton and organizes adherens junctions. The nectin-afadin system co-localizes with the cadherin-catenin system at synapses (Mizoguchi A et al., 2002). The possible association of *NECTIN3* and autism is also supported by the family reported by Sundaram SK et al., 2011. This 3-generation family studied by exome and included 7 individuals with Tourette syndrome. These 7 individuals had 4 novel nonsynonymous variants, one of the variants in *NECTIN3*; none of the unaffected in the family had all four variants. Additional cases may prompt functional studies and possible delineation of the role of *NECTIN3* in neurodevelopment.

**1143W**

**Evaluation of a 12 lysosomal storage disorder gene panel in a Parkinson's disease cohort.** L.J. Racacho<sup>1,2</sup>, D. Durie<sup>1,2</sup>, D.A. Grimes<sup>3,4</sup>, M. Schlossmacher<sup>3,4,5</sup>, D.E. Bulman<sup>1,2,5,6</sup>. 1) Children's Hospital of Eastern Ontario Research Institute, Ottawa, ON, Canada; 2) Newborn Screening Ontario, Ottawa, ON, Canada; 3) Division of Neurology, Ottawa Hospital, Ottawa, ON, Canada; 4) Neuroscience Program, Ottawa Hospital Research Institute, Ottawa, ON, Canada; 5) Department of Cellular and Molecular Medicine, Faculty of Medicine, University of Ottawa, Ottawa, ON, Canada; 6) Department of Pediatrics, Faculty of Medicine, University of Ottawa, Ottawa, ON, Canada.

A genetic link between Parkinson's disease (PD) and Gaucher's disease (GD) across various ethnic populations have provided valuable insight on lysosome pathology in PD. GD is an autosomal recessive condition caused by mutations in the beta-glucocerebrosidase gene (*GBA*) which lead to either the reduction or elimination of enzymatic activity. Carriers of *GBA* mutations have an increased risk of developing PD. The extent of rare variant burden in other lysosomal storage disorder genes for PD is largely unknown. As part of an evaluation process for a diagnostic test of lysosomal storage disorders, we implemented the Accel-Amplicon NGS Panel for 12 classical lysosomal storage disorder genes, *ABCD1*, *ARSB*, *GAA*, *GALC*, *GALNS*, *GBA*, *GLA*, *GLB1*, *GUSB*, *IDS*, *IDUA* and *SMPD1* to assess rare variant burden in 223 individuals diagnosed with idiopathic PD. The one tube solution which incorporates both PCR-based enrichment and dual-barcoded library construction provided a quick and adaptable solution to work within our clinical setting. In our preliminary assessment of *GBA*, we found that missense variants p.(Asp365Lys) and p.(Thr408Met) were detected at allele frequencies of 4.26% and 1.12%, respectively. Previous reports have shown that these variants reduce beta-glucocerebrosidase activity in carriers and are classified as risk alleles for PD.

**1144T**

**DMD gene specific shorter dystrophin isoform's (Dp140) association to the working memory: A novel IBLT strategy based validation.** R. Tyagi<sup>1</sup>, P. Aggarwal<sup>2</sup>, M. Mohanty<sup>2</sup>, V. Dutt<sup>2</sup>, A. Anand<sup>3</sup>. 1) Neuroscience Research Lab, Department of Neurology, Post Graduate Institute of Medical Education and Research, Chandigarh, India; 2) Indian Institute of Technology, Mandi, Himachal Pradesh, India; 3) Department of Neurosurgery, Postgraduate Institute of Medical Education and Research, Chandigarh, India.

**Introduction:** *DMD*, the largest gene in the human genome; encoding the dystrophin protein, is associated with a fatal neuromuscular disorder, Duchenne Muscular Dystrophy. Majorly, deletions and duplications are involved in the pathogenesis of DMD. Along with progressive muscle wasting, DMD has also been associated with cognitive and neuropsychological abnormalities specifically due to brain-specific shorter dystrophin isoforms. **Methodology:** A total of 100 DMD subjects were recruited for identification of the spectrum of pathogenic variants in *DMD* gene. PCR based Multiplex Ligation-dependent probe amplification was performed to detect deletions and duplications. The absence of short dystrophin isoform, Dp140 termed as Dp140 -ve, was predicted based on variant location. General Intelligence was assessed by Malin's Intelligence Scale for Indian Children. Verbal, working memory, and executive functioning were assessed by RAVLT, Digit Span, and Stroop color and word task; respectively. A novel computational strategy based on Instance Based Learning Theory (IBLT) was adopted on Adaptive Control of Thought-Rational cognitive architecture to model human performance. **Result:** Eighty out of 100 DMD subjects harbored deletion (72%) or duplication (8%), out of which 64 were predicted for the absence of Dp140 isoform. Five cases were found to have mild (4/5) and moderate (1/5) mental retardation; and *DMD* variants in these cases were predicted to affect Dp140 isoform. Assessment of cognitive and neuropsychological profiles of the Dp140-ve group revealed alterations in general intelligence, verbal and visual memory, executive functioning. When Dp140 +ve and Dp140 -ve group were compared with control group, Dp140 -ve group performed worse in RAVLT Trial-1 ( $p=0.048$ ), Trial-5 ( $p=0.024$ ), learning capacity ( $p=0.046$ ), immediate recall ( $p=0.031$ ), delayed recall ( $p=0.012$ ), commission ( $p=0.018$ ), LTPR ( $p=0.016$ ), RAVLT-Memory Efficiency Index ( $p=0.007$ ), all measures of stroop task and digit span task. IBLT based modeling revealed DMD groups' non-reliance to recency indicating poor working memory capacity, and lower activation of instance retrieval resulted in increased response time. **Conclusion:** Working memory was found to be affected in the DMD and its association with Dp140 isoform was observed. Modeling strategies can be devised to understand dynamic decision processes. Interventions to improve the working memory may be used as a management of cognitive alterations.

**Depletion of the mRNA export factor GANP underlies axonal neuropathy and intellectual disability.** R. Woldegebriel<sup>1</sup>, E. Ylikallio<sup>1,2</sup>, M. Sainio<sup>1</sup>, L. Mäenpää<sup>1</sup>, C. Bonnemann<sup>3</sup>, S. Donkersvoort<sup>4</sup>, D. Bharucha-Goebel<sup>5</sup>, M. Walsh<sup>4</sup>, Z. Stark<sup>6</sup>, M.-J. van den Boogaard<sup>6</sup>, P. Isohanni<sup>1,6</sup>, T. Lönnqvist<sup>6</sup>, H. Tyynismaa<sup>1,7</sup>. 1) Research Programs Unit, Molecular Neurology, University of Helsinki, Helsinki, Finland; 2) Clinical Neurosciences, Neurology, University of Helsinki and Helsinki University Hospital, Helsinki, Finland; 3) Neuromuscular and Neurogenetic Disorders of Childhood Section, National Institute of Neurological Disorders and Stroke, National Institutes of Health, Bethesda, USA; 4) Murdoch Children's Research Institute, Victoria, Australia; 5) Department of Medical Genetics, University Medical Center Utrecht, Utrecht, The Netherlands; 6) Department of Child Neurology, Children's Hospital and Pediatric Research Center, University of Helsinki and Helsinki University Hospital, Helsinki, Finland; 7) Department of Medical and Clinical Genetics, University of Helsinki, Helsinki, Finland.

Nuclear mRNA export defects have been recognized as an important cause of human diseases from cancer to neurological disease. We recently identified a new recessive disease gene *MCM3AP* to underlie early-onset axonal neuropathy and mild intellectual disability in patients from five families. Others reported three more families with a similar phenotype and biallelic *MCM3AP* variants. *MCM3AP*-related neuropathy is axonal and predominantly motor, with less pronounced sensory findings. The disease is progressive leading to loss of ambulation in childhood, or in milder cases progression is slower and ambulation is preserved in early adulthood. The most consistent additional finding is intellectual disability. *MCM3AP* encodes for the nuclear mRNA export factor GANP (germinal associated nuclear protein), which forms a scaffold for proteins of the TRanscription-EXport-2 (TREX-2) complex in the nuclear envelope, with a proposed role in exporting selective mature mRNAs from the nucleus or in regulating export of stress-related transcripts. The identified homozygous *MCM3AP* variants all cluster in the Sac3 (suppressor of actin) domain, which is implicated in mRNA binding, whereas the compound heterozygous mutations are mostly located outside the Sac3 domain. Early onset and severe disease course is more typical for the compound heterozygous mutations, whereas a more benign disease associates with the homozygous Sac3 mutations. We studied skin fibroblasts of patients who had *MCM3AP* mutations outside the Sac3 domain, and found a marked reduction in GANP immunostaining in the nuclear envelope and by Western blotting. Ultra-deep mRNA sequencing of fibroblasts from five patients confirmed *MCM3AP* depletion on transcriptional level and identified common differentially expressed genes. Our results suggest that defective mRNA binding as well as an overall severe reduction in GANP protein may compromise mRNA export as the pathogenic mechanism. Using cultured motor neurons differentiated from human induced pluripotent stem cells, we showed that GANP is a nuclear envelope protein also in neurons. Our current efforts are focused on understanding the role of GANP in nuclear-cytoplasmic mRNA transport in patient-specific motor neuron models.

**A novel *ABCD1* gene mutation unveil a Colombian female carrier with adrenomyeloneuropathy and a family history of adrenoleukodystrophy.** F. Suarez, M. Manotas, A. Marroquin, R. Quero, A. Paredes. Pontificia Universidad Javeriana, Bogotá D.C., Colombia.

X-linked Adrenoleukodystrophy (X-ALD [MIM 300100]) is the most prevalent peroxisomal disorder in hemizygous males occasionally causes neurological symptoms in female carriers. This disorder is caused by mutations of the *ABCD1* gene located at Xq28 which encodes for the peroxisomal membrane protein ALDP, an essential transmembrane transporter of very long-chain fatty acids (VLCFA>22). Thus, when defective leads to elevated VLCFA levels in plasma and tissues, causing a broad clinical spectrum. In males, it manifests as adrenocortical insufficiency, myelopathy and cerebral demyelination, whereas in female carriers it presents as adrenomyeloneuropathy with heterogeneous severity, ranging from mild hyperreflexia and impaired vibration perception to severe spastic paraparesis. Although elevated VLCFA concentrations in plasma suggests the disease, up to 15% of female carriers can have normal VLCFA levels, and therefore *ABCD1* gene mutational analysis should be executed for confirmation. Our aim is to report a novel mutation associated with the disease in a female carrier with a familial history of X-ALD. We present the case of a 51-year-old female with a six-year history of weakness, spasticity, frequent falls and urinary incontinence who presented to genetics clinic with worsening symptoms. She was previously assessed by neurology under the suspicion of tropical spastic paraparesis, but all infectious etiologies were discarded as well as optic neuromyelitis. Given the negative work up, a demyelinating disease was suspected. Biochemical parameters were evaluated, showing abnormal VLCFA quantification, with increased C26:0 levels and C24:C22 ratio and suggesting a carrier state for X-ALD. In a second interview, she reported a positive family history of her father, who was diagnosed with multiple sclerosis for similar symptoms. Moreover, a cousin on her father's side had amyotrophic lateral sclerosis (ELA) and her nephew died at the age of 22, with a clinical diagnosis of X-ALD and a *ABCD1* mutational analysis showing an uncertain significance variant (VUS), c.2002A>G (p.Thr668Ala). Thereafter we evaluated our patient and found she was heterozygous for the same mutation and with current mutational analyzes, this variant is predicted to disease causing. This case exhibit the first time this variant is found in a patient with the disease phenotype and underlines the relevance of evaluating the family history in women presenting with neurological symptoms.

***CYP2C9* alleles are associated with patient-centered prescribing outcomes in a real-world patient population undergoing phenytoin treatment.** A.E. Fohner, K.K. Thai, D. Ranatunga, A.T. Jelanian, B.L. Lawson, V.X. Liu, C.A. Schaefer. 1) Division of Research, Kaiser Permanente Northern California, Oakland, CA; 2) Department of Neurology, Kaiser Permanente Northern California, Walnut Creek, CA.

Phenytoin is an anticonvulsant medication prescribed > 4million times each year. The Clinical Pharmacogenetics Implementation Consortium recommends lowering phenytoin dose in patients with reduced function *cytochrome P450 2C9* (*CYP2C9*) alleles due to increased risk for side effects. However, the presumed benefits of this recommendation have not been tested in a large real-world healthcare setting, where we hypothesized that reduced function *CYP2C9* alleles would be associated with increased side effects and decreased medication adherence. We identified 1070 members of a large, integrated healthcare delivery system in Northern California who filled an outpatient phenytoin prescription between 1/1/1996 and 8/31/2017 and who had *CYP2C9* genotyping. From the electronic health record, we extracted patient demographics, phenytoin utilization, and phenytoin blood concentration test results. We categorized patients into whether or not they had at least one reduced function *CYP2C9* allele (\*2, \*3, \*5, \*8, \*11, and \*12). We calculated medication adherence using an algorithm validated in a diverse patient population. We performed chart reviews on 413 patients to identify side effects within the first 100 days of treatment that were attributed to phenytoin. Our cohort was 48% male, 83% White, 4% Asian, 5% Black, and 7% Hispanic. It included 22,122 phenytoin prescriptions and 10,245 blood test results. We identified 340 (32%) patients with, and 730 (68%) patients without, reduced function *CYP2C9* alleles. Patients with reduced function alleles had higher phenytoin blood concentrations at their first test (mean 12.7 +/- 7.3) compared to those without (9.22 +/- 5.3; p-value < 0.001). Adjusting for age, gender, and race/ethnicity, patients with reduced function alleles were more likely to have poor medication adherence [odds ratio (OR) 1.66; 95% confidence interval (CI) 1.14–2.40; p-value 0.008], and a shorter time to discontinuing phenytoin (hazard ratio 1.28; 95% CI 1.07–1.52; p-value 0.007), compared to patients without reduced function alleles. Among those with chart reviews, patients with reduced function alleles were not more likely to have recorded side effects (p=0.16). Patients with reduced function *CYP2C9* alleles may have more, non-severe side effects due to higher blood concentrations, which could decrease medication adherence. Using genetic information to guide medication dose and choice could improve patient-centered prescribing outcomes and treatment efficacy.

**Major intra-familial phenotypic heterogeneity and incomplete penetrance due to a CACNA1A pathogenic variant.** J. Van Gils<sup>1</sup>, C. Angelini<sup>1</sup>, P.S. Jouk<sup>2</sup>, D. Lacombe<sup>3</sup>, S. Moutton<sup>3</sup>, F. Riant<sup>3</sup>, G. Sole<sup>4</sup>, E. Tourmier-Lasserve<sup>5</sup>, A. Trimouille<sup>6</sup>, M. Vincent<sup>6</sup>, C. Goizet<sup>1,6</sup>. 1) Service de Génétique Médicale, CHU Bordeaux and Laboratoire MRGM, INSERM U1211, Univ. Bordeaux, Bordeaux, France; 2) Service de génétique médicale, Dijon, France; 3) Service de génétique moléculaire, Hôpital Lariboisière, Paris, France; 4) Service de neurologie médicale, Bordeaux, France; 5) Service de génétique moléculaire - Lariboisière, Paris, France; 6) Centre de référence neurogénétique, Service de génétique médicale, Bordeaux, France; 7) Service de génétique médicale, CHU de Grenoble; 8) Service de génétique médicale, CHU de Nantes.

The CACNA1A gene encodes a calcium-dependent voltage channel, localized in neuronal cells. Pathogenic variants in this gene are known to lead to a broad clinical spectrum including episodic ataxia type 2, spinocerebellar ataxia type 6, familial hemiplegic migraine, and more recently epileptic encephalopathy. We report a large family revealing dramatic variability of neurological manifestations associated with a CACNA1A missense pathogenic variant. The index case had early-onset epileptic encephalopathy with progressive cerebellar atrophy, although his mother and his great-grandmother suffered from paroxysmic episodic ataxia. His grandfather and great-grand-aunt reported no symptoms, but two of her sons displayed early-onset ataxia with intellectual disability. Two of her little daughters suffered from gait disorders, and also from epilepsy for one of them. All these relatives were carriers of the previously described heterozygous variant c.835C>T, p.(Arg279Cys) in CACNA1A (NM\_023035.2). Pathogenic variants in CACNA1A may lead to several different phenotypes, including severe epileptic encephalopathy which was only recently described. We report here the first family leading to major clinical variability and incomplete penetrance. Our family highlights the difficulties to provide accurate genetic counselling concerning prenatal diagnosis regarding highly variable severity of the clinical presentation.

**Usefulness of whole exome sequencing: De novo PURA gene pathogenic variant.** E.M. Albino<sup>1</sup>, J.F. Munoz-Bibiloni<sup>2</sup>, I.M. Gracia-Vega<sup>3</sup>, F. Velez<sup>4,5</sup>, S. Carlo<sup>6,7</sup>, A. Santiago-Cornier<sup>8,9</sup>. 1) School of Health Professions, Medical Sciences Campus, University of Puerto Rico, San Juan, PR; 2) Pediatric Neurology Section, San Jorge Children's Hospital, San Juan, PR; 3) Medical Technology Program, School of Health Professions, Medical Sciences Campus, University of Puerto Rico, San Juan, PR; 4) Genetics Division, Stanford University, Palo Alto, CA; 5) Department of Pediatrics, San Juan City Hospital, San Juan, PR; 6) Genetic Section, San Jorge Children's Hospital, San Juan, PR; 7) Department of Biomedical Sciences, Ponce Health Sciences University, Ponce, PR; 8) Department of Public Health, Ponce Health Sciences University, Ponce, PR; 9) Department of Pediatrics, Universidad Central del Caribe School of Medicine, Bayamon, PR.

GAL was referred to Genetics at 8 ½ months of age due to hypotonia and undescended testes. The infant had significant hypotonia and gross/fine motor delay at the time. Complete metabolic evaluations with a chromosomal microarray were normal. At 10 months of age the infant developed infantile spasms. Brain MRI showed non-specific bilateral white matter hypomyelination. Infantile spasms were improved with antiepileptics by 18 months of age. Whole exome sequencing was requested and a novel pathogenic variant was identified at the PURA gene, c.615\_625 del (p.Ile206Argfs\*84). Myoclonic and focal onset seizures have persisted but other seizure types, such as generalized tonic-clonic, tonic or atonic, can also occur. The PURA gene encodes Pur-alpha, a 322 amino acid protein with repeated nucleic acid binding domains that are highly conserved from bacteria through humans. Pur-alpha is a protein that binds specific DNA and RNA sequence elements. Human PURA, located at chromosome band 5q31, is under complex control of three promoters. The entire protein coding sequence of PURA is contiguous within a single exon. The C.615\_625 del is a frameshift mutation located in exon 1 of the PURA gene. Other frameshift variants, which occur before and after this patient's variant, have been described in the medical literature as pathogenic and some of these results in similar frameshifts with early termination of the protein at the same residue. In neurons, Pura accompanies mRNA transcripts to sites of translation in dendrites. At 4 years of age, GAL has improved truncal stability, is able to roll over and sit on his own but without speech. The frameshift mutation described is consistent with a severe neuro-developmental phenotype that features hypotonia, and gross psychomotor delay with intractable seizures. The Pura protein is especially important for normal brain development. Mutations in PURA gene should be part of the genetic evaluation of infants with profound hypotonia, epileptic encephalopathy and intellectual disability. Study this de novo mutation is an important step toward the clinical and molecular characterization of this disease that has been associated with significant neurological outcome. While targeted gene panels are indicated for analyzing specific mutations, whole exome sequencing was an excellent approach in this case due to the spectrum of neurological manifestations.

**1150T*****MAPT* p.V363I mutation is a rare cause of corticobasal degeneration.**

S. Ahmed<sup>1,2</sup>, A. Pantelyat<sup>6</sup>, A. Butala<sup>3</sup>, M.S. Sabir<sup>2</sup>, L. Ispierto<sup>5</sup>, E. Gelpi<sup>4</sup>, P. Pastor<sup>6</sup>, S.W. Scholz<sup>2,3</sup>. 1) Laboratory of Neurogenetics, National Institutes on Aging, National Institutes of Health, Bethesda, USA; 2) Neurodegenerative Disease Research Unit, National Institute of Neurological Disorders and Strokes, National Institutes of Health, Bethesda, USA; 3) Department of Neurology, Johns Hopkins University Medical Center, Baltimore, Maryland, USA; 4) Neurological Tissue Bank, University of Barcelona-Hospital Clinic, IDIBAPS, 08036 Barcelona, Spain; 5) Neurology Service, Hospital Universitari Germans Trias, Pujol, Badalona, Spain; 6) Neurogenetics Laboratory, Division of Neurosciences, Center for Applied Medical Research, University of Navarra School of Medicine, Pamplona, Spain.

**Background:** Corticobasal degeneration (CBD) is a neurodegenerative tauopathy that presents with heterogeneous clinical features, including asymmetric parkinsonism, dyspraxia, aphasia and cognitive impairment. The genetics of CBD is poorly understood, but few reports exist linking mutations and risk variants in *MAPT* to this rare disease. **Methods:** We performed a genetic evaluation of patients with corticobasal syndrome (CBS) using the NeuroChip Illumina genotyping array followed by validation using Sanger sequencing. **Results:** We identified two patients who were heterozygous for the rare c.1087G>A (p.V363I) mutation in the highly conserved C-terminal region of *MAPT*. *In silico* pathogenicity predictions indicated that this variant is disease-causing, but literature review of previously reported cases was inconclusive. One of the two patients in our cohort was pathologically confirmed and demonstrated 4-repeat tau inclusions consistent with CBD. **Conclusion:** Our report describes two new CBS cases carrying the rare p.V363I *MAPT* mutation, one of which was pathologically confirmed. Taken together, our findings support the notion that this rare missense mutation is pathogenic.

**1151F****Chemical suppressors of nonsense mutations as potential treatment for**

**NGLY1-related disorder.** A. Baradaran-Heravi<sup>1</sup>, A. Balgi<sup>1</sup>, F. Shidmoosavee<sup>2</sup>, J. Tan<sup>2</sup>, J. Jaquith<sup>2</sup>, M. Roberge<sup>1</sup>. 1) University of British Columbia, Vancouver, British Columbia, Canada; 2) The Centre for Drug Research and Development, 2405 Westbrook Mall, Vancouver, British Columbia, Canada.

NGLY1-related disorder is a rare autosomal recessive disease characterized by developmental delay and neurological, hepatic and ophthalmological findings. It is associated with biallelic loss-of-function mutations in *NGLY1*, which encodes an enzyme, N-glycanase 1, involved in deglycosylation of glycoproteins, an essential step in the endoplasmic reticulum associated degradation (ERAD) pathway. Currently, there is no treatment for this disease. Nonsense mutations in *NGLY1* are the most frequent type of mutations in this disease. These mutations change an amino acid codon to a premature termination codon (PTC), resulting in truncated and non-functional protein. High concentrations of aminoglycosides can restore gene function by eliciting PTC readthrough but with low efficiency. We have recently identified an aminoglycoside that is a more potent PTC readthrough inducer than other currently known aminoglycosides. Also, using a yeast high-throughput screen, we have identified a class of compounds that potentiate PTC readthrough by aminoglycosides in mammalian cells. To assess PTC readthrough of *NGLY1* nonsense mutations, we generated HEK-293 cells stably expressing various *NGLY1* nonsense mutations. The aminoglycoside alone at high concentration induced barely detectable N-glycanase 1 production. However, combination of a low concentration of this aminoglycoside with an enhancer significantly increased PTC readthrough at most *NGLY1* nonsense mutations. This combination could also induce PTC readthrough at a *NGLY1* nonsense mutation in fibroblasts derived from a patient with *NGLY1* deficiency. Whether the newly synthesized N-glycanase 1 is enzymatically active remains to be elucidated. These findings open up the possibility of treating a subset of patients with *NGLY1* deficiency caused by nonsense mutations.

**Genetic study of patients with lipoid proteinosis, a disease of medial temporal lobe calcification and skin manifestations.** S. Geiler<sup>1</sup>, L. Yousefian<sup>1</sup>, S. Pajouhanfar<sup>1</sup>, AH. Saeidian<sup>1</sup>, M. Daneshpazhooh<sup>2</sup>, H. Mahmoudi<sup>2</sup>, S. Sotoudeh<sup>2</sup>, P. Mansouri<sup>2</sup>, P. Petramfar<sup>1</sup>, S. Zeinali<sup>3</sup>, J. Uitto<sup>1</sup>, H. Vahidnezhad<sup>1,3</sup>. 1) Thomas Jefferson University, Philadelphia, PA, USA; 2) Tehran University of Medical Sciences, Tehran, Iran; 3) Pasteur Institute of Iran, Tehran, Iran.

Lipoid proteinosis (LP, [OMIM #247100]), also known as Urbach-Wiethe disease, is a rare monogenic multisystemic disorder. Approximately, 250 LP cases exist worldwide. LP manifestations are a consequence of pathogenic mutations in the *ECM1* gene. A primary phenotypic presentation of this disorder is deposition of hyaline-like material in various tissues. In addition, there are medial temporal lobe calcifications which typically manifest within the: amygdalae, hippocampi, hippocampal gyrus and basal ganglia. We analyzed DNA from 18 unrelated families including 27 patients, which were referred to our study through their primary care physician or dermatologist. Prior to genomic analysis, we obtained informed consent, patient and family history, and a blood sample from each patient. Neurological imaging (e.g. CT scan) was utilized to determine if medial temporal lobe calcifications were present. The DNA was extracted from the blood samples and subjected to mutation analysis with PCR and Sanger sequencing. Within our cohort, we identified four previously reported mutations and three novel mutations in *ECM1*. The two primary recurrent mutations were *ECM1*: NM\_004425: c.735\_736delTG, p.C245\* and c.507delT, p.R171Gfs\*7 which were present in 10 unrelated families with a total of 13 patients. Within our cohort we observed a vast spectrum of neuropsychiatric symptoms and disorders. Specifically, we noted the following neuropsychiatric symptoms: epilepsy, hallucinations, memory deficit, mental retardation, social isolation, depression and others. With the continuous acquisition of LP patients we will monitor and assess for intracranial calcifications through imaging techniques. Identifying calcifications and neuropsychiatric symptoms may improve diagnostics and treatment of neuropsychiatric disorders within the LP community. In a holistic sense, addressing the neuropsychiatric phenotype of LP patients will provide a deeper comprehension of neuropsychiatric function that may be applied to the greater population.

**The adult forms of neuronal ceroid lipofuscinoses (ANCLs)** remain the least understood among NCLs. Clinically, they are characterized by progressive dementia and/or epilepsy with cognitive decline and behavioural changes. The hallmark of ANCLs is accumulation of ceroid in brain tissue leading to loss of neurons and neurodegeneration. Genetically, ANCLs can be caused by mutations in following genes: *CLN6*, *CTSF*, *GRN*, *CLN1*, *CLN5*, *ATP13A2* and *DNAJC5*, which remains the only known dominant gene for ANCL. Within the frame of genetic studies of **the Adult NCL Gene Discovery Consortium** we performed exome sequencing in 22 families and sporadic cases evaluated as suspect to have ANCL based on clinico-pathological criteria defined by The Consortium. Up to now we confirmed ANCL diagnosis using exome sequencing in combination with Sanger and targeted resequencing in one Canadian family with autosomal dominant (AD) form of ANCL (*DNAJC5*, p.Y120YCCCLCCFN). We further defined genetic lesions in two cases resulting in an alternate diagnosis, namely one sporadic Italian case (**C19ORF12**, compound heterozygous mutations – neurodegeneration with brain iron accumulation, NBIA-4) and one large Belgian family with AD inheritance and heterogeneous neuropsychiatric phenotype (*C9ORF72* hexanucleotide repeat expansion – fronto-temporal dementia). With this respect we analysed and excluded the *C9ORF72* expansion in additional dominant cases from our study cohort. The annotated exome data set of our study cohort provided a list of highly suggestive candidate variants of unknown significance in functionally relevant genes – *CLN6*, *NPC1*, *GRN*, *CYP27A1*, *SPG11*. Our results demonstrate a poor correlation of primary diagnosis with defined genetic lesions in our probands. This is due to the rarity and heterogeneity in phenotype of ANCLs and neurodegenerative diseases in young adults in general. The correct evaluation of ceroid in tissue samples by pathologists is challenging and needs extensive experie.

**Pathogenic missense variants in the histone acetyltransferase complex component gene *TRRAP* cause autism and syndromic intellectual disability.** S. Ehresmann<sup>1</sup>, B. Cogné<sup>2,3</sup>, E. Beaugerard-Lacroix<sup>1</sup>, J. Rousseau<sup>1</sup>, T. Besnard<sup>2,3</sup>, T. Garcia<sup>1</sup>, S. Petroski<sup>4,5</sup>, S. Küry<sup>2,3</sup>, P.M. Campeau<sup>1,6</sup>, *TRRAP Consortium, CAUSES Study, Deciphering Developmental Disorder Study.* 1) CHU Sainte Justine, Université de Montréal, Montreal, Québec, Canada; 2) CHU Nantes, Service de Génétique Médicale, 9 quai Moncoussu, Nantes, France; 3) l'Institut du Thorax, INSERM, CNRS, UNIV Nantes, 44007 Nantes, France; 4) Department of Medicine, The University of Melbourne, Melbourne, Australia; 5) AstraZeneca Centre for Genomics Research, Precision Medicine and Genomics, IMED Biotech Unit, AstraZeneca, Cambridge, UK; 6) Department of Pediatrics, University of Montreal, Montreal, QC H3T1J4, Canada.

Acetylation of the lysine residues in histones and other DNA-binding proteins play a major role in regulation of eukaryotic gene expression. Regulation of this process is controlled by histone acetyltransferases (HATs/KATs) found in multiprotein complexes that are recruited to chromatin by the scaffolding subunit TRansformation/tRanscription domain Associated Protein (*TRRAP*). *TRRAP* is evolutionarily conserved and is among the top five genes intolerant to missense variation. Through an international collaboration, 17 distinct de novo or apparently de novo variants were identified in *TRRAP* in 24 individuals. A strong genotype-phenotype correlation was observed with two distinct clinical spectra. The first is a complex, multi-systemic syndrome characterized by a wide range of intellectual functioning, including a number of individuals with intellectual disability (ID) and markedly impaired basic life functions and associated with various malformations of the brain, heart, kidneys, and genitourinary system. Individuals with this phenotype had missense variants clustering around the c.3127G>A p.(Ala1043Thr) variant identified in five individuals. The second spectrum manifested with autism spectrum disorder and/or ID and epilepsy. RNA sequencing analysis on affected individual-derived skin fibroblasts showed significant changes in expression of several genes implicated in neuronal function and ion transport. Importantly, we confirmed by quantitative PCR the upregulation expression of the potassium ion transporters *KCNJ8* and *ABCC9*, known to be involved in Cantú syndrome, with which there is some minimal phenotypic overlap. Thus, we describe here the clinical spectrum associated with *TRRAP* variants and suggest dysregulated ion transporters expression as part of the pathophysiology driving the disease.

Jenkins Department of Biophysics, Johns Hopkins University, Baltimore, MD; 9) Department of Biology, Johns Hopkins University, Baltimore, MD; 10) Faculty of Medicine, University of Iceland, Reykjavik, Iceland; 11) Landspítali University Hospital, Reykjavik, Iceland.

Variants in components of the epigenetic machinery have been implicated in many types of intellectual disability. Our group recently identified the chromatin remodeler, *CHD1*, as a cause of autism, speech apraxia, and developmental delay. *CHD1* is an ATP-dependent chromatin remodeler protein, which reorganizes DNA structure by sliding nucleosomes along the DNA. In previous work, we described six female patients with autism, speech apraxia, developmental delay, and facial dysmorphism harboring heterozygous missense variants in *CHD1*. We previously hypothesized a potential dominant negative mechanism of disease, considering the absence of neurological features in a patient with a copy number variant at the *CHD1* locus, although another possible mechanism could be haploinsufficiency with decreased penetrance. Here we report on four additional patients with variants in *CHD1*, two of which do not harbor missense changes. Patient 1 is a 3-year-old male who has limited expressive speech, daily seizures and autistic type behaviors. He harbors a missense variant (p.R827C) in a possible protein-protein interaction region of *CHD1*. Patient 2 is a 17-year-old male with a diagnosis of autism spectrum disorder and speech apraxia. Interestingly, this patient harbors a *de novo* frameshift variant in *CHD1* which is predicted to be haploinsufficient due to a premature stop codon. Alternatively, there may be incomplete activation of the nonsense mediated decay cascade, resulting in a truncated protein. Patient 3 is a 2-year-9-month old male who displays gross motor and expressive speech delay, macrocephaly, stereotypic behaviors, and minor dysmorphic features. This patient harbors a *de novo* single base substitution at the beginning of intron 16. Although this is not a coding variant, it is predicted to affect splicing, which could lead to an altered protein. Patient 4 is a female presenting with developmental delay, intellectual disability, and macrocephaly. She carries a missense variant (p.R568K) in a region of *CHD1* which may be an indirect stabilizer for DNA binding. In conclusion, we describe four additional patients with Pilarowski-Bjornsson syndrome, all of which demonstrate speech apraxia or delay and autism or autistic type behaviors. These data support the hypothesis that Pilarowski-Bjornsson syndrome leads to disease phenotypes through a haploinsufficiency type mechanism and is a genetically determined cause of expressive speech apraxia and autism.

**1156T**

**Expanding the phenotype and recommendations for management in *KMT5B*-associated neurodevelopmental disorder.** S. Sheppard<sup>1</sup>, A. Vitobello<sup>2</sup>, D. Li<sup>1</sup>, H. Hakonarson<sup>1</sup>, E. Bhoji<sup>1</sup>, *KMT5B Consortium*. 1) Children's Hospital of Philadelphia, Philadelphia, PA; 2) Université de Bourgogne-Franche Comté, France.

Heterozygous mutations in *KMT5B*, a histone methyltransferase, cause an autosomal dominant neurodevelopmental disorder that has been described in eleven patients (Stessman et al *Nature Genetics* 2017, Faundes et al *Am J of Hum Genet* 2018). The initial publications have focused on the neurodevelopmental phenotype of these patients. We present a case series of 12 additional patients to further characterize non-neurodevelopmental features of this new syndrome and make recommendations for management. Similar to what was published, the most common feature in our cohort was developmental delay, ranging from mild speech delay with near normal cognitive function to severe global developmental delay. In terms of growth parameters, the majority of the patients have small stature and macrocephaly. There does not seem that there is an easily recognizable facial gestalt associated with this syndrome. About half carry an autism spectrum disorder diagnosis, have hypotonia, and seizures. Multiple patients had GU abnormalities (hypospadias, nephrolithiasis, hydronephrosis with ureterocele, and small kidneys) and GI issues (mostly feeding difficulties ranging from TPN dependence; difficulty swallowing; gastroparesis). Ophthalmologic findings were present in the majority of patients and included hypermetropia, astigmatism, strabismus, and megalocornea. Craniofacial anomalies included craniosynostosis and cleft palate. Dermatologic findings included café au lait spots, hemangioma, and acanthosis nigricans. Cardiac issues included congenital heart disease (VSD, PDA, ASD) and dysautonomia. Finally, there also is musculoskeletal involvement including slight body asymmetry, slight pectus excavatum, genu valgum, bilateral thumb adductus and hypermobile joints. As with all patients with a neurodevelopmental disorder, a child development specialist is important for helping the child maximize his or her potential. Parents and frequent caregivers should be advised of the seizure risk. If there are signs of seizures, there should be evaluation by EEG and neurologist. We also recommend a screening echocardiogram and renal bladder ultrasound as some patients have had congenital heart defects and renal anomalies. Parents should also be aware of feeding issues, as we suspect this may be unrecognized in some patients due to the average short stature. Referrals to other specialists should be made as needed.

***MAP1B* mutations cause intellectual disability and extensive white matter deficit.** G.B. Walters<sup>1,2</sup>, O. Gustafsson<sup>1</sup>, V.K. Eiriksdottir<sup>1</sup>, A.B. Agustsdottir<sup>1</sup>, G.A. Jonsdottir<sup>1</sup>, S. Steinberg<sup>1</sup>, A.F. Gunnarsson<sup>1</sup>, M.I. Magnusson<sup>1</sup>, U. Unnsteinsdottir<sup>1</sup>, A.L. Lee<sup>1</sup>, A. Jonasdottir<sup>1</sup>, A. Sigurdsson<sup>1</sup>, A. Jonasdottir<sup>1</sup>, A. Skuladottir<sup>1</sup>, L. Jonsson<sup>1,3</sup>, M.S. Nawaz<sup>1,2</sup>, P. Sulem<sup>1</sup>, M. Frigge<sup>1</sup>, A. Ingason<sup>1</sup>, A. Love<sup>2,4</sup>, G.L. Norddahl<sup>1</sup>, M. Zervas<sup>1</sup>, D.F. Gudbjartsson<sup>1,5</sup>, M.O. Ulfarsson<sup>1,6</sup>, E. Saemundsen<sup>2,7</sup>, H. Stefansson<sup>1</sup>, K. Stefansson<sup>1,2</sup>. 1) deCODE genetics (Amgen), Reykjavik, Reykjavik, Iceland; 2) Faculty of Medicine, University of Iceland, Reykjavik, Iceland; 3) Department of Pharmacology, Institute of Neuroscience and Physiology, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; 4) Department of Radiology, Landspítali University Hospital, Fossvogur, Reykjavik, Iceland; 5) School of Engineering and Natural Sciences, University of Iceland, Reykjavik, Iceland; 6) Faculty of Electrical and Computer Engineering, University of Iceland, Reykjavik, Iceland; 7) The State Diagnostic and Counselling Centre, Kopavogur, Iceland.

Discovery of variants in the coding sequence of genes that confer risk of intellectual disability (ID) and Autism spectrum disorder (ASD), is an important step towards a better understanding of the pathophysiology of these disorders. Whole genome sequencing (WGS) of 31,463 Icelanders uncovered a frameshift variant (E712KfsTer10) in *microtubule-associated protein 1B (MAP1B)* that associates with ID/low IQ in a large pedigree (genome-wide corrected  $P = 0.022$ ). Additional stop-gain variants in *MAP1B* (E1032Ter and R1664Ter) validated the association with ID ( $P = 4.9 \times 10^{-4}$ ). Carriers have less white matter (WM) volume ( $\beta = -2.1$  SD,  $P = 5.1 \times 10^{-6}$ ), particularly in the corpus callosum (CC) ( $\beta = -2.4$  SD,  $P = 5.5 \times 10^{-10}$ ), corresponding to a WM and CC volume deficit of 24% and 47%, respectively. Furthermore, lower brain-wide fractional anisotropy ( $P = 6.7 \times 10^{-4}$ ), in carriers, may reflect disordered or compromised axons. Here we describe a syndrome involving *MAP1B* loss of function (LoF) variants. *MAP1B* LoF variants are found at a frequency of 1 in 10,000 in public databases which provides an opportunity for further investigations of the role of *MAP1B* dysfunction in neurodevelopmental disorders.

**1158W**

**Case report of a Colombian patient with Wiedemann-Steiner Syndrome (WDSTS).** A. Paredes<sup>1</sup>, J. Prieto<sup>1,2</sup>. 1) Instituto de Genética Humana, Pontificia Universidad Javeriana, Bogotá D.C., Colombia; 2) Hospital de la Victoria.

Wiedemann-Steiner syndrome (WDSTS [MIM:605130]) is a very rare autosomal dominant genetic disorder characterized by pre- and post-natal growth deficiency, mild to moderate intellectual disability, hypertrichosis cubiti and distinctive facial appearance. Is caused by heterozygous mutation in the gene *KMT2A* (previously known as MLL) mapped on chromosome 11q23.3. The *KMT2A* gene is involved in histone modification, it encodes a transcriptional coactivator that plays an essential role in regulating gene expression during early development and hematopoiesis. Currently there are very few confirmed cases worldwide and in Colombia there is no official report of this syndrome. We report a case of an 12-year-old male referred for study facial dysmorphism, delayed psychomotor development and short stature; he was diagnosed at 2 years old with hypothyroidism, treated with levothyroxine until 5 years. On physical examination the patient presented short stature, intellectual disability, facial dysmorphism, narrow palpebral fissures, downslanting palpebral fissures, long eyelashes, bilateral ptosis, long philtrum, thin upper lip, high-arched palate, dysplastic ears and hairy elbows. Was requested G-banded karyotype 46,XY, CGH array normal, finally he was diagnosed with WDSTS based on identification a pathogenic heterozygote variant c.10837C>T (p.Q3613X) in the *KMT2A* gene by whole exome sequencing study. The mutation found in the patient has not been previously reported, is predicted to result in premature termination of the protein product, with the molecular diagnosis we compared the phenotype of the patient to anteriorly reported patients in the literature. The ability of clinicians to recognize distinctive facial features has played an important role in the diagnosis of genetic syndromes, nevertheless its low prevalence and variable clinical phenotype makes it difficult to recognize. As more and more patients with developmental disorders undergo whole exome sequencing to achieve a diagnosis, there will be increasing numbers of individuals identified with Wiedemann Steiner Syndrome.

**1159T**

**An 8-year-old girl with Pitt-Hopkins syndrome: New features and differential diagnosis of developmental delay in Colombia.** J. Prieto<sup>1</sup>, M. Mantas<sup>1</sup>, A. Paredes<sup>1</sup>, R. Quero<sup>1</sup>, J. Acosta<sup>2</sup>. 1) Pontificia Universidad Javeriana, Bogotá D.C., Colombia; 2) Instituto de Ortopedia Infantil Roosevelt.

Pitt-Hopkins syndrome (PHS [MIM 610954]) is an emerging neurodevelopmental disorder falling within syndromic forms of intellectual disability and developmental delay, was originally described in 1978 in two unrelated patients with mental retardation, recurrent episodes of hyperventilation. Currently there are less than 500 confirmed cases worldwide, in Colombia there is no official report of this syndrome. The syndrome is caused by haploinsufficiency of the *TCF4* gene on chromosome 18q21, *TCF4* is involved in embryologic neuronal differentiation and phenotypically is similar to other syndromic such as Angelman syndrome, Rett syndrome, Mowat-Wilson syndrome and ATR-X syndrome. Studies have revealed a molecular variant in *TCF4* in 2% of patients clinically diagnosed with Angelman syndrome and in 1 of 81 children clinically diagnosed with Rett syndrome. We report a case of an 8-year-old girl with intellectual disability, global developmental delay, motor incoordination, hypotonia, stereotypical movements, absence seizures, dysmorphic features such as café au lait spots on scalp, blue scleras, flared nostrils, large mouth, widely spaced teeth with absence of hyperventilation or other breathing abnormalities. Differential diagnoses were discarded such as Rett syndrome and inborn error of the metabolism. She came under Genetic clinical observation at 4 years of age. The girl underwent genetic (karyotype, Comparative genomic hybridization) and neuroradiological (cranial CT and MRI) tests, which proved to be normal. Due to severe neurodevelopmental delay and facial dysmorphisms we completed the genetic investigations with whole-exome sequencing (WES), showed c.1191\_1194delTCAT variant in the *TCF4* gene. This variant has not been reported previously as a pathogenic variant nor as a benign variant. This variant causes a frameshift starting with codon isoleucine 397, changes this amino acid to a Methionine residue, and creates a premature Stop codon at position 64 of the new reading frame, denoted p.I397Mfs\*64. This variant is predicted to cause loss of normal protein function through protein truncation. This variant is a strong candidate for a pathogenic variant. At our knowledge, our patient is the first Colombia case of PHS diagnosed at molecular level. This syndrome should be considered for patients with neurodevelopmental delay and searching for *TCF4* mutations is highly recommended when others overlapping syndromes was excluded.

**1160F****Evidence that biallelic loss-of-function variants in *FBXL3* cause developmental delay/intellectual disability, facial dysmorphism and short stature.**

Guipponi*<sup>9</sup>, *F.A. Santoni*<sup>10</sup>, *A. Megarbane*<sup>7</sup>, *J. Ahmed*<sup>8</sup>, *R. Colombo*<sup>9</sup>, *M. Ansari*<sup>1</sup>, *S.E. Antonarakis*<sup>1,10</sup>. 1) Department of Genetic Medicine and Development, University of Geneva, Geneva, Switzerland; 2) Greek Genome Center, Biomedical Research Foundation of the Academy of Athens, Athens, Greece; 3) Institute of Basic Medical Sciences, Khyber Medical University, Peshawar, Pakistan; 4) Department of Biomedical and Neuromotor Sciences, University of Bologna, Bologna, Italy; 5) Service of Genetic Medicine, University Hospitals of Geneva, Geneva, Switzerland; 6) Department of endocrinology diabetes and metabolism, university hospital of Lausanne, Switzerland; 7) Institut Jerome Lejeune, Paris, France; 8) Institute of Clinical Biochemistry, Faculty of Medicine, Catholic University and IRCCS Policlinico Gemelli, Rome, Italy; 9) Center for the Study of Rare Hereditary Diseases, Niguarda Ca' Granda Metropolitan Hospital, Milan, Italy; 10) iGE3 Institute of Genetics and Genomics of Geneva, Geneva, Switzerland.

*FBXL3* (F-Box and Leucine Rich Repeat Protein 3) encodes a protein that contains F-box and several tandem leucine-rich repeats (LRR) domains. *FBXL3* is part of the SCF (Skp1-Cullin-F box protein) ubiquitin ligase complex that functions as phosphorylation dependent degradation of the central clock protein cryptochromes (CRY1 and CRY2) by the proteasome and its absence causes circadian phenotypes in mice and behavioral problems. No *FBXL3* related phenotypes have been described in humans. By a combination of exome sequencing and homozygosity mapping, we analyzed two consanguineous families with intellectual disability and identified homozygous LoF (loss-of-function) variants in *FBXL3*. In the first family, from Pakistan, an *FBXL3* frameshift variant (NM\_012158.2:c.885del:p.(Leu295Phefs\*25)) was the only segregating variant in five affected individuals in two family loops (LOD score: 3.12). In the second family, from Lebanon, we identified a nonsense variant (NM\_012158.2:c.445C>T:p.(Arg149\*)). In a third patient from Italy, a likely pathogenic missense variant (NM\_012158.2:c.1072T>C:p.(Cys358Arg)) was identified in homozygosity. Protein 3D modeling showed that Cys358 is positioned on 10<sup>th</sup> LRR motif forming a solenoid around CRY2, and that the Cys358Arg change is predicted to influence the binding with CRY2 by destabilizing the structure of the *FBXL3* protein suggesting that this variant may also be LoF. The eight affected individuals from the three families presented with a similar phenotype. They have intellectual disability, developmental delay, short stature and mild facial dysmorphism, mainly large nose with bulbous tip. The phenotypic similarity and the segregation analysis suggest a link of *FBXL3* with syndromic autosomal recessive developmental delay/intellectual disability.

**1161W****Expanding the phenotype of *MED13L*-associated mental retardation and distinctive facial features with or without cardiac defects; MRFACD. *MJ. Hajianpour*<sup>1</sup>, *K. Hunt*<sup>2</sup>, *A. Wattad*<sup>1</sup>, *K. Xixis*<sup>1</sup>. 1) East Tennessee State University, Johnson City, TN; 2) Holston Medical Group, Kingsport, TN.**

Proband is a 4-year-old male with severe developmental delay and no speech, intellectual disability (ID), autism, seizures, ASD, VSD, PDA, renal cyst with hydronephrosis, and dysmorphic features: plagiocephaly, asymmetric face, downslanted palpebral fissures, left exotropia, small/ low-set ears, high nasal bridge, thin upper vermilion, tented upper lip, high arched palate, retrognathia, moderate pectus excavatum, clinodactyly of 5<sup>th</sup> fingers, simian crease, syndactyly between the 2<sup>nd</sup>&3<sup>rd</sup> toes, and 4<sup>th</sup>&5<sup>th</sup> toes (to middle of the toes), and sacral dimple. He has had G-tube feeding due to swallowing incoordination. Proband has no sibling. Mother is 24 yo; with a history of depression, Asperger syndrome, OCD, and obesity, but normal intelligence. Father is 22 yo; with bipolar disorder. Chromosome microarray, metabolic disorders screen, molecular studies for Angelman/ Rett syndrome panel (22 genes), and neurodevelopmental disorders panel (196 genes) were inconclusive. The Whole Exome Sequencing showed only a heterozygous missense mutation (p.P1526T; c.4576C>A) of *MED13L* gene, which was interpreted as a VUS, but likely the cause of the patient's features. Mother tested negative for *MED13L* alteration. The *MED13L* gene on chromosome 12q24.21 is involved in early embryonic development of heart and brain. Pathogenic mutations are associated with autosomal dominant mental retardation and distinctive facial features with or without cardiac defects; and with AD transposition of the great arteries (TGA); dextro-looped 1. Patients may show global developmental delay, moderate to severe ID, and absent speech. Most cases are de novo. Penetrance is reduced, but low-level parental mosaicism has been reported. Reported Features (proband's features are marked with \*): Micrognathia\*, Bulbous nasal tip\*, Abn philtrum\*, Low-set ears\*, Strabismus\*, Abn palmar creases\*, Upslanted palpebral fissures, Truncal hypotonia\*, CHD (dextro-looped TGA, conotruncal defects, and VSD\*). Some patients: Low birth weight\*, talipes equinovarus\*, Seizures\*, Motor delay\*, ataxia, behavioral problems\*. Less common: Autism\*, Limb contractures, camptodactyly\*, ventriculomegaly, global cerebral atrophy, Feeding difficulties\*, sleep problem\*, macroglossia, macrocephaly. Proband's features Not reported: Down-slanted PF (upslanted PF in reports), high nasal bridge, thin upper vermilion, retrognathia, high-arched palate, pectus excavatum, ASD, PDA, renal cyst, clinodactyly of 5<sup>th</sup> fingers, and 2-3 & 4-5 toes syndactyly.

**Novel mutation in *KDM6A* gene associated with Kabuki syndrome type 2: Expanding literature on a rare condition.** *E.M.G. Gershon<sup>1</sup>, M.B. Byler<sup>1</sup>, N.D. Dosa<sup>1</sup>, W.B. Bi<sup>2</sup>, R.L.L. Lebel<sup>1</sup>.* 1) Upstate Medical University, Syracuse, NY; 2) Baylor College of Medicine, Atlanta, GA.

Kabuki Syndrome, also known as Kabuki make-up Syndrome (OMIM #147920), is associated with dwarfism, long palpebral fissures with eversion of the lower eyelid, skeletal anomalies, depressed nasal tip, intellectual disability, and a wide variety of other dysmorphic features. Most cases (56-76%) are associated with dominant mutations in the *KMT2D* gene (OMIM #602113), which maps to chromosome 12q13.12. *KMT2D* codes for a lysine specific methyltransferase. The remaining cases are referred to as Kabuki 2 (OMIM #300867), and are instead associated with dominant mutations in the *KDM6A* gene (OMIM #300128) which maps to Xp11.3, or they are not found to have mutation in either gene. These mutations can present with either familial inheritance or (more often) as a *de novo* event. *KDM6A* encodes a histone demethylase that interacts with the *MLL2* gene which in turn is also associated with the syndrome. Our patient, now 7 years old, presented at 3 years of age with global developmental delay, hearing deficits, poor vision, long palpebral fissures and hypotonia. He was born at 36 weeks via Cesarean Section due to breach presentation. The pregnancy was only complicated by diet controlled gestational diabetes. Whole Exome Sequencing revealed a novel mutation in the *KDM6A* gene: c.3109C>T (p.Q1037X). The mutation is thought to be *de novo* since it is absent in maternal lymphocytes, although gonadal mosaicism cannot be excluded. This case serves to expand the sparse literature available on Kabuki 2.

**1163F**

**Causative novel *USP9X* variants in two Japanese patients with X-linked intellectual disability.** *Y. Tsurusaki<sup>1</sup>, K. Kuroda<sup>2</sup>, H. Murakami<sup>2</sup>, Y. Enomoto<sup>1</sup>, Y. Kimura<sup>1</sup>, Y. Yamanouchi<sup>3</sup>, E. Kondoh<sup>4</sup>, K. Ouchi<sup>4</sup>, M. Masuno<sup>3,4</sup>, K. Kurosawa<sup>2</sup>.* 1) Clinical Research Institute, Kanagawa Children's Medical Center, Yokohama, Japan; 2) Division of Medical Genetics, Kanagawa Children's Medical Center, Yokohama, Japan; 3) Genetic Counseling Program, Graduate School of Health and Welfare, Kawasaki University of Medical Welfare, Kurashiki, Japan; 4) Department of Pediatrics, Kawasaki Medical School, Kurashiki, Japan.

Intellectual disability (ID) affects about 1% of the worldwide population. An IQ score of less than 70 is characteristic. Mutations in more than 100 genes have been found associated with X-linked ID. In 2014, hemizygous mutations in the *USP9X* were described as a cause of X-linked ID in males. *USP9X* encodes an Ubiquitin Specific Peptidase 9. *Usp9x* knockout mouse show reduction in both axonal growth and neuronal cell migration. To identify the pathogenic mutations for two unrelated Japanese patients with ID, we performed targeted resequencing using a TruSight One Sequencing Panel. Genomic DNA libraries were sequenced using MiSeq with 151-bp paired-end reads. Mapping to human genome hg19 was performed using Burrows-Wheeler Alignment. Aligned reads were processed by Picard to remove PCR duplicates. Variants were called using the Genome Analysis Toolkit, and annotated by ANNOVAR. Patient 1 is 4 year-old girl who is the second child of healthy and nonconsanguineous parents. She was delivered at 37 weeks gestation with a birth weight of 2,278 g (-1.1 SD), length 47cm (-0.1 SD), and occipital frontal circumference 30.5 cm (-1.5 SD). Her dysmorphic features consisted of upswept and curly hair, facial asymmetry, prominent forehead, bitemporal narrowing, short palpebral fissures, prominent nose with flared ala nasi, smooth philtrum, thin upper lip, full cheeks, dysplastic ears, tapering fingers, and Blaschko lines. Patient 2 is 1 year-old girl who is the first child of nonconsanguineous parents. The proposita was delivered at 41 weeks and 1 day gestation. Birth weight was 2,968 g (-0.5 SD), length 48.3 cm (-0.9 SD), and head circumference 34.2 cm (0.4 SD). The main clinical manifestations included epicanthus, telecanthus, short columella, depressed nasal tip, bilateral low-set and posteriorly rotated ears, overfolded helices, bifid uvula, umbilical hernia, and bilateral overlapping toes (T23, T45). Targeted resequencing identified two heterozygous mutations in *USP9X* [c.4068\_4072del (p.Leu1357Tyrfs\*12) and c.1201C>T (p.Arg401\*)], respectively. Our study demonstrated that *USP9X* mutations can cause ID and the diagnostic utility of next generation sequencing technologies is obvious.

## 1164W

**Triplet repeat primed PCR (TP-PCR) test for fragile X syndrome: Accuracy and efficiency evaluation as an alternative to conventional diagnostic methods.** H. Gu, M.J. Kim, D. Yang, J.Y. Song, S.I. Cho, S.S. Park, M.W. Seong. Department of Laboratory Medicine, Seoul National University Hospital, Seoul, Korea, Republic of.

**Backgrounds:** The diagnosis of Fragile X syndrome (FXS) was based on fragment analysis (FA) and Southern blot (SB). Recently, large CGG expansion was confirmed by triplet repeat primed PCR (TP-PCR) to facilitate full mutation (FM) screening. We compared FA, SB and TP-PCR results of our hospital to evaluate the accuracy among the tests and efficiency of diagnostic workflow. **Methods:** From November 2013 to March 2018, a total of 462 patients were examined using FA, TP-PCR test as screening test and if necessary, using SB to be confirm the diagnosis. **Results:** Among the total patients, there were 9 FM, 12 premature (PM), 8 intermediate (INT) and 433 normal alleles (NA) patients diagnosed with previous workflow. The TP-PCR results in all the diagnosed groups were in good agreement with the diagnostic criteria according to RN. Of the FM group, 7 were unable to amplify by FA, so FA was confirmed through SB. 2 females with NA in FA were identified as FM carriers by detecting FM allele in SB. TP-PCR detected 200 or more RNs in all cases of FM, particularly both NA and FM in 2 FM carriers. In the PM group, TP-PCR results were consistent with the results from performing both FA/SB and FM alone. It was 8 cases in which observed only homozygous allele in FA, but heterozygous alleles in TP-PCR. In all INT cases, TP-FA and TP-PCR results were consistent in both homozygous and heterozygous alleles. In NA cases, FA and TP-PCR results showed about 94.5% agreement (409/433).

**Conclusion:** The analyzed results showed that the agreement between FA and TP-PCR was very high, even TP-PCR showed higher sensitivity to heterozygous females or high RN. Hence it can be the first choice screening method to substitute for FA. Since FM results of TP-PCR are consistent with those of SB, it is possible to perform a reasonable workflow by reducing unnecessary SB. It is expected that the expanded use of TP-PCR will bring more positive and effective workflow improvement to the diagnosis of FXS in the future.

Intellectual disability (ID) affects 0.5-3% of the general population with 60% of cases remaining without a known cause. Many cases diagnosed by molecular testing reveal variants that have arisen *de novo*. Recent genetic screens in drosophila have identified 165 genes important for nervous system development (Yamamoto *et al.* 2014). Importantly, Yamamoto *et al.* noted that homozygous lethal drosophila genes with more than one homolog in humans were eight times more likely to be associated with human disease. It follows that gene families with a large number of paralogs in humans are more likely to be associated with disease if one member has been linked to disease already. The DEXD/H-box RNA helicase family represents one such gene family, with 58 members, all of which share 8-9 conserved amino acid motifs that make up the helicase core domain. *De novo* missense variants in the conserved motifs of *DHX30* were recently linked to a neurodevelopmental disorder characterized by intellectual disability (ID), developmental delay (DD), and gait abnormalities. We have identified a paralog of *DHX30*, *DHX37* as a candidate disease gene for a similar neurodevelopmental disorder. Five patients with homozygous (2), compound heterozygous (1), and *de novo* (1 confirmed, 1 suspected) missense variants in *DHX37* share a phenotype of ID/DD, brain anomalies, seizures, hypotonia, and vertebral anomalies. All the variants are rare, not present in the Thousand Genomes Project Database (TGP) or ExAC with the MAF for two variants in gnomAD calculated to be 8.3e<sup>-6</sup>, and have CADD scores >29. The variants also occur at residues that are predicted to be conserved by PhyloP and result in deleterious changes by four different prediction algorithms (PolyPhen2, MutationTaster, SIFT and LRT). Additionally, two other paralogs, *DHX16* and *DDX54*, represent candidate disease genes associated with neurodevelopmental phenotypes characterized by ID/DD, hypotonia, and brain anomalies (4 cases). The variants in *DHX16* and *DDX54* occur as *de novo* (3) and compound heterozygous (1) and are also rare, not present in TGP or ExAC, and have CADD scores >23. Together these cases implicate the DEXD/H-box gene family in both dominantly and recessively inherited ID/DD phenotypes and highlight the potential for more than one disease mechanism underlying *DHX30*-related disorders.

Despite the significant progress in unravelling the origins of neurodevelopmental disorders (NDD), up to 50% of affected individuals remain without a genetic diagnosis. Here we demonstrate the power of using short-read whole-genome sequencing (WGS) to identify pathogenic variants in 475 affected individuals with a NDD, as part of the NIHR-BioResource Rare Diseases research study. We identified pathogenic variants in 150/475 (31%) of the individuals, and an additional 101/475 (21%) had a variant of uncertain significance. 90% of them were single-nucleotide variant or indels in coding regions of known NDD-associated genes. However, WGS provided power to detect three additional categories of variants: structural, intronic and mitochondrial variants. Structural variants comprised 19 deletions, 3 duplications, 2 inversions and 1 partial uniparental isodisomy. We also found 2 complex structural variants: a *de novo* deletion-inversion-duplication overlapping *HNRNPU* gene, and a *de novo* duplication-inversion-duplication overlapping *CDKL5* gene. Nanopore long-read WGS was used as complementary tool to resolve the genetic architecture of the latter. Pathogenic intronic variants were also identified, 5 of them being within the splice region of NDD-associated genes. We also identified a deep intronic variant in *TSC2* that caused Tuberous Sclerosis type 2 in a patient who had no molecular diagnosis for many years. Lastly, the mitochondrial genome was also considered and three likely pathogenic variants were identified. One was a missense in *MT-ATP6* gene that had not been previously reported, that was heteroplasmic (83%, with depth = 5681x) in blood from a patient with retinitis pigmentosa and ataxia. Our findings demonstrate the value of using WGS to investigate the genetic causes of NDD by identifying pathogenic single-nucleotide variants, indels and structural variants in coding and intronic regions of the human genome.

Genetic etiologies of developmental delay and intellectual disability (DD/ID) are still being discovered as a result of large-scale genomic sequencing and data sharing. Here we describe a GeneMatcher-facilitated cohort of eleven individuals with variation in the *RALA* gene, which encodes a RAS-like GTPase. All probands present with DD/ID, including significant speech and motor delays. Variable features in at least half of the cohort include facial dysmorphism and seizures. We found nine independent, *de novo*, variants in ten individuals, two of whom are monozygotic twins; the observed rate of *de novo* variants in affected individuals in large cohorts (8 in 16,086 probands) is significantly higher than that expected given estimated mutation rates ( $p=4.93e-11$ ). These nine variants, including eight missense variants and one in-frame deletion, all affect deeply evolutionarily conserved residues that form the GTP/GDP binding region of *RALA*; in fact, six variants affect only two residues, Val25 and Lys128. This three-dimensional localization strongly suggests that these mutations impact the GTPase activity of *RALA* and thereby alter *RALA*-mediated signaling. Supporting this, both cancer- and DD/ID-associated mutations have been observed in spatially similar locations within *RALA* homologs. Further, although there are 34 *RALA* missense variants in large population databases (gnomAD and BRAVO), none occur at any of the 24 GTP/GDP-binding region residues of *RALA* (206 total amino acids), an observation that is likely non-random ( $p=0.017$ ) and suggests that the binding region is highly intolerant to variation in the general population. We also identified one proband with a nonsense variant of unknown inheritance at position 176 of 206. While this variant is not predicted to lead to nonsense-mediated decay and may lead to production of a *RALA* protein missing residues required for membrane localization, its disease relevance is unclear. Characterization of the phenotypes and variation observed here lead us to suggest *RALA* as a new cause for DD/ID, adding to the group of previously established DD/ID genes in the RAS family.

Ahmed<sup>4</sup>, A.M. Waryah<sup>6</sup>, M.T. Sarwar<sup>4</sup>, M. Ansar<sup>1</sup>. 1) Department of Genetic Medicine and Development, University of Geneva, Geneva, Switzerland; 2) Service of Genetic Medicine, University Hospitals of Geneva, Geneva, Switzerland; 3) iGE3 Institute of Genetics and Genomics of Geneva, Geneva, Switzerland; 4) Institute of Basic Medical Sciences, Khyber Medical University, Peshawar, Pakistan; 5) Department of Genetics, University of Karachi, Karachi, Pakistan; 6) Molecular Biology and Genetics Department, Medical Research Center, Liaquat University of Medical and Health Sciences, Jamshoro, Pakistan; 7) Biomedical Research Foundation of the Academy of Athens, Athens, Greece; 8) Department of Medical Genetics, Oslo University Hospital and University of Oslo, Oslo, Norway; 9) Department of Endocrinology Diabetes and Metabolism, University Hospital of Lausanne, Switzerland; 10) Department of Biosciences, Faculty of Life Sciences, Muhammad Ali Jinnah University, Karachi, Pakistan.

Consanguinity, practiced in a substantial fraction of human populations, reveals numerous rare recessive phenotypes because of the extensive regions of homozygosity by descent. The average total genomic homozygosity is 253Mb in the offspring of consanguineous parents; this is 10fold higher than that of 25Mb in outbred individuals. Similarly, the rare homozygous variants (<2% frequency) in the coding regions are on average 57 in the offspring of first-cousins compared to 18 in outbred individuals. In Pakistan, the frequency of consanguineous marriages approaches 70%. We have initiated a Swiss-Pakistani project to identify novel recessive gene candidates for two phenotypes: Intellectual disability (ID) and visual impairment (VI). We have collected samples from 145 ID and 247 VI families of first cousin marriages with at least 2 affecteds. Exome sequence of one affected and genotyping of the whole family (parents, all affected and unaffected siblings) has been completed in 122 ID and 147 VI families to date. The likely causative gene/variant in known genes was found in 67% of the VI and 34% in the ID families. Thus, there are more unknown recessive genes for ID. We have identified 21 novel candidate genes in VI and 15 in ID (to be presented in the conference). International matchmaking identified additional families in 20% of the candidate genes. Careful evaluation of the phenotypes is mandatory to assess the possibility of 2 or more causative genes in certain families, and to minimize false negative results. International databases from consanguineous individuals are needed to facilitate the assignment of pathogenicity to homozygous variants.

**Phenotypic expansion of POGZ-related disorders (White-Sutton Syndrome).** N. Assia Batzir<sup>1,2</sup>, V.R. Sutton<sup>1,2</sup>. 1) Baylor College of Medicine, Houston, TX; 2) Texas Children's Hospital, Houston, TX.

White-Sutton Syndrome (WSS, OMIM #616364) is a recently-identified genetic disorder resulting from *de novo* heterozygous pathogenic variants in the gene *POGZ*. Pathogenicity of *de novo* variants in this gene was suggested from a large cohort of individuals with autism spectrum disorders, schizophrenia and intellectual disability, and it became recognized as a syndrome following the description of 5 individuals with developmental delays, behavioral abnormalities and shared physical features including microcephaly, strabismus, short stature, skeletal abnormalities and typical facial characteristics. This illustrates the "genotype-first" concept where grouping of patients based on similar genetic etiologies leads to the characterization of genetics syndromes. Thus far, over 30 patients have been reported worldwide, however phenotypic characterization and data regarding the natural history and associated features are still incomplete. We undertook a study to better delineate the clinical phenotype of WSS. Information was obtained from medical records of 17 individuals with WSS identified through self-reporting and physician referrals. Gastrointestinal maladies and sleep abnormalities emerged as common features in patients with WSS, and so we further gathered information through validated patient/parent report tools. Results reveal a broad spectrum of intellectual disability/developmental delay, and suggest a wider phenotypic range than previously described. Moreover, a variety of gastrointestinal issues were identified ranging from congenital diaphragmatic hernia to poor feeding in infancy and early-onset obesity. Sleep apnea and sleep disordered breathing were also more common than in the general population. This study expands the phenotypic spectrum of this new syndromic form of intellectual disability and autism.

The RNA helicase *DDX6* is a member of the DEAD-box protein family and plays vital roles in RNA metabolism processes such as translational repression, decapping and RNA decay. Previous *in vitro* and lower *in vivo* models have implicated altered *DDX6* in cellular dysfunction but clinical consequences and pathogenesis in humans have not yet been described. Here we report the identification of multiple unrelated patients carrying private, *de novo* missense mutations in *DDX6*, all presenting with non-epileptic intellectual disability, developmental delay, microcephaly and overlapping dysmorphic features of unknown etiology. All missense variants reside in exon 11 which encodes the highly-conserved C-terminal RecA domain of *DDX6* involved in RNA binding, helicase activity and protein partner binding. Comprehensive *in vitro* functional studies performed on *DDX6* p.Arg373Gln and p.Cys390Arg variants demonstrated that both mutations lead to significant defects in P-body assembly and interactions with protein partners involved in translation repression (and mRNA degradation). Study of patient-derived fibroblasts carrying the p.Cys390Arg mutation demonstrated a significant reduction in total P-body number when compared to an unrelated age-matched control individual. Additional transcriptomic studies in available patient cells revealed among the genes up-regulated an enrichment of mRNA excluded from P-bodies, targets of *DDX6*, and in mRNA encoding protein involved in regulation of translation. Additional patients with *de novo* mutations affecting the same or adjacent amino acid to p.Cys390 were also identified. Collectively, our clinical and molecular data define a novel role for *DDX6* mutations in human neurodevelopmental dysfunction and confirm the implication of this gene in an autosomal dominant form of intellectual disability with developmental delay and dysmorphic features.

**De novo truncating mutations *HNRNPR* gene cause a new syndrome with intellectual disability and microcephaly.** A. Bruel<sup>1</sup>, A. MacInnes<sup>2</sup>, S. Mouton<sup>1,3</sup>, F. Tran Mau-Them<sup>1,4</sup>, F.A.M. Duijkers<sup>5</sup>, M. Cho<sup>6</sup>, R.L Ladda<sup>7</sup>, Z. Powis<sup>8</sup>, K.G Monaghan<sup>9</sup>, Y. Duffourd<sup>1</sup>, C. Philippe<sup>1,3</sup>, L. Faivre<sup>1,3</sup>, C. Thauvin-Robinet<sup>10</sup>. 1) UMR1231 GAD, Inserm - Université Bourgogne-Franche Comté, Dijon, France; 2) Laboratory Genetic Metabolic Diseases, Academic Medical Center, Amsterdam, The Netherlands; 3) Centre de Référence Anomalies du Développement et syndromes malformatifs, centre de génétique, FHU-TRANSLAD, CHU Dijon Bourgogne, Dijon, France; 4) Unité Fonctionnelle d'Innovation diagnostique en maladies rares, FHU-TRANSLAD, CHU Dijon Bourgogne, Dijon, France; 5) Department of Clinical Genetics, Academic Medical Center, Amsterdam; 6) GeneDx, Gaithersburg, Maryland, USA; 7) Department of Pediatrics, Penn State Hershey Children's Hospital, Hershey, USA; 8) Ambry Genetics, Department of Clinical Genomics, Aliso Viejo, California, USA; 9) Centre de Référence Déficience Intellectuelle, centre de génétique, FHU-TRANSLAD, CHU Dijon Bourgogne, Dijon, France.

Approximately 1% of individuals present with an intellectual disability (ID) that can be caused by genetic and/or exogenous factors. Genetic causes are multiple with more than 500 genes associated to isolated ID and more than 2,000 genes involved in syndromic ID reported in OMIM database. The clinical heterogeneity of ID is reflected with the wide genetic heterogeneity. During these last years, NGS has proven to be useful for the identification of the molecular bases of heterogeneous conditions such as ID. However, a large number of results remain non-conclusive because the diagnosis of ultra-rare conditions limits the genotype-phenotype correlations. Broad international data-sharing catalyzes the identification of additional cases and allows the delineation of new syndromes. In this study, we report a girl with ID associated with microcephaly, facial dysmorphism, brachydactyly, short feet and a thin corpus callosum. A trio-based WES strategy identified a *de novo* frameshift variant in the *HNRNPR* gene. To assess the relevance of this finding we asked international collaborators for patients with *HNRNPR* truncating variants. Three additional patients were recruited with *de novo* truncating variant by GeneMatcher. All the 3 patients present with a similar syndromic phenotype including ID, microcephaly, generalized hypotonia, brachydactyly, feeding difficulties and corpus callosum anomalies. The *HNRNPR* gene encodes a nuclear ribonucleo-protein of the large superfamily of the RNP consensus RNA-binding proteins, involved in the nucleic acid metabolism which functions in pre-mRNA processing, in transcriptional and translational regulation. *HNRNPR* is a member of the spliceosome C complex and seems more specifically implicated in the stress granule metabolism. Stress granules are mRNA-protein assemblies formed from nontranslating mRNAs, and are essential in the stress response and may contribute to some degenerative diseases and ID. Functional studies in patient's fibroblasts revealed stress granule defects including mislocalization and associated with a cell death. An ongoing RNAseq in the stress granule transcriptome will enable to identify targets of *HNRNPR* to understand the function of *HNRNPR*. In conclusion, we report *HNRNPR* as a new gene associated with syndromic ID and microcephaly, involved in the stress granule metabolism.

## 1172F

**The GeJo-ARID project: Identification of new genes in individuals with intellectual disability.** R. Buchert<sup>1</sup>, O. Nafie<sup>2</sup>, L. Laugwitz<sup>1,3</sup>, S. Al Hait<sup>4</sup>, M. Sturm<sup>5</sup>, J. Sommerfeld<sup>6</sup>, A. Baraghiti<sup>6</sup>, P.A. Koch<sup>7</sup>, J. Hanselmann<sup>8</sup>, B. Kootz<sup>1</sup>, J. Gohlke<sup>9</sup>, P. Bauer<sup>1</sup>, M. Hamdallah<sup>6</sup>, W. Al Ameri<sup>7</sup>, R. Abou Jamra<sup>8</sup>, A.J. Alfröck<sup>6</sup>, A. Rieß<sup>1</sup>, T.B. Haack<sup>1</sup>, O. Rieß<sup>1</sup>, T. Froukh<sup>6</sup>. 1) Institute of Medical Genetics and Applied Genomics, University of Tübingen, Tübingen, Germany; 2) Mutah University, Jordan; 3) Department of Neuropaediatrics, Developmental Neurology and Social Pediatrics, University of Tübingen, Tübingen, Germany; 4) Private Clinic, Jordan; 5) Dept. of Biotechnology and Genetic Engineering, Philadelphia University, Amman, Jordan; 6) Farah Hospital, Amman, Jordan; 7) Ibn Alhytham Hospital, Amman, Jordan; 8) Institute of Human Genetics, University Medical Center Leipzig, Leipzig, Germany; 9) private practice, Amman, Jordan.

In a bilateral project between Germany and Jordan, we examined 103 Jordanian families with intellectual disability (ID). 80% of the families were consanguineous and 50% had more than one affected child. We conducted whole exome sequencing (WES) for one affected individual per family and prioritized the data according to putative causative variants. In total, we solved 32% of the cases finding mutations in known disease genes, and identified good candidate variants in another 10% of the patients. 63% of the causative variants were autosomal recessive, 30% were *de novo* and 7% were X-chromosomal. In case of identified splice variants we used cDNA to verify aberrant splicing. Using the WES coverage data we also identified 3 large deletions with sizes of 600 kb to 2 Mb which occurred *de novo*, as confirmed with microarray analysis. While data analysis is still in progress we could already identify a new candidate gene, *DENND5A*, and prove the causative effect of bi-allelic *DENND5A* mutations in epileptic encephalopathy. Further, we identified new pathogenic variants in recently identified candidate genes for ID. In one family we identified a homozygous truncating variant in *PUS3*, a gene which was previously implied in another family with similar symptoms. In another family we identified a *de novo* truncating mutation in *YWHAQ*, which was recently linked to epileptic encephalopathy. Currently, we are investigating various other candidate genes which were identified in families in this project. This project demonstrates a beneficial cooperation between various specialties such as pediatricians and human geneticists from Jordan and Germany and helps to improve genetic diagnostics and counselling of children with neurodevelopmental disorders in Jordan. This project is funded through a grant by the DAAD.

Next-Generation sequencing combined with international data sharing has enormously facilitated identification of new disease associated genes and mutations. This is particularly true for genetically extremely heterogeneous entities such as neurodevelopmental disorders (NDDs). Through exome sequencing and world-wide collaborations we identified and assembled 20 individuals with *de novo* variants in *FBXO11*. They present with mild to severe developmental delay associated with a range of features including short (4/20) or tall (2/20) stature, obesity (5/20), microcephaly (4/19) or macrocephaly (2/19), behavioral problems (17/20), seizures (5/20), cleft lip or palate or bifid uvula (3/20) and minor skeletal anomalies. *FBXO11* encodes a member of the F-Box protein family, constituting a subunit of an E3-ubiquitin ligase complex. This complex is involved in ubiquitination and proteasomal degradation and thus in controlling critical biological processes by regulating protein turnover. The identified *de novo* aberrations comprise two large deletions, ten likely gene disrupting and eight missense variants distributed throughout *FBXO11*. Structural modeling for missense variants located in the CASH or the Zinc-finger UBR domains suggests destabilization of the protein. This in combination with the observed spectrum and localization of identified variants and the lack of apparent genotype-phenotype correlations is compatible with loss-of-function or haploinsufficiency as an underlying mechanism. We implicate *de novo* missense and likely gene disrupting variants in *FBXO11* in a neurodevelopmental disorder with variable intellectual disability and various other features.

**Introduction** Large meta analyses of trio exome sequencing in neurodevelopmental disorders (NDD) identify novel disorder genes. However, the yield is relatively low. E.g. the DDD study in the UK described in a cohort of over 7000 trio exome analysis only 94 genes, most of them were known in advance. **Materials and Methods** We performed trio exome sequencing of 199 undiagnosed NDD cases. Sequencing was performed by Centogene (Rostock, Germany) or CeGaT (Tübingen, Germany) using well-established enrichment kits and sequencing platforms. Bioinformatic analyses were performed by Limbus (Rostock, Germany). If exome sequencing did not reveal a clear causative variant in an established NDD gene, we searched for candidate genes on scientific basis. We developed a scoring system using 13 parameters, based on inheritance, gene and variant attributes, and published literature. **Results** A reliable clinical genetic diagnosis was made in 64 (32%) trios. In the remaining 135 (68%) trios, scientific re-evaluation revealed 181 potentially causative variants in candidate genes. We applied our scoring system to prioritize the relevance of these variants. The scores varied between 2 and 11.9. The top 10% of the scores were made by the genes *ASIC1*, *TANC2*, *FBXL19*, *KMT2E*, *GLS* (twice), *ACTL6B*, *GRIN3B*, *CUX1*, *PUM1*, *UNC13A*, *GRIA4*, *SPEN*, *PUM2*, *TOP1*, *NPTX1*, *ETV5*, and *WDFY3*. Within few months, international cooperation has been set up and clinical and functional analyses were performed, and the majority of these candidates is validated and is already published or under review, or a manuscript is under preparation. **Discussion and Conclusion** Our results illustrate the enormous scientific value of the re-evaluation of the substantial amount of negative exome sequencing samples. In comparison to large studies that have meta-analyzed thousands of trio exomes, we achieve a higher yield (15 novel genes out of 135 families) through individual evaluation of each case, systematically scoring, and an approachable and cooperative attitude. We want to present to the conferees our results and encourage them re-evaluate and share in order to fully decipher the genetics of NDD within few years.

## 1175F

**Two novel mutations in DYRK1A gene cause microcephaly and learning difficulties.** WT: Keng<sup>1</sup>, Rachel. Challis<sup>2</sup>, Clare. Logan<sup>2</sup>, Jennie. Murray<sup>2</sup>, Andrew. Jackson<sup>2</sup>, GS. Chng<sup>1</sup>, LH. Ngu<sup>1</sup>, HY. Leong<sup>1</sup>. 1) Genetic Dept, Hospital Kuala Lumpur, Kuala Lumpur, Malaysia; 2) MRC Human Genetics Unit, MRC Institute of Genetics & Molecular Medicine, Western General Hospital, Edinburgh.

DYRK1A codes for a member of the dual-specificity tyrosine phosphorylation-regulated kinase family. Triplication of this highly conserved gene located on chromosome 21q22.1 is thought to play a role in cognitive deficits associated with Down syndrome. Haploinsufficiency of the DYRK1A protein can lead to moderate to severe learning difficulties, microcephaly, epilepsy as well as characteristic facies, scoliosis and short stature. We describe 2 Malaysian patients who have microcephaly and learning difficulties caused by novel de novo heterozygous mutation [c.469delG, p.Asp157IlefsTer8; c.843\_864dup-TAGTATCATTCACTGTGATCTA, p.Lys289Ter] in DYRK1A gene. Both have significant speech deficit. One of them also had additional abnormalities including dystrophic disc with myelinated nerve fibre layer in her left eye, cleft dimple complex on the right cerebrum in brain MRI imaging.

## 1176W

**Expanding the spectrum of BAF-related disorders – *de novo* variants in SMARCC2 cause a syndrome with intellectual disability, developmental delay and growth retardation.** K. SMARCC2 (BAF170, MIM:601734) is one of the invariable core subunits of the ATP-dependent chromatin remodeling BAF (BRG1-associated factor) complex and plays a crucial role in embryogenesis and corticogenesis. Pathogenic variants in genes encoding other components of the BAF complex have been associated with intellectual disability syndromes. Despite its significant biological role variants in *SMARCC2* have not been associated with human disease previously. Using whole exome sequencing and a web-based gene-matching program, we identified 15 individuals with variable degrees of neurodevelopmental delay and growth retardation harboring one of 13 heterozygous variants in *SMARCC2*, most of them novel and proven *de novo*. The clinical presentation overlaps with other BAF-related syndromes (BAFopathies) and includes prominent speech impairment, hypotonia, feeding difficulties, behavioral abnormalities, and dysmorphic features such as hypertrichosis, thick eyebrows, thin upper lip vermilion, and upturned nose. Nine out of the fifteen individuals harbor variants in the highly conserved SMARCC2 DNA-interacting domains (SANT and SWIRM) and present with a more severe phenotype. Two of these individuals present cardiac abnormalities. Transcriptomic analysis of fibroblasts from affected individuals highlights a group of differentially expressed genes with possible roles in regulation of neuronal development and function, namely *H19*, *SCRG1*, *RELN* and *CACNB4*. Our findings suggest a novel SMARCC2-related syndrome which overlaps with the spectrum of BAF-related neurodevelopmental disorders.

## 1177T

**A novel X-linked dominant mutation of *MED12* causes Ohdo syndrome in a female patient.** H. Murakami<sup>1</sup>, Y. Kimura<sup>1</sup>, Y. Enomoto<sup>2</sup>, Y. Tsurusaki<sup>2</sup>, Y. Kuroda<sup>2</sup>, Y. Sugio<sup>3</sup>, K. Kurosawa<sup>1</sup>. 1) Division of Medical Genetics, Kanagawa Children's Medical Center, Yokohama, Japan; 2) Clinical Research Institute, Kanagawa Children's Medical Center, Yokohama, Japan; 3) Department of Pediatrics, Tsudumigaura Medical Center for Children with Disabilities, Yamaguchi, Japan.

*MED12* mutations have been shown to cause X-linked form of Ohdo syndrome, which comprises a heterogeneous group of disorders characterized by intellectual disability (ID) and blepharophimosis. We identified the novel *de novo* missense mutation in *MED12* [MIM 300188](NM\_005120:exon4:cG-514C:p.E172Q) in a female patient with severe ID and congenital anomalies. Patient is a five-year-old female who was first seen by medical genetics at about twelve months due to severe developmental delay (DD). She presented with severe ID/DD and congenital anomalies including ocular hypertelorism, strabismus, epicanthus, low nasal root, wide and thick alae nasi, pointed chin, hyperextension of limb joints, hypoplasia of nails, scoliosis and vitiligo. She was born at full term to non-consanguineous parents after an uncomplicated pregnancy and birth parameters were normal. Her developmental milestones were severely delayed: rolling over at 12 months, sitting at 2 years, walking at 3 years and 6 months. She could not speak meaningful words at 5 years of age. Standard karyotyping was normal. A brain MRI did not reveal abnormalities. We performed exome sequence and identified a novel heterozygous mutation in *MED12* gene. *MED12* encodes a subunit of the Mediator complex, which is required for transcription by RNA polymerase II. Sanger sequencing confirmed that this mutation was *de novo*. This mutation affects evolutionary highly conserved amino acid and is predicted damaging to protein function. Analysis of X-chromosome-inactivation status showed skewed pattern. There has been a very few reports of X-linked dominant mutation in *MED12*. This is a first report about *MED12* mutation that causes severe ID and congenital abnormalities in a female patient.

**1178F**

**Novel biallelic mutations in *SZT2* cause mild intellectual disability and epilepsy: Expanding the phenotypic spectrum.** Y. Nakamura<sup>1</sup>, Y. Togawa<sup>2</sup>, Y. Okuno<sup>3</sup>, H. Muramatsu<sup>4</sup>, K. Nakabayashi<sup>5</sup>, Y. Kuroki<sup>6</sup>, D. Ieda<sup>1</sup>, I. Hori<sup>1</sup>, Y. Negishi<sup>1</sup>, T. Togawa<sup>1</sup>, A. Hattori<sup>1</sup>, S. Kojima<sup>1</sup>, S. Saitoh<sup>1</sup>. 1) Department of Pediatrics and Neonatology, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan; 2) Department of Pediatrics, Toyohashi Municipal Hospital, Aichi, Japan; 3) Center for Advanced Medicine and Clinical Research, Nagoya University Hospital, Nagoya, Japan; 4) Department of Pediatrics, Nagoya University Graduate School of Medicine, Nagoya, Japan; 5) Department of Maternal-Fetal Biology, National Research Institute for Child Health and Development, Tokyo, Japan; 6) Department of Genome Medicine, National Research Institute for Child Health and Development, Tokyo, Japan.

**Background:** The *SZT2* gene is transcribed in many tissues, with predominant expression in brain. Recent reports have revealed that dysfunctional *Szt2* results in hyperactivation of mTORC1 signaling under nutrient-deprived conditions. The first clinical report in 2013 revealed biallelic mutations in *SZT2* caused early-onset epileptic encephalopathy and dysmorphic corpus callosum, followed by the second report of patients with non-syndromic intellectual disability without seizures. Since then, 6 individuals with *SZT2* mutations, all of whom showed severe early-onset epileptic encephalopathy, have been reported. We herein report an additional patient with biallelic mutations in *SZT2*, which were confirmed by genetic and biochemical analyses. **Case report:** The proband is a 4-year-old girl. Neonatal period was uneventful, but she showed developmental delay with holding up her head at 7 months, sitting at 2 years, and walking at 3 years of age. She was not able to speak meaningful words. Seizures began at 3 years, which were readily controlled by valproate. An EEG showed epileptic discharges which rarely occurred. Brain MRI revealed a short and thick corpus callosum. At 4 years of age, she showed macrocephaly, high forehead, hypertelorism, and pectus carinatum. Whole-exome sequencing detected compound heterozygous *SZT2* mutations, namely c.8596dup (p.Tyr2866Leufs\*42) and c.2930-17\_2930-3delinsCTC-GTG, all of which transcripts were experimentally confirmed to result in loss of function. Immunoblotting using the lysates of patient's peripheral leukocytes cultured under amino acid-deprived condition showed increased phosphorylation of S6K protein, indicating abnormal hyperactivation of mTORC1 signaling. **Conclusion:** The severity of this case appears to be intermediate between the previously reported severe and mild phenotypes, which suggests a broad phenotypic spectrum arising from *SZT2* mutations, forming a continuum from epileptic encephalopathy and severe developmental delay to mild intellectual disability without epilepsy. Furthermore, biochemical analyses using peripheral leukocytes might be useful for determining the pathogenicity of *SZT2* variants.

**1179W**

**The first report on a patient with OGT catalytic core mutation causing O-GlcNAc transferase defect.** K. Ounap<sup>1,2</sup>, S. Pajusalu<sup>1,2</sup>, R. Zordania<sup>1</sup>, M.H. Wojcik<sup>3,4</sup>, V. Pravata<sup>5</sup>, D. Van Aalten<sup>5</sup>. 1) Department of Clinical Genetics, United Laboratories, Tartu University Hospital, 2 L. Puusepa street, Tartu 50406, Estonia; 2) Department of Clinical Genetics, Institute of Clinical Medicine, University of Tartu, 2 L. Puusepa street, Tartu 50406, Estonia; 3) Divisions of Newborn Medicine and Genetics and Genomics, Department of Medicine, Boston Children's Hospital, Harvard Medical School, Boston, MA, USA; 4) Broad Institute of MIT and Harvard, Cambridge, MA, USA; 5) School of Life Sciences, University of Dundee, Dow Street, Dundee DD1 5EH, Scotland, United Kingdom.

Five missense mutations in O-GlcNAc transferase (OGT) have recently been reported to cause X-linked intellectual disability (XLID). All of these previously-described cases, missense mutations are located in the tetratricopeptide (TPR) repeats of OGT. Here we report for the first time a missense variant identified in the OG catalytic core. **Case report:** At birth, the patient presented with remarkable facial asymmetry and almost missing toenails were described. Clinical problems started at 4 months of age with very serious stomach pain and gases, and frequent otitis. Development was subsequently delayed between 6 months and 24 months due to recurrent infections and feeding problems. He started to stand at 24 months and to walk at 28 months. At 7 years of age, his height was 127 cm (+1 SD), weight 23.4 kg (0 SD) and OFC 52 cm (-0.5 SD). He presently has moderate to severe intellectual disability. In addition, he has coarse facial features, strabismus, increased drooling, hyperactivity, no speech, muscular hypotonia and mild T2-3 syndactyly. Brain MRI at 5 years of age showed brain atrophy and a mega cisterna magna. X ray investigation showed cone shape epiphyses of T2-T5. Biochemical analyses showed increased thyroglobulin and FSH, and low percentage of activated T lymphocytes (2.0, normal 2.3-7.0 %). **Methods and results:** Trio whole genome sequencing and data processing were performed by Genomics Platform at the Broad Institute of Harvard and MIT (Broad Institute, Cambridge, MA, USA), which identified a *de novo* variant in *OGT* gene's protein domain: C-terminal O-GlcNAc transferase: ChrX(GRCh38): g.71561865A>T; NM\_181672.2: c.1942A>T p.(Asn648Tyr). The variant appeared as *de novo* in protein domain: O-GlcNAc transferase, C-terminal. The mutated p.Asn648 amino acid is highly conserved up to *C. elegans*, and multiple *in-silico* pathogenicity predicting algorithms indicated a damaging effect. Unlike previous OGT mutations described, this mutation is located in the catalytic domain. We have determined the crystal structure of the enzyme to reveal this mutation is proximal to the active site. However, *in vitro* tests of the mutated form of the enzyme has not revealed changes in O-GlcNAc transferase activity. We are currently investigating the effects of this mutation on differentiation of stem cells into neurons and I will report the latest results of this.

**Molecular analysis of *CC2D1A* and *PRSS12* genes in affecteds with cognitive dysfunction.** *I.G. Rasool, M.Y Zahoor, H.Q Abbas.* Institute of Biochemistry and Biotechnology, University of Veterinary and Animal Sciences, Lahore, Punjab, Pakistan.

**Introduction:** Cognitive disability is a group of genetically heterogeneous abnormality that leads to variable degrees of intellectual disability. This disease affects 1-3% of overall population in globe and majority of monogenic variants are not well characterized. It has been shown that such inherited disorders can be caused by mutations in over a large number of different genes and there is evidence for the presence of as yet unknown genes in a significant proportion of patients. **Materials & Methods:** The study was carried for mutational analysis of genes reported for involvement in cognitive dysfunction. We have screened *CC2D1A* and *PRSS12* genes in ten patients of cognitive dysfunction after enrolling with informed written consents. DNA sequencing of selected exons of the genes were carried out by Sanger method through ABI 3130 sequencer. Bioinformatics analysis performed for polymorphism analysis and protein prediction. **Results:** We mapped with one novel mutation in three patients. This is a deletion of A at 331N position (Chr.19: 14034167/14034169) of *CC2D1A* and it leads to frame-shift and production of truncated protein and thus causing moderate level of cognitive dysfunction. This is the third report in the globe for a novel mutation in *CC2D1A* gene in three unrelated affecteds with cognitive dysfunction. **Conclusion:** The cognitive dysfunction is a lifetime burden in the affecteds of this group and their families. This condition advocates the establishment of expanded newborn screening program for this disorder in indigenous and neighboring populations.

**1181F**

**Three individuals with neurodevelopmental disorders caused by heterozygous protein- truncating variants in *KMT5B*.** *K. Takano<sup>1,2</sup>, T. Fukuyama<sup>3</sup>, M. Motobayashi<sup>4</sup>, M. Hosoya<sup>5</sup>, T. Yamaguchi<sup>1,2</sup>, R. Kawamura<sup>6</sup>, K. Wakui<sup>1,2</sup>, Y. Fukushima<sup>1</sup>, T. Kosho<sup>1,2</sup>.* 1) Department of Medical Genetics, Shinshu University School of Medicine, Matsumoto, Nagano, Japan; 2) Center for Medical Genetics, Shinshu University Hospital, Matsumoto, Japan; 3) Neonatology and Developmental Medicine, Shinshu University School of Medicine, Matsumoto, Japan; 4) Division of Neurology, Nagano Children's Hospital, Azumino, Nagano, Japan; 5) Division of Pediatrics, Saku Central Hospital Advanced Care Center, Saku, Japan; 6) Division of Molecular Genetics, Institute for Comprehensive Medical Science, Fujita Health University, Toyoake, Japan.

Mutations in the genes encoding histone lysine methyltransferases (KMTs) or histone lysine demethylases (KDMs) play a role in the pathogenesis of neurodevelopmental disorders (NDDs). The *KMT5B* (*SUV420H1*) gene, encoding a KMT, was first reported to be a candidate gene for autism spectrum disorder (ASD) in 2012. In 2017, *KMT5B* was reported to cause intellectual disability/developmental delay (ID/DD), ASD, febrile seizures, and overgrowth in seven patients (OMIM#617788). Including these reports, only eleven patients have been published. Here, we report a familial case and a de novo case with heterozygous protein-truncating variants in *KMT5B*. **A familial case:** the proband is a 4-years-old boy with infantile hypotonia, mild to moderate DD, autistic features, and epilepsy. His father is healthy. His mother was not good at studying in childhood, though she has never been diagnosed with NDDs. She receives support for housework and child-rearing from her parents now. The elder sister of the proband died from sudden infant death syndrome at age 8 months. Targeted next-generation sequencing (NGS) identified a heterozygous splice-acceptor site variant, c.544-2A>G in *KMT5B* (NM\_017635) in the proband and his mother, which resulted in aberrant splicing evidenced by reverse transcriptase-PCR. **A de novo case:** the proband is a 4-years-old boy with ASD, mild DD, and macrocephaly. There is no family history of NDDs or macrocephaly. Targeted NGS identified a de novo heterozygous frameshift variant (c.2260delG: p.D754Ifs\*6) in *KMT5B* in the proband. The two novel variants in *KMT5B* identified in this series were predicted to be loss-of-function through disrupting the gene. All three individuals had various degrees of ID/DD with or without ASD/seizures/overgrowth. These findings suggest a high phenotypic variability even in the same family associated with heterozygous *KMT5B* variants. Further study would be needed to delineate the disorder including the genotype-phenotype correlations.

**1182W**

**Targeted next-generation resequencing analysis in 105 Japanese subjects with undiagnosed intellectual disability and multiple congenital anomalies.** *D.T. Uehara<sup>1</sup>, K. Tanimoto<sup>2</sup>, J. Inazawa<sup>1,3</sup>.* 1) Department of Molecular Cytogenetics, Medical Research Institute, Tokyo Medical and Dental University, Tokyo, Japan; 2) Genome Laboratory, Medical Research Institute, Tokyo Medical and Dental University, Tokyo, Japan; 3) Bioresource Research Center, Tokyo Medical and Dental University, Tokyo, Japan.

Intellectual disability (ID) is a complex neurodevelopmental disorder, estimated to affect 1-3% of the general population. ID can be non-syndromic or syndromic, the latter of which is usually referred as multiple congenital anomalies (MCA). Due to the high genetic heterogeneity of ID, the diagnosis of a large subset of cases remains unknown. The present study had the goal of detecting disease-associated single nucleotide variants (SNVs) in ID/MCA subjects previously negative for pathogenic copy number variants, through targeted resequencing by a custom panel of 75 genes. In this panel, 61 genes are the most frequently mutated known genes causing ID/MCA, and the remaining 14 genes were included as candidate genes. In total, we have screened 105 patients, in which causative or likely pathogenic variants in known genes were found in 20% of the cases (21/105). Mutations were found in 19 different genes, in which *DDX3X* and *PPP2R5D* were found mutated in more than one patient. Among the cases with available parental samples, *de novo* mutations were identified in *GNAO1* (p.E246K), *SATB2* (p.W535\*), *PPP2R1A* (p.R182W) and *STXBP1* (p.D255Y). As to candidate genes, a missense variant was detected in the *GAP43* (p.A179V) gene. However, as the inheritance could not be determined so far, this variant remains with uncertain significance. The diagnostic yield of 20% is consistent with previous studies and highlights the utility of targeted resequencing for the screening of variants in the most frequently mutated ID/MCA genes.

**1183T**

**Expanding phenotypes of patients with constitutional pathogenic variants in *KAT6A*: Four patients with syndromic intellectual disability.** *T. Uehara<sup>1</sup>, S. Mizuno<sup>2</sup>, A. Kondo<sup>3</sup>, T. Kirino<sup>3</sup>, H. Ootani<sup>4</sup>, T. Okazaki<sup>5</sup>, Y. Yamaguchi<sup>1</sup>, H. Suzuki<sup>1</sup>, Y. Sakaguchi<sup>1,6</sup>, T. Takenouchi<sup>6</sup>, K. Kosaki<sup>1</sup>.* 1) Center for Medical Genetics, Keio University School of Medicine, Tokyo, Japan; 2) Department of Pediatrics, Central Hospital, Aichi Human Service Center, Aichi Japan; 3) Department of Obstetrics and Gynecology, Shikoku Medical Center for Children and Adults, Kagawa, Japan;; 4) Department of Pediatrics, Tottori prefecture Tottori Chuo Hospital, Tottori, Japan; 5) Division of Child Neurology, Department of Brain and Neurosciences, Faculty of Medicine, Tottori University, Tottori, Japan; 6) Department of Pediatrics, Keio University School of Medicine, Tokyo, Japan.

*KAT6A*, which is a member of the MYST family of histone acetyltransferases, has attracted attention as a gene associated with human malignant diseases. Recently, *KAT6A* has also been reported as a gene associated with human neurodevelopmental disorders. The phenotypic spectrum of *KAT6A* haploinsufficiency has yet to be delineated. Here, we report four unrelated patients with pathogenic variants in *KAT6A*. Patient 1 was an 8-year-old male with a *de novo* heterozygous *KAT6A* p.S985R mutation identified in a trio exome analysis. He had a severe intellectual disability (ID), speech disturbance, and dysmorphic facial features including a smooth philtrum, puffy eyebrows, a wide nasal bridge, epicanthal folds, a high arched palate, and preauricular pits. He also had MP joint contractures, cryptorchidism, and epilepsy. Patient 2 was a 10-year-old male with a *de novo* heterozygous *KAT6A* p.V1425TfsTer13 mutation. He had an ID, an atrial septal defect, a hydronephrosis, and dysmorphic facial features including hypertrichosis, a long nose, posteriorly rotated ears, low-set ears, and blephalophimosis. Patient 3 was a 7-year-old female with a *de novo* heterozygous *KAT6A* p.L1456QfsTer9 mutation. She had an ID, an atrial septal defect, and hypothyroidism requiring thyroid hormone replacement therapy. She also had loose skin and dysmorphic facial features including down-slanted palpebral fissures, a flat nose, and a small chin. Patient 4 was a 2-year-old male with a *de novo* heterozygous *KAT6A* p.R1024X mutation. He had a severe ID and a developmental delay. He also had an atrial septal defect, cryptorchidism, hypospadias, an equinus foot, long fingers, and dysmorphic facial features including low-set ears, a long nose, and left ptosis. The four documented patients had ptosis or blephalophimosis and congenital heart defects, both have been previously reported. In addition, three of the four documented patients had genitourinary problems and one had hypothyroidism. Constitutional mutations in *KAT6B*, which is similar in structure to *KAT6A*, cause neurodevelopmental disorders characterized by developmental delay, intellectual disability, ptosis, blephalophimosis, congenital heart defects, hypothyroidism, and genitourinary anomalies. Thus, patients with *KAT6A* mutations may have phenotypes similar to those of patients with *KAT6B* mutations. In conclusion, both hypothyroidism and genitourinary problems should be included in the expanded phenotypes of patients with *KAT6A* mutations.

**1184F**

**Identifying disorder-specific methylation signatures in patients with severe developmental disorders.** J.E. Handsaker, E.J. Gardner, P.J. Short, G. Gallone, L. Parts, J.C. Barrett, M.E. Hurler on behalf of the Deciphering Developmental Disorders study. Human Genetics, Wellcome Sanger Institute, Hinxton, Cambridgeshire, United Kingdom.

Chromatin-modifying genes (CMGs) are a diverse set of genes whose protein products bind to chromatin and regulate cellular processes including proliferation and the regulation of gene expression via modification of histones. Deleterious mutations within CMGs are significantly enriched in patients with severe developmental disorders (DD) and mutations in over 50 CMGs have been robustly associated with DDs. As previous studies have shown that perturbations of the histone code impact DNA methylation, we have characterised methylation profiles in blood-derived DNA from 128 DD probands with *de novo* mutations in one of 22 disease-associated CMGs from the Deciphering Developmental Disorders (DDD) study, a UK-wide cohort of 13,600 children with DD. A median of 5 patient samples were selected per CMG disorder and, along with a selection of age and sex matched negative controls, were methylation profiled using an Illumina EPIC array. Using our methylation data as input to a simple linear correlation model, we sought to identify a CpG methylation signature discriminating between case and control individuals for each CMG disorder. For many CMGs (including *NSD1*, *DNMT3A*, and *EP300*) we were able to establish a signature based on differential methylation, which indicates that such a perturbed phenotype is a general characteristic of CMG disorders, and that these signatures could be diagnostically predictive. We will describe validation of these methylation signatures in additional independent cases run on the same methylation array, as well as quantification of the strength and specificity of these methylation signatures, and exemplification of the diagnostic use of these signatures when the *de novo* status of a variant is not available. We will also describe analyses of the transferability of methylation signatures between centres and across different arrays, using methylation signatures of CMG disorders previously published by other groups. Overall, our study highlights the utility of DNA methylation profiles as biomarkers supporting the diagnosis of CMG disorders.

**Learn as we go: Studying Xia-Gibbs Syndrome through a disease specific registry and community engagement.** Y. Jiang<sup>1,2</sup>, D. Murdock<sup>1,2</sup>, M. Wangler<sup>2,3</sup>, J. Posey<sup>2</sup>, Q. Meng<sup>1,2</sup>, M. Khayat<sup>1,2</sup>, M. Murugan<sup>1,2</sup>, A. McGuire<sup>4</sup>, F. Xia<sup>2</sup>, J. Lupszki<sup>2,5,6</sup>, R. Gibbs<sup>1,2</sup>. 1) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX; 2) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; 3) Department of Pediatric Radiology, Texas Children's Hospital, Houston, TX; 4) Center for Medical Ethics and Health Policy, Baylor College of Medicine, Houston, TX; 5) Department of Pediatrics, Baylor College of Medicine, Houston, TX; 6) Texas Children's Hospital, Houston, TX.

**Background:** The rapid increase in the discovery rate of genes underlying rare Mendelian disease has challenged the pace at which we can systematically study phenotypic and genotypic features that yield insight into disease mechanism. We have combined scientific efforts with interactions with families in order to speed our understanding of Xia-Gibbs Syndrome (OMIM: 615829: XGS), a Mendelian disorder discovered in 2014 and characterized by a *de novo* heterozygous loss of function mutation in the *AHDC1* gene located on chromosome 1p36 (Xia *et al.*, 2014). The disorder was first identified in four individuals, but now approximately 80 families worldwide are known via personal communication and social media. Molecular studies and interaction with the families enable exploration of nuances that can both explain laboratory observations and suggest new experiments. **Methods:** We obtained institutional review board (IRB) approval at Baylor College of Medicine to recruit families to an XGS Registry. For families who consent to join, we provide HIPAA compliant secure links to collect clinical information including: clinical reports, MRI imaging, clinical surveys specifically designed to assess XGS related phenotypes. **Results:** As of June 2018, 34 of the 83 known families have joined the registry and 28 have provided detailed clinical information. We also evaluated 19 families through face-to-face meetings or clinical visits. In addition to consolidating the initial phenotypic descriptions (Jiang *et al.*, 2018) we have (i) identified a 56-year-old individual with XGS (the oldest patient previously known was 21) (ii) established a cohort of individuals with *de novo* missense *AHDC1* variants to further study if this is the unique explanation for pathogenicity and (iii) identified cases with deletions involving *AHDC1* to further explore the XGS phenotype. Families have reported under-appreciated clinical features that now warrant study to identify molecular correlates. Among these are (i) irregular sleep-wake rhythm (ii) sensitivity to barometric pressure, (iii) lack of sweat and/or tears, (iv) sometimes hypersocial behavior. **Conclusion:** Systematic research on rare Mendelian disorders is a learning-as-we-go process and requires extensive community and stakeholder (patient, family, physician, researcher) involvement. A disease gene specific registry is an effective platform to systematically study rare Mendelian disorders and has been used here to advance our knowledge of XGS.

**Purpose:** *RAC3* is an under-examined member of the Rho GTPase gene family that is expressed in the developing brain and linked to key cellular functions. *De novo* missense variants in the homolog *RAC1* were recently associated with developmental disorders. In the *RAC* subfamily, transforming missense changes at certain shared residues have been observed in human cancers and previously characterized in experimental studies. The purpose of this study was to determine whether constitutional dysregulation of *RAC3* is associated with human disease. **Methods:** We discovered a *RAC3* variant in the index case using whole-genome sequencing, and searched for additional variants using international data-sharing initiatives. Functional effects of the variants were assessed using a multifaceted approach generalizable to most clinical laboratory settings. **Results:** We rapidly identified five individuals with *de novo* monoallelic missense variants in *RAC3*, including one recurrent change. Every participant had severe intellectual disability and brain malformations. *In silico* protein modeling, and prior *in vivo* and *in situ* experiments, supported a transforming effect for each of the three different *RAC3* variants. All variants were observed in databases of somatic variation in cancer. **Conclusion:** Missense variants in *RAC3* cause a novel brain disorder, likely through a mechanism of constitutive protein activation.

Next generation sequencing requires next generation phenotyping. Especially in genetically and clinically heterogeneous diseases, such as intellectual disability (ID), phenotyping should be detailed and standardized. Human Phenotype Ontology (HPO) provides >11,000 standardized terms to describe human disease and has previously been combined with literature on disease-gene annotation to provide potential genotype-phenotype correlations. However, since the specificity of an HPO feature in the ID population is unknown, the value of these observations in novel syndromes remains inconclusive. Here we present the results of a unique phenotype database, with detailed and standardized clinical information of 7,697 individuals with developmental delay (DD)/ID who had a SNP-array and/or whole exome sequencing. For 5,935 individuals (77%), clinical information of the diagnostic request form was used, whereas for 1,762 individuals (23%) all clinical data from the medical record was included. As expected, the group of individuals of whom the medical record was checked was represented by more features per individual than the other group (18.4 and 6.6 respectively, *p*-value <0.05, independent samples *t*-test). For all 3,256 reported HPO features the frequency was calculated, which will provide an essential tool for better evaluation and diagnosis of individuals with novel ID syndromes. To correlate phenotypic features in this ID cohort to the general population, we used the frequencies of 65 major congenital malformations in the general population provided by Eurocat, a European network of population-based registries for congenital anomalies and compared these to the frequencies in our database. 58 of 65 (89%) malformations were reported in the DD/ID cohort and for the majority of these (*n*=36, 62%), the frequency in the DD/ID cohort was significantly enriched, showing that major congenital abnormalities are more often seen in individuals with DD/ID than in the general population. Moreover, we translated the HPO features to a phenotypic score for each individual and confirmed that a higher phenotypic score is correlated to obtaining a conclusive genetic diagnosis (*p*-value <0.05, Kruskal Wallis-test). In conclusion, we provide frequencies of HPO features in a large representative cohort of individuals with DD/ID and show that quantification of phenotyping will not only lead to better interpretation of clinical heterogeneity, but also to better understanding of genomic variation.

**1188W****Novel c.5535-1G>A variant in a patient with a mild features of CHARGE syndrome.**

*E. Siavriene<sup>1</sup>, G. Petraityte<sup>1</sup>, V. Mikstiene<sup>1,2</sup>, T. Rancelis<sup>1,2</sup>, Z. Maldziene<sup>1</sup>, A. Morkuniene<sup>2</sup>, E. Preiksaitiene<sup>1,2</sup>, V. Kucinskas<sup>1</sup>.* 1) Department of Human and Medical Genetics, Institute of Biomedical Sciences, Faculty of Medicine, Vilnius University, Vilnius, Lithuania; 2) Center for Medical Genetics, Vilnius University Hospital Santaros Klinikos, Vilnius, Lithuania.

**Background:** CHARGE syndrome (MIM# 214800), which is characterized by a number of congenital anomalies including coloboma, ear anomalies, deafness, facial anomalies, heart defects, atresia choanae, genital hypoplasia, growth retardation, and developmental delay, is caused by heterozygous mutation in the *CHD7* (MIM# 608892) on chromosome 8q12. **Clinical report:** In the present study, we report a female individual with a novel heterozygous splice c.5535-1G>A variant in *CHD7* gene, that has not been reported previously. The patient has many characteristic features of CHARGE syndrome such as visual disturbance, hearing impairment, facial anomalies, congenital heart defect, choanal atresia, and delayed puberty. **Methods:** Whole-exome sequencing (WES) followed by functional genome analysis was conducted for the proband with suspected CHARGE syndrome. In order to elucidate the pathogenicity of the detected variant in *CHD7* gene, proband's total blood RNA was isolated and template cDNA was synthesized. Subsequently, *CHD7* gene 26-27 exon junction was sequenced in cDNA sample using Sanger sequencing. **Results:** Heterozygous *CHD7* gene variant c.5535-1G>A located in the acceptor splice site of intron 26 was identified in proband's DNA sample after analysis of WES data. *In silico*, the alteration of splice acceptor site was predicted to affect pre-mRNA splicing. Sanger sequencing of cDNA revealed that c.5535-1G>A disrupts the original splice acceptor site and activates a cryptic splice site only one nucleotide downstream of the pathogenic variant site. This change causes the deletion of the first nucleotide of exon 27 and leads to a frameshift in cDNA and protein. Our results suggest that the alteration leads to the premature truncation of the protein thus resulting in CHARGE syndrome. **Conclusion:** Functional genomic approach of cDNA analysis provides a unique possibility to understand the etiology and pathophysiology as well as to identify the molecular basis of many hereditary diseases and conditions including those associated with congenital anomalies. The work was funded by the Research Council of Lithuania (No. S-MIP-17-19/LSS-150000-1179, Ingenes project).

**1189T****3-Hydroxy-3-methylglutaryl-coenzyme A lyase deficiency presenting with rhabdomyolysis.**

*E.E. Conboy<sup>1</sup>, M.K. Myers<sup>2</sup>, P. Rinaldo<sup>1</sup>, K.M. Raymond<sup>1</sup>, D. Matern<sup>1</sup>, S. Tortorelli<sup>1</sup>, D. Gavrilov<sup>1</sup>, B.C. Lanpher<sup>3</sup>.* 1) Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN, USA; 2) Critical Care Medicine (Internal Medicine), Mayo Clinic, Rochester, MN, USA; 3) Department of Clinical Genomics, Mayo Clinic, Rochester, MN, USA.

3-Hydroxy-3-methylglutaryl-coenzyme A lyase deficiency (HMGCLD) is a rare inborn error of ketone body synthesis and leucine degradation. The mitochondrial enzyme 3-Hydroxy-3-methylglutaryl-coenzyme A lyase converts 3-Hydroxy-3-methylglutaryl-coenzyme A to acetoacetate and acetyl-coenzyme A. Patients with this disorder are prone to hypoketotic hypoglycemia during a metabolic disturbance. Our patient is a 29 year old male with known HMGCLD and a history of seizures associated with hypoglycemia, last occurring approximately 10 years prior to presentation. He was found down in the field with hypoglycemia (glucose of 20 mmol/L). He was intubated and sedated with propofol for several days. He had significant rhabdomyolysis with a creatine kinase above the detectable limit of 197,500 U/L causing renal failure, and was transferred to our institution for further management. At the time of his hospitalization a plasma acylcarnitine profile was obtained. The concentrations of 3-hydroxyisovaleryl-/2-methyl-3-hydroxybutyryl- carnitine (C5-OH) and 3-methylglutaryl carnitine (C6-DC) were prominently elevated, consistent with the known diagnosis of 3-hydroxy 3-methylglutaryl-(HMG)-CoA lyase deficiency. Rhabdomyolysis is not a known complication of HMGCLD. It is a component of propofol infusion syndrome (PRIS), a combination of findings including metabolic derangements and organ failure that can occur in patients receiving propofol. The current theory regarding the pathophysiology of PRIS proposes that propofol inhibits intracellular energy production by inhibiting the membrane-bound transporter carnitine palmitoyl transferase I (CPT1) as well as a direct inhibitory effect on the mitochondrial respiratory chain. Since HMG-CoA lyase deficiency is also an abnormality of fatty acid oxidation, it may be that patients with this rare genetic disorder are predisposed to PRIS. It seems reasonable to hypothesize that the propofol infusion may have exacerbated or precipitated rhabdomyolysis. This may warrant avoiding propofol in patients with HMG CoA Lyase deficiency.

**A multicenter, double-blind, placebo-controlled, multiple-dose study assessing the safety and efficacy of MNK-1411 in patients with Duchenne muscular dystrophy.** *B.R. Due<sup>1</sup>, P. Becker<sup>2</sup>, T.O. Crawford<sup>3</sup>.* 1) Mallinckrodt ARD Inc., Bedminster, New Jersey; 2) Former employee of Mallinckrodt ARD Inc., Bedminster, New Jersey; 3) Department of Neurology, Johns Hopkins University, Baltimore, Maryland, United States.

**Background:** Duchenne muscular dystrophy (DMD) is a recessive X-linked neuromuscular disorder caused by mutations in the gene for dystrophin, a structural protein essential for the normal development and survival of muscle. Frame-shifting and nonsense mutations in the dystrophin gene are associated with DMD. As the most common muscle disease in children, DMD typically manifests prior to 6 years of age, and results in progressive muscle degeneration and loss of ambulation. Corticosteroids are the only therapy with demonstrable effectiveness that are approved for treatment of all patients with DMD indifferent to the type of mutation. There are substantial off-target effects associated with long-term use of corticosteroids, however, highlighting the need for better therapies. MNK-1411 is a 24-amino-acid synthetic adrenocorticotropic hormone analogue and melanocortin receptor (MCR) agonist with the potential to slow DMD progression via MCR-mediated properties by reducing inflammation and/or attenuating muscle damage. **Objective:** To evaluate the safety and efficacy of MNK-1411 in male patients aged 4 to 8 years with DMD. **Methods:** This is a phase 2, multicenter, double-blind, placebo-controlled, multiple-dose study (ClinicalTrials.gov Identifier: NCT03400852). Patients randomized 2:2:1:1 into the 24-week double-blind phase will receive weight-based doses of subcutaneous MNK-1411 or volume-matched placebo (2x/week). The 4 treatment groups comprise Group A, 0.5-mg MNK-1411 (0.5 mL for patients >20 kg) or 0.4-mg MNK-1411 (0.4 mL for patients ≤20 kg); Group B, 0.25-mg MNK-1411 (0.25 mL for patients >20 kg) or 0.2-mg MNK-1411 (0.2 mL for patients ≤20 kg); Group C, 0.5-mL or 0.4-mL placebo; and Group D, 0.25-mL or 0.2-mL placebo. Patients who complete the blinded phase will be eligible to enter a 24-week open-label extension phase and continue receiving the same volume of MNK-1411. The primary efficacy endpoint is change from baseline in the 10-meter walk/run at Week 24. Adverse events will be monitored throughout the study. **Results:** Approximately 130 patients will be enrolled at 50 global sites; the trial will have 80% power to detect a treatment difference between groups at a significance level of 0.05. **Conclusions:** This study will potentially provide data to support the safety and efficacy of MNK-1411 for treatment of DMD.

**1191W**

**Persistent metabolic abnormalities and hypertrophic cardiomyopathy in a patient with multiple acylCoA dehydrogenase deficiency associated with a frameshift variant in *SLC52A1*.** *R.M. Zambrano<sup>1</sup>, H.R. Meddaugh<sup>1</sup>, S. Sernich<sup>2</sup>, M. Marble<sup>1</sup>.* 1) Department of Pediatrics, Division of Genetics, Louisiana State University Health Science Center, New Orleans, Louisiana; 2) Department of Pediatrics, Division of Pediatric Cardiology, Louisiana State University Health Sciences Center, New Orleans, Louisiana.

Multiple acylCoA dehydrogenase deficiency (MADD) is associated with elevations of metabolites of compounds oxidized by enzymes that depend on Flavin Adenine Dinucleotide (FAD) as a cofactor. MADD can be caused by pathogenic variants in a number of genes involved in riboflavin metabolism and transport including: *ETF*, *ETFDH*, *FLAD1*, *SLC25A32*, *SLC52A1*, *SLC52A2* and *SLC52A3*. MADD associated with pathogenic variants in *SLC52A1* is rare, having been reported in only 2 patients: a transient form associated with maternal riboflavin deficiency (Chiong et al., 2007; Ho et al., 2011) has been reported and the patient responded well to riboflavin supplementation; and a neonate with a maternally inherited intronic variant in *SLC52A1* (Mosegaard et al., 2017). This patient's MADD reportedly resolved with riboflavin supplementation which was discontinued at 30 months of age. MADD phenotype is quite variable and ranges from severe neonatal metabolic crisis to later onset forms presenting with weakness. Some patients develop hypertrophic cardiomyopathy (HCM). We report a new case of MADD associated with a maternally inherited frameshift variant in *SLC52A1* in a neonate with HCM and newborn screening suggestive of MADD. Fat and protein restriction were initiated along with riboflavin and carnitine supplements. The HCM improved, however despite elevated riboflavin levels, metabolic testing continued to show elevated metabolites. She was stable until 4 months old of age when she presented with respiratory failure, pericardial effusion, weakness and worsening HCM and a persistent MADD metabolic profile after a viral infection. We propose that pathogenic variants in *SLC52A1* cause some cases of MADD, with variable severity. The fact that the variant was inherited from an asymptomatic mother in our case and in Mosegaard's case suggests that pathogenic variants in *SLC52A1* are of reduced penetrance and may require other factors (environmental or genetic) to cause disease. Whole exome sequencing failed to identify any other explanation for the phenotype.

**1192T**

**Synergistic effect of mutations in dystroglycanopathies-associated genes? A Brazilian case report.** *M. Lazar<sup>1</sup>, K.M. Rocha<sup>1</sup>, M.C. Varela<sup>1</sup>, G.L. Yamamoto<sup>1,2</sup>, V.N. Takahashi<sup>1</sup>, K. Bagatini<sup>1</sup>, S. Ezquina<sup>1</sup>, M.O. Scliar<sup>1</sup>, J.Y.T. Wang<sup>1</sup>, R. Pavanello<sup>1</sup>, A.S. Bulle Oliveira<sup>3</sup>, M. Zatz<sup>1</sup>, M. Vainzof<sup>1</sup>, M.R. Passos-Bueno<sup>1</sup>.* 1) Human Genome and Stem Cell Research Center (HUG-CELL), University of São Paulo, São Paulo, Brazil; 2) Department of Clinical Genetics, Children's Hospital, Medical School, University of São Paulo, Brazil; 3) Department of Neurology, Neuromuscular Disorders Unit, Federal University of São Paulo, Brazil.

HUG-CELL has implemented targeted massively parallel sequencing (MPS) for diagnosis of several human diseases. Although the high sensitivity rate of ~70% experienced by our laboratory for neuromuscular disorders (NMD), some patients remain undiagnosed. Recently, a 43 year-old-woman presenting muscle weakness was referred to our center for genetic investigation. According to the neurologist request, the patient has relatives affected with FSHD1, and despite she presents proximal tetraparesis and myopathic EMG, normal D4Z4 alleles were reported. Informed consent was signed, in accordance with our ethical regulations. Using a commercial panel with ~6700 genes (TruSight One Expanded - Illumina), we focused our analysis on those involved in NMD. After variant filtering, three heterozygous variations in genes associated with autosomal-recessive dystroglycanopathies were prioritized: *GMPPB* [NM\_013334.3: c.859C>T p.(Arg287Trp); pathogenic rs142908436], *POMT2* [NM\_013382.5: c.1271A>G p.(His424Arg); located in MIR2 domain] and *DAG1* [NM\_004393.5: c.2571T>G p.(Asp857Glu); located in cytoplasmic topological domain of  $\beta$ -dystroglycan] (hg19/HGVS). Both *POMT2* and *DAG1* alterations were absent from disease-associated databases as well as from public variant repositories (gnomAD, ABraOM), and could have deleterious effects, according to multiple lines of computational evidence. Considering that: (1) mannanose-1-phosphate guanyltransferase  $\beta$  and protein O-mannosyltransferase 2 (respectively encoded by *GMPPB* and *POMT2*) are implicated in dolichol-phosphate mannanose (Dol-P-Man) synthesis and (2) the relevance of Dol-P-Man as a mannanose-donor in mannosylation processes of proteins like  $\alpha$ - and  $\beta$ -dystroglycan (encoded by *DAG1*), we hypothesized the identified variants could be interacting in a synergistic manner. Since the available data are insufficient to conclude the molecular diagnosis of the patient, we intend to perform: (1) segregation analysis of those variants in her parents and (2) protein analysis on her muscle biopsy to verify the possible occurrence of defective glycosylation process and/or secondary deficiency of the dystrophin-associated glycoprotein complex. The usage of MPS in clinical practice has increased the detection of patients who carry variants in functionally correlated genes and therefore reinforces the requirement for complementary studies to determine the deleteriousness of concurrent alterations. Financial support: Fapesp/CEPID and CNPq/INCT.

**1193F**

**KI/KO mice carrying a BAG3 mutation homologous to the human P209L myofibrillar myopathy mutation develop a clinical and pathological skeletal muscle phenotype.** *R. Robertson<sup>1</sup>, T. Conte<sup>1</sup>, M.J. Dicaire<sup>1</sup>, R. Bryson-Richardson<sup>2</sup>, J.N. Lavoie<sup>2</sup>, E. O'Ferrall<sup>1</sup>, J.C. Young<sup>1</sup>, B. Brais<sup>1</sup>.* 1) McGill, Montreal, Quebec, Canada; 2) Monash University, Australia; 3) Laval University, Quebec, Quebec.

BAG3 is a co-chaperone to heat-shock proteins important for the degradation of misfolded proteins through chaperone assisted selective autophagy. The recurrent dominant BAG3<sup>P209L</sup> mutation results in a severe myofibrillar myopathy associated with progressive muscle weakness, cardiomyopathy and respiratory failure. Since a homozygote knock-in line (KI) for the mP215L mutation homologous to the human P209L mutation did not have a gross phenotype, we generated heterozygote knock-out (KO) and KI mP215L mice to establish if a further loss of BAG3 expression would lead to a phenotype. Indeed, the KI/KO mice show a significant decrease in voluntary movement compared to wildtype KI/KI mice in the open field starting at 6 months, reminiscent to the decreased activity observed in aging patients. Pathologically, the KI and KI/KO lines both show significantly smaller fiber size, while only the KI/KO mice show clear skeletal muscle histological changes consisting of: centralized nuclei, splitting fibers and inflammatory infiltrate in particular at nerve entry zones and myotendinous junctions. These changes are increased following downhill running only in the KI/KO mice. The KI/KO mP215L line is the first murine model of BAG3 myopathy that may resemble the human skeletal muscle condition. It supports the data generated in zebrafish that to develop the myopathy some significant loss of the protein is needed and not only a gain of function mutation. The observation that the KI/KO mice are more vulnerable to muscle injury may explain in part the slow progression of this myopathy in humans. The further characterization of the BAG3 KI/KO mice will provide insight into the pathophysiology of this myofibrillar myopathy and may demonstrate its usefulness for pre-clinical trials.

Wheeler<sup>1,7</sup>. 1) Stanford Center for Undiagnosed Diseases, Stanford, CA; 2) Department of Pathology, School of Medicine, Stanford, CA; 3) HudsonAlpha Institute for Biotechnology, Huntsville, AL; 4) NIH Undiagnosed Diseases Network, Office of the Director and the National Human Genome Research Institute, National Institutes of Health, Bethesda, MD; 5) Department of Neurology, School of Medicine, Stanford, CA; 6) Department of Genetics, School of Medicine, Stanford, CA; 7) Division of Cardiovascular Medicine, School of Medicine, Stanford, CA; 8) Department of Pediatrics – Medical Genetics, School of Medicine, Stanford, CA.

*ADSSL1* encodes a muscle and cardiac-specific enzyme involved in the interconversion of inosine monophosphate and adenosine monophosphate in the purine nucleotide cycle. Deficiency of *ADSSL1* is thought to impair energy production, metabolic regulation, and synthesis of DNA and RNA. Biallelic loss of function variants in *ADSSL1* have recently been established as the cause of distal myopathy 5 (MPD5; OMIM:617030), an autosomal recessive condition characterized by adolescent onset distal myopathy, facial muscle weakness, elevated serum CK, and rimmed vacuoles. To date, only 3 pathogenic variants have been reported in 9 patients. We evaluated a 33-year-old male at the Stanford Center for Undiagnosed Diseases for slowly progressive myopathy, with involvement of the proximal and distal limb, ocular, facial, ventilatory and cardiac musculature. He presented to care at 23 years old with proximal muscle weakness and elevated CK, although he noted onset of diffuse weakness in childhood. Echocardiogram at 28 years old revealed mild global hypokinesis, decreased left ventricular function (EF=44%) and mild right ventricle dilation. Muscle biopsy showed type 2 fiber predominance, necrotic fibers, rimmed vacuoles and foci of chronic inflammation. His physical exam was notable for atrophic scarring and contractures of the deep finger flexors and elbows. Extensive testing for inflammatory and genetic etiologies were unrevealing. Genome sequencing (GS) revealed a homozygous pathogenic variant in the *ADSSL1* gene: c.910G>A, p.D304N. All 9 patients reported with MPD5 carry the c.910G>A variant in *trans* with a second pathogenic variant. While many aspects of our patient's phenotype overlap with MPD5, dilated cardiomyopathy (DCM) was not reported among the 7 of 9 patients screened with echocardiogram. Targeted-analysis of our patient's GS data did not reveal a pathogenic variant related to DCM. Thus, the association of DCM with the c.910G>A variant remains unclear. Functional studies including RNA sequencing and *in vitro* assay using iPSC-derived cardiomyocytes and skeletal muscle are ongoing. This case contributes to the emerging phenotype associated with biallelic loss of function variants in *ADSSL1*. Functional studies will clarify the association with DCM and underlying mechanism of disease. Ongoing cardiac evaluation of patients with MPD5 will help determine the natural history of cardiac muscle involvement.

MYF5 is member of the Myc-like basic helix-loop-helix transcription factor family and, in cooperation with other myogenic regulatory factors MYOD and MYF5, is a key regulator of early stages of myogenesis. Here, we report three consanguineous families with biallelic homozygous loss-of-function mutations in *MYF5* who define a new clinical disorder characterized by congenital ophthalmoplegia with scoliosis, vertebral, and rib anomalies. The clinical phenotype overlaps strikingly with that reported in several *Myf5* knockout mouse models. Affected members of two families share a haploidentical region that contains a homozygous 10bp frameshift mutation in exon 1 of *MYF5* (NM\_005593.2: c.23\_32delAGTTCTCACC, [p.Gln8Leufs\*86]) predicted to undergo nonsense-mediated decay. Affected members of the third family, who have external ophthalmoplegia harbor a homozygous missense change in exon 1 of *MYF5* (NM\_005593.2: c.283C>T, [p.Arg95Cys]). Using *in-vitro* assays we show that this missense mutation acts as a loss-of-function allele by impairing MYF5 DNA binding and nuclear localization. We performed whole genome sequencing in one affected individual with the frameshift mutation and did not identify additional rare variants in the haploidentical region that might account for differences in severity among the families. These data support the direct role of *MYF5* in rib, spine, and extraocular muscle formation in humans.

**Possible effect of sarcolemmal complex genes on the phenotype of Duchenne muscular dystrophy.** *M. Garcia-Acero*<sup>1,3</sup>, *T. Gamez*<sup>1</sup>, *T. Buitrago*<sup>1</sup>, *M. Guerra*<sup>1</sup>, *R. Garcia-Robles*<sup>2</sup>, *F. Suarez*<sup>1,3</sup>, *P. Ayala-Ramirez*<sup>1</sup>. 1) Instituto de Genetica Humana, Pontificia Universidad Javeriana, Bogota, Colombia; 2) Departamento de Ciencias Fisiológicas, Facultad de Medicina, Pontificia Universidad Javeriana, Bogota, Colombia; 3) Servicio de Genetica, Hospital Universitario San Ignacio, Bogota, Colombia.

**Introduction:** Duchenne muscular dystrophy (DMD), an X-linked recessive inheritance condition, caused by the absence of dystrophin, is characterized by atrophy and progressive muscle weakness. Despite the same altered gene, individuals with DMD have wide clinical variability, initially associated to the altered isoform related to the exon involved, however, individuals with the same mutation have a different clinical course. Given the complexity of the sarcolemma and considering the presence of multiple proteins involved in the maintenance and repair of muscle fiber, we have considered the search for variants in other genes considering a possible oligogenic effect modifier of the phenotype. **Methodology:** Next-generation Sequencing analysis of genes involved in the sarcolemmal complex in individuals with a pathogenic variant in the *DMD* gene using the Invitae Comprehensive Muscular Dystrophy Panel, which analyze sequence changes and exonic deletions/duplications in 55 genes associated with muscular dystrophies. Kaplan-Meier analysis of the clinical course in the presence of other variants. **Results:** 62 patients with pathogenic variants in *DMD* gene were studied. Most patients with codon stop mutations (43.13%), followed by frameshift mutation (27.45%) and intron variants (27.45%), the remaining percentage corresponds to individuals with missense variants (1.97%). In 42 (67.74%) individuals, at least one variant (uncertain significance, probably pathogenic and pathogenic) was documented in another gene, the most frequent being in *PLEC* (n=8), *SYNE1* (n=13) and *SYNE2* (n=7) genes. We mentioned two patients with the same pathogenic variant c.2804-1delG in the *DMD* gene, one of them with additional variants in the *SYNE1* and *FKTN* genes, with early developmental delay and cardiac conduction defect since the age of 4 years. The other patient with other variants in the genes *DMD*, *DES*, *DYSF*, *LAMA2*, *PLEC* and *POMT2* currently with 8 years with difficulty walking but without cardiac compromise. Other patients of 22 and 23 years with the pathogenic variant c.9040dupC in *DMD* and a in *SYNE1* currently with limitation for walking without cardiac or respiratory compromise. **Discussion:** the specific effect of variants in other associated to the sarcolemmal complex in individuals with Duchenne muscular dystrophy is unknown; however, the wide clinical variability may be partially explained due to the dysfunction of other muscle proteins, predominantly involved in muscle repair.

**Recurrent rhabdomyolysis and hyperCKemia: Consideration of broad molecular testing such as WES/WGS is indicated due to the broad differential of conditions.** *L. Massingham*<sup>1,2</sup>, *M.K. Cushing*<sup>1,2</sup>, *J. Schwab*<sup>1,2</sup>, *W. Campbell*<sup>1,2</sup>, *M. Mori*<sup>1,2</sup>, *C. Phornphutkul*<sup>1,2</sup>. 1) Department of Pediatrics, Division of Genetics, Hasbro Children's Hospital/Rhode Island Hospital, Providence, RI; 2) Alpert Medical School of Brown University, Providence, RI.

Recurrent rhabdomyolysis and hyperCKemia without muscle overt muscle weakness can be challenging cases as there are no clear guidelines for best practice. These are often difficult cases as the differential is broad and includes acquired causes, ethnic variation, autoimmune, lab error, and of course hereditary conditions. Even among the hereditary conditions the pathology can stem from metabolic, muscular, or endocrine origin. There are multiple different next generation sequencing panels for rhabdomyolysis and metabolic myopathies, but the genes included in these panels vary greatly by laboratory. We present multiple cases of hyperCKemia without weakness, rather in the setting of episodic pain or rhabdomyolysis, who underwent broad genetic testing, such as whole exome sequencing. For example, a 16 year old girl presented to our clinic with multiple episodes of rhabdomyolysis with CKs >20,000 after strenuous basketball practice. Whole exome sequencing identified a partial deletion of *DMD* involving at least exons 8-11, consistent with her being a "manifesting carrier". She does not report muscle weakness symptoms or exhibit muscle weakness on examination. She doesn't meet the criteria to consider Eteplirsen and the side effects of steroids were thought to outweigh the benefits. The *DMD* gene is not included in all rhabdomyolysis NGS panels. This unexpected diagnosis significantly changes her management, fortunately she does not have any cardiac manifestations of Duchenne muscular dystrophy at this time but she will need to continue with serial surveillance. Another example is a 20 year old young man with elevated CK incidentally found on routine bloodwork. His symptoms included daytime sleepiness and muscle weakness and fatigue after walking for 1 hour. Muscle biopsy revealed no evidence of myositis or dystrophy and no increase in glycogen. Metabolic workup was normal. He previously had a myopathy panel which only revealed one pathogenic variant in the *TK2* gene. Whole exome sequencing identified compound heterozygous changes in the *ANO5* gene (c.191dupA and c.1963T>C). These cases demonstrate the importance of consideration of inherited causes for rhabdomyolysis and hyperCKemia. Broad testing, such as whole exome sequencing or whole genome sequencing should be considered in these patients, even if a targeted panel has already been completed and is negative or inconclusive.

1) Broad Center for Mendelian Genomics and Program in Medical and Population Genetics, Broad Institute of MIT and Harvard, Cambridge, MA, USA; 2) Center for Genomic Medicine, Massachusetts General Hospital, Boston, MA, USA; 3) The Manton Center for Orphan Disease Research, Division of Genetics and Genomics, Boston Children's Hospital, Boston, MA, USA.

The Broad Institute Center for Mendelian Genomics (CMG) performs next generation sequencing to discover new disease genes underlying Mendelian disorders. In collaboration with investigators worldwide, the CMG analyzes diverse rare disease cohorts, including neuromuscular disorders. Congenital myopathies compose a tenth of all neuromuscular disorder cases and are found in around 1 in 16,000 live births. The typical phenotype includes congenital hypotonia and generalized skeletal muscle weakness that is non- or slowly progressive, often accompanied by facial weakness and respiratory insufficiency. Using our open-source, web-based analysis platform, *seqr*, we have achieved an overall diagnostic rate of around 30% through exome sequencing in our neuromuscular cohorts, which include many patients with prior negative gene panel testing. We have identified several high-confidence discoveries, including a novel mode of inheritance for *KDM5B* and a novel phenotype association for *MYLK*. Histone demethylase *KDM5B* has recently been associated with an autosomal recessive syndrome characterized by developmental delay, facial dysmorphism, and camptodactyly. We found a rare de novo nonsense variant in *KDM5B* in a patient with delayed gross motor development, hypotonia, arachnodactyly, and predominance of small type 1 myofibers. If proven pathogenic, this will expand the previously-reported phenotype and mode of inheritance for *KDM5B* variants. *MYLK*, a myosin light chain kinase, has been previously associated with autosomal dominant aortic aneurysm and intestinal/urinary smooth muscle defects. In a patient with muscle weakness resulting in mobility impairment, we discovered compound heterozygous missense and splice variants in *MYLK*. These candidate genes have been submitted to the Matchmaker Exchange through *matchbox* integration in *seqr*. *Seqr* is proving to be an effective collaboration tool in diagnosing patients and discovering new Mendelian disease genes. It features a user-friendly interface that facilitates collaborative analysis by providing a reproducible filter-based variant search; variant- and gene-specific information and links; and variant tagging and annotation to highlight and track discoveries. In the future, we plan to implement analysis of additional types of variation in *seqr*, including uniparental disomy and copy number and structural variation.

*SLC25A42* gene encodes an inner mitochondrial membrane protein that imports Co-enzyme A (CoA) into the mitochondrial matrix. A mutation in this gene was recently reported in a subject born to consanguineous parents who presented with mitochondrial myopathy with muscle weakness and lactic acidosis. In this report, we present 12 additional individuals with the same founder mutation who presented with variable manifestations ranging from asymptomatic lactic acidosis to a severe phenotype characterized by developmental regression and epilepsy. Our report confirms the link between *SLC25A42* and mitochondrial disease in humans, and suggests that pathogenic variants in *SLC25A42* should be interpreted with the understanding that the associated phenotype may be highly variable.

Li<sup>2</sup>. 1) Icahn School of Medicine at Mount Sinai, New York, NY; 2) Department of Human Genetics, Emory School of Medicine, Atlanta, GA.

**Introduction:** *EARS2* is associated with leukoencephalopathy with thalamus and brain stem involvement and high lactate (LTBL). All previously described cases had characteristic MRI findings of diffuse white matter changes and symmetrical signal abnormalities in the thalamus and brain stem. Clinical presentations fall into two groups- severe and mild. The patients in the severe group present before 6 months with marked neurological regression and then clinical stagnation. Patients in the mild group present later in infancy with mild neurological regression but they can regain some milestones. Here, we describe four patients with atypical and distinctive presentations. **Case studies:** Patient 1 is a 6 month old girl who presented at 3 months of age with seizures. Her growth and development were age-appropriate. She had hepatomegaly, abnormal liver function tests, and high lactate. Abdominal ultrasound showed an enlarged liver and MRI of the brain showed restricted diffusion in the white matter and corpus callosum. Basal ganglia and posterior fossa structures were normal. Two mutations in the *EARS2* gene, c.322C>T (p.R108W) and c.328 G>A (p.G110S) were identified. At 6 months of age, her physical growth, language and social development were normal, however, her motor development showed mild delay. Both lactate and liver enzymes were trending down. Patient 2 & 3 are female siblings (currently 2 and 5 years old), who were identified by newborn screening for SCID. They had persistent T cell lymphopenia, lactate elevation, and macrocytic anemia. Additionally, older sibling had failure to thrive and mild developmental delay before 2 years of age, which has resolved now. Bi-allelic, novel, likely pathogenic variants, c.485+4090\_511del5090 and c.667G>A, p.D223N in *EARS2* were detected in both. Patient 4 is 3 year old male with normal development until 12 months of age when he developed rapid regression of milestones. Now he is slowly gaining skills. MRI of the brain at the onset of symptoms was normal. Plasma lactate was elevated to 3.5 at presentation (repeat 1.4). WES identified two VUS in *EARS2* gene. **Conclusion:** Here, we describe patients with *EARS2* mutations with developmental delay, liver abnormalities, macrocytic anemia, and lymphocytopenia without typical "LTBL" presentation. Thus, the clinical spectrum/phenotype of *EARS2*-associated disease is wider than currently recognized. Moreover, *EARS2*-related lymphocytopenia could be detected by newborn screening for SCID. .

**In-Vivo oxidation of 1-<sup>13</sup>C-propionate as a surrogate endpoint for clinical outcomes in propionic acidemia.** O. Shchelochkov<sup>1</sup>, A. Pass<sup>1</sup>, S. Ferry<sup>1</sup>, C. Van Ryzin<sup>1</sup>, C. Chlebowskij<sup>2</sup>, J. Snow<sup>2</sup>, K. Chen<sup>2</sup>, J. Sloan<sup>1</sup>, I. Manoli<sup>1</sup>, A. Thurm<sup>2</sup>, C.P. Venditti<sup>1</sup>. 1) NHGRI, Bethesda, MD; 2) NIMH, Bethesda, MD; 3) NIDDK, Bethesda, MD.

Propionic acidemia (PA) is an organic acidemia caused by the reduced activity of propionyl-CoA carboxylase (PCC). PA is a multi-systemic disorder characterized by accumulation of propionyl-CoA-derived metabolites in body tissues. To date, our ability to predict clinically relevant outcomes based on genotype or biochemical markers has been lacking. We hypothesized that *in vivo* 1-<sup>13</sup>C-propionate oxidation could represent a surrogate biomarker for enzyme activity, and therefore would closely correlate with severity of pathogenic variants, biochemical parameters, growth, and cognitive functioning in patients with PA. Through a dedicated natural history study (The Natural History, Physiology, Microbiome and Biochemistry Studies of Propionic Acidemia, ClinicalTrials.gov ID NCT02890342), we evaluated 27 PA patients, mainly in the in-patient setting. The oxidation of 1-<sup>13</sup>C-propionate was measured in 24 patients. After a single oral or gastric bolus, <sup>13</sup>CO<sub>2</sub> enrichment in expired total CO<sub>2</sub> was analyzed using isotopic ratio mass spectroscopy, and the cumulative percentage of the isotopic dose metabolized over two hours was determined. Baseline VCO<sub>2</sub> production (ml/min) was measured by indirect calorimetry. A previous set of healthy volunteers (n=19) served as controls. Compared to healthy controls (47.7 ± 4.5%, mean±SD), PA patients had decreased oxidation of 1-<sup>13</sup>C-propionate to <sup>13</sup>CO<sub>2</sub> (15.9 ± 13.4% of cumulative dose oxidized, mean ± SD, P<0.0001). Homozygous or compound heterozygous nonsense variants in *PCCA* or *PCCB*, genes that encode the PCC enzyme, were associated with lower 1-<sup>13</sup>C-propionate oxidation (5.7 ± 0.7%) compared to patients with at least one missense or splice site pathogenic variant (19.76±13.1%, P=0.02). 1-<sup>13</sup>C-Propionate oxidation correlated with propionate metabolites including plasma propionylcarnitine (R<sup>2</sup>= 0.53, P=0.0004) and plasma total methylcitrate (R<sup>2</sup>= 0.46, P= 0.003) as well as height Z-scores (R<sup>2</sup>=0.33, P=0.007) and full-scale intelligence quotients (R<sup>2</sup>=0.55, P=0.007). The two-hour cumulative oxidation of 1-<sup>13</sup>C-propionate in a PA patient with two non-sense *PCCB* alleles, who underwent a liver transplant, was 64.2%. 1-<sup>13</sup>C-propionate oxidation was strongly associated with genetic, biochemical, and clinical parameters in PA patients compared to controls, suggesting that this measurement could represent an appropriate surrogate endpoint in therapeutic trials aiming to improve clinical outcomes by increasing propionyl-CoA carboxylase activity.

Mitochondrial dysfunction underlies the pathogenesis of a variety of human neurodegenerative disorders, either directly, e.g., in the case of mitochondrial diseases (MD), or indirectly, e.g. in the case of Parkinson's disease (PD). The complexity of these disorders has so far prevented the development of effective therapeutic strategies. Here, we demonstrate that the microRNAs miR-181a and miR-181b (miR-181a/b) regulate key genes involved in mitochondrial biogenesis and function. We also show that these miRNAs are involved in the global regulation of mitochondrial turnover in the central nervous system through the simultaneous and fine tuning modulation of different gene pathways. We found that miR-181a/b downregulation strongly protects neurons from cell death and significantly ameliorates the disease phenotype in *in vivo* models of both primary and secondary mitochondria-mediated neurodegeneration, such as Microphthalmia with Linear Skin Lesions, Leber hereditary optic neuropathy and PD. Altogether our results indicate that miR-181a/b represent novel gene-independent therapeutic targets for a wide-range of neurodegenerative diseases caused by mitochondrial dysfunction.

**1203W****Characterizing mtDNA variants from 10,000 germline exomes.** *A. Bolze, J. Lu, F. Mendez, Y. Ni, N.L. Washington.* Helix, San Carlos, CA.

Pathogenic variants in mitochondrial DNA (mtDNA) have been reported to cause rare diseases such as Leber's hereditary optic neuropathy (LHON), tubulointerstitial kidney disease or mitochondrial encephalomyopathy, lactic acidosis and stroke-like episodes (MELAS). Deciphering the genetic etiology of rare diseases has benefited from the release of large databases reporting allele frequencies for variants observed in 10,000s-100,000s of individuals such as Bravo (<https://bravo.sph.umich.edu/freeze5/hg38/>) and gnomAD ([gnomad.broadinstitute.org](https://gnomad.broadinstitute.org)). These tools can be used to rule variants out as the cause of a disease on the basis of their allele frequency in the general population, taking into account other parameters such as prevalence, penetrance, inheritance and genetic homogeneity. However, these two resources did not yet have information for mtDNA variants. In order to support rare mitochondrial disease studies, we called and analyzed mtDNA variants based on the germline exomes of a cohort of 10K individuals. The mtDNA variants reported supplement broader mitochondrial resources such as Hmtvar (<http://www.hmtvar.uniba.it/>) and Mitomap (<https://www.mitomap.org/MITOMAP>). We compared the allele frequencies of the variants in our cohort with the allele frequencies in the two mitochondrial resources and characterized the mtDNA variants impacting mitochondrial genes, tRNAs and rRNAs.

**Multi-omics analyses and functional studies in a new model of Barth syndrome and in patient derived cells uncover novel mechanisms of pathogenesis and potential targets for therapeutic intervention.** A. Franca Anzmann<sup>1</sup>, R.N. Cole<sup>2</sup>, B.J. Kirsch<sup>3</sup>, A. Le<sup>3</sup>, F.M. Vaz<sup>4</sup>, S.M. Claypool<sup>5</sup>, H.J. Vernon<sup>1</sup>. 1) McKusick-Nathans Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, MD., Select a Country; 2) Proteomic Core for the Hopkins Conte Digestive Diseases Basic and Translational Research Core Center Johns Hopkins University School of Medicine Baltimore, MD; 3) Department of Pathology and Oncology Johns Hopkins University School of Medicine Baltimore, MD; 4) Laboratory Genetic Metabolic Diseases Academic Medical Center Amsterdam, The Netherlands; 5) Department of Physiology Johns Hopkins University School of Medicine Baltimore, MD.

Barth Syndrome (BTHS) is an X-linked inborn error of metabolism of cardiolipin (CL) synthesis caused by genetic defects in *TAZ* on chromosome Xq28. Clinical manifestations of BTHS include childhood-onset cardiomyopathy, neutropenia, growth defects, and skeletal muscle myopathy. Despite knowledge of the primary metabolic defect in this disorder, there is limited knowledge of downstream mechanisms of cellular pathogenesis and targets for treatment are limited. We developed a CRISPR edited *TAZ* deficient model in HEK293 cells, *TAZ*<sup>Δ45</sup>, and performed semi-targeted lipidomics, shotgun proteomics and targeted metabolomics analyses in the *TAZ*<sup>Δ45</sup> and *TAZ* WT cells. Through these studies we identified pathways representing major bioenergetic shifts in both mitochondrial and cytoplasmic metabolism. Lipidomics studies showed that the *TAZ*<sup>Δ45</sup> cells recapitulate the cardiolipin dysregulation seen in BTHS with a decrease in mature CL, an increase in monolysoCL, and an altered content of CL biosynthetic intermediates. DAVID and KEGG analyses, and analysis of regulatory components of differentially expressed proteins, revealed major pathways of dysregulation in *TAZ*<sup>Δ45</sup> cells including (a) downregulation of mitochondrial respiratory chain complex I (b) alterations in AMPK signaling and fat metabolism pathways and (c) alterations in insulin signaling pathways. Western blotting confirmed key shotgun proteomics findings. Metabolomics analyses intersected with the proteomics studies, showing an increase in the NADH/NAD<sup>+</sup> ratio, increase in cellular AMP content, and altered glycolytic intermediates. Targeted studies in 5 individual BTHS patient derived lymphoblastoid cell lines with different *TAZ* genotypes recapitulated core proteomic findings found in *TAZ*<sup>Δ45</sup>. With these studies we have (a) validated the biological relevance of a novel CRISPR edited *TAZ* cellular model (b) identified mitochondrial complex 1 as a major site of bioenergetic dysregulation in BTHS and (c) identified AMPK signaling, insulin signaling, and fat metabolism as areas of major cytoplasmic bioenergetic dysregulation in BTHS. Clinical correlation of these pathways in individuals with BTHS is underway, with the goal of developing associated endpoints for future targeted therapeutic trials.

**Deletion in mitochondrial peptidase results in lethal juvenile brain disorder with status epilepticus in dogs.** M.K. Hytonen<sup>1,2,3</sup>, R. Sarviaho<sup>1,2,3</sup>, C. Jackson<sup>4</sup>, P. Syrja<sup>3</sup>, K. Matiasek<sup>4</sup>, T. Jokinen<sup>5</sup>, M. Arumilli<sup>1,2,3</sup>, M. Anttila<sup>6</sup>, L.A. Bindoff<sup>7,8</sup>, A. Suomalainen<sup>1</sup>, H. Lohi<sup>1,2,3</sup>. 1) Research Program of Molecular Neurology, University of Helsinki, Helsinki, Finland; 2) The Folkhälsan Institute of Genetics, Helsinki, Finland; 3) Dept Veterinary Biosciences, University of Helsinki, Finland; 4) Section of Clin Comp Neuropathol, LMU Munich, Munich, Germany; 5) Dept Equine Small Animal Medicine, University of Helsinki, Helsinki, Finland; 6) Finnish Food Safety Authority, Evira, Helsinki, Finland; 7) Dept Neurology, Haukeland University Hospital, Bergen, Norway; 8) Dept Clinical Medicine, University of Bergen, Bergen, Norway.

Dogs have emerged as an excellent comparative model for human medicine due to shared genes and because they phenocopy human physiology and dysfunction. Canine complementary models help uncovering new candidate genes, improving the understanding of the molecular mechanisms and opening possibilities for therapeutic trials. In this study, we have investigated an unknown rapidly progressing and lethal canine brain disorder with epileptic seizures beginning at 6 to 12 weeks of age. Detailed clinical investigations and post-mortem examination were carried out and tissues collected for pathology and functional studies. DNA samples were obtained from 7 affected dogs and ~400 unaffected dogs by owner's consent and with ethical permission. A combined approach of homozygosity mapping and exome sequencing was performed to identify the genetic defect. Candidate variants were validated by Sanger sequencing and TaqMan assay. We discovered a novel rapidly progressing recessive juvenile mitochondrial encephalopathy resulting in lethal status epilepticus. Pathology showed a diffuse necrotizing panpolio-encephalopathy with extensive neuronal mitochondrial crowding in two of the affected dogs available for detailed necropsy. Genetic analyses revealed an in-frame 6-bp deletion in a gene encoding for mitochondrial matrix peptidase. Mitochondrial function was assessed by respirometry in the affected and unaffected brain tissues, which demonstrated a significant decrease in respiration. In conclusion, we have characterized a novel canine brain disorder, juvenile mitochondrial encephalopathy with status epilepticus, and identified the genetic cause in a gene coding for a mitochondrial matrix peptidase, that degrades mitochondrial targeting sequences cleaved from imported proteins. Mutations in this gene have been found in one family with a slowly progressing neurodegeneration in humans. In contrast to the human disease, the canine condition is rapidly progressing after birth leading to status epilepticus and death. Further functional and pathological studies aim to uncover pathophysiological details of the canine disease and possible as yet unknown functions of the gene.

## 1206W

**Atypical mitochondrial Leigh syndrome associated with a novel *MT-ATP6* gene variation.** E. Rai<sup>1</sup>, A. Angural<sup>1</sup>, I. Sharma<sup>1</sup>, P. Pandoh<sup>2</sup>, V. Sharma<sup>1</sup>, A. Spolia<sup>1</sup>, V. Singh<sup>1</sup>, S. Razdan<sup>3</sup>, K.K. Pandita<sup>4</sup>, S. Sharma<sup>1</sup>. 1) Human Genetics Research Group, School of Biotechnology, Shri Mata Vaishno Devi University, Katra, Jammu and Kashmir, India, 182320; 2) Acharya Shri Chander College of Medical Sciences and Hospital, Sidra, Jammu, Jammu and Kashmir, India, 180017; 3) Neurology Clinic, 7 Bhagwati Nagar, Jammu, Jammu and Kashmir, India, 180001; 4) Health Clinic, H. No. 62, Lane 11, Swam Vihar, Muthi, Jammu, Jammu and Kashmir, India, 181205.

Leigh Syndrome is a rare, hereditary progressive neurodegenerative disorder of infancy or early childhood that affects all the levels of neuroaxis in affected individuals. Owing to its clinical and genetic heterogeneity, the disorder is mostly misdiagnosed, unfortunately leading to no or delayed optimal medical intervention to the patients. However, through a combinatorial approach including use of advanced clinical diagnostic and advanced molecular biology techniques, identification and characterization of the underpinning molecular etiology of Leigh syndrome has become a possibility. Here, we present a case report on a 9 year old boy having a severe, atypical clinical presentation of Leigh Syndrome- late survival age and bilateral basal ganglia calcifications (in the caudate nuclei)- validated through their genetic screening. Whole Mitochondrial Genome Sequencing of the recruited patient and his mother at different read coverage (first at 100X and later repeated at 500X for validation) revealed a novel, disease associated *MT-ATP6* variation, but with different allele counts between them. A higher allele count in the patient than his mother was concluded as disease-causing. Further, an exhaustive study is required to evaluate the clinical association of bilateral basal ganglia calcification to mitochondrial form of Leigh Syndrome. In conclusion, the present study indicates significance of a combinatorial diagnostic strategy including use of neuro-imaging and Next Generation Sequencing technologies for proper diagnosis of atypical cases of Leigh Syndrome.

Undiagnosed Diseases Network<sup>6</sup>, S.B. Montgomery<sup>4,7</sup>, P. Fisher<sup>1,2</sup>, E.A. Ashley<sup>1,7,8</sup>, J.A. Bernstein<sup>1,3</sup>, M.T. Wheeler<sup>1,7,8</sup>. 1) Stanford Center for Undiagnosed Diseases, Stanford, CA; 2) Department of Neurology, School of Medicine, Stanford, CA; 3) Department of Pediatrics – Medical Genetics, School of Medicine, Stanford, CA; 4) Department of Pathology, School of Medicine, Stanford, CA; 5) HudsonAlpha Institute for Biotechnology, Huntsville, AL; 6) NIH Undiagnosed Diseases Network, Office of the Director and the National Human Genome Research Institute, National Institutes of Health, Bethesda, MD; 7) Department of Genetics, School of Medicine, Stanford, CA; 8) Division of Cardiovascular Medicine, School of Medicine, Stanford, CA.

The mitochondrial fatty acid synthesis (mtFASII) pathway is an organelle-specific pathway for fatty acid synthesis with roots in the mitochondrion's bacterial evolutionary lineage. The mtFASII system remains conserved in mammals despite their independent, eukaryotic cytosolic system for fatty acid synthesis (FASI). FASI operates through a single enzyme whereas mtFASII uses a series of sequential enzymes. The final enzyme in the mtFASII pathway is encoded by *MECR*. Two brothers, ages 4 and 5 years, were evaluated at the Stanford Center for Undiagnosed Diseases (CUD) for a neurodegenerative disease of unknown etiology. They each presented at 6 months with delayed motor milestones and hypotonia, which evolved to include spasticity, an ataxic gait, and progressive loss of motor skills. Additional features include dystonia with hyperkinetic movements (elder brother) as well as ptosis and neck muscle weakness (younger brother). Both have relatively intact receptive language skills and cognition but minimal expressive language. Brain MRIs show bilateral symmetric T2 hyperintensity in the basal ganglia. Extensive biochemical and genetic evaluations, including exome sequencing, were unrevealing. Genome sequencing (GS) sent by the CUD identified two variants in *trans* in *MECR*, present in both siblings: c.830+2dupT and c.-39G>C. Pathogenic variants in *MECR* are associated with mitochondrial enoyl CoA reductase protein-associated neurodegeneration (MEPAN). MEPAN is characterized by (1) childhood-onset movement disorder, (2) signal hyperintensity in the basal ganglia, (3) optic atrophy, and (4) relatively preserved cognition. To date only seven individuals with MEPAN have been reported in the literature. While the c.830+2dupT variant has been described previously, the c.-39G>C variant is novel. It lies in the 5'UTR, a region typically known to influence gene expression levels. Functional studies exploring the effect of the c.-39G>C variant, including RNAseq and untargeted metabolomics, are ongoing. Given *MECR*'s established role in lipoic acid synthesis, the boys began a trial of alpha lipoic acid and MCT oil supplement to their mitochondrial cocktail. This case contributes to the emerging clinical and molecular characterization of MEPAN and expands the scope of potentially disease-causing variants. Additional molecular phenotyping will enhance understanding of the mtFASII pathway and can ultimately inform development of therapeutic drugs for MEPAN patients.

**Preclinical efficacy of systemic messenger RNA (mRNA) therapy as a treatment for propionic acidemia.** L. Jiang, J. Park, L. Yin, A. Frassetto, J. Zhuo, X. Yan, X. Zhu, K. Burke, K. Benenato, C. Mihai, A. Graham, K. Hoar, C. Lukacs, L. Guey, P. Martini. Moderna Therapeutics, Cambridge, MA.

**Background:** Propionic acidemia (PA) is a rare, inherited metabolic disorder with significant morbidity and mortality. The vast majority of PA patients present in the neonatal period with severe metabolic decompensations. Longer-term sequelae include neurologic complications and cardiomyopathy. PA is caused by a deficiency in propionyl CoA carboxylase (PCC), a mitochondrial enzyme composed of 6 alpha (PCCA) and 6 beta (PCCB) subunits. Lack of PCC activity due to mutations in PCCA (PA type I) or PCCB (PA type II) genes results in accumulation of toxic metabolites in all body fluids and tissues. There is no approved therapy for PA and the standard of care is restricted to dietary and other supportive measures. Liver transplant has emerged as an effective yet radical therapeutic option for severely affected patients to normalize PCC activity in the liver, and has been shown to reduce the risk of metabolic decompensations and in some patients, halt the progression of cardiomyopathy. However, liver transplant has significant limitations include the risks of the procedure itself. **Results:** Here we report a novel therapy for PA using a combination of two mRNAs encoding PCCA and PCCB to restore enzymatically active PCC in liver. In vitro studies demonstrated that co-transfection of PCCA and PCCB mRNAs increased PCC activity and encoded protein with the proper subcellular localization in the mitochondria in patient fibroblasts. Single and repeat IV administration of PCCA and PCCB mRNA encapsulated in biodegradable lipid nanoparticles in PA (PCCA hypomorphic) mice resulted in restoration of hepatic PCC activity with a concomitant decrease in plasma levels of disease-associated metabolites. The decrease in disease-associated metabolites was rapid and significant (>50%), persisted for several weeks after a single dose, and was sustained after multiple doses. **Conclusions:** These studies demonstrate preclinical proof-of-concept of systemic PCCA and PCCB mRNA therapy as a treatment for PA..

**A splice mutation in *ATP11A* causes progressive sensorineural hearing loss and maps to the *DFNA33* locus.** J.A. Pater, C. Penney, A. Griffin, N. Abdelfatah, J. Houston, D. O'Rielly, S.S. Stanton, J. Squires, T.L. Young. Craig L. Dobbin Genetics Research Centre, Faculty of Medicine, Discipline of Genetics, Memorial University of Newfoundland, St. John's, Newfoundland and Labrador, Canada.

Although more than 200 hearing loss loci have been mapped, dominant loci are particularly difficult to solve due to the rarity of large extended families, broad critical regions and the large number of heterozygous variants in individual genomes. As part of an ongoing study, we recruited a six-generation family from the genetic isolate of Newfoundland (Canada) with sixteen members affected by bilateral sensorineural hearing loss. The rate of hearing threshold decline was variable with onset as early as one year of age, progressing to a profound loss between the third and sixth decades. All family members screened negative for the 23 deafness mutations that we have previously identified in this founder population. Genome-wide SNP genotyping and two-point linkage analysis on a core pedigree identified a 3.6 Mb linked region (LOD=4.77) that overlapped with *DFNA33* on 13q34. Whole genome sequencing and filtering of variants mapping to the 13q34 critical region identified several candidate variants that co-segregated with hearing loss. Extensive haplotype analysis on the extended family using polymorphic markers revealed two key recombination events that markedly reduced the critical region leaving only one variant in *ATP11A*, which encodes for an integral membrane ATPase. Absent from 340 ethnically-matched population controls, *ATP11A* c.\*11G>A was a predicted splice variant. Whole RNA extracted from blood, followed by reverse transcription PCR, TA cloning and Sanger sequencing revealed that *ATP11A* c.\*11G>A causes alternative splicing in three *ATP11A* isoforms, identifying the *DFNA33* gene. .

Advances in sequencing technologies have revolutionized the fields of genetics and genomics, offering the promise of precision medicine tailored to disease prevention and treatment based on an individual's genomic data. Integral to precision medicine is the interpretation of variant effect in the context of clinical phenotypes. Such task represents a major challenge because of the extraordinary number of genetic variants and the complexities inherent in determining their clinical significance, especially for disorders exhibiting great phenotypic, genetic and allelic heterogeneity. To address this challenge for hearing loss, we have developed the Deafness Variation Database, a comprehensive, configurable, open-access bioinformatics pipeline that integrates all available genetic, genomic and clinical data together with expert curation to generate a single evidence-based classification for each variant in 152 genes implicated in syndromic and non-syndromic deafness. Of the 876,139 variants collated, we classify over 8100 as pathogenic or likely pathogenic, 172,257 as benign or likely benign and 695,709 as variants of uncertain significance; 1270 variants are re-categorized based on expert curation and for 24% of those; the change is of medical significance and impacts patient care. We also define the genomic landscape and mutational signatures of known deafness-causing genes and show that over 96% of coding variants are rare and novel and that pathogenicity is driven by minor allele frequency thresholds, variant effect and protein domain. Our findings provide an intricate and complex portrait of the genomic and mutational landscape of deafness genes and expose unrecognized nuances in specific genes which have major impact on tailoring variant classification guidelines in a disease- and gene-specific manner. This will greatly empower clinical decision-making and improve our understanding of deafness biology.

**Usher syndrome diagnostics in the genomics era: Successes, challenges and opportunities.** *K.T. Booth<sup>1,2</sup>, B. Crone<sup>1</sup>, E. Renkes<sup>1</sup>, B. Anderson<sup>1</sup>, H. Azaiez<sup>1,3</sup>, R.J. Smith<sup>1,3</sup>. 1) Molecular Otolaryngology Renal Research Laboratories, Department of Otolaryngology-Head Neck Surgery, University of Iowa, Iowa City, Iowa; 2) The Interdisciplinary Graduate Program in Molecular Medicine, Carver College of Medicine, University of Iowa, Iowa City, Iowa; 3) Co-corresponding author.*

Accurate variant interpretation is at the heart of genomic medicine. Both missed and mis-diagnoses yield non-ventured personalized therapeutic and intervention opportunities for patients. In genes that exhibit pleiotropy, such as the genes associated with Usher syndrome (USH) which could also cause non-syndromic deafness, elucidating phenotypic outcome based on genetic data often alters treatment avenues and quality of life. We therefore sought to elucidate the genomic landscape of the Usher-causing genes to lay the foundation for more accurate genetic variant interpretation. We collated over 127,300 variants across nine genes (*MYO7A*, *USH1C*, *CDH23*, *PDCH15*, *USH1G*, *USH2A*, *ADGVR1*, *WHRN* and *CLRN1*) and annotated them with minor allele frequency (MAF), variant effect, conservation, deleteriousness predictions and variant classification obtained from the Deafness Variation Database. Pathogenic and likely pathogenic variants represented ~1% of all variants, whereas likely benign and benign accounted for ~21% and variants of unknown significance ~78.2%. Of the known pathogenic variants, ~88% are exonic and ~12% alter splicing. Missense variants are most common and comprise ~38% of reported pathogenic variants, followed by frameshift indels, nonsense, splice-altering and in-frame indels (~26.5%, ~19.7%, ~12%, ~2.4%, respectively). Start/stop loss, synonymous and UTR variants make up <1% each. Novel and rare variants (MAF <0.5%) constitute 81% of all variants and >95% of coding variants, showcasing the complexities of distinguishing disease-causing variants from variants of unknown significance. In conclusion, we provide for the first time a comprehensive overview of the genetic landscape of the Usher syndrome genes. We established informative gene- and phenotype-specific MAF cutoffs for pathogenicity and specific variant types which will ultimately enhance variant classification and improve genotype-phenotype associations, thereby improving genetic diagnostics and advancing precision medicine for individuals affected with this disorder.

**1212W****Genetic heterogeneity of hearing loss in sporadic cases from Pakistan.**

*M. Ramzan, S. Naz, Baylor-Hopkins Center for Mendelian Genomics. University of the Punjab, Lahore, Punjab, Pakistan.*

Hearing loss affects up to 8% of Pakistani population. Genetic and allelic heterogeneity is one of the key features of recessively inherited nonsyndromic familial deafness. Although sporadic individuals with hearing loss are common in Pakistan, a comprehensive evaluation of genes involved in their phenotype has not been reported. We ascertained 21 unrelated individuals affected with sensorineural, moderate to severe hearing loss who were all born to consanguineous parents. Whole-exome sequencing was performed on DNA obtained from these individuals. We examined homozygous exonic and splice-site variants from the exome data for which the allele frequencies were <0.01 in public databases including ExAC and gnomAD. Both known and new variants in genes previously implicated with hearing loss; *GJB2*, *SLC26A4*, *OTOF*, *RDX*, *ESRRB*, *BSND* and *CABP2*, were found responsible for the phenotype in 13 participants. The maximum number of individuals had mutations in *OTOF*, followed by those with *GJB2*, *BSND* and *SLC26A4* variants. While variations in all other genes are known to cause moderate to severe hearing loss, those affecting *ESRRB* have only been described associated with profound deafness. This finding further strengthens the involvement of modifiers which control the degree of hearing loss in humans. Variants predicted to be pathogenic in genes not known to cause disorders were found in two individuals. These may represent newly implicated genes for hearing loss and remain to be evaluated further. No homozygous variant in a known deafness gene or a predicted pathogenic variant in any other gene was found for six participants. This could be due to the involvement of compound heterozygous or de novo variants in the etiology of their phenotype. Our work reveals similar genetic heterogeneity of hearing loss in sporadic individuals with hearing loss as that observed in those affected with familial deafness. Funded by HEC 3288, Pakistan.

**1213T****“Enhancing” the DFNB1 locus: Targeted sequencing and functional characterization of non-coding elements affecting *GJB2* expression.**

*S. Rentas<sup>1</sup>, S.E. Raible<sup>2</sup>, D. Mceldrew<sup>1</sup>, I.D. Krantz<sup>2</sup>, N.B. Spinner<sup>2</sup>, A.N. Abou Tayoun<sup>3</sup>.* 1) Division of Genomic Diagnostics, Department of Pathology and Laboratory Medicine, The Children’s Hospital of Philadelphia, Philadelphia, PA; 2) Division of Human Genetics, Department of Pediatrics, The Children’s Hospital of Philadelphia, Philadelphia, PA; 3) Al Jalila Children’s Specialty Hospital, Dubai, UAE.

Bi-allelic pathogenic variants in the *DFNB1* locus cause 50% of all recessively inherited non-syndromic sensorineural hearing loss (SNHL). While genomic diagnostics for this disorder is highly successful in identification of pathogenic variants in the coding sequence, up to 30% of individuals present with only a single deleterious variant in *GJB2*, giving an inconclusive answer for their phenotype. Importantly, this high percentage of *GJB2* carriers is significantly greater than the coincidental carrier rate in the general population, indicating these individuals likely carry a second pathogenic variant that is not detected by conventional testing. Multiple large deletions upstream of *GJB2* have been shown to contribute to deafness by significantly reducing its expression, and recent work from our group mapped a 95 kb critical region that is shared across reported upstream deletions in individuals with SNHL. This noncoding region has a high degree of histone acetylation (H3K27Ac) indicating the presence of uncharacterized distal regulatory elements that control *GJB2* expression. We hypothesize variants within this 95 kb critical region will be found as the second hit in carriers of a single pathogenic variant in *GJB2* and clinical diagnosis of non-syndromic SNHL. To test for novel pathogenic variants in the 95 kb critical region, we designed and carried out a targeted capture of this region followed by next-generation sequencing in a cohort of SNHL individuals who are heterozygous for a pathogenic variant in *GJB2*. The variants identified were compared to 15,496 whole genomes, using data in the Genome Aggregation Database (gnomAD). To complement the sequencing analysis, we have undertaken an unbiased approach to screen for functional enhancer elements in the 95 kb critical region. For these studies, we are generating BAC-focused libraries containing this region of interest and performing STARR-seq (Self-Transcribed Active Regulatory Region Sequencing) in a model cell line that abundantly expresses *GJB2*. Altogether, the combination of approaches taken here provide novel insights into the uncharacterized enhancer elements that promote *GJB2* expression, and aim to improve diagnostic yield in hereditary hearing loss testing.

**1214F**

**Genomic characterization of hereditary sensorineural hearing loss in the Louisiana Acadians and Mexican Mayans.** A. Umrigar<sup>1</sup>, D. Mercer<sup>1</sup>, A. Hurley<sup>2</sup>, M. Norman<sup>3</sup>, A. D'Angelo<sup>1</sup>, C. Hicks<sup>1</sup>, R. Hernandez<sup>1</sup>, J. Lesher<sup>1</sup>, F. Tsien<sup>1</sup>. 1) Department of Genetics, Louisiana State University Health Sciences Center, New Orleans, LA; 2) Department of Communication Disorders, Louisiana State University Health Sciences Center, New Orleans, LA; 3) Louisiana Deaf Blind Project, Louisiana State University Health Sciences Center, New Orleans, LA; 4) Division of Genetics, Universidad Juárez Autónoma de Tabasco, Tabasco, Mexico.

In the United States, at least 1/1000 children are born with complete sensorineural hearing loss (SNHL) per year, with 50-80% of cases due to genetic mutations. Cases of congenital and pre-lingual SNHL are caused by mutations in over 100 known genes that contribute to the development, function, and maintenance of inner ear structures. Many developed nations have implemented successful newborn screening programs to identify infants with hearing loss and provide early intervention services. Although these programs are effective in the identification of hearing loss, they are not always able to determine the etiology. Next generation sequencing and diagnostic panels have become increasingly reliable and less expensive for clinical use. Despite these advances, the diagnosis of genetic SNHL still presents challenges for health care providers due to genetic heterogeneity and variable expressivity. In some cases, genetic hearing loss is associated with other clinical features that may not become apparent until later in life. Pursuing a genetic diagnosis is especially important for individuals who come from ethnic backgrounds with high rates of consanguinity. In order to further our understanding of genetic SNHL, our group is studying individuals from two founder populations, the Louisiana Acadians and the Mexican Mayans. Samples are screened for genetic abnormalities using cytogenetic analysis, fluorescence *in situ* hybridization (FISH), PCR, and targeted sequencing. When indicated, whole exome sequencing (WES) is employed followed by a filtration of variants based on phenotypic effect. Pathway analysis is then used to discover affected cellular processes. Preliminary data from patients and families recruited from rural Acadian Louisiana and remote Mexican Mayan communities indicate the presence of hereditary, congenital and pre-lingual syndromic and non-syndromic SNHL. Evaluation of more than 300 family members and patients demonstrate a higher incidence of rare and novel variants than in the general population. The majority of the families had more than one gene alteration detected, usually within the same individual. The genetic analysis of these founder populations will further our understanding of rare and/or novel intra-familial genetic mutations that affect these populations, providing caregivers and health professionals with the information necessary for care and education of deaf individuals and families in their communities.

**1215W**

**Expansion of the phenotype associated with variants in the cilium intraflagellar transport RAB28.** C. Jespersgaard<sup>1</sup>, T.D. Hjortshøj<sup>1</sup>, M. Fang<sup>2</sup>, T. Ilginis<sup>3</sup>, M. Bertelsen<sup>3</sup>, N. Bech<sup>3</sup>, H. Jensen<sup>3</sup>, C.A.B. Hey<sup>1</sup>, L.B. Møller<sup>1</sup>, Z. Tümer<sup>1</sup>, T. Rosenberg<sup>3</sup>, K. Brøndum-Nielsen<sup>1</sup>, K. Grønskov<sup>1</sup>. 1) Kennedy Center, Department of Clinical Genetics, Rigshospitalet, Copenhagen, Denmark; 2) BGI-Shenzhen, Shenzhen 518083, China; 3) Department of Ophthalmology, Copenhagen University Hospital, Rigshospitalet-Glostrup, Denmark.

**Background:** Retinal dystrophy encompasses a range of diagnoses and modes of inheritance, and over 250 genes have been associated. Retinitis pigmentosa (RP), a group of generalized retinal dystrophies, characterized by degeneration of rod and cone photoreceptors, has been associated with many causative genes. Some of the affected genes in RP encode proteins in the primary cilium, a sensory organelle present on most cell types. Pathogenic variants in these genes causes ciliopathy and several organs can be affected, such as heart, eye, kidney, the skeletal system and obesity. Many of the genes associated with ciliopathies are involved in the intraflagellar transport, a process for the assembly and maintenance of cilia. **Methods:** Two brothers from a consanguineous family were referred for genetic counselling. The brothers presented with RP, excessive myopia and polydactyly. The combination of RP and polydactyly led to a suspicion of Bardet Biedl syndrome although the clinical criteria were not fulfilled. Previous investigations included array analysis and sequencing of at the time known BBS and related ciliopathy genes (*BBS1-17*) without any causative variants detected. We performed sequencing of 125 genes previously associated with retinal dystrophies on the index patient. **Results:** The variants were evaluated and classified according to the ACMG guidelines. A homozygous variant in the index in *RAB28* was detected and verified by Sanger sequencing in both brothers. The c.55G>A (NM\_004249.3) p.(Gly19Arg) variant, located in the GTPase domain, has not previously been described in individuals with RP. It is reported with very low frequency in the gnomAD database (1 in 30824 alleles). **Discussion:** We present two brothers from a consanguineous family homozygous for a missense variant in *RAB28*. Pathogenic variants in *RAB28* have been reported previously in patients with cone-rod dystrophy and although *RAB28* has been identified as a GTPase in the cilium formation no other phenotypes than cone-rod dystrophy have been associated with the gene. This resembles the phenotypic spectrum of another intraflagellar transport protein - IFT172. In *IFT172* the phenotypic spectrum spans from isolated RP to severe ciliopathy as in Mainzer-Saldino syndrome, where patients have skeletal, renal, hepatic, brain and retinal abnormalities. It has been speculated that modifying alleles may be involved and explain the phenotypic spectrum although it requires cohorts with large sample size.

**1216T**

**Autosomal recessive non-syndromic keratoconus: Homozygous frameshift variant in the candidate novel gene *GALNT14*.** *T. Froukh<sup>1</sup>, A. Hawwari<sup>2</sup>*. 1) Philadelphia university, Amman, Jordan; 2) Sight and insight eye clinic, Amman, Jordan.

Keratoconus (KC) is usually bilateral, noninflammatory progressive corneal ectasia in which the cornea becomes progressively thin and conical. Despite the strong evidence of genetic contribution in KC, the etiology of KC is not understood in most cases. In this study, we used whole exome sequencing to identify the genetic cause of KC in two siblings to first cousin parents. We identified a homozygous frameshift variant (NM\_001253826.1:c.60del;p.Leu21Cysfs\*6) in the gene N-acetylgalactosaminyltransferase 14 (*GALNT14*). We have prioritized this variant as a strong candidate causative to KC for two reasons. Firstly, the variant does not exist in the public databases: EXAC, gnomAD, 1000 genome project, Exome variant server (EVS), and Greater Middle East (GME) Variome project and neither in our in-house exome database (~3000 exomes). Moreover, none of the public or in-house exome databases harbor homozygous loss of function variant in the candidate gene. Secondly, *GALNT14* catalyzes the initial reaction in O-linked oligosaccharide biosynthesis, the transfer of an N-acetyl-D- galactosamine residue to a serine or threonine residue on mucins including ocular mucins. As a result, 55% of the ocular mucin is O-linked glycan. It was proved that alteration of mucin O-glycosylation at the ocular surface is described with eye diseases. We have linked in this study an association between the truncated protein *GALNT14* and KC. This study is one of the very few studies that identifies and links homozygous loss of function mutations to KC.

**1217F**

**Biallelic *CPAMD8* variants associated with congenital glaucoma and anterior segment dysgenesis.** *E. Souzeau<sup>1</sup>, O.M. Siggs<sup>1</sup>, D.A. Taranath<sup>1</sup>, T. Zhou<sup>1</sup>, A. Dubowsky<sup>2</sup>, S. Javadiyan<sup>1</sup>, A. Chappell<sup>1</sup>, A. Narita<sup>3</sup>, J.E. Elder<sup>4,5</sup>, J. Pater<sup>1</sup>, J.B. Ruddle<sup>4,6,7</sup>, J.E.H. Smith<sup>8,9,10</sup>, L.S. Kearns<sup>5,7</sup>, S.E. Staffier<sup>4,6,7</sup>, A.W. Hewitt<sup>6,7,12</sup>, D.A. Mackey<sup>11,12</sup>, K.P. Burdon<sup>1,12</sup>, J.E. Craig<sup>1</sup>*. 1) Department of Ophthalmology, Flinders University, Flinders Medical Centre, Adelaide, Australia; 2) SA Pathology, Flinders Medical Centre, Adelaide, Australia; 3) Geelong Eye Centre, Geelong, Australia; 4) Department of Ophthalmology, Royal Children's Hospital, Melbourne, Australia; 5) Department of Paediatrics, University of Melbourne, Melbourne, Australia; 6) Centre for Eye Research Australia, Royal Victorian Eye and Ear Hospital, Melbourne, Australia; 7) Department of Ophthalmology, University of Melbourne, Melbourne, Australia; 8) Department of Ophthalmology, Children's Hospital at Westmead, Sydney, Australia; 9) Discipline of Ophthalmology, University of Sydney, Sydney, Australia; 10) Department of Ophthalmology, Macquarie University, Sydney, Australia; 11) Centre for Ophthalmology and Visual Science, University of Western Australia, Lions Eye Institute, Perth, Australia; 12) Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia.

**Purpose:** Childhood glaucoma is a significant cause of irreversible blindness in children. The condition is clinically and genetically heterogeneous, with both primary and secondary causes. Anterior segment dysgeneses are associated with developmental defects of the ocular anterior chamber and can cause secondary glaucoma by impairing drainage of the aqueous humor, thereby increasing intraocular pressure. Biallelic pathogenic variants in the *CPAMD8* gene have previously been associated with anterior segment dysgenesis, myopia and ectopia lentis but not with childhood glaucoma. **Methods & Results:** We performed whole genome sequencing on an individual with a suspected diagnosis of primary congenital glaucoma and his unaffected parents, and identified biallelic predicted deleterious variants in *CPAMD8*. We then performed whole exome sequencing on 84 additional probands with a suspected diagnosis of primary congenital glaucoma recruited in the Australian and New Zealand Registry of Advanced Glaucoma, from which we identified biallelic variants in an additional two families. In total, we have identified five novel predicted deleterious variants in *CPAMD8* in four individuals from three families. *CPAMD8* variants explained 3.6% (3/84) of cases in our cohort. Common ocular features included corectopia, iris stromal hypoplasia, iris transillumination defects, iridodonesis, ectopia lentis and myopia. Cataracts were present in all individuals above 20 years of age. All four individuals required surgery to control intraocular pressure and glaucoma. *CPAMD8* expression was highest in tissue of neuroectodermal origin (including the ciliary body and corneal epithelium of adult anterior segment), suggesting a role for *CPAMD8* in drainage structures of the eye. **Conclusion:** We extend the phenotypic spectrum associated with *CPAMD8* variants to anterior segment dysgenesis with congenital glaucoma, adding *CPAMD8* to the list of childhood glaucoma-associated genes.

**1218W**

**The *PMEL* gene and merle in the domestic dog: A continuum of insertion lengths leads to a spectrum of coat color variations in Australian shepherds and related breeds.** B.C. Ballif, C.J. Ramirez, C.R. Carl, K. Sundin, M. Krug, A. Zahand, L.G. Shaffer, H. Flores-Smith. Paw Print Genetics, Genetic Veterinary Sciences, Inc.

Merle is a distinct coat color and pattern characterized by patches of diluted eumelanin (black pigment) interspersed among areas of normal pigmentation. In dogs, this variegated pattern is caused by an insertion of a SINE element into the canine *PMEL* gene. Although variation in the length of the SINE insertion (due to a variable-length poly(A)-tail) has been observed to be associated with variation in merle coat color and patterning, no systematic evaluation of the correlation between the length of merle insertion variants and coat color and pattern has been conducted and published in the scientific literature. We performed high resolution analysis of the SINE insertion lengths in 175 dogs (99 Australian shepherds, 45 miniature Australian shepherds, and 31 miniature American shepherds) and compared the genotypes with the coat phenotypes. Lengths varied from 201 – 277 base pairs (bp) indicating that variants can occur in virtually any size along the entire continuum. Genotype-phenotype correlation of 126 dogs with only a single SINE insertion (m/M) identified at least four major phenotypic clusters designated as 'cryptic', 'atypical', 'classic' and 'harlequin' merle. However, we identified several phenotypic outliers that did not cluster within these major groupings suggesting that insertion size is not the only factor responsible for merle phenotypic variability. In addition, we identified 25 dogs with two SINE insertions (M/M) and 24 dogs with more than two *PMEL* (merle) alleles, indicating mosaicism. Genotype-phenotype correlation of M/M dogs indicate that cryptic merle alleles often act like non-merle (m) alleles when combined with atypical, classic and harlequin sized alleles. The finding of mosaicism has important implications for the dog's phenotype and the ability to potentially transmit various alleles to its offspring. Furthermore, we identified examples of the SINE insertion poly(A)-tail expansion and contraction between generations, which also has important implications for breeding practices and determining mating pairs to avoid producing 'double merle' dogs that often have large patches of white fur and auditory and ophthalmologic defects. These findings demonstrate that there is a continuum of merle insertion lengths associated with a spectrum of coat color and patterns and that genotype-phenotype exceptions and overlap make it difficult to strictly assign insertion sizes with an expected coat color, although some generalizations are possible.

**1219T**

**Biallelic loss-of-function variants in *RAX2*, encoding a homeobox-containing Rax transcription factor, cause autosomal recessive inherited retinal disease.** S. Van de Sompele<sup>1</sup>, C. *RAX2* encodes a member of the homeobox-containing Rax family of transcription factors, which play a pivotal role in late retinogenesis in vertebrate species by regulating the spatial expression of photoreceptor-specific genes. So far, only four monoallelic *RAX2* variants have been tentatively implicated in autosomal dominant cone-dominated retinal disease. Here we report biallelic missense, frameshift and structural variants in *RAX2* identified by whole exome sequencing, in five unrelated index cases of Belgian, British, Italian and Spanish origin, diagnosed with non-syndromic autosomal recessive retinitis pigmentosa (RP) with a variable age of onset. Protein structure analysis of the two novel missense variants revealed a loss of Rax2 protein folding and/or stability, in agreement with a loss-of-function effect. Modeling of the previously reported dominant *RAX2* missense variant on the other hand demonstrated potential roles in homeodomain/DNA higher order complex formation with no effect on protein stability or DNA binding, thus compatible with a gain-of-function effect. Haplotype analysis in three Belgian RP cases sharing the same *RAX2* frameshift variant c.335dup suggested a common ancestry. Fine-mapping and bio-informatics analysis of the two identified structural variants affecting *RAX2* disentangled their underlying mechanisms. In summary, our findings support a role for *RAX2* as a novel disease gene for autosomal recessive RP. This study uncovered the first structural variants affecting *RAX2* and a founder allele in Belgian RP patients. The identification of biallelic pathogenic *RAX2* variants in five unrelated families may suggest a role in other autosomal recessive RP cases with an unknown molecular diagnosis.

**Identification of genetic causes of paediatric cataracts, including novel cataract genes, achieved using whole genome sequencing and linkage analysis.** J.L. Jones<sup>1</sup>, B. McComish<sup>1</sup>, M.A. Corbett<sup>2</sup>, J. Charlesworth<sup>1</sup>, J. Gecz<sup>3</sup>, J.E. Craig<sup>1</sup>, K.P. Burdon<sup>1</sup>. 1) Menzies Institute for Medical Research, University of Tasmania, Hobart, Tasmania, Australia; 2) Adelaide Medical School, Robinson Research Institute, University of Adelaide, Adelaide, South Australia, Australia; 3) Department of Ophthalmology, Flinders University, Bedford Park, South Australia, Australia.

Whole genome sequencing is enhancing the ability to identify disease causing mutations in inherited paediatric cataracts (PC), a heterogeneous rare disease that causes visual impairment. We are investigating families from Australia's largest repository of PC DNA. Nine large families, with at least 3 affected individuals each, were selected for linkage analysis using genome-wide genotyping on Illumina OmniExpress SNP arrays. Parametric linkage analysis, using Merlin, was performed with a relevant disease model for each family. Whole genome sequencing of an affected individual from each family was performed on an Illumina X10 platform. The Churchill pipeline was used to align fastq files to hg19, and variant calling was performed using SAMtools for SNPs and Platypus for indels. Structural variants will also be considered. Variants within putative linkage regions are filtered for frequency (MAF <0.01) and predicted functionality (using tools such as CADD). Novel cataract genes were identified as candidates in the two largest families and are undergoing further investigation, in a zebrafish model. In family 66, the PC have been linked to a 6.8Mb region at Xq24 (LOD=2.53) and two additional regions at 1q42.2-1q43 and 3q26.31-3q26.32 (LOD=2.44). A whole genome sequence (Complete Genomics™) of the proband enabled the identification of a 127kb deletion at Xq24, which truncates the *PGRMC1* gene following exon 1. This variant was not detectable by prior exome or Sanger sequencing and highlights the utility of whole genome sequencing for identifying putative disease causing structural and non-coding variants. The *ERO1B* c.662C>T (p.Ala221Val) variant on chr1 segregates, but is not highly conserved and a mini-gene splicing assay was unable to detect altered splicing in human lens epithelial cells despite in silico predictions. In family 24, segregating variants have been identified in novel cataract genes *SH3KBP1* and *PHEX*, both in the Xp22.2-p22.11 linkage region (LOD=1.63). In the smaller families, linkage analysis has reduced the search area down to a manageable 1-12% of the whole genome and analysis is ongoing. This work has identified novel disease causing genes for PC and can provide these Australian families with a molecular diagnosis and enable genetic screening of family members. The discovery of novel genes will expand the suite of genes available for genetic testing in other patients and improve our understanding of cataract pathogenesis.

**Two candidate genes for rare cases of autosomal recessive non-syndromic hearing impairment in the gene loci DFNB33 and DFNB81.** R. Birkenhager, M. Trabandt, S. Arndt, A. Aschendorff, R. Laszig. Department of Otorhinolaryngology, Head and Neck Surgery, University Medical Center Freiburg, Killianstrasse 5, D-79106 Freiburg, Germany.

Hearing impairment is the most prevalent sensorineural disorder and also the most common birth defect. Approximately one of every 1000 newborns is born profoundly deaf and one of every 300 newborns has a permanent mild-to-profound congenital hearing impairment. More than half of pre-lingual hearing impairment cases occur due to genetic factors. Currently, over 120 genes and over 180 loci have been identified for non-syndromic hearing impairment. Autosomal recessive non-syndromic hearing loss (ARNSHL) is a genetically heterogeneous sensorineural disorder, with prelingual hearing loss and absence of other clinical manifestations. Based on the clinical diagnosis it is not possible to recognize in which gene mutations are present. This is only feasible in exceptional cases (7/180). The aim of this study is to identify the responsible genes in rare cases of German families with prelingual ARNSHL. Hearing testing BERA/Electrocochleography and radiological a high-resolution CT scan was carried out. Mutational analysis of two affected family members was performed using direct sequencing of the coding exon and intron transitions of the genes *GJB2* (MIM 121011) and *GJB6* (MIM 604418), including deletion analysis. For investigation of autosomal recessive nonsyndromic hearing loss genes, whole exome sequencing was performed, with the "INVIEW HUMAN EXOME" platform; array Agilent Genomics SureSelectXT All Exon V5. No mutations could be identified in the *DNFB1* gene locus, containing the genes *GJB2* and *GJB6*. A further targeted analysis of other genes was not possible; therefore complete exome sequencing took place. All known genes and loci for autosomal recessive and dominant hearing impairment were analyzed. Only in the genes *DPP7* (MIM 610537), located on Chromosome 9q34.3 (DFNB33), and the gene *MUC16* (MIM 606154), located on chromosome 19p (DFNB81) two heterozygous mutations were detected; in the gene *DPP7* two splice site mutations and in the gene *MUC16* missense mutations c.40666G>A, p.D13556N and c.40655C>T, p.T13552I.

**1222T**

**Novel mutations of *SCN9A* gene in patient with congenital insensitivity to pain identified by whole genome sequencing.** *G.B. Christensen, K. Day, S. Austin, M. Miller, H. Escobar, L. Nadauld.* Intermountain Precision Genomics, Intermountain Healthcare, St. George, UT.

Congenital Insensitivity to Pain (CIP) is a very rare condition distinguished by inability to perceive pain, beginning at birth. Biallelic loss-of-function mutations in *SCN9A* are a known cause of CIP. *SCN9A* encodes the voltage-gated sodium channel Nav1.7, which is essential to nociceptor function and pain sensation. Here we describe whole genome sequencing results for a Caucasian male child symptomatic of CIP. DNA was collected from the child and both parents and sequenced on the Illumina NovaSeq platform. Sequence alignment and joint variant calling was performed with Sentieon. Structural variation analysis and consensus calling was performed with the Parliament method on the DNAnexus platform. Golden Helix VarSeq software was used for variant annotation and analysis. Whole genome sequencing identified two potential loss-of-function variants in *SCN9A*: a *de novo* missense variant (NM\_002977.3:c.4651T>C, NP\_002968.1:p.Cys1551Arg) in exon 26; and a paternally inherited deletion resulting in the complete loss of exon 17 (NC\_000002.11:g.167128623\_167131901del, NP\_002968.1:p.Val948\_Val1106del). Both variants are heterozygous, and neither has been reported previously. Point mutations in exons 17 and 26 of *SCN9A* have previously been associated with CIP and other pain disorders. One previous study also associated CIP with the loss of exon 17 due to a splice donor mutation. Whole genome sequencing proved particularly valuable for this case by enabling clear identification of the intronic breakpoints of the exon 17 deletion. We are working to confirm the phase of the identified variants with long-range haplotyping technology. If confirmed as biallelic, we believe that these variants may explain the patient's phenotype.

**A novel *CRYGD* gene mutation loci results in non-syndromic autosomal dominant congenital cataract and high myopia in a Chinese family.** *R. Zheng, D. Luo, L. Jiang.* University of Electronic Science and Technology of China, Chengdu, China.

**Background** Almost one-third of congenital cataracts are autosomal dominant congenital cataract, resulting in blindness and opacity of the lens. Mutations in *CRYGD* have been reported in families of cataract patients, and this gene encodes the lens gamma D protein which is the main protein of the vertebrate eye lens and maintains the lens's transparency and refractive index. The purpose of this study was to identify the disease-causing mutation in a Chinese family affected by bilateral, autosomal dominant congenital cataract. **Methods** Detection of candidate gene mutations and linkage analysis of microsatellite markers were executed for known candidate genes. Using the candidate gene in all affected family members Molecular mapping and clone screening potential genetic mutations and mutations confirmed by a single enzyme digestion. **Results** The proband was diagnosed with congenital cataract and high Myopia, who have a novel mutation in *CRYGD* gene, c.104G>A(Ser35Leu), and variation from grandmother (grandmother's sisters also have the mutation), after by his father inherited Index (the patient). This mutation was not found in unaffected family members. Sequence analysis confirmed that the Ser35 amino acid residue is highly conserved. **Conclusions** The novel missense mutation c.104G>A of the *CRYGD* gene is the first report of a non-syndromic, autosomal dominant congenital cataract along with high myopia, thereby underline the important role of lens gamma D protein in the physiological and the refractive effect of the eye.

**1224W**

**Punctiform and polychromatic pre-Descemet corneal dystrophy: Report of two families, clinical findings, and the identification of a segregating intronic variant using whole-exome sequencing.** *D.D. Chung<sup>1</sup>, J. Alio del Barrio<sup>2</sup>, A.B. Barrington<sup>1</sup>, K. Jatavallabhula<sup>1</sup>, V. Swamy<sup>1</sup>, A.J. Aldave<sup>1</sup>.* 1) Ophthalmology, Stein Eye Institute, UCLA, Los Angeles, CA; 2) Visum Alicante, C/ Cabañal, N1 03016 Alicante, Spain.

**Purpose:** To report the clinical features and genetic basis of two previously unreported families with punctiform and polychromatic pre-Descemet corneal dystrophy (PPPCD). **Methods:** Slit lamp examination and diagnostic corneal imaging were performed for members of two families with PPPCD. DNA was collected from examined individuals of both families and whole exome sequencing (WES) was performed on 10 members of the first family. Alignment, variant calling and annotation were performed using commercially available software programs. Novel or rare variants that segregated with the affected status were validated by Sanger sequencing and were screened for in the family members who did not undergo WES and in the second family. Identified non-coding variants that segregated with the affected status in both families were characterized using in silico prediction tools. **Results:** Eight of the 13 members of the first family and three of the six members of the second family were diagnosed with PPPCD based on the presence of polychromatic opacities in the posterior corneal stroma of each eye. No novel or rare non-synonymous coding variants that segregated with the affected status in the first family were identified with WES. An intronic variant on Chromosome 10 segregated with the affected phenotype in both families with PPPCD. In silico prediction tools predicted the intronic variant to create a cryptic donor splice site. **Conclusions:** We report only the 9th and 10th families with PPPCD, demonstrating an autosomal dominant inheritance pattern. Whole exome sequencing led to the identification of an intronic variant in both PPPCD families that is predicted to create a cryptic donor splice site.

**Disparities in discovery of pathogenic variants within autosomal recessive non-syndromic hearing impairment by ancestry.** *I. Chakchouk, D. Zhang, Z. Zhang, H. Dai, R. Lyn P. Santos-Cortez, I. Schrauwen, S. M. Leal.* Molecular & Human Genetics, Baylor College of Medicine, Houston, TX.

Hearing impairment (HI) is characterized by an extensive genetic heterogeneity. Although the explosion in HI gene discovery accredited to technological advances has yielded 104 Non-Syndromic (NS) HI genes, among which 68 are involved in autosomal recessive (AR) NSHI, we demonstrate that for most populations the majority of genes and variants explaining ARNSHI etiology remain to be elucidated. Pathogenic and likely pathogenic ARNSHI variants were selected based on ClinVar, Deafness Variation Databases, and allele frequencies from gnomAD were used to determine the contribution of ARNSHI genes to HI etiology per population. The estimated amount of ARNSHI explained by known pathogenic or likely pathogenic variants varies greatly by population, e.g. 88.1% for Ashkenazi Jews but only 4.7% for Africans/African Americans. Even within European populations, there is variability, although known ARNSHI genes and variants explain 24.2% of ARNSHI in non-Finnish Europeans they only explain 8.7% in Finns. There was also variability amongst Asians with 15.5% of ARNSHI explained in East Asians, but twice as much for South Asians (30.6%). This variability may be explained by the number of studies and clinical sequencing performed within specific populations in addition to the unique genetic background of isolated populations, e.g. Finns and East Asians and the rarity of admixture with other populations. As expected *GJB2* has the highest contribution to ARNSHI in all populations represented in gnomAD, with the exception of *MYO15A* in South Asians. Furthermore, although *GJB2* c.35delG (p.G12fs) is very frequent amongst several populations, due to an ancient founder, other common *GJB2* variants were population-specific e.g. p.W24X in South Asians [minor allele frequency (MAF)= $4.45 \times 10^{-3}$ ] and p.L79fs in East Asian (MAF= $6.15 \times 10^{-3}$ ). We also reveal for several rare ARNSHI variants, that were previously observed in one population/family, to have higher frequencies in other ancestry groups, e.g. *USH1C* p.Q723X was previously reported in a single Chinese family, although in gnomAD it is prevalent in Africans/African Americans MAF= $2.16 \times 10^{-3}$ . In conclusion, we illustrate the need for additional gene discovery for ARNSHI particularly for specific ancestries, e.g. individuals of African-descent. The knowledge on the population specific spectrum of ARNSHI variants which this study has uncovered helps to define the genetic etiology of ARNSHI and aids in genetic testing.

**1226F****A pathogenic haplotype, common in Europeans, causes autosomal recessive albinism and uncovers missing heritability in OCA1. K.**

*Grønskov<sup>1</sup>, C. Jespersgaard<sup>1</sup>, G.H. Bruun<sup>2</sup>, K. Brøndum-Nielsen<sup>1</sup>, B.S. Andreassen<sup>2</sup>, T. Rosenberg<sup>3</sup>.* 1) Kennedy Center, Rigshospitalet, Glostrup, Hovedstaden, Denmark; 2) Department of Biochemistry and Molecular Biology and the Villum Center for Bioanalytical Sciences, University of Southern Denmark, Odense, Denmark; 3) Department of Ophthalmology, Kennedy Center, Copenhagen University Hospital, Rigshospitalet, Glostrup, Denmark.

Oculocutaneous albinism (OCA) is a genetically heterogeneous disorder which affects the eyes, skin and hair. Six genes are associated with autosomal recessive OCA (*TYR*, *OCA2*, *TYRP1*, *SLC45A2*, *SLC24A5* and *LRMDA*), while *GPR143* is associated with X-linked ocular albinism (OA) which only affects the eyes. Molecular genetic analysis of the seven genes provides a genetic diagnosis in approximately 60% of individuals with a clinical diagnosis of OA/OCA. This leaves a considerable number of individuals with albinism without a genetic diagnosis; a large number of these are heterozygous for a causative sequence variation in *TYR*. The number is in excess of what could be explained by the carrier frequency. To identify missing causative sequence variants we used a NGS based approach, genotyping and segregation analysis. We report a putative pathogenic haplotype segregating in accordance with an autosomal recessive inheritance pattern. This haplotype includes two rare SNVs in non-coding regions (100 kb upstream of the *TYR* translation start site and in intron 3) and two common coding SNVs (rs1042602A (p.S192Y) and rs1126809A (p.R402Q)). The haplotype covering 143 SNPs in *TYR* and surrounding regions is designated: "GYGQ". It is found in 15% of affected individuals in our cohort either as compound heterozygotes with a pathogenic *TYR* sequence variant or as homozygotes. Individuals homozygous for the haplotype have a partial albinism phenotype. The haplotype was not detected among 32 unaffected family members who are carriers of a pathogenic *TYR* sequence variation (measured by the presence of one of the rare SNVs). An explanation for the pathogenicity of the haplotype could be the combination of p.S192Y and p.R402Q, although we cannot completely rule out that the two rare SNVs or a yet undetected mutation could be causative. However, the SNV in intron 3 was analysed by minigene analysis and showed no effect on splicing. The upstream SNV is located in a region not evolutionary conserved and not known to possess enhancers. CNV analysis of the NGS data showed no pathogenic CNVs. In conclusion, the haplotype GYGQ can provide a molecular genetic diagnosis to a substantial number of individuals with albinism. Furthermore, as individuals homozygous for GYGQ have only a partial albinism phenotype, these could be clinical diagnosed as unexplained bilateral subnormal vision and/or nystagmus and should be analysed clinically and molecularly for albinism.

**1227W****The mutation detections in two Chinese families with aniridia. M. Gu<sup>1</sup>,**

*Y. He<sup>1</sup>, H. Ying<sup>2</sup>, X. Wei<sup>1</sup>, L. Chen<sup>1</sup>, W. Yang<sup>2</sup>, C. Tao<sup>2</sup>, Z. Wang<sup>1,3</sup>.* 1) Shanghai Jiao Tong University School of Medicine, Shanghai, China; 2) Department of Ophthalmology, Ren-ji Hospital at SJTUSM, Shanghai, China; 3) Research Center for Experimental Medicine, Rui-Jin Hospital at SJTUSM, Shanghai, China.

Aniridia (MIM 106210) is a kind of ocular disorders with a bilateral congenital absence or malformation of the iris. The disorder usually occurs in childhood with a prevalence of 1:40 000. Frequently associated ocular abnormalities include cataract and corneal abnormalities. About two-thirds of cases are familiar with dominant inheritance; the others are sporadic. Most cases are associated with mutations or deletions of the *PAX6* gene. However, aniridia is also a heterogeneous disorder with more than 5 disease-associated genes identified to date. These genes are *ELP4*, *TRIM44*, *FOXE3*, *FOXC1*, *PITX2*. We investigated two Chinese families with autosomal dominant aniridia. The study was approved by the committee of Shanghai Jiao Tong University School of Medicine. After informed consent was obtained, all family members who agreed to participate in this study were evaluated by experienced ophthalmologist. All affected members underwent interrogation and ophthalmological examinations. We found that five patients from family 1 were completely consistent with the clinical features of aniridia, and nine patients from family 2 had the phenotype of aniridia, ptosis and cataract. Screening for *PAX6* gene mutations was carried out in the 2 families by Sanger sequencing. The result showed that there was a known *PAX6* gene mutation C. 718C>T (p. Arg240) in Family 1, but no mutation of *PAX6* gene occurred in family 2. Considering the genetic heterogeneity of aniridia, we directly performed whole exome sequencing. We further selected eight highly suspicious genes for sequencing analysis. We finally identified a missense mutation [c.542C>T (p.Ser180Tyr)] in myosin heavy chain13 (*MYH13*, MIM 603487) at chromosome 17p13 in all affected individuals of family 2. Such genetic mutation was not detected in unaffected members in the family or in 300 unrelated, ethnically matched individuals (i.e., 600 chromosomes). *MYH13* was specifically expressed in the extraocular muscles for function in eye movement. We also checked *MYH13* sequence information in the database of the 1000 Genomes Project. No such variation (c.542C>T) in *MYH13* was found. These data suggest that the *MYH13* mutation is a disease-associated genetic variation cosegregating with the aniridia phenotype in this family. *In vitro* and *in vivo* studies on the molecular mechanism of *MYH13* gene mutations are underway. This work is partially supported by National Natural Science Foundation of China (Proj. No. 30470951, 31071107).

**Novel genes implicated in rare congenital inner ear and cochleovestibular nerve malformations.** I. Schrauwen<sup>1,2</sup>, E. Kari<sup>3</sup>, J. Mattox<sup>4</sup>, L. Llac<sup>5</sup>, J. Smeeton<sup>5</sup>, I. Chakchouk<sup>6</sup>, M. Naymik<sup>6</sup>, D.W. Raible<sup>6</sup>, J.A. Knowles<sup>7</sup>, J.G. Crump<sup>8</sup>, S.M. Leal<sup>1</sup>, M.J. Huentelman<sup>2</sup>, R.A. Friedman<sup>3</sup>. 1) Center for Statistical Genetics, Molecular and Human Genetics Department, Baylor College of Medicine, One Baylor Plaza, Houston, TX 77030; 2) Neurogenomics Division and Center for Rare Childhood Disorders, Translational Genomics Research Institute, 445 N 5th str, Phoenix, AZ 85004; 3) Division of Otolaryngology, Head and Neck Surgery, Department of Surgery, University of California, San Diego, ECOB- East Campus Office Building Room 3-013, 9444 Medical Center Drive, Mail Code 7220, La Jolla, CA 92037; 4) Tina and Rick Caruso Department of Otolaryngology- Head and Neck Surgery, Keck University of Southern California School of Medicine, 1975 Zonal Ave., Los Angeles, CA 90033; 5) Department of Stem Cell Biology and Regenerative Medicine, University of Southern California Keck School of Medicine, 1975 Zonal Ave., Los Angeles, CA 90033; 6) Department of Biological Structure, University of Washington, 1959 NE Pacific Street, Seattle, WA 98195; 7) SUNY Downstate Medical Center, Department of Cell Biology - MSC 5, 450 Clarkson Avenue, BSB 2-5, Brooklyn, NY 11203.

Congenital inner ear malformations affecting both the osseous and membranous labyrinth can have a devastating impact on hearing and language development. With the exception of an enlarged vestibular aqueduct, non-syndromic inner ear malformations are rare, and their underlying molecular biology has thus far remained understudied. In the era of next generation sequencing and with the increasing sensitivity of imaging techniques, rare inner ear malformations are now more effective to identify and characterize. Each of these cases can provide a unique and invaluable insight into the development of the ear or the normal hearing process. In addition, abnormalities in cochleovestibular anatomy can provide challenges for cochlear implantation, and a genetic diagnosis and understanding of the molecular basis might help with identifying the correct therapeutic intervention for these unique cases. By using a family-based trio exome sequencing approach, we are studying children with rare malformations to identify molecular factors that might be important in the developing inner ear and/or cochleovestibular nerve. We previously identified compound heterozygous variants in *MASP1* in a child with absent cochlear nerves. Here, we will present the identification of *de novo* loss-of-function variants in *GREB1L* [c.4368G>T;p.(Glu1410fs) and c.982C>T;p.(Arg328\*)] in two affected individuals with absent cochleae and 8<sup>th</sup> cranial nerve malformations. The cochlear aplasia in these affected individuals suggests that there is a developmental arrest or problem at a very early stage of inner ear development, e.g. during the otic pit formation. The crucial function of *Greb1l* in craniofacial development is also evidenced in knockout mice, which develop severe craniofacial abnormalities. In addition, we show that *Greb1l*<sup>-/-</sup> zebrafish exhibit a loss of or abnormal sensory epithelia innervation. In conclusion, we demonstrate that *GREB1L* variants underlie rare congenital inner ear and/or cochleovestibular nerve malformations. We will present an overview of these results in addition to any newly identified novel candidates from our ongoing studies. The combination of imaging and the molecular basis of rare inner ear malformations can ultimately lead to a more effective individually tailored therapeutic and 'personalized medicine' approach for affected children. .

**miR-204 overexpression exerts a protective role in inherited retinal diseases.** S. Banfi<sup>1,2</sup>, M. Karali<sup>1,2</sup>, E. Marrocco<sup>1</sup>, I. Guadagnino<sup>1</sup>, M. Pizzo<sup>1</sup>, A. Carissimo<sup>1</sup>, I. Conte<sup>1</sup>, E.M. Surace<sup>1,3</sup>. 1) Telethon Institute of Genetics and Medicine (TIGEM), Pozzuoli (NA), Naples, Italy; 2) Medical Genetics, Department of Precision Medicine, University of Campania "L. Vanvitelli", Naples, Italy; 3) Department of Translational Medicine, University of Naples 'Federico II', Naples, Italy.

Introduction: Inherited retinal diseases (IRDs) are progressive neurodegenerative conditions of the retina that represent a main cause of genetic blindness in the Western world. Their high genetic heterogeneity hinders the development of effective gene-based therapies. We have recently demonstrated that the microRNA miR-204 is essential for retinal function and plays a pathogenic role in IRD in humans. Therefore, we assessed the potential therapeutic action of this microRNA in IRDs. Materials and Methods: We delivered by subretinal injection an adeno-associated viral vector carrying the miR-204 precursor to the *Aip1* knockout and the P347S-*RHO* transgenic mouse lines, models of autosomal recessive and dominant forms of IRDs, respectively. The impact on retinal function and degeneration was assessed by electroretinographic and immunohistological analyses. Results: We detected a notable improvement of the ERG response in the miR-204-injected eyes of P347S-*RHO* mice. This effect persisted for two months post-injection and was prevalent under photopic conditions that reflect cone activity. We also observed a preservation of cone photoreceptors and a significant decrease in apoptotic photoreceptor cells. Photoreceptors were better preserved also in miR204-injected eyes of *Aip1* knockout mice. Transcriptome analysis suggested that dampening of microglia activation represents one of the main mechanisms underlying the neuroprotective effect of miR-204. Conclusions: Our findings indicate that the subretinal delivery of miR-204 attenuates retinal degeneration in IRD mouse models and preserves retinal function, supporting the gene-independent therapeutic potential of this microRNA.

**Lack of association between CTG repeats in the *DMPK* gene and audiological and vestibular findings.** M. Arenas-Sordo, D. Gutiérrez-Tinajero, M. Trujillo-Bracamontes, B. Rivera-Mercado, A. Martínez-García Ramos, O. Hernández-Hernández, J. Magaña-Aguirre. Genetics, Instituto Nacional de Rehabilitación, Mexico City, Mexico City, Mexico.

**Introduction.** Myotonic dystrophy type 1 (DM1) is a neuromuscular disease, progressive and multisystemic, caused by an unstable mutation of CTG repeats in the *DMPK* gene locus 19q13.3. **Purpose.** The present work shows the results from audiovestibular findings and time of evolution from the disease, and their correlation with a CTG repeats in the *DMPK* gene. **Methods.** 58 patients with molecular diagnosis for DM1 and their controls were analyzed. The controls were matched exact in sex and age. All of them had a comprehensive audiological and vestibular evaluation. Audiograms classified the range, nature and degree of hearing loss and speech audiometry detected the sensorial or conductive nature of hearing loss. Tympanometry, acoustic reflex threshold, and transient otoacoustic emissions were part of the evaluation. The impact of the vestibular disease in daily life was evaluated by the Dizziness Handicap Inventory (DHI) test. Falling in patients with balance deficiency and vestibular disorders was measured by the dynamic gait index (DGI). We made a correlation index looking for if there is or not association between the repeats number and each one of the audiological and vestibular characteristics. **Results.** From the 58 patients, 64% were male and 36% women, 69% had familial background of the disease. Almost half of the patients (48%) had some degree of sensorial hearing loss, of them, with a conventional audiometry, 53% of the patients had some manifestation comparing with just 8.6% of the controls ( $p=0.0001$ ); falls in high frequencies were also more important in patients than in controls ( $p=0.001$ ). In High frequencies audiometry there were also differences ( $p=0.00001$ ). The vestibular manifestations were present in 21 patients (36.2%),  $p=0.00001$ . Nistagmus was present in 2 patients, none of the controls, the DHI test, in its 3 scales showed that 53.4% had some degree of disability none of the controls ( $p=0.00001$ ). The 3 correlations that show  $p$  statistically significant were DGI and DHI with CTG number repeats ( $-0.3215/p=0.0313$  and  $0.3143/p=0.0355$  respectively) and high frequency audiometry ( $0.3422/p=0.0230$ ), with evolution time of the disease. **Conclusions.** The falls in high frequencies and superficial hearing loss were the findings more frequent. It was low correlation between CTG repeat number with ocular saccades test and in the DGI; with the time of evolution association was only with high frequency audiometry.

**A patient with early-onset high myopia caused by a homozygous mutation in *FAM161A*.** A. Bouman<sup>1</sup>, M. van Tienhoven<sup>1</sup>, N. Dzino<sup>2</sup>, A.A.H.J. Thiadens<sup>2</sup>, L.H. Hoefsloot<sup>1</sup>, V.J.M. Verhoeven<sup>1</sup>, J.A. Kievit<sup>1</sup>. 1) Department of Clinical Genetics, Erasmus Medical Center, Rotterdam, the Netherlands; 2) Department of Ophthalmology, Erasmus Medical Center, Rotterdam, the Netherlands.

Myopia is the most common ocular disease occurring worldwide. In the last few years many new monogenetic causes of isolated early-onset high myopia have been discovered. Whole Exome Sequencing has proven to be a powerful tool in identifying underlying causes of non-syndromic high myopia. Recently, *FAM161A* has been identified as a new candidate gene for this condition. Mutations in this gene have previously been described in patients with retinitis pigmentosa (RP28, OMIM#606068). In this report we present an additional case of a young girl with early onset myopia (over -5 diopters in both eyes at the age of 4 years) without additional ocular or systemic features. No signs of RP were observed by routine ophthalmologic exams. A homozygous nonsense mutation was identified in *FAM161A* by Whole Exome Sequencing (gene-panel analysis). This particular mutation has been described in literature previously in a young patient with a similar phenotype. At this point, it is hard to speculate about the (potential) risk on developing RP in a later stage of life for this particular group of young patients. Additional ophthalmologic exams and follow-up will be performed for our patient. We conclude that mutational screening of *FAM161A* in young patients with early onset (high) myopia could be helpful in identifying its underlying cause. Additional patients with early onset high myopia caused by a mutation in *FAM161A* could be contributive regarding a future cohort description. Email: a.bouman@erasmumc.nl.

**1232F**

**A heterozygous heterozygous variant p.S319G c.955 A>G of DNMT3A causing Tatton-Brown-Rahman in a mother and son.** A. Tsai, K. Lenhart, A. Meher. peds/genetics, university of colorado, Aurora, CO.

Tatton-Brown-Rahman syndrome (TBRS) is a genetic overgrowth disorder characterized by tall stature, dysmorphic facial features and moderate intellectual disability. While *de novo* heterozygous variants in *DNMT3A* (2p23.3) are known to be causative for TBRS, recent cases of familial transmission have also been reported. We report a boy referred to genetic services due to severe anxiety, developmental delay, sleeping disorder and abnormal gait. Upon initial physical examination, he showed >98 percentiles on growth parameters, prominent glabella ridges, brushy eyebrows, hyperflexible joints, mild 2/3 syndactyly, pes planus, and mild skin acanthosis nigricans. Neurological examination also showed significantly poor balance, aggression and irritability. Initial genetic testing by chromosomal microarray showed the proband carried paternally-inherited gains in 2p22.1 and 3p26.3. As the father was asymptomatic, additional testing was warranted. Indeed, follow-up testing by an expanded trio ASD/ID NGS panel revealed a maternally-inherited variant of uncertain significance (VUS) in the *DNMT3A* gene (c.955A>G; p.Ser319Gly). Interestingly, the mother shared characteristic TBRS physical features with her son, and self-reported a learning disability, as well as a history of migraines, seizures, anxiety and depression. Family history was also significant for three siblings with learning disabilities, although *DNMT3A* status has not been confirmed. Although the c.955A>G; p.Ser319Gly VUS has not been previously reported, the TBRS-like phenotype seen in this family indicate a likely causal relationship. Therefore, we maintain clinical correlation and an in-depth dysmorphological examination remains a powerful tool in clinical diagnoses.

**1233W**

**A novel neurogenetic syndrome with RALA mutation.** N. Okamoto<sup>1,2</sup>, Y. Shibukawa<sup>2</sup>, A. Takata<sup>3</sup>, N. Miyake<sup>3</sup>, N. Matsumoto<sup>3</sup>. 1) Department of Medical Genetics, Osaka Women's and Children's Hospital, Izumi, Osaka, Japan; 2) Department of Molecular Medicine, Osaka Women's and Children's Hospital, Izumi, Osaka, Japan; 3) Department of Human Genetics, Yokohama City University Graduate School of Medicine, Yokohama, Japan.

**[INTRODUCTION]** RAL (RAS like proto-oncogene) signaling pathway is a RAS down-stream effector. RAL belongs to the RAS superfamily and shares a structural similarity with RAS. Human cells have two genes, *RALA* and *RALB*, both of which are associated with cancers. We report a girl with a novel pathogenic variant in *RALA*. She showed severe intellectual disability (ID) and autism spectrum disorder (ASD). She also shared some features with Noonan syndrome. **[CLINICAL REPORT]** The 8-year-old female was the first child of healthy and non-consanguineous Japanese parents. She was hypotonic and her developmental milestones were markedly delayed. Physical examination identified relative macrocephaly (+1.5SD) and dysmorphic features including frontal bossing, epicanthal folds, low-set ears, flat nasal bridge, and high arched palate. Her physical growth was within normal range. She spoke no meaningful words. She was diagnosed with severe ID and ASD. Her walking was unsteady. Routine laboratory investigations and brain MRI revealed no significant abnormalities. **[METHOD]** With the approval of our institutional ethics committee, the samples were analyzed using Whole Exome Sequencing. Precise methods have been reported by Takata et al. (Cell Rep. 2018). **[RESULTS]** The patient had a *de novo* variant in *RALA* (chr7:39726339,G>A(;hg19)::p.V25M). This variant was classified as a consensus-damaging missense *de novo* mutation in ASD cohort (Takata et al.). It was not found among public databases and in house data. **[DISCUSSION]** There have been no reports on the association of the *RALA* variant and genetic disorders. It has been reported that *RALA* is activated in various cancers. We suppose that germline mutation of *RALA* causes a novel Noonan-like neurogenetic syndrome.

**1234T**

**A recognizable specific facial phenotype during adolescence and early adulthood in three unrelated patients with Dravet syndrome.** *M.K. Thong<sup>1</sup>, S. Chowdhury<sup>2</sup>, Y.C. Ying<sup>3</sup>, M. Vaithalingam<sup>3</sup>, N.K. Batumalai<sup>4</sup>, Y. Yakob<sup>5</sup>, S.A. Abdul Wahab<sup>5</sup>, T.B. Khoo<sup>6</sup>.* 1) Department of Pediatrics, University of Malaya, Kuala Lumpur, Malaysia; 2) Newcastle University Malaysia; 3) Department of Pediatrics, Melaka-Manipal Medical College, Melaka, Malaysia; 4) Department of Pediatrics, Hospital Melaka, Malaysia; 5) Molecular Diagnostics and Protein Unit, Institute for Medical Research, Kuala Lumpur, Malaysia; 6) Department of Pediatrics, Institute of Pediatrics, Hospital Kuala Lumpur, Malaysia.

**Background:** Dravet syndrome (OMIM #607208) is an early-onset epileptic encephalopathy and has not been reported to be associated with dysmorphism or pubertal abnormalities. An earlier study showed no significant differences were detected using photogrammetric indices between children with Dravet syndrome and their unaffected siblings and the study concluded there was absence of specific facial phenotype in children with Dravet syndrome. **Methods:** We report on three unrelated Asian male patients, aged 15 to 27 years with Dravet syndrome confirmed by presence of pathogenic *SCN1A* variants, who presented with specific facial features that only occurred during adolescence and early adulthood. These patients were followed up longitudinally since early childhood. **Results:** The patients showed normal development during the first 2 years of life. Childhood photos showed normal facial features with no dysmorphism. During adolescence, they presented with lack of facial hair, sloping broad foreheads with overhanging supraorbital ridges and deep-set eyes and a tendency to keep an open mouth. These striking features were immediately recognizable as unique and similar in all the patients. **Conclusions:** These dysmorphism and the discordance in the Tanner Staging, the hunched posture with hip and knee flexion when walking, are supportive of an expanded Dravet syndrome phenotype only evident in adolescence and early adulthood.

**1235F**

**A new *SMARCE1* variant in a patient with oculoauriculofrontonasal syndrome.** *S. Yano<sup>1</sup>, A. Fujimoto<sup>1</sup>, N. Matsumoto<sup>2</sup>, N. Miyake<sup>2</sup>, J. Morin-Leisk<sup>2</sup>, M. Gillespie<sup>3</sup>, H. Gao<sup>3</sup>.* 1) Genetics/Pediatrics, University of Southern California, Los Angeles, CA; 2) Human Genetics Yokohama City University, Yokohama, Japan; 3) Fulgent Genetics, Temple City, CA.

**Introduction:** Oculoauriculofrontonasal syndrome (OAFNS) is a rare disorder with features of both oculoauriculovertebral spectrum and frontonasal dysplasia. Carey and Yong first coined the term, OAFNS, in 1981 while Golabi et al. described the first case in 1983. The etiology of OAFNS is unknown although it is thought to be a result of the abnormal development of structures in the midface and in the first and the second branchial arches. A sporadic occurrence and autosomal dominant transmission are suggested based on the past reported cases of OAFNS. Herein, we report a case of OAFNS who was found to have a de novo heterozygous *SMARCE1* variant that is not previously reported in the literature. *SMARCE1* encodes the protein which is a part of the large ATP-dependent chromatin remodeling complex SWI/SNF. Human analogs of SWI/SNF complex are BAF complex. Heterozygous mutations in the BAF complex-related genes are reported in patients with Coffin-Siris syndrome. **Case Study:** Proband was born to a G2P1SAb1 19-year-old female and a non-consanguineous 32-year-old male. She was a full-term baby and was delivered by NSVD. At birth, she was diagnosed with multiple minor anomalies including right microtia and left low set ear as well as congenital heart defects (patent ductus arteriosus (PDA) and bicuspid aortic valve). At age 3 years, she was noted to have failure to thrive, microcephaly, hypotonia, bilateral hearing loss, hypertelorism, broad bifid nose, depressed nasal bridge, widely spaced maxillary central incisors, right ear skin tag, right eye coloboma, a thin upper lip, and macrostomia. She had long slender fingers and toes with normal fingernails and toenails. She had severe delay in intellectual and motor development. Brain MRI studies at one years of age showed hypogenesis of the splenium of the corpus callosum. Whole exome sequencing was performed at age 10 years with her parents and a healthy younger brother. A novel de novo *SMARCE1* missense alteration c.752G>A; p.Arg251Gln, was identified and confirmed by Sanger sequencing in the patient. **Discussion:** We could not verify that the novel de novo missense alteration is the sole cause of the patient's phenotype of OAFNS. Further studies with more cases are necessary to evaluate if *SMARCE1* is responsible for OAFNS. It might be necessary to include the other genes involved in SWI/SNF complex to identify the responsible gene(s) for OAFNS.

**1236W**

**Proposed clinical diagnostic criteria for Myhre syndrome: Preparation for evidence-based guidelines.** *L.J. Starr<sup>1</sup>, A.E. Lin<sup>2</sup>.* 1) University of Nebraska Medical Center, Omaha, NE; 2) MassGeneral Hospital for Children, Boston, MA.

Myhre syndrome is a distinctive connective tissue disorder with progressive serious comorbidities caused by de novo missense gain-of-function mutations in SMAD4 (at position 500 and 496). It is increasingly identified by clinical exome sequencing (at least 60 reported, and 15 new patients examined at our centers). Deaths were noted in 20% in the largest reviews, with additional patients known anecdotally. Serious complications are due to pericardial disease, restrictive cardiomyopathy and severe restrictive lung disease. Because of an urgent need to enhance clinical recognition, we propose diagnostic criteria which should lead to more rapid molecular confirmation. It is possible that not all families desire or can afford genetic testing. Furthermore, these criteria will allow assessment whether they can be viewed as evidence-based guidelines.

**METHODS:** Patients from the literature and new patients were compared to the following proposed clinical diagnostic criteria for Myhre syndrome. We also tested single patients with syndromes resembling Myhre syndrome. I. Diagnosis was based on fulfillment of 5/7 of these defined criteria: •Characteristic facial features •IUGR, short stature, or compact habitus •Hearing loss •Restrictive airway, interstitial lung disease •Cardiac (especially coarctation, PDA, descending aorta hypoplasia, pericarditis, restrictive cardiomyopathy) •Connective tissue/fibroproliferation (limited extension of joints, thick skin, straight spine, post-instrumentation fibrosis, fibrotic and thick scarring) •Neurodevelopmental delay, intellectual disability, autism spectrum disorder, anxiety II. The presence of the typical pathogenic *SMAD4* mutation and a score of 2 or more is sufficient for diagnosis of Myhre syndrome. **RESULTS:** Though likely a biased sample, all molecularly confirmed patients with Myhre syndrome fulfilled these diagnostic criteria. **DISCUSSION:** Establishing diagnostic criteria for any syndrome is an iterative process which begins with prior knowledge and is refined as more patients are studied. With a larger cohort, the power of this analysis may be sufficient to suggest clinical diagnosis require all 7 features. **CONCLUSION:** We propose the diagnosis of Myhre syndrome use these clinical criteria to decrease the risk of incorrect or missed diagnoses in a condition where careful anticipatory management is critical for optimal quality of life and survival. We plan to update the current management suggestions into evidence-based guidelines.

**Adopting a gene through Human Disease Genes website series facilitates a clinical diagnosis for rare genetic disorders.** *B.B.A. de Vries<sup>1</sup>, M.J. Nabais Sa<sup>1</sup>, S. Jansen<sup>1</sup>, A. van Remortele<sup>1</sup>, J. Ewals<sup>1</sup>, M. Verbruggen<sup>1</sup>, D.A. Koolen<sup>1</sup>, H.G. Brunner<sup>1</sup>, E. Eichler<sup>2</sup>, J. Gecz<sup>3</sup>.* 1) Department of Human Genetics, Nijmegen, Netherlands; 2) Department of Genome Sciences, University of Washington School of Medicine, Seattle, Washington 98185 USA; 3) Adelaide Medical School and the Robinson Research Institute, University of Adelaide, SA 5000 Australia.

Human Disease Genes website series (HDG) is an international library of websites for professional information on the clinical consequences of novel variants in the human genome (<http://humandiseasegenes.nl/>). HDG is an initiative of the Human Genetics Department, Nijmegen, in collaboration with the University of Washington and the University of Adelaide. Each website is moderated by a dedicated team of clinicians and molecular biologists, and collects and provides up-to-date mostly unpublished clinical information about one specific gene or copy number variant. HDG aims to fill the gap between first publication of several cases and consecutive publication of a large review paper. Professionals can use the information of the new and rare disorder for counseling and will have the opportunity to share clinical data. Patients, parents and caregivers will find useful information on the disease and have the opportunity to share detailed clinical information through the website of our partner GenIDA. HDG is also a platform where researchers can collect and share (functional) data. Recently a new version of the websites has been launched which not only allows collection of phenotype data using HPO (<http://humandiseasegenes.nl/wac/professionals/uploadclinicalinformation/>) but also provides an up-to-date overview of the clinical data that have been collected (<http://humandiseasegenes.nl/wac/graphandchart/>). These tools will be highly valuable for the clinical practice. So far, over 100 genes have been adopted (<http://humandiseasegenes.nl/genewebsites/>) by more than 60 moderators worldwide (<http://humandiseasegenes.nl/moderators/>). If you wish to adopt a gene and join the team of moderators please, contact us at the poster or send us a mail to [info@humandiseasegenes.com](mailto:info@humandiseasegenes.com).

**22q11.2 deletion syndrome: An update from the 22q and You Center at the Children's Hospital of Philadelphia.** *I.M. Campbell, S.E. Sheppard, T.B. Crowley, D.E. McGinn, A. Bailey, M.J. McGinn, M. Unolt, J.F. Homans, H.R. Salmons, J.W. Gaynor, E. Goldmuntz, O.A. Jackson, L.E. Katz, M. Mascarenhas, V.F.X. Deeney, R.M. Castelein, K.B. Zur, T. Kolon, C.B. Solot, E.M. Moss, R. Gur, K.E. Sullivan, B.S. Emanuel, E.H. Zackai, D.M. McDonald-McGinn.* Division of Human Genetics, Children's Hospital of Philadelphia, Philadelphia, PA.

**Background:** 22q11.2 deletion syndrome (22q11.2DS) is caused by recurrent low copy repeat mediated copy number losses of chromosome 22. The Children's Hospital of Philadelphia has been involved in the clinical care of individuals with what is now known as 22q11.2DS since our initial report of the association with DiGeorge syndrome in 1982. **Methods:** We utilized our continuously growing longitudinal cohort and reviewed the medical records of 1,421 patients with laboratory confirmed 22q11.2 deletion and evaluated by the 22q and You Center following the introduction of FISH studies from 1992 to 2018. **Results:** The mean age at diagnosis was 3.8 years  $\pm$  7.5 years. The vast majority of patients (84%) had the typical LCR22A-LCR22D deletion, and only 7% of these typical deletions were inherited from a parent harboring the deletion constitutionally. However, 5% of individuals harbored other nested deletions that would not be identified by traditional 22q11.2 FISH, as FISH probes are located between LCR22A-LCR22B. Such cases would require an orthogonal technology such as MLPA, chromosomal microarray, or massively parallel sequencing to diagnose. Major medical problems included immunodeficiency (77%); congenital heart disease (CHD) (69%) including 35% with severe anomalies such as tetralogy of fallot and pulmonary atresia; palatal abnormalities (68%); gastrointestinal difficulties including GERD, dysphagia and constipation (66%); endocrine dysfunction including hypocalcemia, hypothyroidism, and growth hormone deficiency (55%); cervical spine abnormalities (50%); renal anomalies (16%); and airway abnormalities including tracheomalacia and subglottic stenosis (7%). Mean full-scale IQ was 76  $\pm$  13.5, with no significant IQ difference between individuals with and without CHD. We also analyzed the dermatoglyphic patterns of our cohort and noted no substantial differences from previously reported normal controls. Interestingly, 74% of our cohort described themselves as Caucasian, with only 9% of African descent, differing demographically from our general hospital population of approximately 35% African American. **Conclusions:** These ethnicity results suggest a bias in diagnosis due to failure to recognize facial features, differences in access to our referral center, or possibly population variations in a heritable predisposition to development of 22q11.2 deletions. Further surveillance of our patients will likely elucidate additional clinically relevant findings as they age.

**1239W**

**Germline KRAS mutation-related schwannomatosis.** *M. Serey<sup>1</sup>, L. Messiaen<sup>2</sup>, H. Cave<sup>3</sup>, L. Chamard<sup>1</sup>, S. Valmary Degano<sup>4</sup>, L. Van Maldergem<sup>1</sup>, J. Piard<sup>1</sup>.* 1) Centre de Genetique Humaine, Universite de Franche-Comte, Besancon, France; 2) Department of Genetics, University of Alabama, Birmingham, Alabama; 3) Department of Genetics, Robert Debré University Hospital and Paris-Diderot University, Paris, France; 4) Department of Anatomopathology, Université de Franche-Comté, Besançon, France.

Schwannomas are benign tumors of the peripheral nerve sheath. Schwannomatosis is characterized by a predisposition to develop multiple schwannomas and. In case of multiple schwannomatosis, germline mutations of *SMARCB1* and *LZTR1* have been described. However, their identification only accounts for a limited number of cases and in many instances, establishing its molecular basis remains elusive. Its typical clinical presentation is made of multiple benign schwannomas, in early adulthood, associated to a chronic pain syndrome that can be exquisitely located at the site of the tumor or be diffuse and widespread. We describe here a 50 year-old female patient with a full-blown *KRAS*-related Noonan Syndrome and a large series of schwannomas becoming symptomatic from the age of 37 onwards. She underwent multiple surgeries. Later, neurological complications resulted in walking impairment and permanent cervical pain. In her case, a c.40G>A (p.Val14Ile) germline *KRAS* heterozygous missense mutation was identified. Sequencing of *NF2*, *LZTR1*, *SMARCB1* and MLPA on paraffin-embedded blocks taken during surgical procedures was tedious but resulted in identification of the same *LZTR1* frameshift c.2092\_2093insA mutation in three independent samples. There is an additional *NF2* c.172\_189del mutation with MLPA suggestive of the other *NF2* locus deletion in one of these samples and a loss of the *LZTR1* wild type allele in another sample. Only one patient with a similar association has been reported until now. The observation of two unrelated patients with *KRAS*-associated Noonan Syndrome and schwannomatosis suggests that a constitutional mutation in *KRAS* might be considered the third underlying cause of multiple schwannomatosis. It is a well-known phenomenon that mutations in genes encoding proteins belonging to the RAS-pathway are common to tumors and to constitutional disorders called rasopathies. Only a limited number of these constitutional disorders act as cancer-prone conditions, noticeably in Costello syndrome due to mutations in *HRAS* and, based on our second report of multiple schwannomas, in *KRAS*-related Noonan syndrome. Hence, clinical surveillance of *KRAS*-associated Noonan syndrome patients is strongly recommended for occurrence of these tumors, and conversely, in case of schwannoma, a careful dysmorphological examination may help diagnosing Noonan syndrome.

**1240T**

**De novo *PHF6* mutation in a girl with Borjeson-Forssman-Lehmann syndrome.** Y. Kuroda<sup>1</sup>, H. Murakami<sup>1</sup>, Y. Enomoto<sup>1</sup>, Y. Tsurusaki<sup>1</sup>, T. Uehara<sup>2</sup>, K. Kosaki<sup>2</sup>, K. Kurosawa<sup>2</sup>. 1) Division of Medical Genetics, Kanagawa Children's Medical Center, Yokohama, Kanagawa, Japan; 2) Center for Medical Genetics, Keio University School of Medicine, Tokyo, Japan.

Borjeson-Forssman-Lehmann syndrome (BFLS) is X-linked recessive disorder with moderate to severe intellectual disability, epilepsy, hypogonadism, obesity, and dysmorphic features. BFLS results from a mutation or deletion of *PHF6* gene encoding a plant homeodomain (PHD)-like finger protein. Female carriers are usually unaffected, but twelve female patients with BFLS have been reported with intellectual disability and recognizable dysmorphic features. We reported a female BFLS patient with de novo *PHF6* mutation. Patient is 16 year-old girl who is the first child of healthy and nonconsanguineous parents. She was delivered at 38 week gestation with a birth weight of 2862 g (0.47 SD), length 49.5 cm (0.74 SD), and occipital frontal circumference (OFC) 30.5 cm (-1.81SD). Cranial CT showed the slightly enlargement of ventricles at 1 months. She had atrial septal defect and repair surgery was performed at 1 year and 10 months of age. At six months, she developed the enlargement of OFC and cranial CT indicated a hydrocephalus, subdural hemorrhage, and atrophic cortex. She soon underwent a ventriculoperitoneal shunt due to hydrocephalus. She started visual contact at 3 months, smiling at 5 months, rolling at 9 months, and walking with support at 8 years of age. She could not speak recognizable words at 16 years-of-age, and showed signs of a severe intellectual disability. At the age of 16 years, she was 148.0 cm, with a weight of 42.7 kg. Her dysmorphic features consisted of prominent supraorbital ridges, prominent eyebrows with high arch and synophrys, deep-set eyes, a marked zygomatic arch, a high nasal bridge, a short nose with bulbous nasal tip, a prominent chin, clouded teeth, long shaped, and posterior rotated ears and prominent earlobes, tapering fingers, bilateral syndactyly of the fourth and fifth fingers of the foot, linear hyperpigmentation of skin, and hirsutism. Karyotype was 46,XX. and chromosomal microarray analysis showed no pathogenic copy number variation. In trio exome sequencing, de novo *PHF6* mutation, *PHF6*c.733-3\_733-2delTA was identified. X-inactivation study of lymphocytes showed a skewed inactivation pattern. The skewed X-inactivation pattern was noted in almost of female patients of BFLS. This patient had consistent dysmorphic features among previously reported female patients and severe intellectual disability. No patient had been reported with hydrocephalus, which may be new clinical findings in female BFLS.

**Molecular findings of 21 Brazilian patients with Cornelia de Lange syndrome.** J.R.M. Ceroni<sup>1</sup>, H. Ao<sup>2</sup>, I. Furquim<sup>1</sup>, V.E.H. Kim<sup>1</sup>, R.S Honjo<sup>1</sup>, G.L. Yamamoto<sup>1</sup>, D.R. Bertola<sup>1</sup>, T. Mizuguchi<sup>2</sup>, N. Matsumoto<sup>2</sup>, C.A. Kim<sup>1</sup>. 1) Unidade de Genética do Instituto da Criança do Hospital das Clínicas da FMUSP; Av. Dr. Enéas de Carvalho Aguiar, 647 - Cerqueira César, São Paulo - SP, Brazil, ZIPCODE: 05403-000 PHONE: +55(11)2661-8671; 2) Department of Human Genetics, Yokohama City University Graduate School of Medicine; 22-2 Seto, Kanazawa, Yokohama, Kanagawa Prefecture, Japan, 236-0027, PHONE: +81 45-787-2311.

**Introduction:** Cornelia de Lange syndrome (CdLS) is a rare genetic disorder caused by mutations in five genes - *NIPBL*, *RAD21*, *SMC3*, *SMC1A*, *HDAC8*, with different inheritance patterns. Autosomal dominant CdLS is caused by mutations in *NIPBL*, *RAD21* and *SMC3*, whilst *SMC1A* and *HDAC8* cause X-linked CdLS. Analysis of the five genes combined detects approximately 70% of cases. Although phenotype varies from mild to severe, the typical aspects of the syndrome are characteristic craniofacial appearance with synophrys, highly arched eyebrows, long, smooth philtrum, micrognathia, intellectual disability, limb abnormalities, hirsutism, gastroesophageal reflux, short stature, hearing loss. Moreover, clinical overlap with other syndromes, including different forms of autosomal dominant mental retardation, Rubinstein-Taybi, Fetal alcohol syndrome, Wiedmann-Steiner, Alazami-Yuan syndrome, has been described. **Objective:** To characterize the molecular findings of a Brazilian cohort of patients with clinically suspected CdLS. **Methods:** Informed consent was obtained from all patients or parents/guardians prior to the study. All patients were clinically evaluated at the genetic unit. Whole exome sequencing (WES) was performed in 21 probands (17 trios). **Results:** WES revealed pathogenic variants in CdLS genes in 12/21 (57.1%) patients: *NIPBL* (11 patients) and *SMC1A* (1 patient). Other pathogenic variants were found in 3/21 (14.3%) patients: *SETD5* (Autosomal dominant mental retardation 23), *ANKRD11* (KBG syndrome) and *ZMYND11* (autosomal dominant mental retardation 30). Also, one patient had a variant of unknown significance in *EP300* (Rubinstein-Taybi syndrome 2); this patient was adopted, therefore analysis of biological parents' samples were unavailable. In 5/21 (23.8%) patients no candidate variants for the phenotype were found. **Conclusions:** Most pathogenic variants were found in *NIPBL* 11/21 (52.4%), in accordance with the literature. Syndromes with overlapping features with CdLS, indeed Autosomal dominant mental retardation 23 and KBG syndrome were diagnosed. Moreover, one patient with typical phenotype of CdLS presented a pathogenic variant in *ZMYND11* (autosomal dominant mental retardation 30), a syndrome previously associated only with neurologic phenotype. We suggest *ZMYND11* as an additional gene associated with CdLS, reinforcing the strength of WES in genomic analysis. This is the first report of the molecular aspect of CdLS in a Brazilian Cohort. Support by CNPQ 304852/2016-3.

**1242W****A zebrafish model of *foxe3* deficiency demonstrates lens and eye defects with dysregulation of key genes involved in cataract formation in humans.**

S. Htun<sup>1</sup>, M. Krall<sup>1</sup>, D. Anand<sup>2</sup>, D. Hart<sup>2</sup>, S. Lachke<sup>2,4</sup>, A. Slavotinek<sup>1</sup>. 1) Department of Pediatrics, University of California San Francisco, San Francisco, CA; 2) Department of Biological Sciences, University of Delaware, Newark; 3) Department of Biochemistry and Biophysics, Cardiovascular Research Institute, University of California San Francisco, San Francisco; 4) Center for Bioinformatics and Computational Biology, University of Delaware, Newark.

The Forkhead box E3 (*FOXE3*) gene encodes a transcription factor with a forkhead/winged helix domain that is critical for development of the lens and anterior segment of the eye. Monoallelic and biallelic deleterious sequence variants in *FOXE3* cause aphakia, cataracts, sclerocornea and microphthalmia in humans. We used CRISPR/Cas9 injections to target the *foxe3* transcript in zebrafish in order to create an experimental model of loss of function for this gene. Larvae that were homozygous for an indel variant, c.296\_300delITGCAG demonstrated severe eye defects, including small or absent lenses and reduced eye size. This phenotype demonstrated an autosomal recessive pattern of inheritance and was fully penetrant. The lenses of the homozygous *foxe3* indel mutants showed more intense staining with zl-1 antibody compared to control lenses, consistent with increased lens fiber cell differentiation. RNA-Seq result found significant dysregulation of genes expressed in the lens and eye whose orthologues are associated with cataracts in human patients, including *cryba2a*, *cryba111*, *mipa* and *hsf4*. We compared the differentially expressed genes from the *foxe3* indel mutant fish with orthologous genes enriched in the mouse embryonic day (E)12.5 lens according to the bioinformatics database resource iSyTE2.0. We found that 181 genes that were 1.5-fold up- or down-regulated in the *foxe3* indel mutant fish exhibit enriched expression in iSyTE data from the E12.5 lens. Among the *foxe3* down-regulated genes that are also iSyTE lens-enriched are interesting candidate genes for lens development, such as *griffin* (galectin family protein in lens), *mipb* (associated with cataract), *crygmx* (lens gamma crystallin), *cryba2b* (associated with cataract), *tmod1* (associated with lens fiber skeleton organization), *six5* (associated with cataract) and *aldh1a3* (associated with microphthalmia/anophthalmia), as well as new uncharacterized candidates, such as *rnf10* and *tcf7*, among many others. As lens fiber differentiation involves an accumulation of crystallin proteins, the increased crystallin gene expression in the *foxe3* indel larvae is consistent with the hypothesis that *foxe3* inactivation is required for lens fiber differentiation, in that a deficiency of *foxe3* increases the expression of genes involved in this process. These findings demonstrate that this new zebrafish *foxe3* mutant model is highly relevant to the study of the gene regulatory networks conserved in vertebrate lens and eye development.

**1243T****A 1.9 MB interstitial deletions of 10q23.2q23.31 in a boy with juvenile polyposis.** H. Numabe<sup>1</sup>, Y. Morishima<sup>1</sup>, N. Inagaki<sup>1</sup>, S. Shiyanagi<sup>2</sup>, Y. Hayashi<sup>2</sup>, H. Kawashima<sup>1</sup>. 1) Clinical Genetics Center, Tokyo Medical University Hospital, Tokyo, Japan; 2) Department of Gastrointestinal and Pediatric Surgery, Tokyo Medical University, Tokyo, Japan.

A boy was born after premature rupture of the membranes at 36 weeks and 1 day of gestation. Apgar scores at 1 and 5 min were 7 and 8, respectively. His birth weight was 2910 g (+1.45 SD), height 50.3 cm (+1.99 SD), and head circumference 36.0 cm (+2.75 SD). At 1 month of age, he was referred to us because of macrocephaly and exhibited frontal bossing, low-set ears, high-arched palate, laryngeal stridor, and cryptorchidism. Echocardiography and abdominal ultrasonography revealed no abnormalities. The initial G-banding karyotyping showed reciprocal translocations 46,XY,t(1;10)(p36.2;q23.2),t(2;7)(p13;p13). The karyotypes of his parents were normal 46,XX and 46,XY. At 2 years and 2 months of age, he underwent a colonoscopy that revealed 51 polyps in his colon. Two months later, a polypectomy was performed, removing 35 polyps. Histopathology indicated juvenile polyps in all cases. Whole-genome SNP microarray analysis revealed a 1.9 MB interstitial deletion of 10q23.2q23.31. arr[hg19] 10q23.2q23.31(88,121,043-90,005,755)x1. The Online Mendelian Inheritance in Man database includes 7 (*LDB3*, *BMPR1A*, *GLUD1*, *MINPP1*, *PAPSS2*, *KLLN*, and *PTEN*) in this interval. *LDB3* is an autosomal dominant causative gene of dilated cardiomyopathy 1C with or without LVNC, hypertrophic cardiomyopathy 24, left ventricular noncompaction 3, and myofibrillar myopathy 4. *BMPR1A* is an autosomal dominant causative gene of the infantile form of juvenile polyposis syndrome, hereditary mixed polyposis syndrome 2, and juvenile intestinal polyposis. *GLUD1* is an autosomal dominant causative gene of hyperinsulinism-hyperammonemia syndrome. *MINPP1* is an autosomal dominant causative gene of follicular thyroid carcinoma. *PAPSS2* is an autosomal recessive causative gene of brachyolmia 4 with mild epiphyseal and metaphyseal changes. *KLLN* is a causative gene of Cowden syndrome 4. *PTEN* is an autosomal dominant causative gene of Bannayan-Riley-Ruvalcaba syndrome, Cowden syndrome 1, Lhermitte-Duclos syndrome, and Macrocephaly/autism syndrome, and is an autosomal recessive causative gene of the VATER association with macrocephaly and ventriculomegaly, and a causative gene for somatic endometrial carcinoma, somatic malignant melanoma, PTEN hamartoma tumor syndrome, and head and neck somatic squamous cell carcinoma. In this case, juvenile polyposis is recurrent and aggressive. The boy will need frequent surveillance for not only polyposis, but also thyroid carcinoma and other neoplasms associated with Cowden syndrome.

**1244F**

**A novel variant in *REN* explains a familial case of congenital anomalies of the kidney and urinary tract (CAKUT).** A.A. Dillio<sup>1,2</sup>, J. Wang<sup>1</sup>, V.M. Siu<sup>2,3,4</sup>, E. Brown<sup>2</sup>, G. Singh<sup>2</sup>, R.A. Hegele<sup>1,2</sup>. 1) Robarts Research Institute, Schulich School of Medicine and Dentistry, Western University, London, Ontario, Canada; 2) Department of Biochemistry, Schulich School of Medicine and Dentistry, Western University, London, Ontario, Canada; 3) Medical Genetics Program Department of Pediatrics, London Health Sciences Centre London, Ontario, Canada; 4) Children's Health Research Institute, London Health Sciences Centre London, Ontario, Canada.

Congenital anomalies of the kidney and urinary tract (CAKUT) comprises a group of diseases affecting kidney and urinary tract morphology. Although CAKUT is the most common form of congenital malformation, presentation is phenotypically heterogeneous, with a wide range of disease severity and outcomes. Here we present a consanguineous Old-Order Amish couple, who have had two children featuring CAKUT symptoms and severe oligohydramnios by 20 weeks' gestation. Both probands succumbed to pulmonary hypoplasia shortly after birth. We hypothesized the CAKUT phenotype is caused by a single rare, large-effect, autosomal recessive variant. We used a combination of autozygosity mapping and whole-exome sequencing to investigate the genetic basis of the CAKUT phenotype. Both probands' DNA samples were subjected to CytoScan HD microarray to interrogate for regions of autozygosity. Upon confirmation of no genetic dosage abnormalities, the eldest proband's DNA sample was whole-exome sequenced using the Illumina HiSeq 4000. Nonsynonymous rare variant prioritization was performed within Golden Helix VarSeq to identify candidate variants, incorporating the regions of autozygosity. We identified a novel homozygous nonsense variant, p.Tyr297\*, in the renin (*REN*) gene and Sanger sequencing confirmed variant co-segregation within the family. At this time, a second closely-related family came forward with their child affected with the CAKUT phenotype, and two unaffected children. Again, Sanger sequencing confirmed co-segregation in this family. All unaffected individuals were heterozygous carriers of the *REN* candidate variant. Fibroblast samples were obtained from both probands for immunoblotting assays, from which we observed significantly decreased *REN* expression when compared to fibroblasts with wild-type *REN*. Transcript expression will be analyzed using RT-PCR. Variants in *REN* have previously been associated with renal tubular dysgenesis; however, functional studies have not confirmed their connection to CAKUT. Additionally, *REN* is not a primary gene screened for mutations in CAKUT patients. Nonetheless, the renin-angiotensin system has a proven role in many aspects of renal branching morphogenesis, which is further confirmed by this finding. These results will add to the current limited knowledge of CAKUT genetics. By stratifying the heterogeneous CAKUT phenotypes by genotype, prognosis prediction will improve and allow for more appropriate genetic counselling for families.

**CHARGE syndrome with atypical clinical phenotypes diagnosed by whole exome sequencing.** H. Pang, H. Wang, A. Wright, B. Shah, S. Li, H. Wang. Department of Pediatrics, University of Oklahoma Health Sciences Center, 1100 N. Lindsay, Oklahoma City, OK, 73104, USA.

**Introduction:** CHARGE syndrome (OMIM# 214800) is a rare autosomal dominant genetic disorder caused by pathogenic variants in *CHD7*. Clinical diagnosis is based on the main features of coloboma, heart defects, choanal atresia, retarded growth and development, genital abnormalities, and ear anomalies. We described here two patients with atypical phenotypes diagnosed by whole exome sequencing (WES). **Case description:** Case 1 is a 1-year-old male with multiple congenital anomalies including interrupted aortic arch, VSD, bilateral cleft lip and palate, and 3<sup>rd</sup> and 4<sup>th</sup> syndactyly, L vocal cord paresis, bilateral renal artery stenosis. The FISH, karyotype, and microarray results were normal. After the identification of pathogenic variants in *CHD7* via WES, further investigation revealed bilateral optic nerve colobomas. Case 2 is a 35 weeks premature male with prenatal history of polyhydramnios, PDA, VSD, left-sided congenital diaphragmatic hernia (CDH); postnatal additional findings of conotruncal defects, absent thymus with decreased TRECs, lymphopenia, hypocalcemia, hypoparathyroidism, right-sided facial palsy, seizure-like activities. Considering 22q11.2 deletion syndrome, however, the SNP array result was negative and WES was performed. **WES findings:** WES trio studies were performed. Two heterozygous variants c.4609 A>T (p.Lys1537\*) located in exon 20 and c.7922dupT (p.Leu2641Phefs\*12) located in exon 21 in the *CHD7* gene (NM\_017780.3) was detected for case 1 and case 2, respectively. None of these variants has been reported previously in the literatures. Both variants are *de novo* and are predicted to cause loss of normal protein function. Based on the ACMG guidelines, they were classified as pathogenic variants for CHARGE syndrome. **Conclusions:** Emerging studies reported the wide spectrum of phenotype in CHARGE syndrome and clinical overlap with 22q11.2 deletion syndrome. Immune dysfunction has also been reported in CHARGE syndrome. Our study provided more evidences for the expanded spectrum of phenotype in CHARGE syndrome. WES is a powerful tool in the clinical practice for patients with atypical clinical presentations. We reported two novel pathogenic variants in the *CHD7* gene. Updated diagnostic criteria with inclusion of molecular diagnosis for CHARGE syndrome should be considered for patients with atypical phenotypes.

**Expanding the clinical spectrum of *KDM6A*-associated Kabuki syndrome.** C.T. Myers<sup>1</sup>, J.T. Bennett<sup>2,3</sup>, J.L. Merritt<sup>1,2</sup>, K.D. Tsuchiya<sup>1</sup>, J. Vogel<sup>1</sup>, L. Rogge<sup>1</sup>, J.M. Thies<sup>1</sup>, K. Foss<sup>1</sup>, C.R. Paschal<sup>1</sup>. 1) Seattle Children's Hospital, Seattle, WA, USA; 2) Department of Pediatrics, University of Washington, Seattle, WA, USA; 3) Center for Developmental Biology and Regenerative Medicine, Seattle Children's Research Institute. Seattle, WA, USA.

Kabuki syndrome (KS) is a rare disorder that is recognized clinically by characteristic facial features, minor skeletal and dermatoglyphic abnormalities, intellectual disability, and postnatal growth deficiency. Clinical findings in patients with KS are variable, but can also include congenital anomalies, increased susceptibility to infections, feeding difficulties, seizures, and hearing loss. KS has an autosomal dominant inheritance pattern, with the majority of cases being sporadic. Pathogenic variants in *KMT2D* account for 56-75% of cases, whereas pathogenic variants in *KDM6A* are less frequent (5-8%) and not well-described. We report the clinical and molecular findings of two individuals, each with a pathogenic deletion involving *KDM6A* that was identified by chromosome microarray analysis (CMA). Patient #1 is a 5 year old girl who presented with developmental delay, dysmorphic features, and low serum carnitine beyond the neonatal period. A 519 Kb interstitial deletion of Xp11.3 was identified. This deletion includes the entire coding region of *KDM6A*, and the two other genes in the deleted segment, *DUSP21* and *CXorf36*, have not been well-characterized. Parents were not available for testing. Patient #2 is a female infant who presented with hypoglycemia, hypotonia, bilateral hip dysplasia, feeding difficulties requiring nasogastric feeding, and dysmorphic features. She was found to have a 26 Kb deletion that includes two exons within *KDM6A*, which was confirmed by quantitative PCR. Parental testing revealed that this was a *de novo* change. The two cases presented here highlight the variable phenotype of *KDM6A*-associated KS. The facial features of both individuals were considered to be mildly dysmorphic, but consistent with KS. Both patients reported feeding difficulties, albeit of different severity. To date, approximately 40 patients with *KDM6A* variants have been reported, including 6 with exonic or whole gene deletions. Neonatal hypoglycemia has been reported in a subset of patients with *KDM6A* variants, including one other patient with hyperinsulinemia. Other variable features include long halluces, hypertrichosis, joint laxity, and congenital heart defects. The molecular subtype of *KDM6A* abnormality may contribute to the severity of the phenotype. In females, X-inactivation patterns in different tissues are also likely to contribute to phenotypic manifestations. Larger studies are needed to more fully characterize the spectrum of *KDM6A*-associated KS.

**KBG syndrome diagnosed in a 4-month-old infant with failure to thrive caused by deletion of the *ANKRD11* gene.** H. Wang, H. Pang, XF. Wang, YM. Kim, SB. Li, KJ. Wierenga. Department of Pediatrics, The University of Oklahoma Health Sciences Center; 1100 N Lindsay Ave, Oklahoma City, OK 73104.

**INTRODUCTION:** KBG syndrome (OMIM148050) is an autosomal dominant disorder characterized by multiple congenital anomalies including macrodon-tia, distinctive craniofacial features, short stature, and developmental delay. The diagnosis of KBG syndrome is by detection of pathogenic variant in the *ANKRD11* gene or deletion of the 16q24.3 region encompassing *ANKRD11*. More than 100 individuals have been reported. However, KBG syndrome diagnosed in the infant has rarely been described. **CASE DESCRIPTION:** This is a 4-month-old infant born at 35 weeks with birth weight of 4lbs and 2ozs. She stayed in NICU for 21 days due to difficulty feeding, failure to thrive (FTT) and NG-tube was required. Except small VSD, no other abnormalities were found. At age of 4 months, she was re-hospitalized for FTT with both weight and height below 0 % centiles. G-tube was placed. Mild dysmorphic facial features were noticed including triangular face, hypertelorism, relatively long philtrum and thin lips. The comprehensive laboratory workup were negative. The initial whole genome single nucleotide polymorphism (SNP) array was performed followed by duplication/deletion study of Next Generation Sequencing (NGS). **RESULTS:** SNP array revealed a deletion on chromosome 16q24.3 with size range of 46.7kb to 100.1kb based on the two different values of Log R ration. The deleted region include intron 2 of *ANKRD11* gene (NM\_013275.5) at the minimal or whole coding exons at the maximum. Due to the uncertain size of the deletion, further deletion/duplication study of the *ANKRD11* gene was performed which revealed a heterozygous deletion of all coding exons. **CONCLUSIONS:** The age at the diagnosis in most of the reported cases are from about 1 year to adulthood. Diagnosis of KBG syndrome in the early infant could be challenging as the major feature may be just failure to thrive. Detection of the whole *ANKRD11* gene deletion in our case establish the diagnosis. Except one reported case diagnosed at prenatal stage, the patient we reported here is at the youngest age diagnosed with KBG syndrome. Importantly, uncertain size of deletion found on microarray should be further characterized by alternative methods.

**1248W**

**Mechanistic basis of Takenouchi-Kosaki syndrome: Electron microscopic studies of platelets in patients and functional studies in model organism.** T. Takenouchi, T. Uehara, K. Kosaki. Keio University, Tokyo, Japan.

We recently reported two unrelated individuals with thrombocytopenia accompanied with intellectual disability, who had a *de novo* mutation, p.Tyr64Cys, in *CDC42* in both patients. The characteristic hematologic feature, *i.e.* increased platelet size and decreased platelet count (macrothrombocytopenia) was compatible with the existing evidence in mice that homozygous knock- mice in *cdc42* causes similar platelet phenotype. Identification of multiple unrelated patients who had similar phenotype and had a *de novo CDC42* mutation established that these patients represent a new syndromic form of thrombocytopenia, which was eponymized as "Takenouchi-Kosaki syndrome" (OMIM #616737). Later, Motokawa M. *et al.* reported the third patient with this condition, and we recently evaluated one additional patient. In the present study, detailed phenotypic comparison was made in a total of four patients with Takenouchi-Kosaki syndrome. Morphologic analysis of platelets derived from three affected individuals was performed using electron microscopy. We further performed the functional analysis of p.Tyr64Cys in *CDC42* through CRISPR/Cas9 gene editing with *Caenorhabditis elegans*. The cardinal features in Takenouchi-Kosaki syndrome include intellectual disability accompanied with structural brain abnormalities and sensorineural deafness, macrothrombocytopenia, and camptodactyly. Electron microscopic analysis of platelet showed increased vacuoles and alpha granules. Functional analysis of p.Tyr64Cys in *CDC42* in model organism suggested hypomorphic effects of the mutant allele. Takenouchi-Kosaki syndrome is clinically recognizable by the intellectual disability, macrothrombocytopenia, and presence of a *de novo* mutation in *CDC42*, *i.e.*, p.Tyr64Cys.

**Deleterious mutation of *NSD1* gene in a Senegalese patient with SOTOS syndrome.** R. Ndiaye Diallo<sup>1</sup>, K. Diallo<sup>1</sup>, B. Niang<sup>2</sup>, E. Pasmant<sup>3</sup>, JPD. Diop<sup>1</sup>, Y. Dia<sup>1</sup>, SS. Mbacke<sup>1</sup>, PA. Diop<sup>1</sup>, O. Faye<sup>1</sup>, M. Vidaud<sup>3</sup>, A. Dieye<sup>1</sup>. 1) Faculty of Medicine, Pharmacy and Dentistry University Cheikh Anta Diop Dakar, Senegal; 2) Service de Pédiatrie Hôpital d'Enfant Albert Royer CHUN de Fann, Dakar, Senegal; 3) MCU-PH IEA7331, Université Paris Descartes Service de Génétique et Biologie Moléculaires, Hôpital Cochin, Paris.

Sotos syndrome is a rare autosomal dominant childhood overgrowth condition, characterized by distinctive facial features, intellectual disability, macrocephaly and overgrowth of the body in early life. In almost 90% of cases, mutations occurred in the gene encoding nuclear receptor-binding SET domain containing protein 1 (*NSD1*). Here we report a Senegalese patient diagnosed with SOTOS syndrome at age 3 months. He was the second child of a nuclear family and has excessive body growth (size > Z3DS), macrocephaly and facial dysmorphism (pronounced occipital horns, elongated face, palpebral anti-mongoloid clefts). After informed consent of both parents, blood samples were collected from the index case and each parent for genetic testing. Genomic DNA was extracted and all coding exons and flanking intronic regions of *NSD1* (NM\_022455.4), *DNMT3A* (NM\_175629.6) and *SETD2* (NM\_014159.6) genes, were screened for mutations by multiplex PCR followed by next generation sequencing of amplicons. Identified mutations were systematically verified by Sanger technology. We identified in the index case a heterozygous mutation in exon 5 of the *NSD1* gene, leading to a frameshift and premature termination of protein synthesis: c.2306dup (NM\_022455); p. Gly771Trpfs\*38 (NP\_071900). This mutation occurs *de novo* in the index case and was not detected in either parents. This is the first case of SOTOS syndrome genetically diagnosed in Senegal.

**1250F**

**Complete spectrum of *PIK3CA* mutations in isolated lymphatic malformations.** C.V. Cheng<sup>1</sup>, D. Jensen<sup>2</sup>, A.E. Timms<sup>2</sup>, G. Shivaram<sup>3,5</sup>, R.A. Bly<sup>4,5</sup>, S. Ganti<sup>4,5</sup>, A. Kirsh<sup>2</sup>, W.B. Dobyns<sup>1,6</sup>, M.W. Majesky<sup>2</sup>, J.T. Bennett<sup>4,5,6</sup>, J.A. Perkins<sup>4,5</sup>. 1) Center for Integrative Brain Research, Seattle Children's Research Institute, Seattle, WA; 2) Center For Developmental Biology And Regenerative Medicine, Seattle Children's Research Institute, Seattle, WA; 3) Interventional Radiology, Seattle Children's Hospital, Seattle, WA; 4) Seattle Children's Hospital, Division of Pediatric Otolaryngology, Department of Otolaryngology/Head and Neck Surgery, University of Washington, Seattle, WA; 5) Vascular Anomalies Program, Seattle Children's Hospital, Seattle, WA; 6) Seattle Children's Hospital, Division Of Genetic Medicine, Department Of Pediatrics, University of Washington, Seattle, WA.

Somatic mosaic activating mutations in *PIK3CA* are the most common cause of isolated lymphatic malformations (LMs). According to a previous study, 4 frequently mutated residues, "hotspots," (p.E542K, E545K, H1047R and H1047L) account for 80% of LMs. Although non-hotspot mutations in *PIK3CA* are prevalent in human sporadic cancers, they have never been reported in LMs. This data is sparse and the complete spectrum of *PIK3CA* mutations in isolated LMs has yet to be determined. We used single molecule molecular inversion probes (smMIPs) to sequence *PIK3CA* in 287 samples across 88 individuals with isolated LMs. This technique permits detection of low-level alternate allele fractions (AAF) of genetic variants with barcoding. The data was analyzed using the mosaic variant caller PISCES. As a secondary method for targeted confirmation, we used droplet digital PCR (ddPCR). *PIK3CA* genotypes and AAFs were also correlated with clinically relevant variables. Fifty-four of the 88 individuals had pathogenic or likely pathogenic *PIK3CA* variants with sufficient sequencing coverage, yielding a diagnostic rate of 61% by smMIPs. Of all the mutations detected in *PIK3CA*, 93% of the variants are in 1 of the 4 hotspots. We also identified 3 non-hotspot mutations (p.G106V, Q546K, and F937S), 1 of which has never been reported, and 2 of which have been previously reported in both cancer and overgrowth syndromes. Variants were generally detected in resected LM tissue and not in blood or skin overlying the lesion, and AAFs ranged from 1 to 22%. Preliminary genotype-phenotype comparisons suggest a correlation between less severe LMs and non-hotspot mutations. Full gene sequencing using smMIPs to detect low-level AAFs in tandem with sensitive analysis algorithms is an effective method for uncovering mutations across the *PIK3CA*-LM spectrum. However, since the overwhelming majority of detected variants are in hotspots, a sensitive, allele-specific method like ddPCR may be a more efficient first line assay. Identification of the underlying genetic etiology of isolated LMs is valuable as enthusiasm for medical therapies like sirolimus and other PI3K-AKT-mTOR inhibitors increases.

Gemelli IRCCS, Università Cattolica del Sacro Cuore, Rome, Italy; 5) ArQule, Inc., Burlington, Massachusetts, United States of America.

Proteus syndrome (PS) is an ultra-rare disease characterized by progressive, disproportionate, segmental overgrowth caused by a somatic gain of function mutation p.Glu17Lys in the oncogene *AKT1*. The disease has high morbidity and mortality rates as well as increased risk of cancer development. Below is a case report of a 15 year old girl with a molecular diagnosis of PS and a relapsed inoperable *AKT1*(p.Glu17Lys) mutant low grade serous ovarian cancer (LGSOC) treated with the *AKT*inhibitor miransertib on a compassionate basis. During the first six years of life, the patient underwent multiple surgical amputations due to progressive overgrowth of hands and feet. At the age of 12 she underwent a bilateral salpingo-oophorectomy and hysterectomy due to LGSOC (International Federation of Gynecology and Obstetrics, FIGO stage IA). Targeted deep sequencing assay of PI3K/AKT pathway genes and comprehensive cancer panel (409 genes) showed the only oncogenic driver of LGSOC was the single mosaic gain of function mutation in *AKT1*gene(p.Glu17Lys,15% mutant allele frequency). Twenty months after surgery, CT detected a recurrent solid mass close to the bladder and a partial portal vein thrombosis. Considering significant contraindications to standard therapeutic options, neither cytoreductive surgery nor palliative cytotoxic chemotherapy was recommended. After approval by local EC and baseline biochemical and imaging staging, the patient started treatment with miransertib at 100 mg/ daily, 7 days on and 7 days off every 14 days. After 16 weeks of treatment CT showed a partial response (PR), according to RECIST 1.1 criteria and a complete resolution of the portal thrombosis. The 12-month CT scan confirmed the ongoing PR (-50% from baseline). During treatment a progressive reduction in bone and connective tissue overgrowth, especially in the hands, was observed; moreover, the patient reported a progressive improvement in joint mobility (hands, spine and knees) and, therefore, in her quality of life. No major side effects were recorded during 12 months of therapy. To our knowledge, this is the first documented case of PS showing a relapsed *AKT1*(p.Glu17Lys)mutant LGSOC, in which treatment with an *AKT*inhibitor led to an objective reduction of overgrowth lesions and sustained tumor response. Clinical and molecular data give a unique insight into the pathogenesis of this neoplasm in patients with PS and demonstrate that personalized medicine is feasible in ultra-rare diseases.

**SUZ12 related overgrowth.** *W.T. Gibson*<sup>1,2</sup>, *S.S. Cyrus*<sup>1</sup>, *N. Tkachenko*<sup>3</sup>, *K. Avela*<sup>4</sup>, *B.H.Y. Chung*<sup>5</sup>, *H.M. Luk*<sup>6</sup>, *S. Choufani*<sup>7</sup>, *R. Weksberg*<sup>7</sup>. 1) Department of Medical Genetics, University of British Columbia, Vancouver, BC, Canada; 2) Provincial Medical Genetics Program, Children's and Women's Health Centre of British Columbia, Vancouver, BC Canada; 3) Centro Hospitalar do Porto, Portugal; 4) Helsinki University Hospital, Department of Clinical Genetics, Finland; 5) Department of Paediatrics & Adolescent Medicine, University of Hong Kong, China; 6) Clinical Genetic Service, Department of Health, Hong Kong, China; 7) Genetics & Genome Biology Program, Hospital for Sick Children, Toronto, Canada.

The Polycomb Repressive Complex type 2 (PRC2), is a chromatin regulator, which mono-, di- or tri-methylates lysine 27 on Histone 3 (H3K27)- a repressive methylation mark. Three components of PRC2 have been implicated in rare overgrowth syndromes: Enhancer of Zeste 2 (*EZH2*), Embryonic Ectoderm Development (*EED*) and Suppressor of Zeste 12 (*SUZ12*). In 2011, coding mutations in *EZH2* were found to be causative of Weaver Syndrome. Weaver Syndrome features overgrowth (tall stature and macrocephaly), intellectual disability, early bone maturation, characteristic facial features and susceptibility to malignancies. Subsequently, people with a phenotype similar to Weaver Syndrome were found to have *de novo* coding mutations in *EED*. This led to the recognition of the Cohen-Gibson Syndrome. In 2017, the first case of an individual with a rare coding variant in *SUZ12* and an overgrowth phenotype was described. Here we present 4 individuals (3 families – from Portugal, Finland and Hong Kong) with rare coding variants in *SUZ12*, the largest cohort to date. A c.1807T>C; p.(Phe603Leu) variant was transmitted from father-to-son; the c.1715\_1716insCA; p.(Leu572fsPheTer11) and c.1878delT; p.(Phe626LeufsTer7) variants were identified in individual probands. Emerging features of *SUZ12*-overgrowth include prenatal overgrowth, postnatal tall stature, macrocephaly, large hands and feet and early bone maturation. Intellectual disability is variable and may be absent. None of the cases reported to date have developed haematological or solid malignancies. Notably, constitutional pathogenic variants in *NSD1* cause Sotos Syndrome, and the mutations that disrupt *NSD1*'s methylation of H3K36 result in a "downstream" DNA methylation signature in patients with Sotos syndrome. Since coding variants affecting PRC2 members also perturb its H3K27 methylation, these mutations may also generate a characteristic DNA methylation signature. Furthermore, rare variation in PRC2 complex members is collectively common among individuals not known to have rare genetic syndromes (as described within the ExAC and gnomAD populations). Given the multiple clinical features manifest by patients with syndrome-causing mutations in PRC2 members, and the population-wide prevalence of rare coding variants in *EZH2*, *EED*, *SUZ12* and other epigenetic regulators, it is plausible that rare coding variants in epigenetic regulators may also confer risk for common, complex diseases in the general population.

**1253F**

**Identification and validation of variants of uncertain significance in novel candidate genes for 46, XY disorders/differences of sex development (DSD).** *A. Parivesh*, *H. Barseghyan*, *M. Almalvez*, *M. Bramble*, *E. Délot*, *E. Vilain*. Center for Genetic Medicine Research, Children's National Medical Center, Washington, DC.

**Background:** Disorders/differences of Sex Development (DSD) have an estimated frequency of 0.5% of live births encompassing a variety of urogenital abnormalities ranging from mild hypospadias to sex reversal. Exome sequencing was performed on a subset of DSD cases with 46, XY karyotype identifying the underlying cause in ~35% of cases. To investigate the relevance of variants of unknown significance (VUS) in the unresolved cases, we utilized a mouse model in which the presence of a Y chromosome from the *poschiavini* strain (*Y<sup>pos</sup>*) on a C57BL/6J (B6) background results in XY undervirilization and sex reversal, a phenotype characteristic to human 46, XY DSD cases. We measured RNA expression of the genes carrying VUS in 46 XY human cases and assessed differences of expression between the gonads of B6-*Y<sup>pos</sup>* and under-virilized B6-*Y<sup>pos</sup>* males at E11.5. This identified a list of 15 new candidate genes for XY DSD. **Objective:** To validate the novel candidate genes for 46, XY DSD by assessing the possible effects of novel mutations on protein function. **Methods:** Among the candidate genes identified by this study, *Adamts16* is expressed in embryonic gonadal tissue under the control of sex-determining gene *Sox9*. *ADAMTS16* belongs to the ADAMTS family of integral membrane and secreted glycoproteins that have matrix metalloproteinase functions and have several known proteolytic substrates. It is known to bind and cleave  $\alpha 2$  macroglobulin (*A2MG*). *A2MG* and *ADAMTS16* in wild-type and two mutant forms were cloned into bacterial vectors for protein expression. *in vitro* binding/cleavage assays using the purified proteins were used to assess the mechanisms by which the novel *ADAMTS16* mutations affect binding to and/or cleavage of *A2MG*. **Results:** Mouse studies and exome sequencing identified 15 novel candidate genes potentially involved in 46, XY DSD pathogenesis. We used *in silico* prediction algorithm and showed that the two mutant forms of *ADAMTS16* (p.Arg100Trp; p.Phe469Val) should affect propeptide cleavage and peptidase activity respectively. We have set up an *in vitro* model that allows us to test this hypothesis and provide functional validation for some of the novel candidate genes that harbor VUS.

**1254W**

**IDH1 and IDH2 mutations in a cohort of patients with Ollier disease and Maffucci syndrome.** E.S. Partan<sup>1,2</sup>, R. Martin<sup>2</sup>, S. Robbins<sup>1,2</sup>, L. Cirulli<sup>3</sup>, D. Valje<sup>2,4</sup>, N. Sobreira<sup>2,4</sup>. 1) Predoctoral Training Program in Human Genetics, Johns Hopkins School of Medicine, Baltimore, MD; 2) McKusick-Nathans Institute of Genetic Medicine, Johns Hopkins School of Medicine, Baltimore, MD; 3) Duke University School of Medicine, Duke University, Durham, NC; 4) Department of Pediatrics, Johns Hopkins School of Medicine, Baltimore, MD.

IDH1 and IDH2 catalyze the oxidative decarboxylation of isocitrate to  $\alpha$ -ketoglutarate ( $\alpha$ KG). Variants in the active sites of IDH1 (p.R132) and IDH2 (p.R140/R172) result in the neomorphic ability of the enzyme to instead convert  $\alpha$ KG to 2-hydroxyglutarate. Germline heterozygous variants in *IDH2* cause D-2-hydroxyglutaric aciduria type 2 (D2HGA). Somatic *IDH1* and *IDH2* variants have been observed in a wide variety of cancers. These variants have also been identified in 80% of the enchondromas, chondrosarcomas, and vascular anomalies in individuals with Ollier disease (OD) and Maffucci syndrome (MS). OD and MS are related conditions characterized by enchondromas with a 30% risk of chondrosarcoma transformation; individuals with MS also have vascular anomalies. We performed Sanger sequencing and/or whole exome sequencing on germline DNA from 25 probands with OD or MS and on tumor DNA from 16 samples from 11 probands. We identified an *IDH1*-p.R132C variant in a spindle cell hemangioma sample from a patient with MS; this variant was not present in two enchondromas from the same proband. The same p.R132C variant was also found in an enchondroma and chondrosarcoma of two probands with OD, while another proband with OD had a p.R132H variant. We also identified a proband with OD who had a homozygous *IDH1*-p.M91T (gnomAD 8.121e-6) variant in a chondrosarcoma and a heterozygous *IDH2*-p.I152T (gnomAD 0) variant in an enchondroma. Another proband with metaphyseal enchondromatosis with D2HGA had a heterozygous germline *IDH1*-p.R132C and a heterozygous somatic *IDH2*-p.T435M (gnomAD 0.003) variant in two enchondroma samples, the latter of which was not found in his blood. Finally, two other probands with enchondromatosis each had a germline, rare, heterozygous *IDH2* variant inherited from an unaffected parent (p.D225N and p.T435M). In summary, we identified *IDH1* or *IDH2* variants in the tumor samples of six probands, three of which were not in the previously identified positions, and germline variants in three probands, two of which were in novel positions. The identification of rare *IDH1* and *IDH2* variants not previously described in these disorders, the occurrence of germline variants, and the occurrence of multiple variants in some probands are novel findings in this group of disorders. Further investigation of the function of these different germline and somatic variants in isolation or in combination may improve our understanding of the pathophysiology of these disorders.

**A familial novel whole *CDKN1C* gene deletion in siblings with Beckwith-Wiedemann syndrome and Dandy-Walker malformation.** D. Aljeaid, R.J. Hopkin. Human Genetics, Cincinnati Children Hospital Medical Center, CINCINNATI, OH., OH.

Beckwith-Wiedemann syndrome (BWS) is a human genomic imprinting disorder with estimated prevalence of 1:10,340. It affects males and females equally. Originally described by Beckwith and Wiedemann (in 1953 and 1964) with hallmark features of omphalocele, macroglossia and macrosomia. The phenotypic features of BWS are highly variable that include hemihyperplasia, visceromegaly and increased risk of embryonal tumors. BWS is caused by genetic and epigenetic changes within two imprinting domains on chromosome 11p15 resulting in excess expression of growth genes. We present a family with two affected siblings (male and female) exhibiting clinical features of BWS and Dandy-Walker malformation due to a novel whole gene deletion of *CDKN1C*. Both patients were identified with omphalocele on prenatal ultrasound, additional findings of polyhydramnios, placentomegaly, macroglossia and DWM with enlarged cisterna magna and cerebellar vermis hypoplasia were detected by fetal MRI. On exam, they both had ear creases and pits. Family history significant for a brother who died at 2 months of age with sudden infant death syndrome, 6-year-old sister with umbilical hernia and 1-year-old brother with ear pits. Both siblings had normal chromosome microarray, IC1 and IC2 methylation testing and *CDKN1C* sequencing. Deletion of the entire coding sequence of *CDKN1C* gene was identified by deletion/duplication analysis. Maternal blood analysis was negative for the deletion, raising the suspicion of germline mosaicism. Paternal and siblings' testing are pending at this time. It's been reported that up to 15% of cases of BWS are familial and commonly due to *CDKN1C* mutations (maternally inherited with 50% recurrence risk), chromosome 11p15 abnormalities and genetic alterations with IC1. Pathogenic variants (mainly loss of function) in *CDKN1C* gene accounts for ~5% of sporadic cases and 40% of familial cases. Abnormalities of central nervous system have rarely been reported in BWS, such as Chiari malformation, hydrocephalus, schizencephaly and posterior fossa abnormalities including DWM, vermis hypoplasia and Blake's pouch cyst. Associated molecular defects reported involved the centromeric imprinted domain on 11p15.5 that includes IC2 and *CDKN1C*. It's been suggested that these genes are implicated in midline development of multiple organs including the brain. Clinical findings of this family provide additional support of CNS involvement in BWS and illustrate the phenotypic spectrum of BWS.

## 1256F

**A de novo gain-of-function mutation in MYCN causes a novel megalencephaly syndrome.** K. Kato<sup>1,2</sup>, F. Miya<sup>3,4</sup>, N. Hamada<sup>5</sup>, Y. Negishi<sup>1</sup>, Y. Narumi-Kishimoto<sup>6</sup>, H. Ozawa<sup>6</sup>, H. Ito<sup>6</sup>, I. Hori<sup>1</sup>, A. Hattori<sup>1</sup>, N. Okamoto<sup>7</sup>, M. Kato<sup>8</sup>, T. Tsunoda<sup>3,4</sup>, Y. Kanemura<sup>9</sup>, K. Kosaki<sup>10</sup>, Y. Takahashi<sup>6</sup>, K. Nagata<sup>6</sup>, S. Saitoh<sup>1</sup>. 1) Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan; 2) Nagoya City University Graduate School of Medical Sciences.; 3) Tokyo Medical and Dental University, Tokyo, Japan; 4) RIKEN Center for Integrative Medical Sciences, Yokohama, Japan; 5) Aichi Human Service Center, Kasugai, Japan; 6) Shimada Ryoiku Center Hachioji, Tokyo, Japan; 7) Osaka Women's and Children's Hospital, Osaka, Japan; 8) Showa University School of Medicine, Tokyo, Japan; 9) Osaka National Hospital, National Hospital Organization, Osaka, Japan; 10) Keio University School of Medicine, Tokyo, Japan.

**Background:** In this study, we aimed to identify the gene abnormality responsible for pathogenicity in an individual with an undiagnosed neurodevelopmental disorder with megalencephaly, ventriculomegaly, hypoplastic corpus callosum, intellectual disability, postaxial polydactyly and neuroblastoma. We then explored the underlying molecular mechanism with *in vitro* and *in vivo* experiments. **Methods:** Trio-based whole-exome sequencing was performed to identify disease-causing gene mutation. Biochemical and cell biological analyses were carried out to elucidate the pathophysiological significance of the identified gene mutation. **Results:** We identified a *de novo* heterozygous missense mutation (NM\_005378.5; c.173C>T; p.Thr58Met) in the MYCN gene, at the Thr58 phosphorylation site essential for ubiquitination and subsequent MYCN degradation. The missense mutation was not listed in any public databases (e.g. ExAC) and Thr58 residue is evolutionally conserved. Mycn in whole-tissue extracts of mouse brains at various developmental stages showed high expression level at E13.5, then gradually decreased to its lowest level by postnatal day. The mutant MYCN (MYCN-T58M) was non-phosphorylatable at Thr58 and subsequently accumulated in cells and appeared to induce CCND1 and CCND2 expression in neuronal progenitor and stem cells *in vitro*. The mutation also promoted neuronal cell proliferation in the intermediate and subventricular zones during corticogenesis in mouse embryos. **Conclusions:** We identified a *de novo* c.173C>T mutation in MYCN. The temporal expression pattern of Mycn protein in the mouse brain reflected the situation in humans, and suggests Mycn plays an important role during corticogenesis. MYCN-T58M leads to stabilization and accumulation of the MYCN protein, leading to prolonged CCND1 and CCND2 expression. This may promote neurogenesis in the developing cerebral cortex, leading to megalencephaly. While loss-of-function mutations in MYCN are known to cause Feingold syndrome, this is the first report of a germline gain-of-function mutation in MYCN causing a novel megalencephaly syndrome similar to, but distinct from, CCND2-related megalencephaly-polymicrogyria-polydactyly-hydrocephalus syndrome. The data obtained here provides new insight into the critical role of MYCN in brain development, as well as the consequences of MYCN defects.

## 1257W

**Biallelic mutations in EXOC3L2 cause a novel syndrome that affects the brain, kidney and blood.** A. Shalata<sup>1</sup>, S. Lauhasurayotin<sup>2,3</sup>, Z. Leibovitz<sup>4</sup>, S. **Background** Dandy-Walker malformation features include *agenesis/hypoplasia* of the cerebellar *vermis*, cystic dilatation of the *fourth ventricle* and enlargement of posterior fossa. Although Dandy-Walker malformation is relatively common and several genes were linked to the syndrome, the genetic cause in the majority of cases is unknown. Ciliary ... **Objective:** to identify the mutated gene responsible for Dandy-Walker malformation and kidney disease in two unrelated families. **Methods:** Medical assessment, sonographic, MRI imaging and pathological studies followed by CMA-chromosomal microarray analysis and WES-whole exome sequence were performed in three fetuses in the first family and in one patient in the second unrelated family. **Results:** We report four subjects from two unrelated families with homozygous mutations in the Exocyst Complex Component 3-Like-2 gene (*EXOC3L2*). *EXOC3L2* functions in trafficking of post-Golgi vesicles to the plasma membrane. In the first family a missense mutation in a highly conserved amino acid, p.Leu41Gln, was found in three fetuses; all had severe forms of Dandy-Walker malformation that was detectable by prenatal ultrasonography and confirmed by autopsy. In the second family the affected child carried a nonsense mutation, p.Arg72\* and no detected protein. He had peritrigonal and cerebellar white matter abnormalities with enlargement of the ventricular trigones, developmental delay, pituitary hypoplasia, severe renal dysplasia and bone marrow failure. **Conclusion:** We propose that biallelic *EXOC3L2* mutations lead to a novel syndrome that affects hindbrain development, kidney and possibly the bone marrow.

**1258T**

**Association of hydrocephalus and renal dysplasia with a homozygous *DLG5* frameshift variant in an alternatively spliced exon.** F. Vogel<sup>1</sup>, Z. Yüksel<sup>1</sup>, A. Alhashem<sup>2</sup>, K. Kampe<sup>1</sup>, K.K. Kandaswamy<sup>1</sup>, M. Werber<sup>1</sup>, A.M. Bertoli-Avella<sup>1</sup>, A. Rolfs<sup>1,3</sup>, P. Bauer<sup>1</sup>. 1) Centogene AG, Rostock, Germany; 2) Prince Sultan Military Medical City, Pediatrics, Riyadh, Saudi Arabia; 3) Albrecht-Kossel-Institute for Neuroregeneration, Medical University Rostock, Rostock, Germany.

The *DLG5* gene encodes the 1919-residue DLG5 protein which is composed of numerous functional domains, and has been implicated in a variety of cellular structures and processes. Homozygous knockout of the murine homologue *Dlg5* results in fully penetrant but variably severe hydrocephalus and renal cysts. Certain *DLG5* haplotypes have been suggested to predispose to inflammatory bowel disease, but a *DLG5*-linked monogenic phenotype has not previously been reported. We investigated a pediatric female patient diagnosed with obstructive hydrocephalus, renal dysplasia, atrial septal defect type II, and cleft lip and palate. Bilateral ventriculomegaly and echogenic kidneys had been noticed at gestational week 22. The parents are first cousins and there is a history of intra-uterine fetal death due to similar congenital abnormalities. Whole exome sequencing (WES) of the index case in a routine diagnostic setting did not reveal potentially pathogenic variants in known disease genes. An extended analysis of the WES data in a research frame identified the homozygous *DLG5* frameshift variant c.3081\_3106del (p.Arg1027fs) in *DLG5*. Sanger sequencing confirmed this finding, and revealed heterozygosity in both healthy parents. We were therefore very surprised to note that data from the Exome Aggregation Consortium (ExAC) strongly suggest that heterozygous presence of a truncating *DLG5* variant is not tolerated (probability of loss-of-function intolerance = 1.00). A more detailed analysis, however, revealed that our variant and the resulting pre-terminal stop codon localize to the alternatively spliced in-frame exon 15. The shorter of the corresponding isoforms is therefore predicted to escape nonsense-mediated decay, and this, in turn, implies that certain functions of DLG5 may be retained upon presence of the c.3081\_3106del variant. Our clinical-genetic findings, together with those on the murine *Dlg5* knockout, characterize *DLG5* as a novel recessive disease gene in humans. Theoretical considerations suggest that heterozygous truncating variants in exons other than exon 15 may be associated with a potentially distinct phenotype. Further studies are necessary to test this hypothesis.

**1259F**

**De novo structural and single-nucleotide variants (SNVs) underlying associations between birth defects and childhood cancers: An assessment from the Genetic Overlap Between Anomalies and Cancer in Kids (GOBACK) Study.** H. Li<sup>1</sup>, P. Mishra<sup>1</sup>, S. Sisoudiya<sup>2</sup>, M.E. Scheurer<sup>3,4</sup>, R.A. Gibbs<sup>1,2</sup>, P.J. Lupo<sup>3,4</sup>, S.E. Plon<sup>2,3,4</sup>, A. Sabo<sup>1</sup>. 1) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX; 2) Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; 3) Department of Pediatrics, Baylor College of Medicine, Houston, TX; 4) Texas Children's Cancer Center, Texas Children's Hospital, Houston, TX.

As validated in our population-based study of 10 million live births, one risk factor for childhood cancer is being born with congenital anomaly. However, little is known about genetic architectures underlying this association, especially the role of structural variants (SVs), which are likely to be important. Here, we evaluated methods for identifying SVs, as well as SNVs, and pinpointed candidate variants underlying the congenital anomaly-cancer (CAC) phenotypes. Methods: From GOBACK, we selected 18 trios with various CAC combinations and performed WGS (40X). SVs were detected via 4 callers: Lumpy, Delly, BreakDancer, and Manta, followed by merging and filtering via SURVIVOR. A consensus call was made by at least 2 callers. We kept *de novo* events that were not detected by any caller in both parents and eliminated variants identified in the 1K Genomes Project as well as an internal project of healthy controls. Rare *de novo* SNVs were identified via Platypus and were annotated with respect to genes and functions using multiple algorithms. Results: We identified 4 *de novo* deletions across the 18 probands. While 3 of those were intergenic, a 5kb *de novo* intragenic deletion was validated in a patient with acute lymphocytic leukemia (ALL) and multiple anomalies. This *de novo* mutation resulted in an exonic deletion of *USP9X*, which encodes a deubiquitinating enzyme. Notably, *USP9X* is among the top genes recurrently mutated somatically in pediatric tumors, including ALL, and *USP9X* loss-of-function mutations are known to cause a similar multiple-anomaly syndrome as observed in this kid. Additionally, we identified 12 *de novo* nonsynonymous SNVs that may alter the function of protein-coding genes, including several that have been reported in congenital anomalies or cancers, such as *FOXK2*. We also identified a likely functional intronic mutation that overlaps with regulatory histone markers within *TCF12* in a patient with diencephalic syndrome (DS) and pilocytic astrocytoma (PA). *TCF12* has been implicated in multiple cancers, including PA, which is known to relate to the pathogenesis of DS. Conclusion: The GOBACK study has resulted in discoveries of several variants, both SVs and SNVs, that may underlie CAC phenotypes. The identification of a 5kb *de novo* deletion in a patient illustrates the need for comprehensive evaluation of all types of variants, from SNVs to SVs. Validation studies on children with similar CAC and assessment of a full spectrum of SVs are underway.

**1260W**

**Missense variants in *PLS3* in patients with X-linked congenital diaphragmatic hernia.** F. Petit<sup>1,2</sup>, B.R. Pober<sup>3</sup>, R.D. Clark<sup>4</sup>, P. Giampietro<sup>5</sup>, H.H. Ropers<sup>6</sup>, H. Hu<sup>6</sup>, A-S. Jourdain<sup>2</sup>, F. Frenois<sup>2</sup>, M-A. Delrue<sup>7</sup>, B. Gilbert-Dussardier<sup>8</sup>, L. Devisme<sup>2,9</sup>, B. Keren<sup>10</sup>, S. Manouvrier-Hanu<sup>1,2</sup>, P. Bhayani<sup>11</sup>, M. Loscertales<sup>11</sup>, P.K. Donahoe<sup>11,12</sup>, F.A. High<sup>11,13</sup>, M. Longoni<sup>11,12</sup>. 1) Clinique de Génétique, CHU Lille, Lille, France; 2) EA7364 RADEME, Université de Lille, Lille, France; 3) Department of Pediatrics, Massachusetts General Hospital, Harvard Medical School, Boston, MA, USA; 4) Loma Linda School of Medicine, Loma Linda, CA, USA; 5) Drexel University School of Medicine, Philadelphia, PA, USA; 6) Max Planck Institute for Molecular Genetics, Berlin, Germany; 7) Service de Génétique, CHU Bordeaux, Bordeaux, France; 8) Service de Génétique, CHU Poitiers, EA3808, Université de Poitiers, Poitiers, France; 9) Institut de Pathologie, CHU Lille, Lille, France; 10) Département de Génétique, Hôpital Pitié Salpêtrière, CHU Paris, France; 11) Pediatric Surgical Research Laboratories, Massachusetts General Hospital, Boston, MA, USA; 12) Department of Surgery, Harvard Medical School, Boston, MA, USA; 13) Department of Surgery, Boston Children's Hospital, Boston, MA, USA.

Congenital diaphragmatic hernia (CDH) has an incidence of around 1/3000 births. The most frequent genetic causes of sporadic CDH are recurrent chromosome abnormalities and *de novo* autosomal mutations. However, several lines of evidence suggest the existence of X-linked loci for CDH. Linkage analysis in a three-generation family with X-linked CDH in 10 affected individuals pointed to a 3 Mb region on the X chromosome (LOD score > 3), comprising 14 protein-coding genes. Using exome sequencing, we identified a familial missense variant in *PLS3* within this interval. Additional missense variants were discovered in 2 unrelated families with 2 and 3 affected males, respectively. These *PLS3* variants alter highly conserved residues and co-segregate with a novel multiple-anomaly congenital condition, characterized by CDH with or without heart and anterior body wall defects in males, and mild dysmorphic features in some female carriers. *PLS3* is expressed almost ubiquitously in solid tissues with replicative potential and has been shown to be required for the maintenance of actin microfilament bundles. Loss-of-function mutations and deletions have been reported previously in families with X-linked osteoporosis and osteoporotic fractures (MIM# 300910). We hypothesize that distinct mechanisms are at play with CDH-associated *PLS3* variants, as they map to the actin-binding domain of the protein, and they are predicted by *in silico* structural modeling to specifically disrupt interaction with actin. Published functional evidence in yeast supports a deleterious effect of substitutions at one of these residues, a fully conserved tryptophan in the actin-binding site, in the Plastin 3 ortholog fimbrin. We also showed that Pls3 is expressed in the diaphragm and lung mesenchyme of E13.5 mouse embryos. The expression pattern and timing are compatible with a role in diaphragm development for Plastin 3. Based on human and functional evidence, we propose that *PLS3* is a candidate for syndromic X-linked CDH.

**1261T**

**Mutation spectrum of the *KMT2D* gene for the Kabuki syndrome in Korea.** Y. Yeon, Y. Gu, M. Kim, S. Cho, M. Seong, S. Park. Seoul National University Hospital, Seoul, Select a Country.

Kabuki syndrome (KS) is characterized by distinct dysmorphic facial features, mental retardation and congenital anomalies including short kidneys, skeletal and intestinal abnormalities, cardiac and immunological defects. The *KMT2D* and *KDM6A* are the only causative genes which are known to cause KS. Whole exome sequencing (WES) was performed on 12 suspected patients with Kabuki syndrome through the rare disease genetic diagnosis project in Korea. This study revealed that 75% of probands (12 patients) harbored causative mutations in *KMT2D* genes. 55.9 % (6 / 9) of all positive cases were small insertion and deletion (indel) mutation, and nonsense mutation by single nucleotide substitution account for 33.3% (3 / 9). There was one missense mutation. From 5 small indel mutations, four were occurred by one base deletion, but a splicing mutation by complex indel was found in one case. For negative cases, meticulous reevaluation based on WES can uncover other novel causative genes.

## 1262F

**Dual diagnoses: The first 400 patients of the CAUSES Research Study.**

A.M. Elliott<sup>1</sup>, J. Mwenifumbo<sup>1</sup>, C. du Souich<sup>1</sup>, S. Adam<sup>1</sup>, C. van Karnebeek<sup>2</sup>, T.N. Nelson<sup>3</sup>, M. Couse<sup>1</sup>, L. Armstrong<sup>1</sup>, G. Aubertin<sup>1</sup>, R. Salvarinova<sup>2</sup>, S. Stockler<sup>2</sup>, M.L. McKinnon<sup>1</sup>, S. Lewis<sup>1</sup>, L. Clarke<sup>1</sup>, G. Horvath<sup>2</sup>, E. Lopez<sup>2</sup>, K. Selby<sup>2</sup>, A. Lehman<sup>1</sup>, J.M. Friedman<sup>1</sup>, *The CAUSES Study*. 1) Department of Medical Genetics, University of British Columbia, Vancouver, British Columbia, Canada; 2) Department of Pediatrics, University of British Columbia, Vancouver, British Columbia, Canada; 3) Department of Pathology and Laboratory Medicine, University of British Columbia, Vancouver, British Columbia, Canada.

**Background:** Genome-wide (exome or whole genome) sequencing (GWS) is particularly useful in patients with rare disease and can identify multiple concomitant single gene disorders in one patient. CAUSES, a trio-based translational research study, provides GWS to 500 children with suspected genetic disorders. Once the candidate variant list is generated, there is a multidisciplinary team approach to the discussion of variants that includes bioinformaticians, clinical and laboratory geneticists, genetic counsellors, and the referring physician(s). Variants are classified on a research basis as definitely causal, probably causal, uncertain or negative, taking clinical findings and family history into consideration. Definite, probable and uncertain (but compelling candidate) disease-causing variants are validated by Sanger sequencing and interpreted by a clinical laboratory. **Methods:** We reviewed Sanger-confirmed variants in the first 400 families seen in the CAUSES study to identify patients with >1 candidate gene potentially explaining the phenotype(s). Patients with an incidental/secondary finding as their second causal variant were not included. **Results:** In total, 19 patients (4.75%) underwent Sanger validation of >1 gene. Combinations of research classifications for causality included: two patients - definite/definite; two - definite/probable; four - definite /uncertain (including one patient with three genes Sanger validated); five- probable/uncertain and five with both variants classified as uncertain. **Discussion:** We reviewed this cohort of 19 patients and determined features that are shared, distinct and unanticipated based on the diagnoses. As an illustrative example, a male patient presented with mild developmental delay, cleft of the soft palate, severe aortic valve stenosis and aortic arch hypoplasia, imperforate anus, sacral vertebral anomalies and 12<sup>th</sup> rib hypoplasia. Facial dysmorphism included hirsutism, bushy eyebrows, long palpebral fissures and a short nose. This patient was subsequently found to have variants in both *KMT2D* (Kabuki) and *CHD7* (CHARGE). He lacked some of the cardinal features of each disorder but many of his findings can be seen in both disorders. This analysis highlights genotype/phenotype correlations and the importance of determining all relevant diagnoses in order to optimize clinical treatment, care and genetic counselling.

## 1263W

**Integrated sequence analysis approaches improve genomic diagnosis of birth defects.** K. Meltz Steinberg<sup>1,2</sup>, D. Baldrige<sup>2</sup>, J. Wambach<sup>2</sup>, D. Wegner<sup>2</sup>, D. Spencer<sup>1,3</sup>, M. Shinawi<sup>2</sup>, F.S. Cole<sup>2</sup>. 1) McDonnell Genome Institute, Washington University School of Medicine, St. Louis, MO; 2) Department of Pediatrics, Washington University School of Medicine, St. Louis, MO; 3) Department of Medicine, Washington University School of Medicine, St. Louis, MO.

Structural birth defects affect approximately 3% of US born infants and are a common cause of infant mortality. Although environmental factors can cause birth defects, a majority is caused by inherited or *de novo* genetic variants; however, the current diagnostic yield from genomic testing only ranges between 25-40%. To improve diagnostic success in children with structural birth defects, we integrated exome, whole genome, and transcriptome sequencing data from 56 affected trios. Our bioinformatic pipeline identifies and characterizes single nucleotide variants (SNVs), small insertions/deletions (indels), copy number (CNVs) and structural variants (SVs). We first confirmed the sensitivity of our approach by correctly identifying, in a blinded fashion, 100% of pathogenic variants in ten trios previously diagnosed by clinical exome sequencing. Secondly, we reanalyzed with our pipeline 12 trio exomes that were non-diagnostic and identified biallelic pathogenic variants in two patients. For example, in a child with short stature, small hands and feet, cone-shaped epiphyses of hands and feet, brachytelephalangy of digits, dolicocephaly, persistent sagittal suture, and ADHD, we identified a novel missense and a rare non-canonical splice variant in *PHYH*, a gene mutated in Refsum disease. We confirmed exon 3 skipping encoded by the non-canonical split site variant in approximately half the *PHYH* transcripts in the proband's peripheral blood transcriptome and elevated serum phytanic acid concentration that is biochemically diagnostic of Refsum disease. Thirdly, we developed a CNV/SV detection strategy that combines three paired end/split read callers with two read depth callers. We benchmarked our pipeline on Genome in a Bottle samples, NA12878 and NA24385. For deletions ranging in size from 1kb to 1Mb, sensitivity ranges from 91.2 to 95.7%. We then compared sequenced based CNV/SV calls in the probands with CytoScanHD chromosomal microarray variant calls. We validated 100% of clinically relevant deletions and duplications greater than 100kb. Additionally, for all deletions 50-100kb and greater than 100kb we have 73% and 93% sensitivity, respectively. On average per proband, we identify five coding deletions and ten coding duplications that overlap ClinGen likely pathogenic or pathogenic variants. We conclude that we have developed a robust, integrated approach that improves diagnostic success in children with birth defects.

**1264T**

**Failure to detect germline pathogenic variants in mTOR pathway (PIK3CA-AKT-mTOR) does not exclude a clinical diagnosis. A case report.** A.I. Sanchez, J.A Rojas. Pontificia Universidad Javeriana, Bogota, Colombia.

**Introduction:** mTOR pathway diseases encompasses well known neurological disorders characterized by altered cortical architecture, intractable epilepsy, megalencephaly, severe ID, and autistic spectrum disorder. Germline and somatic mutations in different genes of this pathway are responsible for Smith-Kingsmore syndrome (SKS), ganglioglioma, focal cortical dysplasia, tuberous sclerosis complex, *PIK3CA* gene related overgrowth spectrum disorders (PROS) and isolated hemimegalencephaly among others. **Case report:** 5 years old male with megalencephaly, global developmental delay, and seizures born at 38 weeks. Mom 15 yo G1P1 and father 19 yo. No consanguinity. C-section for breech presentation, birth weight 3,04 Kg. At age 8 months old found to have hypotonia, global developmental delay, speech delay. Started PT, OT and speech therapy with slow improvement of milestones. Followed by neurology/DBBP and physical medicine. Walked at 4 yo. At age 5 yo, has difficulties for walking, says only 5 words, no phrases. Half brother on dad's side with severe global developmental delay and epilepsy; 20 yo paternal aunt with intellectual disability and no verbal communication. PE: macrocephaly (HC: 56 cm) prominent forehead, epicanthal folds, wide nasal bridge, cupped ears, narrow arched palate. Metabolic labs were normal (lactate/pyruvate, plasma AA, urinary organic acids and ammonia). Normal brain MRI. Proton brain MR spectroscopy with variations in NAA/Cr and Cho/Cr ratios compatible with developmental delay. Microarray was normal. Trio whole exome sequencing (certified genetic laboratory) was normal and trio whole genome sequencing (certified genetic laboratory) was positive for two heterozygous VUS in *FRAS1* gene (c.4556G>A p.Arg1519Gln and c.7171G>A p.Gly2391Ser), no genotype/phenotype correlation. **Conclusions:** Differentials include SKS and isolated megalencephaly with intellectual disability due to possible brain *mTOR* or *PIK3CA* somatic mutations, respectively. Brain biopsy in this case is difficult. Paternal gonadal mosaicism has to be taken into account in this case as well as an incomplete penetrant disorder. A clinical discernible disorder in this patient is probably due to mTOR pathway dysregulation. This is of interest because of therapeutic approaches (mTOR inhibitors). Overlapping phenotypes due to malregulation in any component of mTOR pathway are based on the presence of germinal or somatic mutations in the same gene and in the degree of mosaicism.

**1265F**

**Identification of potential regulatory variants causing Branchio-Oto-Renal syndrome in an extended pedigree using Whole Genome Sequencing (WGS).** P.A. Sanchez-Lara<sup>1</sup>, C.E. Schwartz<sup>2</sup>, C. Bodea<sup>3</sup>, R.L. Maas<sup>3</sup>, J.M. Graham, Jr.<sup>1</sup>. 1) Pediatrics, Cedar Sinai Medical Center/University of California Los Angeles, Los Angeles, CA; 2) Greenwood Genetics Center, Greenwood, SC; 3) Division of Genetics, Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, MA.

Branchio-oto-renal (BOR) syndrome is an autosomal dominant disorder characterized by deafness, branchial arch anomalies, ear malformations, and renal anomalies. It has a prevalence of 1/40,000 and accounts for 2% of profoundly deaf children. The genetics of BOR syndrome is complex. Approximately 40% of patients with BOR syndrome have a mutation in the *EYA1* gene on chromosome 8q13.3, with over 203 published mutations spanning all 16 exons. In addition to coding sequence variants, 20% of mutations in *EYA1* involve complex cytogenetic rearrangements resulting in deletions or duplications. However, no variants or mutations spanning *EYA1* regulatory regions have been reported in the medical literature. The second most common gene associated with BOR syndrome is *SIX5* on chromosome 19q13.3, accounting for 2.5% of cases, followed by *SIX1* on chromosome 14q23, which is implicated in 2% of cases (Smith 2009). Approximately 55% of BOR syndrome cases have an unidentified mutation despite meeting clinical diagnostic criteria. Taken together, figure suggests that other genes may be involved. We present a large 5-generation family with 11 living affected individuals that meet the clinical criteria for BOR syndrome. Clinical findings include: branchial cleft cysts, ear anomalies (microtia, ear tags, ear pits), hearing loss, epibulbar dermoids, renal anomalies, facial nerve palsy, gustatory lacrimation, and seizures. Sanger sequence analysis of the *EYA1* gene did not identify any mutation or potential candidate. A BAC array and two independent high-density SNP arrays (Affymetrix 6.0 and NimbleGen 2.1M platforms) that included coverage for the *EYA1* locus revealed no copy number variations. Data from the SNP Array was used for linkage and flagged a region between rs11785226 and rs7018254 on chromosome 8. *EYA1* is at chr8:72109668-72268979, just outside of the linkage region (chr8:53,680,808-72,017,177) [hg19]. We hypothesized that the phenotype in this family was due to a non-coding regulatory variant in the *EYA1* gene. Unfortunately it was not possible to test *EYA1* gene expression on a sample from this family given that the gene is not expressed in blood or skin cells. Through the NIDCR sponsored Facebase2 project, additional samples were obtained and Whole Genome Sequencing (WGS) was completed on several affected individuals in the pedigree. Potential candidate regulatory elements can be assessed via future *in vitro* functional assays.

**1266W**

**Intra-familial variable expressivity of orofacioidigital syndrome type 1 in three generations of French Canadian family.** S.A. Basalom, L.R. Russell. Medical Genetics, McGill University, Montreal, Quebec, Canada.

**Background** Orofaciodigital syndrome (OFD) type 1 (MIM 311200) is a rare, X-linked ciliopathy that is generally lethal in males. The clinical features are highly variable and include alterations in the face, oral cavity, limbs, kidney and brain. Intellectual disability has been reported in 46-58% of affected individuals. We report the clinical features, radiological findings and the *OFD1* variant in a woman, her mother and her child. **Clinical cases** The proband is a 31 year old French Canadian female who presented in childhood with mild intellectual disability and syndactyly of the hands and feet, the latter requiring surgery. Surgery for cleft palate was reportedly performed in infancy. At 29 years of age, she presented with new onset, unprovoked seizures. On MRI she was found to have agenesis of the corpus callosum with neuronal migration abnormalities including polymicrogyria of the frontal and parietal lobes, bilateral band heterotopia, subependymal heterotopia, mainly on the left, cerebellar vermis hypoplasia and abnormal cerebellar folia. The cerebral hemispheres were asymmetric, the left hemisphere being more hypoplastic than the right. The physical exam showed microcephaly, mild facial asymmetry, high arched palate and multiple gingival frenulae. We also noted clinodactyly and syndactyly of several fingers but no brachydactyly or polydactyly. After she became pregnant at 31 years, a fetal MRI at 31 6/7 weeks gestation showed a female fetus with bilateral frontal polymicrogyria, agenesis of corpus callosum with secondary colpocephaly, and pontocerebellar hypoplasia with extremely hypoplastic cerebellar vermis. The daughter was born at term and on physical examination had lingual hamartomas, bifid tongue and natal teeth. A postnatal MRI confirmed the prenatal findings. On physical examination, the infant's grandmother had syndactyly of the left hand, left double hallux and lingual hamartomas. **Results** A comprehensive brain malformation panel revealed a frameshift heterozygous, likely pathogenic variant in *OFD1*: c.1168\_1171delAATT. **Conclusion** This family demonstrates well the intra-familial variable expressivity present in *OFD1*. As well, the late diagnosis of *OFD1* in the proband suggests that *OFD1* may be underdiagnosed. We recommend consideration of *OFD1* in the differential diagnosis of brain malformations in females, particularly when there is a wide spectrum of malformations.

**1267T**

**Post-natal correction of a BBsome gene, *Bbs8*, rescues fertility in a mouse model of Bardet-Biedl syndrome.** M.R. Cring, J.E. Garrison, G. Kim, V.C. Sheffield. University of Iowa, Iowa City, IA.

Bardet-Biedl syndrome (BBS) is a genetically heterogeneous, autosomal recessive disorder that affects primary cilia biogenesis and function. The cardinal features of BBS include retinal degeneration, obesity, polydactyly, kidney anomalies, intellectual disability, and male infertility. No treatments are currently available for this disease. There are 21 genes currently known that can independently cause BBS. Eight of these protein products together form a complex called the BBsome, which is important for trafficking proteins to the cell membrane and well as retrograde trafficking along the ciliary axoneme. Males with BBS are infertile as they predominately lack spermatozoa flagella. When flagella are present, they are typically shortened or dysmorphic, and TEM images show clear disorganization of microtubules and outer dense fibers. Otherwise, acrosome formation and nuclear condensation appears normal. Using a gene trap mouse model which allows for post-natal correction of a BBsome component, *BBS8*, we have shown that post-natal correction of *BBS8* can rescue fertility. Furthermore, we show that this correction is not time dependent, and can occur in older mice as well as young mice. TEM imaging shows that microtubule and outer dense fiber organization are rescued following post-natal correction of *BBS8*. Using a conditional knock-out mouse model for *BBS8*, which allows disruption of *BBS8* following tamoxifen administration, we show that flagella are still present in mice for at least 15 days following *BBS8* knock-out. This indicates that BBS proteins are expressed early during the process of spermatogenesis. Future work is aimed at determining how long flagella persist after loss of *BBS8*. We also intend to use CRISPR-Cas9 mediated homologous recombination in a mouse model to repair the most common BBS mutation and thereby address potential therapies for BBS patients.

**1268F****Expanding the phenotype of CEP55-related disorders: A case report.**

R. Mostafavi<sup>1</sup>, A. Choudhri<sup>2,3</sup>, E.K. Pivnick<sup>2,4</sup>. 1) St. Jude Children's Research Hospital, Memphis, TN; 2) Le Bonheur Children's Hospital, Memphis, TN; 3) University of Tennessee Health Science Center, Memphis, TN; 4) UT Le Bonheur Pediatric Specialists, Memphis, TN.

CEP55 is a centrosomal protein with a key role in mitosis and cytokinesis. CEP55 also contributes to stabilization of the Akt/PI3K pathway to suppress Caspase-3 mediated apoptosis. In interphase, CEP55 localizes to the centrosome and is later recruited to the midbody to facilitate completion of cytokinesis after phosphorylation occurs at residues S425 and S428, and subsequently at S436 by Erk2, Cdk1, and Plk1 respectively. CEP55 protein lacking residues 355-464 cannot undergo phosphorylation, which prevents dissociation of CEP55 from the centrosome and recruitment to the midbody in cytokinesis. TSG101 and ALIX bind with CEP55 and colocalize at the midbody to enable abscission. Previous case reports of CEP55-related disorders present as lethal autosomal recessive ciliopathies. A homozygous nonsense variant (c.256C>T; p.R86\*) was found in two fetuses with Meckel-like syndrome (hydranencephaly and encephalocele, cystic hygroma, renal cysts, and clubfeet). Also, a homozygous nonsense variant (c.1274C>A; p.S425\*) was identified in 3 fetuses of another family with features of MARCH syndrome (multinucleated neurons, anhydramnios, renal dysplasia, cerebellar hypoplasia, and hydranencephaly). We present 3 sisters with microlissencephaly, dysmorphic features, and severe intellectual disability who are homozygous for a CEP55 splice site variant (c.1191+2T>C). Parents are consanguineous and are heterozygous for the CEP55 variant. Our cases, as well as the previous case reports, demonstrate the clinical heterogeneity of CEP55-related disorders. The previously reported cases were more severely affected than our siblings, who are currently living at ages 19, 14, and 3 years. However, the homozygous nonsense mutation at position 86 in the Meckel-like family is thought to result in lack of the TSG101- and ALIX-binding domain of CEP55, disrupting abscission. The homozygous nonsense mutation in the MARCH syndrome family resulted in truncation of CEP55 and lack of the 3 phosphorylated serine residues that are necessary for CEP55 dissociation from the centriole and localization to the midbody. The milder phenotype of our cases may be due to the loss of the phosphorylated residues and aberrant RNA splicing. RNA studies for these sisters are in process. Given the phenotypic variation of our cases and those previously reported, CEP55 should be included in workup of patients presenting with a suspected ciliopathy.

**1269W****Whole exome sequence identified the deletion in 5' UTR or upstream intronic region of CREBBP in a patient with Rubinstein-Taybi syndrome.**

Y. Enomoto<sup>1</sup>, Y. Tsurusaki<sup>1</sup>, Y. Kuroda<sup>2</sup>, H. Murakami<sup>2</sup>, K. Ida<sup>2</sup>, M. Umegae<sup>2</sup>, N. Harada<sup>2</sup>, Y. Kimura<sup>1</sup>, T. Naruto<sup>1</sup>, K. Kurosawa<sup>1,2</sup>. 1) Clinical Research Institute, Kanagawa Children's Medical Center, Yokohama, Kanagawa; 2) Division of Medical Genetics, Kanagawa Children's Medical Center, Yokohama, Kanagawa; 3) Clinical Laboratory, Kanagawa Children's Medical Center, Yokohama, Kanagawa.

Rubinstein-Taybi syndrome (RSTS) is an autosomal dominant disease characterized by broad thumbs and great toes, short stature, moderate to severe intellectual disability (ID) and a distinct facial appearance. Their common facial features are downslanted palpebral fissures, low hanging columella, high palate, grimacing smile, and talon cusp. RSTS arises in rate of about 1/100,000-125,000. The causative genes are CREBBP and EP300, which have similar functions as histone acetyltransferase that regulates transcription via chromatin remodeling. 50-70% of patients have mutation in CREBBP and 3% have mutation in EP300. Here we report a Japanese boy patient with RSTS. He has severe ID, broad great toes, hirsutism, exotropia, congenital heart defects (CoA, VSD), cryptorchidism. Pathogenic variant was not detected in CREBBP by panel-based next-generation sequencing (Haloplex (Agilent Technologies)). However, CNV analysis using whole exome sequence (WES) detected a *de novo* deletion in the region including ADCY9, which localizes in the proximity to CREBBP. The deletion breakpoints are unclear at present. However, WES data showed normal 2 copies alleles in at least coding region of exon1 in CREBBP. Thus, there is a possibility that the deletion in 5' UTR or upstream intronic region of CREBBP caused the disease in patient.

**1270T**

**Alterations in *TANGO2* on the intact chromosome 22q11.2 allele as a possible cause of sudden death.** D.M. McDonald-McGinn<sup>1</sup>, B. Nowakowska<sup>2,4</sup>, T.B. Crowley<sup>2</sup>, M. Unolt<sup>1,3</sup>, D.E. McGinn<sup>1</sup>, T. Gambin<sup>2</sup>, M. Geremes<sup>2</sup>, M. Hestand<sup>4</sup>, R. Ahrens-Nicklas<sup>1</sup>, E.H. Zackai<sup>1</sup>, S. Hopkins<sup>2</sup>, V. Vetter<sup>2</sup>, S. McCormack<sup>1</sup>, M. Falk<sup>1</sup>, J. Vermeesch<sup>4</sup>. 1) Human Genetics, Children's Hospital of Philadelphia and UPENN School of Medicine, Philadelphia, PA; 2) Instytut Matki Dziecka, Warsaw, Poland; 3) Ospedale Bambino Gesù and La Sapienza University, Rome, Italy; 4) KU Leuven, Leuven, Belgium; 5) Neurology, Children's Hospital of Philadelphia and UPENN School of Medicine, Philadelphia, PA; 6) Cardiology, Children's Hospital of Philadelphia and UPENN School of Medicine, Philadelphia, PA; 7) Endocrinology, Children's Hospital of Philadelphia and UPENN School of Medicine, Philadelphia, PA.

**Background:** 22q11.2DS is the most common CNV in humans with an incidence of ~1/2000 live births. Highly variable phenotypic expressivity is a hallmark of the condition as no clinical feature is fully penetrant. We previously described allelic variations of genes within the 22q11.2 region of the non-deleted chromosome unmasking autosomal recessive conditions to explain such variability. Here we report the first patients with both 22q11.2DS and deletions/mutations of the *TANGO2* gene on the other allele. Homozygous and compound heterozygous variants in *TANGO2* have been identified in patients with recurrent metabolic encephalomyopathic crises associated with rhabdomyolysis, cardiac arrhythmias, and neurodegeneration. Thus, this novel observation is critical in providing surveillance/intervention (perhaps lifesaving) for this subset of vulnerable patients. **Methods:** Sequencing was performed using Illumina HiSeq after exome capture with the Sure Select All Human V6 design. ANNOVAR was used to annotate relevant information for gene names, predicted variant pathogenicity, reference allele frequencies, metadata from external resources, and then added to the VCF. A HMZDeFinder algorithm was used to search for small, hemizygous deletions within 22q11.2 and compared with WES from 164 samples sequenced on the same platform and processed using the same pipeline as controls. **Results:** Two putative hemizygous deletions encompassing 9 exons of *TANGO2*, were identified in two unrelated patients, including one with a vascular ring, hearing loss, hypotonia, microcephaly, brisk reflexes, episodic dystonia, hypocalcemia, hypothyroidism, hypoglycemia and a SUDC at age 5 years. *TANGO2* truncating mutations were then found in 5 additional patients of our 1422 followed with 22q11.2DS. Deletions and mutations were validated by Sanger sequencing and parental origin was estimated. **Conclusions:** We hypothesize that the deletion including *TANGO2* is responsible for the SUDC in our 5 year old patient and that the deletion and mutations in *TANGO2* are responsible for the atypical features in our remaining 5 patients. Overall, deletions and mutations in *TANGO2* are common and based on our data may occur in as many as 1:200 patients with 22q11.2DS. Thus, investigation of the other allele in all patients with 22q11.2DS appears to be warranted to ensure identification of autosomal recessive conditions that could alter the overall phenotype, approach to genetic counseling and medical management.

**1271F**

**Multiple *de novo* genes variants: A frequent issue in homozygous admixed Puerto Rican (Hispanic) population.** A.S. Cornier<sup>1,2,3</sup>, F. Velez<sup>4,5</sup>, S. Carlo<sup>1,6</sup>, E. Albino<sup>7</sup>. 1) Genetic Section, San Jorge Children's Hospital, Santurce, PR; 2) Department of Public Health, Ponce Health Sciences University, Ponce, PR; 3) Department of Pediatrics, Universidad Central del Caribe School of Medicine, Bayamon, PR; 4) Department of Pediatrics, San Juan City Hospital, San Juan, PR; 5) Genetics Division, Sandford University, Palo Alto, CA; 6) Department of Biochemistry, Ponce Health Sciences University, Ponce, PR; 7) School of Health Professions, Medical Science Campus, University of Puerto Rico.

Populations with a high degree of homozygosity and admixture may produce individuals with several pathogenic dominant variations within different genes. This poses a challenge in determining which one(s) or how much of the respective proteins alterations is/are responsible for the phenotype. We are presenting the case of a three year old female, initially evaluated at 12 months in the Genetics clinic due to hypotonia and developmental delay. The child is the product of a non-consanguineous marriage. She was born to a 26-year-old female G2P2 with an unremarkable pregnancy. BW: 7lbs 13oz and BL: 19 ½ inches. Developmentally, she rolled over at age 7 months, sat at 9 months, and crawled at 15 months of age. At age 18 months, she was not walking nor had any language. Physical examination was significant for frontal bossing, mild hypertelorism, long eyelashes and moderate to severe peripheral and central hypotonia. Initial laboratory work up demonstrated marked ketosis and lactic/pyruvate aciduria with normal amino acids analysis, as well as normal carnitine, acylcarnitines and ammonia profiles. Chromosomal microarray studies showed a 426 kb gain of 1p31.3 arr [hg19]1p31.3 (61,699,735-62,125,907) x3. Whole exome sequencing studies documented five novel *de novo* variants, including an SCN8A heterozygous variant c.1084G.T (p.Ala362Ser), a TRPV4 heterozygous variant (c.69T.G p.Ser23Arg); a ZBTB18 heterozygous variant (c.1140G.T p.Met380Ile), a RERE heterozygous (variant, pathogenic?) c.2483C.G (p.Pro828Arg), and heterozygous pathogenic variant on MARS2, c.171dupA(p.Thr573Asnfs\*49). Similar variants in four of these genes have been determined to have an autosomal dominant mode of inheritance, and are responsible for developmental delay, intellectual disabilities and hypotonia. We have characterized the genotype/phenotype associated to these mutations in this patient by establishing the molecular pathophysiology of the variants and its implications in our patient's phenotype. Multiple gene mutations/variations including more than one genetic disorder are not uncommon in the Puerto Rican population. The availability of comprehensive genetic variation data from cohorts of Hispanic patients have the potential to greatly improve the identification of disease-associated genetic variants in densely populated small geographical areas such as Puerto Rico. This provides insight into the complexities of admixture and homozygosity within the context of clinical phenotypes.

**1272W****Using deep phenotyping to refine the association of location of XPD mutations with function.**

G.W. Nelson<sup>1</sup>, M.A. Levoska<sup>2,3</sup>, J.M. Pugh<sup>2</sup>, P.F. Hannon<sup>4</sup>, D. Tamura<sup>2</sup>, E.R. Heller<sup>5</sup>, S.G. Kahn<sup>2</sup>, M. Scheibye-Knudsen<sup>6</sup>, J.J. DiGiovanna<sup>2</sup>, K.H. Kraemer<sup>2</sup>. 1) Advanced Biomedical Computing Center, Frederick National Lab, NCI, Frederick, MD, MD; 2) Laboratory of Cancer Biology and Genetics, NCI, Bethesda, MD; 3) Medical Research Scholars Program, NCI, Bethesda, MD; 4) Michigan State University College of Human Medicine, East Lansing, MI; 5) Department of Dermatology, University of Pennsylvania, Philadelphia, PA; 6) DNA Repair Section, National Institute on Aging, Baltimore, MD.

XPD is a helicase component of the TFIIH complex, involved in both DNA repair and transcription. Different variants in XPD cause radically different phenotypes, reflecting the dual function of the protein and the complex, with repair-affecting variants causing xeroderma pigmentosum (XP) while transcription-affecting variants cause trichothiodystrophy (TTD). XP is characterized by extreme sensitivity to sun damage and sun-induced cancers. The characteristic symptom of TTD is brittle, sulfur-deficient hair, but subjects have a broad range of disorders: skeletal, developmental, immune, and beyond. In addition there is an intermediate phenotype, sharing milder aspects of the two diseases. Both XP and TTD have a range of severity, suggesting a multidimensional gradation of phenotypes. We sought to obtain a more complete picture of the range of phenotypes, and better predictors of the severity of disease, by deep phenotyping 67 subjects with two inherited mutations in XPD. We used data on 176 phenotypes, including characteristic symptoms (e.g. degree of sun sensitivity, and hair structure), a wide range of additional disease phenotype (hearing loss, skeletal abnormalities, measures of developmental delay) and standard clinical measurements. Previous studies have mapped mutations associated with XP and TTD onto the 3D structure of XPD, but there is not a simple dichotomy between these diseases. Our deep phenotyping data gives a continuous and multidimensional measure of phenotypic variation, with the primary axis distinguishing XP and TTD. Also, assigning individual variants to a specific disease is confounded by most subjects being compound heterozygotes, but PCA separates the effect of the individual's two mutations, as long as one of the mutations occurs twice or more. We present the 51 mutations present in our subjects, mapped onto the structures of XPD and TFIIH determined by x ray crystallography and freeze fracture EM. Coloring the residues by the principal components of the phenotypes reveals a continuum of functional information about each mutation site. A novel observation is that mutations associated with an intermediate phenotype occur preferentially on protrusions of XPD, possibly indicating a role in TFIIH complex formation. A limitation is that some mutations will significantly alter protein structure, and some mutations fall on the tail of the TTD protein, whose structure is undetermined.

**1273T****TAB2 deletion syndrome in a female with cardiac abnormality, short stature and normal intelligence.**

M.C. van Rijn<sup>1</sup>, M.F.C.M. Knapen<sup>2</sup>, M.W. Wessels<sup>1</sup>, F.S. Jehee<sup>1</sup>, L.J.C.M. van Zutven<sup>1</sup>. 1) Dept. Clinical genetics, Erasmus MC, Rotterdam, Zuid-Holland, Netherlands; 2) Dept. of Obstetrics and Prenatal Medicine, Erasmus MC Rotterdam, Zuid-Holland, Netherlands.

A 32 years old Romanian patient was referred for genetic counselling during her first pregnancy because of a suspected syndromic condition. She was operated twice before the age of 1 year for obstruction of the oesophagus or stomach, medical details were no longer available. At the age of 6 years she was diagnosed with a perimembraneous VSD and mitral valve and tricuspid valve prolaps with moderate insufficiency. Psychomotor development was normal. The father of our patient was reported to have similar cardiac problems and physical features as well as a normal intelligence. Physical examination showed a disproportionate short stature (-2,7 SDS) with a relatively long trunk and short extremities, and a small head circumference (-2,5 SD). She had some dysmorphic features including, long face, small eyes with short palpebral fissures, a beaked nose with a broad tip of the nose, small mouth with a high palate, retrognathia, small jaws and dental crowding. The hands were small with short fingers, feet were short (size 2-3) and broad with relatively short toes and a sandal gap. A large scar was visible on the abdomen after juvenile gastric surgery. There was hyperlaxity of some of the joints. As some of the features resembled Feingold syndrome, DNA analyses was performed of the MYCN gene, no pathogenic variant was found. SNP array analysis (0.15 Mb resolution) revealed a loss of 2.7 Mb in band 6q24.3q25.1, containing 19 genes including the TAB2 gene (OMIM 605101). Ultrasound was regularly performed during pregnancy revealing no abnormalities in the fetus. A healthy baby boy was born. DNA analysis showed he was not a carrier of the maternal TAB2 deletion. About 40 TAB2 deletion syndrome patients were described in the medical literature so far (Cheng 2017). Overlapping features are facial dysmorphisms, short stature, cardiac abnormalities and connective tissue abnormalities. Most patients show developmental delay and/or intellectual disability. In addition to this patient with normal intelligence, only one family is described with several affected persons without intellectual disability. Gastric or esophageal abnormalities requiring surgery in childhood were not reported so far.

**1274F**

**Early onset developmental delay and epilepsy in pediatric patients with WDR45 variants.** *H. Wang, H. Chen, Y. Qian, Y. Lu, X. Dong, B. Wu, W. Zhou.* Children's Hospital of Fudan University, Shanghai, China.

**Background:** Developmental delay (DD) is a neurological disorder presented with defects in gross motor, fine motor, language and cognition. WDR45 is one of the disease-causing genes of DD. Previously, WDR45 de novo mutations were reported in certain adult and pediatric patients due to iron accumulation. **Clinical report:** We reported five pediatric female patients with DD and epilepsy. Their ages were below 3 years at the first consultation and precise diagnosis were difficult based on clinical information and phenotype. **Methods:** Children with DD and/or epilepsy presenting to the molecular diagnostic center of Children's Hospital of Fudan University were enrolled between May 2016 and May 2017. Whole-exome sequencing (WES) was conducted for patients and their parents. We described the phenotypes of these patients carrying WDR45 variants. Furthermore, we overexpressed the candidate variants in HeLa cells to evaluate their effect on autophagy and detected the changes using Western blot and immunofluorescence staining with confocal microscopy. **Results:** In 623 enrolled pediatric patients (274 females; 487 below 6 years), five WDR45 de novo mutations were detected, including c.19C>T (p.Arg7\*), c.401G>C (p.Arg134Pro), c.503G>A (p.Gly168Glu), c.700C>T (p.Arg234\*), and c.912delT (p.Ala305Leufs\*25). All the five patients with WDR45 variants exhibited DD and epilepsy. The missense mutations of p.Arg134Pro and p.Gly168Glu showed accumulation of LC3-containing autophagic structures and abnormally enlarged cell volume compared with the control HeLa cells. Western blotting revealed a significant increase in LC3II/GAPDH. **Conclusion:** The identification of WDR45 mutations provided further evidence that WES played an important role in the diagnosis of neurological disorders with common phenotypes, and WDR45 is associated with neurological disorders and not very rare in Chinese female pediatric patients with DD and/or epilepsy. The diagnosis of patients with WDR45 mutations enabled the precise genetic counseling of parents for subsequent children.

**1275W**

**Whole exome sequencing in a patient with congenital developmental abnormalities reveals a variant within PDGFA, a gene of uncertain significance as likely causal.** *A. Gupta, E. Conboy, P. Pichurin, E.W. Klee.* Mayo Clinic, Rochester, MN.

**Statement of purpose:** We report a newborn female with multiple congenital anomalies including cloacal anomalies (abnormality of the vagina, uterus didelphys, unilateral renal agenesis, anal atresia, imperforate anus), cerebellar hypoplasia, atrial septal defect, patent ductus arteriosus and bilateral talipes equinovarus. After birth she was noted to have urinary retention, abdominal distention, unilateral facial palsy and subjectively hypertelorism. She had a healthy full sibling and no affected family members. **Methods:** Genomic DNA was extracted from whole blood of the proband and parents. Whole Exome Sequencing (WES) trio test was carried out through GeneDx, the XomeDx test which included evaluation of variants that are identified to be de novo, compound heterozygous, homozygous, heterozygous and X-linked in addition to relevant analysis based on the family structure and reported phenotype.

**Results:** WES revealed a heterozygous de novo missense Variant of Uncertain Significance- c.443G>T p.R148L within *PDGFA*, designated a Gene of Uncertain Significance with potential relationship to the phenotype of the patient.

**Discussion:** This gene encodes a member of the protein family comprised of both platelet-derived growth factors (PDGF) and vascular endothelial growth factors (VEGF) and binds and activates PDGF receptor tyrosine kinases, which play a role in a wide range of developmental processes. Although no pathogenic variants in *PDGFA* have been reported in association with a specific human disease to date, abnormal PDGF signaling has been implicated in a range of diseases such as cancer, atherosclerosis, restenosis, pulmonary hypertension, and retinal diseases, as well as in fibrotic diseases, including pulmonary fibrosis, liver cirrhosis, scleroderma, glomerulosclerosis, and cardiac fibrosis. Homozygous *Pdgfa*-null mice have been shown to die at the prenatal stage or postnatal stage before age 6 weeks and develop lung emphysema secondary to failure of alveolar septation, reduced numbers of oligodendrocytes and a dysmyelinating phenotype, abnormal Leydig cell development and spermatogenic arrest, and abnormalities and reduction in the size of most other organs. The evidence from animal knockout models of *PDGFA* and role of PDGF signaling in various developmental pathways seem to suggest the variant within *PDGFA* to be potentially responsible to the patient's phenotype of congenital developmental malformations.

**1276T**

**Diagnostic dilemmas in the next-generation sequencing era: Novel Mendelian phenotype, blended phenotype or phenotypic expansion.** M. Muriello<sup>1</sup>, G. McCarrick<sup>1</sup>, C. Smith<sup>1</sup>, H. Levy<sup>1,2</sup>, D. Valle<sup>1</sup>, H. Dietz<sup>1</sup>, N. Sobreira<sup>1</sup>. 1) McKusick-Nathans Institute of Genetic Medicine, Johns Hopkins University, Baltimore, MD; 2) Johns Hopkins University, School of Medicine, Baltimore, MD.

Whole exome sequencing (WES) has been the main tool for the discovery of novel disease genes related to rare Mendelian phenotypes in clinic and research. Mostly by using WES, the number of genes with phenotype-causing variants described in OMIM went from 2,346 in 2009 to 3,917 in June 7<sup>th</sup> 2018. Still, approximately 80% of the 19,000 known genes are not related to a disease phenotype and 3,352 Mendelian or suspected to be Mendelian phenotypes do not have a known molecular basis (OMIM, June 7<sup>th</sup>, 2018). So, it is not surprising that more than 50% of the clinical WES are non-diagnostic. But, most unsolved WES uncover multiple candidate variants in known disease genes that could be related to a phenotypic expansion or to a blended phenotype. Chong et al. (2015) described that among the 617 novel discoveries identified by the Centers for Mendelian Genomics, 363 were related to new phenotypes and 198 were related to phenotypic expansions. Posey et al. (2017) described that 4.9% of 2076 cases submitted to WES where blended phenotypes. Here we describe 4 unrelated probands in whom we performed WES and did not identify the causative variant(s) in a known disease gene. Each proband was an isolated case with a unique multiple congenital anomalies phenotype without a clinical diagnosis. Briefly, Case 1 is a 10 year old male with gingival hyperplasia, dysmorphic features, and dysplastic phalanges; Case 2 is a 12 year old male with hypoplastic left heart syndrome, developmental delay and eosinophilic esophagitis; Case 3 is a 14 year old female with aortic root dilation, scoliosis, Chiari malformation, and radioulnar synostosis; and Case 4 is a 43 year old female with microcephaly, Pierre-Robin sequence, facial dysmorphisms, and congenital ocular defects. As part of the Baylor-Hopkins Center for Mendelian Genomics, we performed WES of the proband and their parents (father of case 1 was not available for WES). Using PhenoDB analysis tool, we identified the best candidate variants in each proband but no causative variant(s) in a known disease gene related to their phenotype was identified. In all of them, a small list of candidate variants in novel and known disease genes was created and the possible novel disease genes were submitted to GeneMatcher, PhenomeCentral, MyGene2 and *matchbox*. In each proband we excluded, to the best of our ability, the possibility of phenotypic expansion and blended phenotype and suggest that they each, have a novel rare Mendelian phenotype.

**Effective use of off-target reads in evaluation of copy number variation from aligned exome data: Validation study in 325 undiagnosed patients.** H. Suzuki<sup>1</sup>, T. Uehara<sup>1</sup>, H. Yoshihashi<sup>2</sup>, H. Fukushima<sup>3</sup>, R. Sumazaki<sup>3</sup>, Y. Yamaguchi<sup>1</sup>, T. Takenouchi<sup>1,4</sup>, R. Kosaki<sup>5</sup>, K. Kosaki<sup>5</sup>. 1) Center for Medical Genetics, Keio University School of Medicine, Tokyo, Japan; 2) Department of Medical Genetics, Tokyo Metropolitan Children's Medical Center, Tokyo, Japan; 3) Department of Child Health, Faculty of Medicine, University of Tsukuba, Ibaraki, Japan; 4) Department of Pediatrics, Keio University School of Medicine, Tokyo, Japan; 5) Divisions of Medical Genetics, National Center for Child Health and Development, Tokyo, Japan.

[Back ground] Next generation sequencing is used to detect single nucleotide variants and short insertions and deletions on a genome-wide scale. Currently, large copy number variations [CNV] are screened by microarray. There have been several attempts to detect such large CNV from aligned short reads from exome sequencing by evaluating read-depth information in regions targeted by the bait (i.e. on-target region) that mainly captures the coding regions. Those programs basically neglect off-target regions of the genome. Recently, a revolutionary algorithm EXCAVATOR2 which exploits read-depth information of off-targeted regions concurrently with on-targeted regions was proposed using simulated genome data. Here we validated performance of EXCAVATOR2 using real patient data. [Materials and Methods] Patients with multisystem disorders who were suspected to have genetic diseases were ascertained through the Japanese genome project on rare and undiagnosed diseases. These patients were analyzed both by 1) comparative genomic hybridization, 2) standard exome analysis followed by EXCAVATOR2. Two methods of analysis were performed by two researchers who were blinded for each other's results. In both analysis, the threshold was set as 1 Mb for detection of both gains and losses. Results from comparative genomic hybridization was considered as gold standard. Potential CNVs detected by EXCAVATOR2 only within the off-target regions were discarded from further analysis. [Results] Initial analysis of a cohort of 93 patients with array CGH detected 7 patients with CNV (1.3-9.7 Mb). Analysis of the same cohort with EXCAVATOR2 detected all these 7 patients with "proven" CNVs. Hence, sensitivity and specificity of EXCAVATOR2 compared with array CGH was 100% and 100%, respectively. In another cohort of 232 patients with standard exome analysis, 19 patients had CNVs (1.3-14.7 Mb) which detected further analyzed by EXCAVATOR2. All these 19 patients were confirmed by using array CGH. [Discussion] We demonstrated analytic validity of EXCAVATOR2 in clinical settings involving 325 undiagnosed patients. Effectiveness of the software EXCAVATOR2 that use both off-target and on-target reads was unequivocal in evaluation of copy number variation from aligned exome data. Hence, exploitation of exome data allows detection of both base-level mutations and mega base-level structural changes in a single assay rather than tiered approach with microarray and NGS.

**Singleton exome strategies in under-represented populations.** *E. Ullah<sup>1</sup>, B. Guan<sup>1</sup>, CE. Prada<sup>2,3</sup>, RB. Hufnagle<sup>1</sup>.* 1) Ophthalmic Genetics and Visual Function Branch, National Eye Institute, Bethesda, MD; 2) UC Department of Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; 3) Hospital Internacional de Colombia, Santander, Colombia.

Accurate molecular diagnostics are critical to care and management for patients with Mendelian genetic disorders. Recent advances in sequencing technologies have both revolutionized the pace of new gene discovery and increased the probability of genetic diagnosis. Whole-exome sequencing (WES) is reported to identify the disease-causing mutations in approximately 25-40 % of cases of monogenic disease. Here, we use WES as the first approach to genetic diagnosis in previously untested patients from an under-represented population in healthy population databases (Colombia, South America). We recruited 128 singletons with a variety of genetic disorders. About 50% cases had multisystem presentation while in the remaining cases the genetic disorder affected mainly neuromuscular (12%), muscular (7%), neural (6%), metabolic (5%), cardiac (5%), skeletal (4%), immune (4%), eye (2%), renal (2%), reproductive (2%) and dermatologic (1%) tissues. Family history was known for 12% of cases whereas 88% were sporadic. We employed a case vs control approach where one patient served as a case and the remaining as controls (1:N-1 strategy), and standard variant filtering strategies. This analysis solved 41 % of the cases in total, identifying a previously reported mutation or a rare coding variant matching the gene-associated phenotype and inheritance pattern. One reported truncating allele NM\_001195798.1:c.11G>A, NP\_000518.1:p.W4\* in the *LDLR* gene was identified in three unrelated patients with familial hypercholesterolemia, indicating a likely founder allele. Subsequent analysis of solved cases revealed that positive family history and phenotypes predominantly affecting a single tissue were more likely to be solved by this approach. Additionally, this cohort permits for curation of common variants in the Colombian population for further studies. Semi-automation of variant prioritization process and calculation of population variant frequencies is expected to further increase the efficiency and reproducibility of this approach. We conclude that WES as the first approach to genetic diagnosis and use of a large cohort for case-control analysis is effective for rapid identification of disease-causing mutations. This approach can also be applied to cohorts where control data is not available, and identify common founder alleles, improving the cost-effectiveness of molecular diagnostics in these settings.

**Treatment of the FXTAS and FXPOI mouse model with the antioxidant tempol.** *I. Gazy<sup>1</sup>, M.S. Lange<sup>2</sup>, E. Musselwhite<sup>3</sup>, X. Zhao<sup>1</sup>, G. Hoffman<sup>2</sup>, J. Johnson<sup>2</sup>, K. Usdin<sup>1</sup>.* 1) NIDDK, National Institutes of Health, Bethesda, MD, 20892, USA; 2) Department of Biology, Morgan State University, Baltimore, MD 21251, USA; 3) Department of Obstetrics and Gynecology, University of Colorado-Denver, Aurora, CO 80045, USA.

The human *FMR1* gene contains a CGG repeat tract in the 5'untranslated region. Premutation (PM) alleles have 55-200 CGG repeats and carriers of such PM are at risk of developing two distinct Fragile X-related disorders: FX-associated tremor/ataxia syndrome (FXTAS) and FX-associated primary ovarian insufficiency (FXPOI). FXTAS is a late-onset neurodegenerative disorder characterized by intention tremor, cerebellar ataxia, parkinsonism and cognitive decline. While FXTAS is more prevalent in male PM carriers than female carriers, females are also at risk of developing the ovarian dysfunction disorder FXPOI. Previous work on human carriers as well as on a PM knock-in mouse model that recapitulates many of the pathologies observed in PM carriers, have implicated mitochondrial dysfunction as well as oxidative damage in the pathogenesis of FXTAS and FXPOI. We envision that oxidative damage can potentially contribute to the pathology of these disorders in 2 different ways. First, oxidative stress can be deleterious to the normal function of the brain and ovaries by damaging the biomolecules necessary for normal cell function. Additionally, oxidative damage is thought to promote CGG repeat expansions and this could potentially contribute to pathology by enhancing the toxic effects of CGG containing transcripts. Antioxidants have been proposed to be generally beneficial in cases of premature ovarian failure or ovarian damage unrelated to the FX PM. Furthermore, antioxidants are currently being tested as treatments for neurodegenerative disorders as well as for Fragile X syndrome. We, therefore, decided to test the effect of tempol, an antioxidant that crosses the blood brain barrier, on repeat instability, brain pathology as well as ovarian function in PM mice. Ultimately, this work should help assess whether antioxidants have therapeutic potential for these disorders.

**Introduction:** A novel cohesinopathy caused by a founder mutation in *SGOL1* termed Chronic Atrial and Intestinal Dysrhythmia Syndrome (CAID) was described in 16 French Canadians and 1 Swede. This disorder is characterized by cardiac and gastrointestinal involvement. So far no neuropsychiatric symptoms have been reported, which is remarkable taking into account that the brain is the organ most sensitive to cohesin disruption. The population genetic analysis of this disorder determined that the rare disease-causing haplotype was of northern European origin. Here, we report on the first cases of CAID syndrome due to c.67A>G mutation in *SGOL1* in Latin America, which showed the combination of sick sinus syndrome and chronic intestinal pseudo-obstruction plus neurological involvement. **Materials and Methods:** Patient 1, is a 31 years old Colombian male, who since the age of 13 began with vomiting, abdominal distention and intestinal dysmotility leading to intestinal failure. At the age of 28 years old, he was diagnosed with sick sinus syndrome. Basic imagenologic studies including resonance enterography as well as intestinal biopsy with electron microscopy were carried out. Subsequently, Holter test and molecular analysis were performed. Patient 2, is a 13 years old Colombian boy, who a year ago presents with abdominal pain, vomiting, intestinal pseudo obstruction, bradycardia and behaviour impairment. Imagenological studies including brain MRI, intestinal biopsy and ecocardiography were performed. Finally, whole exome sequencing was done. **Results:** Both initial imagenological studies demonstrated delay in intestinal transit with loop dilatation; the resonance enterography suggested the presence of chronic intestinal pseudo occlusion syndrome. In patient 1, Holter test showed cardiac sinus dysfunction and in patient 2, ecocardiography displayed systolic dysfunction of left ventricle. The intestinal microscopic findings included fibrosis of muscular layer. Sanger sequencing and whole exome sequencing demonstrated a homozygous mutation in *SGOL1* (c.67A>G; p.Lys23Glu). **Conclusion:** The description of these cases confirmed the presence of patients with CAID syndrome in Latin America, probably a second cluster. The finding of neuropsychiatric involvement could expand the phenotype, what would be expected knowing that central nervous system is affected in all cohesinopathies previously described; or might be a variant of the clinical presentation in Latin America. .

**Addressing missing heritability in rare genetic diseases.** M. Tarailo-Graovac<sup>1,2</sup>, B.I. Drögemöller<sup>2,4</sup>, P.A. Richmond<sup>3,5</sup>, A.B.P van Kuilenburg<sup>6</sup>, G. Horvath<sup>4,7</sup>, C.J Ross<sup>3,4</sup>, C.D. van Karnebeek<sup>3,6</sup>, W.W. Wasserman<sup>3,5</sup>. 1) 1)Departments of Biochemistry, Molecular Biology and Medical Genetics, Cumming School of Medicine, University of Calgary, Calgary, AB, Canada; 2) Alberta Children's Hospital Research Institute, University of Calgary, Calgary, AB, Canada; 3) Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver, BC, Canada; 4) BC Children's Hospital Research Institute, Vancouver, BC, Canada; 5) Departments of Medical Genetics and Pediatrics, Centre for Molecular Medicine and Therapeutics, Vancouver, BC, Canada; 6) Departments of Clinical Chemistry, Pediatrics and Clinical Genetics; Laboratory Genetic Metabolic Diseases, Academic Medical Center, University of Amsterdam, Amsterdam, The Netherlands; 7) Department of Pediatrics, Division of Biochemical Diseases, University of British Columbia.

Rare genetic diseases have low prevalence individually, but collectively are common. Accurate diagnosis is crucial as it enables counselling; appropriate/ tailored clinical management as well as identification of targets for treatment. However, diagnosing rare diseases poses a challenge, and despite extensive, expensive clinical tests, low diagnostic rates, misdiagnoses, and delays to appropriate care are not uncommon. In recent years, with the advent of high throughput sequencing (HTPS), we have witnessed an important step forward in diagnosis of rare disorders (from ~10% using traditional to ~40% using genome-wide genetic testing). Simultaneous profiling of a subset of (i.e. using gene panels) or the majority of protein-coding regions (i.e. using whole exome sequencing, WES) in an individual has reduced the dependency of diagnosis on traditional approaches, and has allowed hypothesis-guided prioritization based on both exome and phenome information. Nonetheless, even with those advances establishing a diagnosis is still a challenge and in most phenotypic categories more than 50% of rare disease patients remains undiagnosed. A plausible explanation for the missing heritability in rare suspected genetic diseases may be in the preferred technology used so far. Exome sequencing approaches capture only a small (<2%) portion of the genome and are very limited in the capacity to detect structural variants (SVs), copy number variants (CNVs), insertions, translocations, inversions, tandem repeat expansions, as well as non-coding and deep-intronic variants. Here we report on our cohort of rare disease patients who underwent deep clinical phenotyping but remained undiagnosed despite extensive tests including exome sequencing. Our expanded genome-wide analyses revealed the following source of missing heritability: (1) non-uniform capture of targeted exomes; (2) spectrum of pathogenic structural variation; (3) somatic mosaicism; (4) phenocopy (i.e. known well-defined clinical phenotype caused by novel, unsuspected gene); and (5) complex composite effects of multi-gene defects. Our data shows that whole genome sequencing (WGS) substantially improves diagnostic/discovery potential of HTPS, and advocates the importance of utilizing the WGS for its potential to detect "all" classes of genetic variation in a single test.

**The prevalence of suspected pathogenic mutations for early and adult onset dominant disorders in a healthy Israeli population.** S. Tzur<sup>1,2</sup>, N. Ruhman Shaha<sup>3</sup>, L. Bazak<sup>4</sup>, T. Talmy<sup>1</sup>, N. Mizrahi<sup>1</sup>, S. Kovo<sup>1</sup>, R. Attali<sup>1</sup>, H. Ostre<sup>1</sup>, L. Basel-Salmon<sup>3,5,6,7</sup>. 1) Emedgene Technologies, Tel Aviv, Israel; 2) Laboratory of Molecular Medicine, Rambam Health Care Campus, Haifa, Israel; 3) Raphael Recanati Genetic Institute, Rabin Medical Center Beilinson Campus, Petah Tikva, Israel; 4) Department of Pathology, Albert Einstein College of Medicine, Bronx, NY, USA; 5) Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel; 6) Pediatric Genetics Unit, Schneider Children's Medical Center of Israel, Petah Tikva, Israel; 7) Felsenstein Medical Research Center, Rabin Medical Center, Petah Tikva, Israel.

**Introduction** Evaluating the frequency of suspected pathogenic mutations for early and adult onset dominant disorders among healthy individuals has two main implications: (1) for adult onset disorders, we can learn about the prevalence of such variants in asymptomatic individuals and about disease penetrance; (2) for early onset severe dominant disorders, such analyses of healthy adults could contribute to better understanding of the limitations in clinical predictive genomics in the context of prenatal genome sequencing. **Methods** We analyzed the exomes of 166 apparently healthy subjects, while applying stringent criteria for pathogenicity including only rare, known pathogenic or loss of function variants in all genes implicated in dominant conditions. For each variant, we assessed risk and predicted effect based on the available literature and bioinformatic tools. **Results** For diseases of adult onset, 20 suspected variants were found in 18 individuals (11%), predominantly in genes associated with cardiac, metabolic, and oncologic conditions. For early onset diseases, upon first analysis, 7 individuals (4%) presented suspected pathogenic mutations. However, interpretation of these variants proved challenging since in large part we identified mutations in genes that are: more likely to cause a dominant disease exclusively with missense variants, cause more severe disease when found in recessive forms, cause relatively mild disorders, have old ClinVar submissions, or have a relatively high allele count in gnomAD. Finally, after deep investigation, none of the mutations was considered to be unambiguously pathogenic. **Conclusions** For adult onset dominant diseases, we found a high prevalence (11%) of suspected pathogenic mutations with potential clinical implications. We may recommend a follow up study for these individuals including medical assessment, genetic counseling and surveillance. For early onset dominant diseases, preliminary analysis revealed suspected findings in 4% of the cohort. However, a deep investigation revealed that none were unambiguously pathogenic or harmful. These results have serious ramifications pertaining to prenatal diagnostics, since the initial analysis wrongly demonstrated a high rate of individuals with early onset disorders. This may prompt errant clinical decision making in prenatal diagnosis if not performed with caution. This study emphasizes the complexity and precautionary measures involved in predictive genomics.

**1283F**

**Biallelic variants in CBL in brothers with intellectual disability and Noonan-like syndrome.** G. Gotway<sup>1,2</sup>, C. Hornbuckle<sup>2</sup>. 1) University of Texas Southwestern Medical Center, Dallas, TX; 2) Children's Medical Center Dallas.

Two full brothers 18 months apart in age presented with developmental delays and hyperpigmented macules and moles. The older brother (A) walked at 18 months and did not speak until after age 2; the younger brother (B) did not sit until a year of age, walked after age 2 and did not speak until age 4. Both were in life skills classes in school and cannot live independently as adults. Patient A had bilateral retinal detachment at age 15 and was diagnosed 3 months later with a grade 1 cerebellar pilocytic astrocytoma. At that time, he was noted to have several café-au-lait (CAL) macules and numerous darker pigmented macules and moles. Patient B had similar lesions, and their mother and several of her relatives carried a clinical diagnosis of neurofibromatosis. *NF1* sequencing was unremarkable. A sequencing panel for Noonan syndrome revealed two variants in the *CBL* gene in both brothers; one (c.1099C>A; p.Gln367Lys) was rated likely pathogenic and the other (c.1129A>G; p.Thr377Ala) was rated a variant of uncertain significance. The LP variant was found in the mother and maternal great grandmother, both of whom have CAL macules but no moles. The mother had learning disabilities but lives independently, and has a lipomatous tumor on her hip. The maternal grandmother, an obligate carrier, has a diagnosis of Coat's disease and CAL macules. The mother has a brother and maternal half-brother in special education who were not tested. The father was found to carry the VUS. He also had learning problems in school, but does not have a history of CAL macules; he is adopted, and does not know his family history. Both variants occur in exon 8, which contains the linker domain of the CBL protein and is a hotspot for pathogenic changes. Both variants are absent from control databases (gnomad, ESP, 1000 genomes). The Glu367 position has been found to be altered in two other patients, one with a Noonan-syndrome like phenotype and one with chronic myelomonocytic leukemia. The Thr377 position has not been reported to be altered in any other germline cases, but the same alteration was seen in a seminoma, and a different missense at this site was reported in a study of somatic mutations associated with hematopoietic clonal expansion. The more severe neurologic impairment and skin findings in the brothers raises the possibility that this is a case of biallelic pathogenic variants, one likely being a milder hypomorphic allele.

## 1284W

**Genotype-phenotype correlation of mutations in *PIGN* causing Fryns syndrome, MCAHS and neurological phenotypes.** U. Kini<sup>1</sup>, A. Tardivo<sup>1</sup>, A. Pagnamenta<sup>2</sup>, J. Taylor<sup>2</sup>, T. Kinoshita<sup>3</sup>, Y. Murakami<sup>3</sup>, DDD Study. 1) Oxford Centre for Genomic Medicine, Oxford University Hospitals NHS FT, Oxford, Oxfordshire, United Kingdom; 2) Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford; 3) abumoto Department of Intractable Disease Research, Research Institute for Microbial Diseases, Osaka University, Osaka, Japan.

About 30 genes encoding the GPI anchor pathway are responsible for the post-translational modification of approximately 150 proteins within the cell. While genes in the early part of the pathway have been mostly reported to cause a pure neurological phenotype (intellectual disability +/- seizures), genes in the later part can have additional findings of congenital malformations including Hirschsprung disease, diaphragmatic hernia, genito-urinary abnormalities and cleft palate. Recessive mutations in *PIGN* have been reported to cause intellectual disability, seizures, Fryns syndrome and MCAHS (multiple congenital abnormalities, hypotonia, seizures). No genotype-phenotype correlation has been established as yet. **Methods:** We studied 38 patients (10 new and 28 from the literature) with recessive mutations in *PIGN*. The 10 new patients were ascertained by exome sequencing either in a clinical setting or via the DDD study. FACS analysis and expression studies were carried out to prove pathogenicity in appropriate cases. **Results:** *PIGN* consists of 2 pfam domains (phosphodiesterase and PigN). The PigN domain includes most of the 14 transmembrane (TM) domains except for the first and the last TM domains. 11/38 (29%) were reported to have lethal Fryns syndrome and showed biallelic severe loss of function (LOF) mutations (intragenic deletions, frameshifts and stop mutations). All mutations were present in the phosphodiesterase or PigN domains; the exception was one patient with homozygous missense mutations in the TM domain. 16/38 (42%) patients had a MCAHS phenotype; all patients had at least one mild missense mutation and at least one of the mutations was in the PigN domain. The remaining 11/38 (29%) had a pure neurological phenotype. Both mild missense and severe LOF mutations were reported in these cases but were restricted to the phosphodiesterase domain. **Conclusion:** Biallelic severe LOF mutations lying in any domain of *PIGN* results in lethal Fryns syndrome. The presence of at least one mutation in the PigN domain results in the MCAHS phenotype, while mutations restricted to the phosphodiesterase domain cause a pure neurological phenotype.

## 1285T

**When two is worse than one: Machine-learning-based identification of digenic disease genes based on network and genomic data.** S. Mukherjee<sup>1,4</sup>, J.A. Capra<sup>1,3,4,5</sup>, J. Meiler<sup>2,4,5,6</sup>. 1) Department of Biological Sciences, Vanderbilt University, Nashville, TN; 2) Department of Chemistry, Vanderbilt University, Nashville, TN; 3) Vanderbilt Genetics Institute, Vanderbilt University Medical Center, Nashville, TN; 4) Center for Structural Biology, Vanderbilt University, Nashville, TN; 5) Department of Biomedical Informatics, Vanderbilt University Medical Center, Nashville, TN; 6) Department of Pharmacology, Vanderbilt University School of Medicine, Nashville, TN.

Identifying the genetic causes of rare diseases can significantly enhance treatment options, and the integration of whole exome and genome sequencing into clinical diagnosis provides a comprehensive perspective on a patient's mutations. However, identifying genetic variants that contribute to disease among thousands of mutations in a patient's genome remains challenging. Recognizing this, the NIH has established the Undiagnosed Diseases Network (UDN) with the goal of diagnosing patients with rare, complex, and unresolved diseases by combining genome sequencing and genetic analyses with the latest tools for identifying the effects of individual variants and their potential contributions to rare disease. Despite substantial efforts, more than half of UDN cases remain unsolved. Synthetic lethality studies in model systems have highlighted the importance of gene-gene interactions to the genetics of diverse phenotypes. Furthermore, hundreds of human digenic diseases are known, where variants in a pair of genes act synergistically to cause disease phenotypes, even when mutations in the genes individually are benign. However, there is no high-throughput method for identification of gene pairs with the potential to cause digenic disease when mutated in patients. We hypothesized that digenic gene pairs could be distinguished from non-digenic pairs based on their functional, network, and genomic properties, such as shared biochemical pathways, shared phenotypes, coexpression, network proximity, and haploinsufficiency. We trained a random forest (RF) machine learning classifier using a positive set of clinically curated gene pairs associated with digenic diseases from the Digenic Diseases dAtabase (DIDA). Using the attributes described above as features, we evaluated the ability of the classifier to distinguish known digenic gene pairs from negative sets of gene pairs in which simultaneous mutations were not associated with disease. The RF classifier was able to accurately distinguish the digenic disease pairs from the negative sets; it achieved an average area under the curve (AUC) of 0.9 in the Receiver Operating Characteristic (ROC) curve and 0.5 in the Precision-Recall (PR) curve in 10-fold cross validation. Our work demonstrates that digenic gene pairs can be accurately identified by their functional and network attributes. We are now using this pipeline to find potentially causal digenic gene pairs in patients with unsolved rare diseases from the UDN.

**MCM3 and MCM7: New causative genes underlying Meier-Gorlin syndrome.** K.M. Knapp<sup>1</sup>, F.L. Harms<sup>2</sup>, C.W. Ockeloen<sup>3</sup>, E. Bongers<sup>3</sup>, A.P. Jackson<sup>1</sup>, N. Pachter<sup>4</sup>, J. Denecke<sup>5</sup>, K. Kutsche<sup>2</sup>, L.S. Bicknell<sup>1</sup>. 1) Department of Pathology, Dunedin School of Medicine, University of Otago, Dunedin, New Zealand; 2) Institute of Human Genetics, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; 3) Department of Human Genetics, Radboud University Medical Center, Nijmegen, Netherlands; 4) MRC Human Genetics Unit, Institute of Genetics and Molecular Medicine, University of Edinburgh, Edinburgh, UK; 5) Genetic Services of Western Australia, King Edward Memorial Hospital, Subiaco, Western Australia, Australia; 6) Department of Pediatrics, University Medical Center Hamburg-Eppendorf, Hamburg, Germany.

Meier-Gorlin syndrome (MGORS) is a rare genetic disorder characterized by primordial dwarfism, microtia, and patellar aplasia/hypoplasia, which is caused by impaired DNA replication initiation. Eight causative genes encoding essential components of the pre-replication (pre-RC) and pre-initiation complexes (pre-IC) have been identified to date. By performing Chromium whole-genome sequencing on a MGORS cohort we have identified biallelic variants in two novel disease genes not previously associated with MGORS: *MCM3* and *MCM7*. These genes encode subunits of the replicative helicase complex MCM2-7, which represents a component of the pre-RC complex. One individual is homozygous for a missense variant in *MCM3*, and structural modelling indicates that substitution of this highly conserved residue would disrupt interactions with ORC2 and CDC6. For *MCM7*, we have identified two unrelated individuals with biallelic pathogenic variants. Both individuals are compound heterozygous for a different truncating allele (predicted to lead to nonsense-mediate mRNA decay) *in trans* with a different missense variant, which based on the essential nature of MCM subunits, is likely a hypomorphic allele. The affected residues are strongly conserved, with one residue being located within the core of *MCM7* and the other within a region identified as required for *MCM3* and ATP binding. Based on these structural implications, we hypothesize that the *MCM3* and *MCM7* variants identified disrupt pre-RC chromatin loading, reducing proliferative potential and thereby cause Meier-Gorlin syndrome. There is also some phenotypic variation amongst these individuals, and their clinical features will be discussed in context with the previously described individual with biallelic *MCM5* variants, as well as the wider mutation-positive MGORS cohort.

**1287W**

**CysteinyI-tRNA synthetase (CARS) mutations cause a multi-system, recessive disease phenotype that includes tissues dependent on cysteine.** M.E. Kuo<sup>1,2</sup>, W. Introne<sup>3</sup>, M.C. Malicdan<sup>3</sup>, W.A. Gahl<sup>3</sup>, A. Antonellis<sup>1,4,5</sup>. 1) Cellular and Molecular Biology Program, University of Michigan, Ann Arbor, MI; 2) Medical Scientist Training Program, University of Michigan, Ann Arbor, MI; 3) NIH, Undiagnosed Diseases Program and Office of the Clinical Director, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD; 4) Department of Human Genetics, University of Michigan, Ann Arbor, MI; 5) Department of Neurology, University of Michigan Medical School, Ann Arbor, MI.

Aminoacyl-tRNA synthetases (ARSs) are a class of highly specialized, essential enzymes responsible for performing a crucial step of protein translation: charging tRNA molecules with cognate amino acids. Consistent with the essential function and ubiquitous expression of these enzymes, mutations in 32 of the 37 ARS-encoding loci have been implicated in severe, early-onset recessive phenotypes involving many different tissues. Current evidence based on genetic and functional studies suggest a loss-of-function mechanism; however, our understanding of the allelic and locus heterogeneity of ARS-related disease is incomplete. To date, cysteinyI-tRNA synthetase (*CARS*) variants have not been implicated in any human disease phenotype. In collaboration with the NIH Undiagnosed Diseases Program, we identified a patient with recessive microcephaly, developmental delay, and brittle hair and nails who is homozygous for p.Ser688Glnfs\*2 *CARS*. Based on the recessive phenotype and the phenotypic overlap between this patient and patients with recessive diseases associated with other ARS enzymes, we hypothesized that p.Ser688Glnfs\*2 *CARS* causes a loss-of-function effect that is responsible for the phenotype of our patient. Interestingly, *CARS* encodes two protein isoforms that harbor different C-terminal amino-acid sequences, and the p.Ser688Gln\*2 *CARS* variant is predicted to truncate the protein upstream of both C-termini. Here, we present unpublished clinical, genetic, and functional studies that support the pathogenicity of p.Ser688Glnfs\*2 *CARS*. Protein expression studies on patient fibroblasts revealed that a single, truncated protein isoform is expressed and stable. An *in vivo* yeast complementation assay using the human *CARS* gene revealed that p.Ser688Glnfs\*2 *CARS* causes severely reduced yeast cell growth compared to wild-type *CARS*, which is consistent with a loss-of-function allele and the recessive phenotype. In sum, our findings for the first time implicate a loss-of-function *CARS* allele in human inherited disease; this notion is supported by the identification of two additional patients with *CARS* mutations by a collaborating group. Interestingly, *CARS* is the first ARS associated with brittle hair and nails, which likely reflects the high cysteine content in human keratins. As such, this study improves our understanding of the clinical and locus heterogeneity of ARS-related human disease phenotypes.

**Severe PI3Kinase overgrowth syndrome treated with the AKT inhibitor miransertib.** A.D. Irvine<sup>1,2,3</sup>, O. Kubassova<sup>5</sup>, M. Hinton<sup>5</sup>, B. Schwartz<sup>4</sup>, J. Kazakin<sup>4</sup>, V. Dvorakova<sup>1,3</sup>. 1) Dermatology, Our Lady's Children's Hospital, Dublin, Leinster, Ireland; 2) Clinical Medicine, Trinity College Dublin, Dublin 2; 3) National Childrens Research Centre, OLCHC, Dublin 12, IRELAND; 4) ArQule, Inc., Burlington, MA, USA; 5) IAG, Image Analysis Group, Philadelphia, USA; 6) IAG, Image Analysis Group, London, UK.

Somatic activating mutations in phosphatidylinositol 3-kinase (PI3K) and serine-threonine protein kinase (AKT1) have been shown to cause abnormal segmental overgrowth phenotypes. Miransertib (ARQ 092) is a novel highly selective oral AKT-inhibitor with a proven in-vitro efficacy. Its potential as a therapeutic option for overgrowth patients who have exhausted conventional treatment methods was investigated through the assessment of the longitudinal MRI data acquired from one patient between 12/2015 and 04/2018 with the treatment started on 06/2016. A term baby girl had a large posterior thoracic wall lipoma and large feet at birth. Progressive lipomatous overgrowth and leg length discrepancy were treated with repeated surgical procedures during her first ten years. Progressive replacement of normal tissues with fatty overgrowth resulted in severe subcutaneous, intra-abdominal and paraspinal involvement causing obstructive uropathy with bladder displacement and neuropathic bladder dysfunction, impaired mobility and dysfunctional sitting and lying posture. At 13yrs the patient was wheelchair bound and a suprapubic catheter was required to relieve obstructive uropathy. Sirolimus was commenced age 15 but discontinued after 12 months due to disease progression. The patient was unable to lie flat due to respiratory compromise caused by extreme diaphragm elevation by intraabdominal lipomatous overgrowth with flank pain caused by massive lipomatous distension. Surgical remedy was deemed impossible due to the infiltrative nature of the fatty overgrowth incasing vital structures in the patient's retroperitoneum. Cellular studies indicated high levels of AKT activation in affected fibroblasts. ARQ 092 was commenced on compassionate basis at a dose of 30 mg OD. The patient experienced improvement in her respiratory compromise and flank pain and was able to lie flat at night. Radiologist analysis of serial volumetric DIXON MRI analysis defined regions of interest on slices of the in-phase images to define areas of fatty overgrowth (using Dynamika software as a platform for imaging data analysis). Calculated volumes of fatty overgrowth declined by approximately 15% after treatment commenced. The patient has now completed 22 months of therapy with clinically stable disease and clear radiological improvement. The drug was well tolerated with no significant toxicities other than hyperlipidaemia comparable to lipid profile derangement previously noted on sirolimus therapy.

**Mutations in mTOR and MAPK pathways cause heterogeneous lymphatic anomalies.** D. Li<sup>1</sup>, M.E. March<sup>1</sup>, T.W. Wenger<sup>2</sup>, C. Seiler<sup>3</sup>, A. Gutierrez-Uzquiza<sup>4</sup>, C. Kao<sup>4</sup>, E. Pinto<sup>4</sup>, E.J. Bhoji<sup>4</sup>, J. Strausbaugh<sup>5</sup>, J.B. Belasco<sup>5,6</sup>, Y. Dor<sup>4,5</sup>, H. Hakonarson<sup>1,5,7</sup>. 1) Center for Applied Genomics, The Children's Hospital of Philadelphia, Philadelphia, PA; 2) Division of Craniofacial Medicine, Seattle Children's Hospital, Seattle, WA; 3) Zebrafish Core Facility, The Children's Hospital of Philadelphia Research Institute, Philadelphia, PA; 4) Center for Lymphatic Imaging and Interventions, The Children's Hospital of Philadelphia, Philadelphia, PA; 5) Department of Pediatrics, University of Pennsylvania School of Medicine, Philadelphia, PA; 6) Division of Oncology, The Children's Hospital of Philadelphia, Philadelphia, PA; 7) Divisions of Human Genetics and Pulmonary Medicine, The Children's Hospital of Philadelphia, Philadelphia, PA.

Lymphatic anomalies are thought to arise through defects that occur during lymphatic development, which include a variety of diagnoses: lymphangiectasia, central conducting lymphatic anomaly (CCLA), generalized lymphatic anomaly (GLA), congenital chylothorax, and lymphedema. Although recent studies have demonstrated benefit of sirolimus in the treatment of GLA, the absence of clear clinical distinctions between these entities, due to their rarity and lack of accepted standardized nomenclature, has hampered development of innovative therapies. We report exome sequencing results in 35 independent patients, including a four-generation pedigree structure consistent with autosomal dominant inheritance. Seven pathogenic variants are identified in seven families in four genes encoding components of RAS/MAPK signaling (*ARAF*, *BRAF*, *KRAS*, and *PTPN11*) and a receptor tyrosine kinase (*EPHB4*). Splicing mutation in *EPHB4* (c.2334+1G>C), leading to use a cryptic splice donor with retention of 12-bp intron sequence resulting in reduced phosphorylation and loss of function effect, was identified in the four-generation pedigree with proband diagnosed with CCLA. The family history is notable for edema of low extremities, and variable chylous effusion. Zebrafish *ephb4a* morpholino resulted in lymphatic vessel misbranching and developmental deformities effectively rescued by mTOR and MEK inhibitors. We also identified a recurrent somatic gain-of-function *ARAF* mutation (c.604T>C:p.S214P) in a 12-year-old male with advanced anomalous lymphatic disease unresponsive to sirolimus therapy and in another unrelated adult patient. Endothelial cell studies showed the mutation altered actin skeleton and cadherin organization, which were fully reversed by inhibition of MEK signaling. Functional relevance of the mutation was also validated by recreating a lymphatic phenotype in a zebrafish model, with rescue of the anomalous phenotype using a MEK inhibitor. Subsequent therapy of the lead proband with a MEK inhibitor led to dramatic clinical improvement, with remodeling of the patient's lymphatic system with resolution of the lymphatic edema, marked improvement in his pulmonary function tests, cessation of supplemental oxygen requirements, and near normalization of daily activities. Taken together, our work demonstrates the realization of precision medicine approach enabled through a novel genetic discovery in a patient with lymphatic anomaly of a previously unknown etiology.

**Characterization of lymphatic anomaly-associated mutations in a cell model system.** *M.E. March<sup>1</sup>, D. Li<sup>1</sup>, A. Gutierrez Uzquiza<sup>1</sup>, L. Matsuoka<sup>1</sup>, R. Pellegino da Silva<sup>1</sup>, J. Garifallou<sup>1</sup>, C. Kaminski<sup>1</sup>, J. Smiler<sup>1</sup>, C. Kao<sup>1</sup>, H. Hakonarson<sup>1,2,3</sup>. 1) Center for Applied Genomics; Children's Hospital of Philadelphia; 2) Department of Human Genetics, Children's Hospital of Philadelphia, Philadelphia, PA; 3) Department of Pediatrics, The Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA.*

Central conducting lymphatic anomaly is a rare, congenital, and progressive disorder in development of lymphatic vessels and architecture. Multiple patients diagnosed with lymphatic anomaly have been analyzed through whole exome sequencing at the Center for Applied Genomics. Although treatment for lymphatic anomaly is typically performed with inhibitors of the mTOR pathway, we have identified mutations in three genes that are canonically associated with signaling through the ERK pathway. Mutations have been found in a fourth gene with existing but less well established connections to ERK signaling. Functional characterization of the discovered mutants has begun with expression of each wild type or mutant protein in an endothelial cell line. Overexpression of one mutant (in the *ARAF* gene) clearly alters cell morphology, intracellular actin structures, and localization of the vascular endothelial cell adhesion molecule (VE-CAM), such that cells form less complete cell-cell junctions. Perturbations in cell structure and morphology are reversed upon treatment of the cells with inhibitors of ERK signaling. Characterization of the other mutants is currently underway, and may provide evidence for alterations to treatment of lymphatic anomaly patients in which ERK-related mutations have been observed.

**Conservative management of pseudoanodontia of two cases of GAPO syndrome and Cleidocranial dysplasia.** *M.I. Mostafa, M.A. AbdelRahmen, M.A. Abdelkader, M.I. Mehrez.* National Research Centre, Dokki, Cairo, Egypt.

GAPO syndrome (OMIM # 230740) is a very rare genetic disorder. GAPO is an acronym for syndrome's main manifestations: (G) Growth retardation, (A) Alopecia, (P) Pseudoanodontia (clinical absence of teeth due to a failure in eruption) and (O) Optic atrophy. Autosomal recessive mode of inheritance has been suggested in several reports. Cleidocranial dysplasia (CCD; OMIM #119600), is an autosomal dominant skeletal dysplasia affecting the formation of both bone and teeth. The main dental characteristic features are supernumerary teeth and Pseudoanodontia. In this report, conservative management of pseudoanodontia of two cases of GAPO Syndrome and Cleidocranial dysplasia is suggested. The dental management of 19-year old male suffered from Cleidocranial dysplasia depended on preservation of the unerupted teeth by orthodontic traction after their surgical exposure. In spite of the long duration of treatment, the patient and operators were satisfied with the outcome. Dental management of GAPO syndrome is also a challenging procedure. Pseudoanodontia resulting from the unerupted primary and permanent teeth causes an increase in bone ridge volume in a buccolingual direction. This condition hinders the installation of dentures. Surgical removal of teeth, even if partial, seems too complicated. Unlike Cleidocranial dysplasia, surgical exposure of the impacted teeth followed by orthodontic traction is not recommended because teeth are ankylosed. In the presented case, conventional complete denture was suggested. The outcome after more than three years of follow up was unexpectedly excellent. Both the parents and the patient were satisfied especially regarding retention, function and esthetics. Management of pseudoanodontia is still challenging due to lack of researches on such rare cases. Each case should be managed independently according to its own clinical and radiographic presentation combined with results of previously reported cases. The best way of management could be the easiest one.

**Both hetero- and homozygote IDCCA syndrome-associated G-protein  $\beta$ -subunit 5 knockout mice demonstrate heart rate perturbation and cardiac dysfunction.** P. De Nittis<sup>1</sup>, A. Sarre<sup>2</sup>, J. Chrast<sup>1</sup>, C.D. Koopman<sup>3,4</sup>, J. Bakkers<sup>3,4</sup>, W.F. Simonds<sup>5</sup>, T. Pedrazzini<sup>6</sup>, A. Reymond<sup>1</sup>. 1) Center for Integrative Genomics, University of Lausanne, Lausanne, Switzerland; 2) Cardiovascular Assessment Facility, University of Lausanne, Lausanne, Switzerland; 3) Department of Medical Physiology, Division of Heart and Lungs, University Medical Center Utrecht, Utrecht, The Netherlands; 4) Hubrecht Institute-KNAW, University Medical Centre Utrecht, Utrecht, The Netherlands; 5) Metabolic Diseases Branch/NIDDK, National Institutes of Health, Bethesda, MD, USA; 6) Experimental Cardiology Unit, Department of Cardiovascular Medicine, University of Lausanne Medical School, Lausanne, Switzerland.

Cardiac electrophysiology is controlled by the sympathetic and parasympathetic branches of the autonomic nervous system. Parasympathetic modulation of cardiac output is primarily mediated by acetylcholine via M<sub>2</sub>-muscarinic receptors (M<sub>2</sub>R). The activation of M<sub>2</sub>R triggers G-protein-dependent switching of G-protein-gated inwardly rectifying K<sup>+</sup> channels (GIRK), hyperpolarizing the cell membrane. The kinetic of M<sub>2</sub>R-GIRK signaling is negatively regulated by "regulator of G-protein signaling" (RGS) proteins. In particular, the heterotrimeric G-protein  $\beta$ -subunit 5 (GNB5)-RGS6 complex is involved in cardiac GIRK deactivation. In human, inactivating mutations in *GNB5* are causative of the autosomal recessive Intellectual Developmental Disorder with Cardiac Arrhythmia (IDCCA) syndrome (MIM:#617173) with impaired cardiac sinus conductance as one cardinal symptom. *Gnb5*-null mice recapitulated many of the corresponding human disease phenotypes such as learning deficiencies, hyperactivity, impaired motor coordination and perturbed vision. Here, we used *Gnb5* knock-out mice to assess *Gnb5*-mediated signaling in the autonomic control of the heart. We monitored the electrophysiological properties of the heart in homozygous (KO, n=8), heterozygous (HET, n=8) and wild-type (WT, n=7) young-adult male mice using *in vivo* ECG (electrocardiography) telemetry. Cardiac function was assessed by two-dimensional and M-mode echocardiography. KO mice were smaller than WT and HET mice ( $p < 0.001$ ), and had a smaller heart ( $p < 0.05$ ), but exhibited a better cardiac function, as judged by an increase in fractional shortening and ejection fraction ( $p < 0.01$  as compared to WT mice). Surprisingly, HET mice also exhibited better function when compared to WT littermates. Moreover, baseline ECG parameters were not different between groups. However, KO mice treated with carbachol (CCh), a parasympathomimetic, presented significant CCh-induced bradycardia. In contrast, the anti-parasympathetic drug atropine had the same effect in KO, HET and WT mice. Altogether, our data demonstrate that *Gnb5* KO mice exhibit altered heart rate responses to pharmacological manipulations that were consistent with impaired parasympathetic activity, a result further corroborated by studies in zebrafish larvae, knocked-out for both *gnb5a* and *gnb5b* paralogs. We conclude that even a partial reduction in *Gnb5* function can perturb normal heart activity, and that *Gnb5* signaling is essential for its parasympathetic control.

**A Japanese patient with a novel missense mutation affecting the same amino acid as the recurrent *PACS1* mutation.** N. Miyake<sup>1</sup>, S. Ozasa<sup>2</sup>, H. Mabe<sup>2</sup>, S. Kimura<sup>3</sup>, N. Matsumoto<sup>1</sup>. 1) Yokohama City University, Yokohama, Japan; 2) Kumamoto University, Kumamoto, Japan; 3) Children's Sleep & Development Medical Research Center, Hyogo Prefectural Central Rehabilitation Hospital, Kobe, Japan.

*PACS1* (phosphofurin acidic cluster sorting protein 1, MIM\*607492) encodes PACS1 protein, which is a trans-Golgi-membrane traffic regulator. *PACS1* is highly expressed in human fetal brain and widely in various tissues. A single unique missense mutation in *PACS1* (NM\_018026.3:c.607C>T, p.Arg203Trp) is known to cause Schuurs-Hoeijmakers syndrome (MIM#615009), characterized by intellectual disability (severely affected language development), characteristic face (arched eyebrows, widely-spaced eyes, wide mouth with downturned corners, and thin upper vermilion), oral aversion, seizures, and brain structural abnormalities. To date, at least 31 patients with *PACS1* mutation have been reported. Interestingly, all had the identical missense mutation (c.607C>T, p.Arg203Trp) occurring *de novo*. By trio-based whole exome sequencing, we analyzed a girl showing developmental delay, short stature, growth impairment, hypotonia, microcephaly and characteristic dysmorphic face, and identified a different *PACS1* mutation at the same amino residue (c.608G>A, p.Arg203Gln) only in the proband. We confirmed this variant occurred *de novo*. This amino acid is located very close to the functionally important CK-binding motif (Arg196 to Tyr200), implying that Arg203 is functionally important. In addition, our patient showed similar clinical features to those observed in the patients with the recurrent mutation, further supporting the prediction that the novel variant (c.608G>A, p.Arg203Gln) is also pathogenic. A previous report suggests that the recurrent *PACS1* mutation is likely to have dominant-negative or gain-of-function effects. Generally hotspot mutations strongly suggest "gain-of-function". In addition, at least five variants leading *PACS1* truncation have been registered in public control database, suggesting that these loss-of-function *PACS1* variants may result in no phenotype or different phenotype effects from those seen in Schuurs-Hoeijmakers syndrome. Since information on the mechanism by which *PACS1* mutation causes disease is still limited, further analysis of additional patients is required.

**1294T****Study of genetic defects in patients with malformations affecting digits.**

A. Rai<sup>1</sup>, P. Srivastava<sup>1</sup>, P. Sharma<sup>1</sup>, N. Gupta<sup>2</sup>, R.D. Puri<sup>3</sup>, S.J. Patil<sup>4</sup>, P. Ranganath<sup>5</sup>, K. Gowrishankar<sup>6</sup>, A. Dutta<sup>7</sup>, J.P. Soni<sup>8</sup>, S. Danda<sup>9</sup>, K. Mandal<sup>1</sup>, S.R. Phadke<sup>1</sup>. 1) Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India; 2) Division of Genetics, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, India; 3) Institute of Medical Genetics & Genomics, Sir Ganga Ram Hospital, New Delhi, India; 4) Department of Medical Genetics, Narayana Multispecialty Hospital, Bangalore, India; 5) Department of Medical Genetics, Nizam's Institute of Medical Genetics, Hyderabad, Telangana, India; 6) Kanchi Kamakoti CHILDS Trust Hospital, Chennai, India; 7) North Bengal Medical College & Hospital Sushrutnagar, Siliguri, India; 8) Dr. S.N. Medical College, Jodhpur, India; 9) Christian Medical College & Hospital, Vellore, India.

Malformations affecting digits are the most frequent congenital malformation in human occurring in about one in 1000 neonates. Polydactyly and oligodactyly indicates increase or decrease in the number of digits. Other anomalies affecting digits are camptodactyly, clinodactyly, brachydactyly and arachnodactyly. The anomalies of digits can be isolated or syndromic. Hundred cases with malformations affecting digits were studied for genetic etiologies using Sanger sequencing, cytogenetic microarray and exome sequencing. After detailed phenotyping cases with monogenic disorders with known causative genes, Sanger sequencing has been done. Cases of unknown etiology were subjected to chromosomal microarray and exome sequencing. For genes of monogenic disorders having more than 10 exons exome sequencing has been done. Sanger sequencing identified causative variants in 13 cases (9 were known and 4 were novel) out of 27 monogenic malformation cases affecting digits. These include *ECEL1*, *FGFR2*, *ROR2*, *PITX1*, *TP63* and *SOST1*, *NOG1* genes. Chromosomal microarray identified copy number variations in two cases out of 19 cases; 7q21.2-q22.1 deletion (7 MB) in a patient with split hand-split foot malformation and sensorineural hearing loss and 13q31.1 deletion (1.4 MB) in a patient with short 5<sup>th</sup> metacarpal and ptosis, genu valgum. By homozygosity mapping, two candidate genes were identified in a patient with Arthrogyrosis Renal Dysfunction and Cholestasis and in a patient with Ellis-van Creveld syndrome which was further subjected to exome sequencing due to its large genes. Samples for exome sequencing were outsourced which were sequenced using Nextera Rapid Capture Exome from Illumina and raw data were analysed for disease causing variations. Exome sequencing identified causative variants in 23 cases (10 were known and 13 were novel) out of total 59 cases. This study showing the efficacy of these three techniques in evaluating the genetic cause of limb malformation affecting digits. The mutation data was used for providing genetic counseling to the families. The mutation data was used for providing genetic counseling to the families. Exome sequencing data of 26 cases in whom the causative variants were not identified is being analysed for variants in novel genes.

**1295F****Mutation spectrum and phenotypic features of Asian patients with clinical suspicion of Noonan syndrome.** E.C. Tan, A.L. Koh, E.S. Tan, M.S. Brett, A.H.M. Lai, S.S. Jamuar, I. Ng. KK Women's & Children's Hospital, Singapore, Singapore.

The aims of this study were to identify the underlying mutations and characterize the phenotypic features of patients with clinical suspicion of Noonan syndrome from our population. The 17 subjects of Southeast Asian descent were identified from the hospital's Genetics clinics after assessment by the attending clinical geneticists. Next generation sequencing was performed with a custom-designed targeted gene panel using the HaloPlex™ Target Enrichment System and the MiSeq System. Complete data for all 17 patients was available for only eight features, of which short stature was the most common (71%), followed by pectus deformity (47%). Heterozygous missense mutations were found in 13 patients: eight in *PTPN11*, three in *SOS1*, and one each in *RIT1* and *KRAS*. All are previously reported mutations that have been identified in other patients with Noonan syndrome. Seven of these mutations were *de novo* while two were inherited. The inheritance of the identified mutations (all *PTPN11*) for the remaining four subjects was unknown as parental samples were not available. The two inherited mutations (one each for *PTPN11* and *SOS1*) were from parents who had some features of Noonan syndrome. Eleven of the 13 patients with identified mutations had low-set ears while 10 had short stature. Nine had cardiac defects, with pulmonary stenosis found in five patients. Four of the eight patients with *PTPN11* mutations had atrial septal defect. Only two had pulmonary stenosis which is reported to be common for *PTPN11* mutation carriers, while another two had hypertrophic cardiomyopathy, which is negatively associated with *PTPN11* mutations. Our study provides the mutation and phenotypic spectrum of Noonan syndrome from a new population group. Our diagnostic yield was 76.5% for a panel of 14 genes, similar to what others reported. While the mutation spectrum in our patients appeared to be similar to populations elsewhere, indicating that there are no population-specific hotspots; the clinical manifestations seemed to be heterogeneous. Our patients with the same mutations or affected gene did not have similar clinical phenotypes with each other or with what had been reported in other studies. Although the four patients who did not have a mutation identified had fewer clinical features, they might have mutations in genes that were not in the panel.

**1296W**

**Mouse model of Costello syndrome: Impaired hepatic energy homeostasis and resistance to high-fat diet induced obesity in mice with a heterozygous Hras G12S mutation.** D. Oba<sup>1,6</sup>, S. Inoue<sup>1</sup>, S. Miyagawa-Tomita<sup>2</sup>, Y. Nakashima<sup>3</sup>, T. Niihori<sup>4</sup>, S. Yamaguchi<sup>4</sup>, Y. Matsubara<sup>1,5</sup>, Y. Aoki<sup>1</sup>. 1) Medical Genetics, Tohoku university school of medicine, Sendai, Japan; 2) Veterinary Technology, Yamazaki gakuen University, Tokyo, Japan; 3) Pediatrics, Seirei Hamamatsu General Hospital, Shizuoka, Japan; 4) Pediatrics, Shimane University, Faculty of Medicine, Shimane, Japan; 5) National Center for Child Health and Development, Tokyo, Japan; 6) Medical Genetics, Saitama Children's Medical Center, Saitama, Japan.

Costello syndrome is a "RASopathy" that is characterized by hypertrophic cardiomyopathy, dysmorphic facial appearance, growth retardation, hypoglycemia and predisposition to malignancies. Our group identified that germline *HRAS* mutations cause Costello syndrome in 2005. Overview of *HRAS* mutations reported in Costello syndrome patients reveals that more than 80% of patients with Costello syndrome have a *HRAS* G12S mutation. Clinical manifestations, including hypoketotic hypoglycemia, increased resting energy expenditure and severe growth deficiency, suggest metabolic impairment in patients with Costello syndrome. Mouse models of Costello syndrome with a *HRAS* G12V mutation have been reported. However, mice with the most frequent G12S mutation have not been generated. In this study, to explore the mechanisms of energy reprogramming by the oncogenic *HRAS* mutation *in vivo*, we generated new knock-in mice expressing a heterozygous *Hras* G12S mutation (*Hras*<sup>G12S/+</sup>). *Hras*<sup>G12S/+</sup> exhibited dysmorphic facial features, including a round head and a shortened nasal bridge, cardiomegaly with cardiomyocyte hypertrophy and kidney anomalies. *Hras*<sup>G12S/+</sup> mice showed resistance to high-fat diet induced obesity with microvesicular hepatic steatosis. Under fasted conditions, hypoketosis and elevated blood levels of long-chain fatty acylcarnitines were observed. In addition, decreased hepatic gene expressions associated with mitochondrial fatty acid oxidation was observed in *Hras*<sup>G12S/+</sup> mice compared with wild type (*Hras*<sup>+/+</sup>) mice. We also examined an intraperitoneal glucose tolerance test (IPGTT) and gene expressions related to glucose, organic acid and glutamine metabolism in liver tissues. These findings suggest the altered energy homeostasis, including impaired mitochondrial fatty acid oxidation, in *Hras*<sup>G12S/+</sup> mice. Further analysis showed elevated fecal lipid levels in *Hras*<sup>G12S/+</sup> mice compared with *Hras*<sup>+/+</sup> mice under fed a high-fat diet, suggesting impaired lipid absorption in *Hras*<sup>G12S/+</sup> mice. Our findings suggest that altered energy homeostasis as well as fat malabsorption would be associated with the lean phenotype in *Hras*<sup>G12S/+</sup> mice during high-fat diet feeding..

**1297T**

**Mutation spectrum and clinical manifestations in low-mosaic patients with Tuberous Sclerosis Complex (TSC).** K. Giannikou<sup>1</sup>, K. Lasseter<sup>1</sup>, J.M. Grevelink<sup>2</sup>, M.E. Tyburczy<sup>3</sup>, K.A. Dies<sup>3</sup>, J. Glass<sup>4</sup>, L. Hamieh<sup>1</sup>, A. Thorne<sup>5</sup>, A. Nag<sup>6</sup>, D. Krueger<sup>6</sup>, S. Ruoss<sup>7</sup>, D.N. Franz<sup>8</sup>, E.A. Thiele<sup>9</sup>, M. Sahin<sup>3</sup>, D.J. Kwiatkowski<sup>1</sup>. 1) Division of Pulmonary and Critical Care Medicine and of Genetics, Brigham and Women's Hospital and Harvard Medical School, Boston, Massachusetts, United States of America; 2) Boston Dermatology and Laser Center, Massachusetts General Hospital, Boston, United States of America; 3) Department of Neurology, Boston Children's Hospital and Harvard Medical School, Massachusetts, Boston, United States of America; 4) Department of Human Genetics, Cincinnati Children's Hospital Medical Center, Cincinnati, Ohio, United States of America; 5) Center for Cancer Genome Discovery, Dana Farber Cancer Institute, Boston, Massachusetts, United States of America; 6) Department of Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, Ohio, United States of America; 7) Pulmonary and Critical Care Medicine, Stanford University, California, United States of America; 8) Department of Neurology, Massachusetts General Hospital, Boston and Harvard Medical School, Massachusetts, United States of America.

**Background:** Tuberous Sclerosis Complex (TSC) is due to mutations in *TSC1/TSC2*. Mosaicism is well-known in TSC, and has been associated with milder symptoms. The prevalence of mosaicism in different organ systems and tissues in TSC has not been studied in detail. **Aim:** To define the mutation prevalence in multiple tissues from TSC patients with low allele frequency mosaicism, and to correlate the degree of mosaicism in various tissues/cell types with clinical features. **Material and methods:** 34 TSC patients (12 male, 22 female; 3 familial cases; median age 25 yrs) who contacted our lab for genetic analysis, and had <10% mutant allele frequency [MAF] in *TSC1/TSC2* in DNA from blood, saliva, or/and skin lesions are reported. 176 different DNA samples from these 34 patients were analyzed, including normal skin, skin lesions (e.g. angiofibroma, unguinal fibroma), cultured cells (melanocytes, keratinocytes, fibroblasts), blood, saliva, urine and semen. Mosaic mutations were identified by targeted MPS (Illumina) performed on >1 skin lesion per patient and use of custom code in Unix/Python/Matlab with mean target coverage of 660 reads. All mutations identified were validated by amplicon NGS in all patient samples. **Results:** The mosaic patients all met diagnostic criteria for TSC. Facial angiofibroma (86%) and renal angiomyolipoma (61%) were common, while autism/intellectual disability (21%) and LAM (8%) were uncommon in comparison to other TSC series (e.g. full heterozygous pediatric cases from Dabora *et al.*, AJHG 2001). Three patients (9%) had *TSC1* germline mutations and 31 (91%) had *TSC2* mutations; 8 of them had a second *TSC2* somatic hit seen only in skin lesions. Saliva and normal skin DNA MAFs were generally similar to blood DNA. However, skin lesion MAFs were significantly (>3-fold) higher than blood DNA for 22 of 23 cases, with 6 showing zero MAF in blood DNA. Two women with MAF 0.2% and 5.9% in blood DNA had a child with TSC. Three mildly affected men with MAF 0%, 1.4%, and 6.9% in blood had no evidence of the mutation in two different semen samples analyzed, while two men had a *TSC2* mutation in semen (MAF 2.6%-16.7%) with blood MAFs of 2.3% and 3.9%, respectively. **Conclusions:** TSC due to low-level (<10% MAF) mosaicism has a distinctive clinical appearance. Analysis of TSC skin lesions as well as multiple samples enhances mutation detection and can clarify first vs. second hit mutations. Transmission risk can be assessed through analysis of sperm DNA in mosaic TSC men.

**1298F****Phenotypic and mutational spectrum of twenty-six Egyptian patients with Sjögren-Larsson syndrome: Identification of novel and founder *ALDH3A2* gene mutations.**

*M.S. Abdel-Hamid<sup>1</sup>, M.Y. Issa<sup>2</sup>, G.M.H. Abdel-Salam<sup>2</sup>, S.F. Abdel-Ghafar<sup>1</sup>, M.S. Zaki<sup>2</sup>.* 1) Medical Molecular Genetics, National Research Centre, Giza, Cairo, Egypt; 2) Clinical Genetics, National Research Centre, Giza, Cairo, Egypt.

Sjögren-Larsson syndrome (SLS) is a rare neurocutaneous recessive disorder characterized by congenital ichthyosis, spastic diplegia and intellectual disability. It is an inborn error of lipid metabolism caused by recessive mutations in the *ALDH3A2* gene encoding the fatty aldehyde dehydrogenase that play a pivotal role in metabolism of long-chain aliphatic aldehydes and alcohols. In this report, we describe the clinical, neuroradiological and molecular findings of 26 patients derived from 19 unrelated Egyptian families with SLS. All patient shared the typical clinical characteristics of SLS including spasticity, ichthyosis and intellectual disability. Brain MRI showed deep white matter affection as demyelination in all patients varied in severity and found to correlate well with the severity of the presentation. Mutational analysis of the *ALDH3A2* gene revealed 11 distinct pathogenic mutations including 7 previously unreported ones. The mutations identified were 6 missense, 2 splice site, 1 nonsense, 1 inframe deletion and a large intragenic deletion of exon 1. Three mutations (p.S365L, p.R9\* and p.G400R) were recurrent in our patients with frequencies ranging from 16% to 26%. Interestingly, patients carrying the two mutations p.S365L and p.R9\* shared similar haplotypes suggesting possible founder effects in our population. In conclusion, [MP1] we presented a large cohort of patients with the characteristic clinical and brain imaging findings of SLS but with variable severity. We also identified many novel and founder *ALDH3A2* mutations thus expanding the mutational spectrum of the disorder. .

**1299W****Identification of new sequence variants in rare-genetic disease-causing genes using high-throughput DNA sequencing.**

*M.C. Ergoren<sup>1,8</sup>, E. Manara<sup>2</sup>, K. Terali<sup>3</sup>, S. Paolacci<sup>2</sup>, P. Enrico<sup>4</sup>, B. Sanlidag<sup>5</sup>, E. Dirik<sup>6</sup>, G. Mocan<sup>6</sup>, S. Bertelli<sup>8</sup>.* 1) Medical Biology, Near East University, Faculty of Medicine, Nicosia, Cyprus; 2) MAGI Euregio, Bolzano, Italy; 3) Medical Biochemistry, Near East University, Faculty of Medicine, Nicosia, Cyprus; 4) MAGI'S LAB, Rovereto, Italy; 5) Pediatrics, Near East University, Faculty of Medicine, Nicosia, Cyprus; 6) Medical Pathology, Near East University, Faculty of Medicine, Nicosia, Cyprus; 7) Medica Genetics, Uludag University, Faculty of Medicine, Bursa, Turkey; 8) Experimental Health Sciences Research Center (DESAM), Near East University, Nicosia, Cyprus.

The Human Genome Project was accomplished in draft form in 2001. In the last two decades, approximately 50% of genes causing 7,000 rare monogenic disorders, which are often difficult to diagnose based only on symptoms, have been identified. More than 50% of individuals with rare genetic disorders are yet to be diagnosed and treated in order to improve their quality of life. Generally, suggestive clinical features can be used to distinguish one condition from another; however, in some cases these clinical features overlap with a number of other genetic conditions. In our current study, the recent high-throughput genomic technology, which involves whole-exome sequencing (WES), was used to detect rare-genetic disease-causing variants and proved itself as a successful strategy for gene identification. Here, WES was used to sequence trios as well as larger pedigrees. An in-house bioinformatics pipeline was also employed to select pathogenic variants. Accordingly, we identified novel genetic variants each of which causes neonatal progeroid (Wiedemann–Rautenstrauch) syndrome, Treachers–Collins syndrome, or Joubert syndrome. The translational effects of these variants were predicted by *in silico* molecular modelling. Our study highlights the importance of discovering rare-disease-causing variants both in clinical diagnosis and in improved understanding of the underlying molecular mechanisms.

**Short rib polydactyly with Joubert syndrome associated with a novel KIAA0753 mutation: Expanding the phenotype of skeletal ciliopathies.** S. Albanyan<sup>1</sup>, A. Hammarsjö<sup>2,3</sup>, G. Grigelioniene<sup>2,3</sup>, S. Blaser<sup>1</sup>, K. Millar<sup>1</sup>, S. Telesca<sup>4</sup>, D. Chitayat<sup>1,4</sup>. 1) The Hospital for Sick Children, Toronto, ON, Canada; 2) Department of Molecular Medicine and Surgery, Center for Molecular Medicine, Karolinska Institutet, Stockholm, Sweden; 3) Department of Molecular Medicine and Surgery, Center for Molecular Medicine, Karolinska Institutet, Stockholm, Sweden and 3) Clinical Genetics, Karolinska University Hospital, Stockholm, Sweden; 4) Dept. of Obstetrics and Gynecology, The Prenatal Diagnosis and Medical Genetics Program; University of Toronto, Toronto, Ontario, Canada.

Skeletal ciliopathies are a rare group of diseases with significant genetic heterogeneity and phenotypic overlap. The main features of skeletal ciliopathies include thoracic hypoplasia, short tubular bones with metaphyseal dysplasia, trident pelvis and polydactyly. Extra skeletal manifestations include abnormalities of the brain, retina, genitalia, kidney, and liver. To date, at least 30 genes have been identified in association with skeletal ciliopathies. Mutations in KIAA0753 have recently been reported in association with, orofacioidigital syndrome (OFD), Joubert syndrome (JBTS) with growth hormone deficiency, short rib thoracic dysplasia in combination with Joubert syndrome (JBTS). We report a biallelic, pathogenic variant in KIAA0753 in female siblings born to a consanguineous couple. Both had short-rib polydactyly and molar tooth brain sign. Both the first and second sibling died shortly after birth of respiratory failure. Physical exam on the first child revealed macrocephaly, wide fontanelles, frontal bossing, micrognathia, low-set ears, small nose with a broad nasal bridge, short and bowed limbs, and brachydactyly. Fetal radiography showed narrow thorax, trident ilia with spikes at the sacroscliac notches and short bowed humeri, femora, tibiae, radii and ulnae. ArrayCGH was normal female and showed loss of heterozygosity of many segments. The second sibling was conceived naturally two years later and ultrasound done at 20 weeks gestation showed mild ventriculomegaly, abnormal 4th ventricle, abnormal cerebellar vermis and short tubular bones and a bell shaped chest. Fetal MRI at 22 weeks gestation showed mild ventriculomegaly and molar tooth abnormality. Examination after delivery showed prominent forehead, short limbs and right postaxial polydactyly. Skeletal survey showed short ribs with metaphyseal flaring, handlebar clavicles, hypoplastic lower pelvis and polydactyly. Brain MRI showed multiple congenital abnormalities in the posterior fossa, and a "molar tooth" appearance of the midbrain, consistent with Joubert syndrome. In summary, our results alongside clinical data from 8 previously reported patients indicate that KIAA0753-related ciliopathy syndrome constitutes a phenotypic continuum from lethal skeletal dysplasia, with severe thoracic hypoplasia, bowed limbs, and JBTS features at the severe end, to non-lethal metaphyseal skeletal dysplasia with mild thoracic hypoplasia, JBTS and OFD at the mildest phenotypic end of the spectrum.

**1301F**

**Characterization of an emerging X-linked trichothiodystrophy due to a novel truncating variant in RNF113A.** D.T. Belefrod<sup>1</sup>, A. Abu-El-Haija<sup>1</sup>, P.M. Martin<sup>2</sup>, S. Rego<sup>1</sup>, A. Huang<sup>3</sup>, G. Capodanno<sup>3</sup>, J.T. Shieh<sup>1,2</sup>, J. Van Ziffle<sup>2</sup>, N. Risch<sup>2</sup>, A. Slavotinek<sup>1</sup>, B. Mendelsohn<sup>1</sup>. 1) Division of Medical Genetics, University of California, San Francisco, San Francisco, CA; 2) Institute for Human Genetics, University of California, San Francisco, San Francisco, CA; 3) Division of Pediatric Endocrinology, University of California, San Francisco, San Francisco, CA.

Trichothiodystrophy (TTD) is an emerging group of heterogeneous conditions characterized by short stature, photosensitivity, seizures, immune deficiency, endocrinopathies, intellectual disability (ID), and brittle, sulfur-deficient hair with "tiger-tail" banding pattern on polarizing light microscopy. Corbett *et al.* 2015 described the first X-linked TTD caused by a nonsense mutation in *RNF113A*. We now contribute to the phenotypic spectrum of this rare, X-linked TTD by providing a detailed characterization of a ten year old boy with non-photosensitive TTD due to a previously-unreported truncating variant in *RNF113A*. The patient presented in status epilepticus with a history of refractory seizures, transient neonatal hyperinsulinism, failure to thrive with G-tube dependence, duodenal strictures, hypergonadotropic hypogonadism, and global developmental delay. OFC, weight, and height were 2 SD below the mean for age. He had facial differences and 2-3 toe syndactyly. His hair was sparse and brittle and his skin showed diffuse cutis marmorata without ichthyosis. He also had bilateral undescended testes and a small phallus with elevated gonadotropins and was hypogammaglobulinemic and lymphopenic with multiple infections. Clinical whole exome sequencing was performed as a duo (proband and mother) as part of the Prenatal and Pediatric Genomic Sequencing Program (P3EGS) at UCSF and showed a maternally inherited hemizygous truncating variant in *RNF113A*, c.903\_910delGAGACCA (p.Gln302fs\*12). Brain MRI showed diffuse dysmorphology. Hair banding pattern on polarized light microscopy was nondiagnostic. Maternal X-inactivation studies showed skewed X-inactivation with a ratio of 100:0. Ours is the first report of a non-familial X-linked TTD caused by a novel truncating *RNF113A* variant. A single prior report described two male first cousins with microcephaly, ID, sparse brittle hair, facial differences, seizures, frequent infections, brain dysmorphology, and variable endocrinopathies including severe growth failure, central adrenal insufficiency, diabetes insipidus, and gonadal dysgenesis with microphallus. While the duodenal strictures seen in our patient were not reported, other structural GI differences were described. Interestingly, our patient's mother had short stature and 100% skewed X-inactivation as seen in other obligate female carriers. However, further studies are ongoing and are essential in characterizing the full phenotypic spectrum of this condition.

Craniofrontonasal syndrome (CFNS) is an X-linked disorder caused by *EFNB1* mutations, in which females are more severely affected than males. Severe male phenotypes are associated with mosaicism, supporting cellular interference for sex bias in this disease. Although many variants have been found in the coding region of *EFNB1*, just two pathogenic variants have been identified in a same nucleotide in 5' UTR, disrupting the stop codon of an upstream open reading frame (uORF). uORFs are known to be part of a wide range of post-transcriptional regulation processes and only recently has their association with human diseases come to light. In the present study, we analyzed *EFNB1* in a female patient with typical features of CFNS. We identified a variant, located at c.-411, creating a new upstream ATG (uATG) in the 5'UTR of *EFNB1*, which is predicted to alter an existing uORF. Dual-luciferase reporter assays showed significant reduction in protein translation, but no difference in the mRNA levels. Our study demonstrates, for the first time, the regulatory impact of uATG creation on *EFNB1* levels and suggests that this region should be target in molecular diagnosis of CFNS cases without pathogenic variants in the coding and splice sites regions of *EFNB1*.

**Argininosuccinic aciduria in Korean population: Its low prevalence among the Urea cycle disorders.** G. Kim<sup>1</sup>, D. Kim<sup>2</sup>, Y. Kim<sup>2</sup>, B. Lee<sup>1,2</sup>, H. Yoo<sup>1,2</sup>. 1) Medical Genetics & Genomics, Asan Medical Center, Seoul, Soouth Korea; 2) Department of Pediatrics, Asan Medical Center, University of Ulsan College of Medicine.

In Korea, more than 90% of newborns are screened for inborn metabolic disorders by tandem mass spectrometry as part of the newborn screening program. Urea cycle disorders (UCDs) are included in this screening. Argininosuccinic aciduria (ASA) may be suspected in newborns showing the elevation of citrulline in their screening. ASA is the is caused by an argininosuccinate lyase deficiency and is biochemically characterized by elevation of citrulline, argininosuccinic acid and arginine deficiency. Clinically, patients with ASA exhibit hyperammonemia and other characteristic features including hepatic fibrosis, hypertension, neurocognitive deficiencies, and trichorrhexis nodosa. In the current study, we retrospectively reviewed the clinical findings, biochemical profiles, and genotypic characteristics of five Korean patients with ASA, who showed typical phenotypes and biochemical findings of the disease. Molecular analysis of these patients revealed six novel ASL mutations. Of note, these five patients were the all patients identified in Korea over the two-decade period. ASA is the second most common inherited UCD in the USA and European countries (17%), whereas ASA was as rare as 5.1–5.6 % in Japan and 6.3% in Korea, making it the fourth most common UCD in these East Asian countries. Although there were no epidemiological surveys of UCDs, ASA is expected to be extremely rare in other East Asian countries, including China and Taiwan. In contrast, ASA was the most common UCD in Malaysia. These findings suggest that there are the ethnic differences in the prevalence rates of each UCD among various populations.

Harmatz<sup>14</sup>. 1) Enzyvant, Basel, Switzerland; 2) Children's National Medical Center, Washington, DC, USA; 3) Montreal Children's Hospital, Montreal, Canada; 4) Children's Hospital of Cordoba, Cordoba, Argentina; 5) Cukurova University Hospital, Adana, Turkey; 6) Karolinska University Hospital, Stockholm, Sweden; 7) Dokuz Eylul University Hospital, Izmir, Turkey; 8) Sir Ganga Ram Hospital, Delhi, India; 9) Cairo University Children's Hospital, Cairo, Egypt; 10) Istituto Giannina Gaslini, Genoa, Italy; 11) Hacettepe University Hospital, Ankara, Turkey; 12) University of Milan, Milan, Italy; 13) Enzyvant, Boston, USA; 14) UCSF Children's Hospital Oakland, Oakland, USA.

**Introduction:** Farber disease is a rare lysosomal storage disease caused by mutations in both alleles of the *ASAH1* gene. The resulting deficiency of the lysosomal enzyme acid ceramidase causes accumulation of the pro-inflammatory and pro-apoptotic sphingolipid ceramide. The resulting broad spectrum of symptoms and severity may delay diagnosis or lead to misdiagnosis. The study described here is the first comprehensive and systematic clinical study of the natural history of Farber disease and is currently ongoing. **Materials and methods:** The Observational and Cross-Sectional Cohort Study of the Natural History and Phenotypic Spectrum of Farber Disease (NCT03233841) was designed to collect data on demographics, clinical presentation and phenotype, and diagnostic history including enzyme activity and *ASAH1* mutations when available, using retrospective and prospective data on living patients diagnosed with Farber disease who have or have not undergone hematopoietic stem cell transplantation (HSCT), as well as medical history data on deceased patients. In addition, prospective clinical assessments will be used to assess the changes in symptoms over time. **Results:** Demographic data is available on 24 patients, including 12 living and 12 who are deceased. The ratio of females to males is 10/14. The average age of the living patients is 11.7 years, with ages ranging between 2 and 28 years. 9 living patients (75%) are below the age of 18 years, with an average age of 6 years. 8/12 (67%) of the living patients and 10/12 (83%) of the deceased patients were born in the last 10 years. Countries of birth of the patients able to be enrolled so far include Afghanistan, Argentina, Canada, Egypt, India, Iraq, Italy, Mexico, Sweden, Syria, Turkey, and the USA. **Conclusions:** From November 2017 through May 2018, 24 patients representing the full phenotypic spectrum of Farber disease, from rapidly progressive (severe), to slowly progressive (attenuated) have been enrolled from 12 centers in 7 countries. 75% of the living patients are under 18 years of age and 83% of the deceased patients were born in the last decade. Additional centers are expected to be enrolling patients over the coming months. The systematic analysis of this unique set of data will hopefully expand and deepen the understanding of acid ceramidase deficiency, as well as contribute to the information available for the evaluation of future potential therapies.

**Our genematcher data sharing experience: 10 days on average to confirm the pathogenicity of a candidate gene.** C. Thauvin-Robinet<sup>1,2,3,4</sup>, A.L. Bruehl<sup>1,2</sup>, A. Vitobello<sup>1,2</sup>, F. Tran Mau-Them<sup>1,2</sup>, S. Nambot<sup>1,2,3</sup>, V. Quéré<sup>1,2</sup>, P. Kuentz<sup>1</sup>, J. Thevenon<sup>1,3</sup>, M. Assoum<sup>1</sup>, S. Moutton<sup>1,3</sup>, N. Houcinat<sup>1,3,4</sup>, N. Jean-Marçais<sup>1,3</sup>, M. Lefebvre<sup>1,2</sup>, A.L. Mosca-Boydron<sup>1,2</sup>, P. Callier<sup>1,2</sup>, C. Philippe<sup>1,2</sup>, L. Faivre<sup>1,3</sup>. 1) UMR1231 GAD, Inserm - Université Bourgogne-Franche Comté, Dijon, France; 2) Unit for Innovation and Genomic Diagnosis of Rare Diseases, FHU-TRANSLAD, Dijon University Hospital, Dijon, France; 3) Centre of Reference for Rare Diseases: Development disorders and malformation syndromes, Genetics Department, FHU-TRANSLAD, Dijon University Hospital, Dijon, France; 4) Centre of Reference for Rare Diseases: Development disorders, Genetics Department, FHU-TRANSLAD, Dijon University Hospital, Dijon, France.

The number of rare diseases is assessed between 6,000 and 7,000, with more than 200 diseases newly described every year, assigned to known gene, novel genes, or without molecular basis. Therefore, the total number of rare genetic disease was predicted to be around 15,000. Whole-exome or -genome sequencing (WES/WGS) appears highly powerful to identify the molecular basis of heterogeneous conditions such as intellectual disability and/or multiple congenital anomalies (ID/MCA), particularly resistant to older approaches because of frequent *de novo* mutations. However, a large majority of results remain so non-conclusive, linked to the difficulty in recruiting an adequate number of affected individuals with ultra-rare conditions, the heterogeneous clinical spectrum, the uncertain functional impacts of variants and the small number of known genes involved in diseases (~3,500 genes). Data-sharing aims to facilitate recurrence in ultra-rare conditions by identifying additional patients carrying variants in the same gene, in order to draw definitive conclusions on their implication in the disease. Several web-based tools have been developed during the last years and grouped in MatchMaker Exchange. In this study, we report the experience of a regional center that has implemented WES as a first-line diagnostic test since 2013, and attached to a research lab devoted to gene identification, in using GeneMatcher during the last 2.5 years to share candidate genes that are not yet known as responsible of human disease. We have shared 70 candidate genes identified by WES performed in individuals affected by ID/MCA. We evaluated the ability to determine the involvement of these genes and the necessary timeframe: 60/70 genes (85%) were matched to at least one other mutated individual. Data-sharing permitted to confirm the implication of 24/70 genes (39%) in ID/MCA and to rule out 6% of genes. The waiting period between submission and the first match varied, with an overall median of 4 hours. When a match occurred, the median response time between the first email to contact a submitter and the response was estimated at 31 hours. The rapid identification of these new genes remained essential for clinical characterization, genetic counselling and for translation to the diagnostic field. The introduction of friendly genematching tools, such as GeneMatcher, appeared therefore an essential step for the rapid identification of new genes responsible for ID/MCA.

**1306T**

**Two novel FOXC2 gene mutations result in autosomal domain hereditary distichiasis in Chinese families.** L. Jiang, D. Luo, R. Zheng. University of Electronic Science and Technology of China, Chengdu, Sichuan, China.

Distichiasis presents as double rows of eyelashes arising from aberrant differentiation of the meibomian glands of the eyelids, and it may be sporadic or hereditary. *FOXC2* gene mutations in hereditary distichiasis are rarely reported. Here, we examined two unrelated Chinese families with hereditary distichiasis but without lymphedema or other features of LD syndrome. The *FOXC2* gene was amplified and sequenced in all family members. Clinical examinations showed distichiasis, lower eyelid ectropion, congenital ptosis and photophobia in all affected individuals. Sequence analysis revealed two different frameshift mutations respectively, one is c.936 dup CGCCGCC and the other is c.937dupGCCGCT, in the coding region of the *FOXC2* gene. Although the two novel mutations inset different number of bases in different position, caused the same protein truncation (p.Tyr313CysfsX 464). These novel mutations are the first report of a *FOXC2* mutation in hereditary distichiasis in the Chinese population. This novel frameshift mutation causing distichiasis not only expands the germline mutation spectrum of the *FOXC2* gene in the Chinese population, but also increases the understanding of the phenotypic and genotypic correlations of *FOXC2*, and may potentially lead to improved genetic counseling and specific treatment for families with *FOXC2* in the future.

**1307F**

**Retrospective examination of the clinical utility of clinical whole genome sequencing in the Illumina iHope program.** A. Malhotra<sup>1</sup>, C.M. Brown<sup>1</sup>, J. McEachern<sup>1</sup>, K. Robinson<sup>1</sup>, D. Henry<sup>2</sup>, F. Sirchia<sup>3</sup>, J.C. Ward<sup>4</sup>, D.R. Bentley<sup>1</sup>, J.W. Belmont<sup>1</sup>, D.L. Perry<sup>1</sup>, R.J. Taft<sup>1</sup>. 1) Illumina, Inc, San Diego, CA; 2) Pediatrics, University of California, San Francisco, CA; 3) Città della Salute e della Scienza University Hospital, Medical Genetics Unit, Turin, 10126, Italy; 4) Division of Genetics, Department of Pediatrics at UTHSC, Memphis, TN.

Clinical whole genome sequencing (cWGS) can detect multiple variants types including single nucleotide variants, small insertions and deletions, copy number variants, and mitochondrial variants in a single test. This approach has only been recently implemented for clinical use therefore data evaluating the impact of cWGS on patient care is limited. To investigate the clinical utility of cWGS, surveys were administered to the ordering providers for 77 probands enrolled in the Illumina iHope program, a philanthropic initiative that aims to provide cWGS to patients with rare and undiagnosed disorders who have limited access to genomic testing. The ordering providers were asked questions related to change in management as a result of the cWGS results. To date, 59 responses have been received, which includes 36 probands with at least one reported variant with potential clinical implications. Of these 36 cases with a genetic finding, 29 (80%) reported that cWGS provided a new diagnosis which was not previously suspected. In addition, the survey results indicated that cWGS resulted in a change in medical management for 24 (66%) cases. The most frequently reported change in management was the implementation of condition-specific supportive interventions, for example, additional testing and therapies including speech, physical and occupational therapy, renal imaging, hearing tests, and echocardiograms. Additionally, in one case, cWGS allowed the proband to subsequently be placed on a kidney transplant list, while in another case, monitoring for Wilms tumor through periodic ultrasounds has been implemented for a child diagnosed with Bohring-Opitz syndrome. Testing also had implications for additional family members in some cases, for example a maternally inherited X-linked likely pathogenic variant resulted in a recommendation to screen maternal family members. Of the 36 responses where a variant was detected, suspected diagnoses were ruled out in five probands, and four additional responses specifically noted that the results of cWGS resulted in avoidance of future unnecessary testing since the molecular diagnosis explained the proband's phenotype. In summary, the results of this study support that cWGS may be beneficial for individuals with diverse clinical presentations.

**1308W**

**Homozygosity stretches around homozygous mutations for autosomal recessive disorders in patients from non – consanguineous families from India: Inheritance by descent is common.** S.R. Phadke, P. Srivastava, P. Sharma, A. Rai, S. Masih. Dept of Medical Genetics, Sanjay Gandhi PGIMS, Lucknow, Uttar Pradesh, India.

In India the custom of marriages amongst caste groups has been followed for ages. We have seen that for many rare autosomal recessive (AR) disorders, the affected individuals are homozygous for rare disease causing pathogenic variations, suggesting effects of inbreeding. Hence we analysed the exome sequencing data of cases with pathogenic/likely pathogenic sequence variations for autosomal recessive disorders for the homozygous regions around the causative sequence variations. All 24 cases with AR disorders from consanguineous families were homozygous for the disease causing variations (12 out of 24 being novel variations) and had large (Average – 77.2 Mb, Range - 5 Mb to 271 Mb) stretches of homozygosity around the disease causing pathogenic or likely pathogenic variations. For AR disorders from non-consanguineous families, the disease causing variations were in homozygous form in 13 (9 being novel) out of 19 cases and 6 were compound heterozygous. In the cases with homozygous pathogenic variations from non-consanguineous families; there were stretches of homozygosity around the causative sequence variations (Average - 27.9 Mb, 0.6 Mb to 188 Mb). We also reviewed our data of SNP microarray of cases from 50 consanguineous and 50 nonconsanguineous families. In cases born to consanguineous parents the sizes of Regions of Homozygosity (ROH) regions were 28 Mb to 770 Mb (average 251.44 Mb i.e. 8.75 % of genome per case (range 0.97% to 26.78% of total genome). Though third degree consanguinity is the commonest, many families have consanguineous marriages in previous generations as well leading to homozygosity of more than 10% of the genome. In cases born to non-consanguineous parents, the sizes of runs of homozygosity regions varied from 3 Mb to 49 Mb (0.10 % to 1.7% of total genome; average 0.74%). Twenty six cases had runs of homozygosity stretching more than 5 Mb while 24 cases did not have any region of homozygosity more than 5 Mb. Though 52% cases had ROH regions more than 5 Mb only 8 of 26 had more than 1% genome with ROH (upto 1.7%). Long stretches of homozygosity around homozygous rare pathogenic variants supports the notion that the system of marriages between closed groups (castes) has many founder mutations and using the strategy of homozygosity by descent even in non-consanguineous families can be fruitful in identifying novel pathogenic variations and novel genes. .

**1309T**

**Novel structural variants originating in *F8* non-coding regions explain previously unresolved cases of severe hemophilia A.** M.M. Wheeler<sup>1</sup>, J.M. Johnson<sup>2,3</sup>, G.F. Pierce<sup>4</sup>, C. Watson<sup>5</sup>, B.A. Konkle<sup>2,6</sup>, D.A. Nickerson<sup>1</sup>, NHLBI Trans-Omics for Precision Medicine. 1) University of Washington, Seattle, WA; 2) Bloodworks NW, Seattle, WA, USA; 3) University of Washington, Department of Medicine, Seattle, WA, USA; 4) National Hemophilia Foundation, New York; 5) American Thrombosis and Hemostasis Network, Chicago, IL; 6) Division of Hematology, University of Washington, Seattle, WA, USA.

Hemophilia A is an X-linked bleeding disorder resulting from deficiency in coagulation factor VIII. Numerous genetic variants (>2000) affecting the *F8* gene have been implicated as causative of hemophilia A. These include single nucleotide variants (SNVs), indels and structural variants (SVs) such as copy number variants and large intra-chromosomal inversions. For the vast majority of patients, causative variants are identified using targeted sequencing of *F8* coding regions or the use of methods which detect known SVs (e.g. inverse shifting PCR, long-range PCR, MLPA). However, these approaches fail to explain 1-3% of hemophilia A cases. In this study, we specifically performed analyses using whole genome sequence (WGS) data from 38 cases of hemophilia A that remained unexplained after exhausting available clinical testing methods. These cases were present in the My Life, Our Future hemophilia study recently sequenced by the NHLBI TOPMed program, and comprised mild (N=22), moderate (N=5) or severe (N=11) factor VIII level deficiencies. WGS analyses revealed several mild and moderate cases harbored *F8* deep intronic variants recently associated with hemophilia (N=8) and/or likely causal variants in the functionally-related *VWF* gene (N=11). In 6 severe hemophilia cases, analyses detected *F8* SVs strongly supported by WGS evidence (i.e. supported by multiple types of read evidence and multiple reads). Two deletions in intron 6 were detected in a single hemophilia case, a finding which suggests intron 6 may contain regulatory elements critical for *F8* expression. Moreover, three distinct large inversions were detected in five other cases: one case with a 720Kb inversion with breakpoints in *F8* intron 6 and *SPRY3* intron 1, one case with a 20Mb inversion with breakpoints in *F8* intron 1 and *INTS6L* intron 8, and three cases with a 7.4Kb inversion with breakpoints in *F8* intron 25 and the *SMIM9* intron 1. These SV events have not been previously reported in hemophilia and were also not present in the larger, sequenced My Life, Our Future dataset (N=2182), indicating these SVs are novel and likely causative of severe hemophilia A. Based on these analyses, our prediction is that additional deleterious SVs remain to be discovered in unexplained cases of severe hemophilia A. This work demonstrates comprehensive analyses that include detection of SVs and variants in non-coding region should be broadly applied to unexplained cases of Mendelian conditions.

**Illumina Clinical Services Laboratory contributions to the ClinVar and ClinGen knowledge bases.** S. Schmidt, A. Malhotra, A.J. Coffey, N.J. Burns, R. Rajkumar, K. Bluske, A. Chandrasekhar, A.R. Clause, F. Mullen, J. AVECILLA, M. Bennett, M. Rajan, D.R. Bentley, D.L. Perry, R.J. Taft. Illumina, Inc, San Diego, CA.

The human genetics community is increasingly reliant on public, centralized and vetted databases of information. ClinVar is a valuable resource of variants and their classifications, derived from clinical testing or evidence in the literature. In 2016, the Illumina Clinical Services Laboratory (ICSL) launched an ongoing program to provide systematic ClinVar donations and content updates. In 2017, ICSL launched a Gene Curation Programme that uses the ClinGen Gene Curation Framework to build a resource of curated gene-disease associations (GDAs). ClinVar submissions to date have been derived from variants interrogated as part of the Illumina TruGenome™ Predisposition Screen, a physician-ordered clinical whole genome sequencing (cWGS) test intended for generally healthy adults. Variants are interpreted using a classification scheme based on ACMG guidelines, but with an additional classification category, variant of unknown significance-suspicious (VUS-S). In addition to manual curation, the variant curation workflow utilizes an autocategorization algorithm that incorporates information about allele frequency, disease prevalence and penetrance estimates, and inheritance mode. Recently, 122,000 ICSL ClinVar entries were updated, including 40,000 classification changes. In addition, >10,000 new entries were submitted. A further submission of >50,000 variants derived from the predisposition screen is planned in 2018. Gene curation is a prerequisite for variant interpretation. ICSL's gene curation process includes investigation of disease mechanism and production of evidence summaries that describe both gene function and key phenotypic features of the associated disease. The current pipeline contains 194 genes including 147 GDAs for the ACMG 59 genes. To evaluate concordance, 16 GDAs previously curated by ClinGen were completed by ICSL. All curations were concordant with the clinical validity awarded. Forty-one GDAs previously curated by the BabySeq Project were also curated. Of the 41, 28 (68%) were fully concordant. Of the 13 discordant GDAs, ten classifications from the BabySeq Project were upgraded, with more evidence added to strengthen the association. ICSL's in-depth and rigorous curation methodology aims to provide high quality and accurate evidence-based classifications. The contributions made by ICSL will therefore help maximize the benefit of ClinVar and the ClinGen Knowledge Base for all users.

**Using UK Biobank to assess the pathogenicity, penetrance and expressivity of monogenic disease variants.** M.N. Weedon, B. West, M. Tuke, S. Jones, A.R. Wood, T. Laver, R.N. Beaumont, J. Tyrrell, A.T. Hattersley, T.M. Frayling, C.F. Wright. University of Exeter, Exeter, United Kingdom.

The UK Biobank (UKB) presents an excellent opportunity to assess the pathogenicity and penetrance of clinically important monogenic variants. However, this opportunity is thought to be limited because the genotyping quality of rare variants in the UKB is uncertain. Here we describe a systematic method for evaluating the analytical validity of rare variant genotypes from the UKB arrays, investigate the relationship between data quality and minor allele frequency (MAF), and evaluate the association of a subset of clinically-interesting, well-genotyped variants with relevant phenotypes in UKB. We evaluated the analytical validity of 4688 putatively clinically relevant variants using cluster intensity plots and classified 29% as being high quality. Minor allele frequency was an extremely good predictor of the likelihood of a variant being genotyped well by the UKB genotyping arrays: the false positive rate (FPR) was ~7% at MAF>0.00005, but FPR~60% at MAF>0.00001. All variants at MAF<0.000005 as being low quality. We then focused on variants with MAF>0.00001 that are good quality and have been reported as a cause of a monogenic disease in ClinVar or where variants in genes are known to cause two specific monogenic diseases: Maturity-Onset Diabetes of the Young (MODY) and developmental disorders. We assessed the frequency of these variants in the population and the association of the variants with 408 clinically relevant traits available in UKB. We identified several rare variants classified as pathogenic with substantially reduced penetrance or variable expressivity. For example, the P415A *PER3* variant that has been reported to cause familial advanced sleep phase syndrome is present at 0.5% frequency in the population and associated with only an 8 min ( $P=2 \times 10^{-14}$ ) advance in sleep timing. We also observed novel associations with relevant traits for heterozygous carriers of some rare recessive conditions, e.g. heterozygous carriers of the R799W *ERCC4* variant that causes Xeroderma pigmentosum have a 0.3SD ( $P=2 \times 10^{-8}$ ) increased ease of sunburning. Within our two disease subsets, we were able to refine the penetrance estimate for the R114W *HNF4A* variant in diabetes (only ~10% by age 40yrs), and refute the previous disease-association of *RNF135* indevelopmental disorders. In conclusion, this study shows the power of the UK Biobank to define the effect of rare variants, which will be much enhanced in future when genome-wide sequencing data become available.

**Explaining the unexplained with genetics: Patients with bronchiectasis have a higher frequency of pathogenic variants linked to the disease.** *J. Bastarache, G. Bernard, J. Denny, L. Bastarache.* Vanderbilt University Medical Center, Department of Medicine, Nashville, TN., USA.

**Background** Bronchiectasis can be caused by Mendelian diseases such as cystic fibrosis (CF) & primary ciliary dyskinesia (PCD), but most affected patients are not diagnosed with a genetic condition. We leveraged clinical & genetic data for 35,842 de-identified subjects to test the **hypothesis** that patients with unexplained bronchiectasis have a higher frequency of pathogenic alleles in genes linked to bronchiectasis compared to unaffected controls.

**Methods** We identified cases with bronchiectasis without a diagnosis of CF or PCD by manual review. Using ClinVar & OMIM we found 38 pathogenic variants that cause CF, PCD, or other diseases linked to bronchiectasis for which we had extant Exome BeadChip genotype data. We used regression analysis to compare the frequency of these variants among bronchiectasis cases (n=240) & controls (n=31,689) using a dominant model. We used a PheWAS to find additional phenotypes associated with bronchiectasis. **Results** 23 of 240 bronchiectasis cases (9.6%) carried a pathogenic allele, significantly more than unaffected controls. One individual was homozygous for a pathogenic *CFTR* mutation (p.Leu206Trp) & had a clinical syndrome consistent with CF. Two individuals were heterozygous for mutations in both *CFTR* & *SCNN1G*. The remaining 20 individuals were heterozygous a single pathogenic allele in *CFTR*, a PCD gene, or *SCNN1G*. Variants in *SCNN1G* were not significantly enriched on their own, consistent with the previously described digenic inheritance with *CFTR*. PheWAS of bronchiectasis cases revealed associations with CF- and PCD-related phenotypes, such as hypovolemia (p=1e-11; OR=3.3) & hearing loss (p=2e-8; OR=2.45). **Conclusions** Cases with clinically unexplained bronchiectasis are more likely to carry pathogenic alleles linked to bronchiectasis, and more likely to have additional phenotypes characteristic of CF or PCD. These results suggest our bronchiectasis cohort is enriched for patients with undiagnosed Mendelian disease. Given the limited variants on our genotyping platform, we cannot establish how many symptomatic heterozygotes carry a second pathogenic allele. With the advent of gene specific treatments for diseases like CF, identifying these patients in clinical practice may be important.

Associations results

**Noninvasive immunohistochemical diagnosis and novel MUC1 mutations causing autosomal dominant tubulo-interstitial kidney disease.** *M. Zivna<sup>1</sup>, K. Kidd<sup>2</sup>, A. Pristoupilova<sup>1</sup>, V. Baresova<sup>1</sup>, B. Blumenstiel<sup>3</sup>, M. Harden<sup>3</sup>, H. Hartmannova<sup>1</sup>, K. Hodanova<sup>1</sup>, V. Stranecky<sup>1</sup>, A. Vrbacka<sup>1</sup>, P. Vyletal<sup>1</sup>, L. Piherova<sup>1</sup>, J. Zivny<sup>4</sup>, H. Hulkova<sup>1,5</sup>, V. Robins<sup>6</sup>, O. Viklicky<sup>6</sup>, A. Greka<sup>3,7,8</sup>, A.J Bleyer<sup>1,2</sup>, S. Kmoch<sup>1,2</sup>.* 1) Research Unit for Rare Diseases, Department of Pediatrics and Adolescent Medicine, First Faculty of Medicine, Charles University, Prague, Czech Republic; 2) Section on Nephrology, Wake Forest School of Medicine, Winston-Salem, NC, USA; 3) Broad Institute of Harvard and MIT, Cambridge, Massachusetts, USA; 4) Institute of Pathophysiology, First Faculty of Medicine, Charles University, Prague, Czech Republic; 5) Institute of Pathology, First Faculty of Medicine, Charles University in Prague and General University Hospital, Prague, Czech Republic; 6) Nephrology Department, Institute for Clinical and Experimental Medicine, Prague, Czech Republic; 7) Brigham and Women's Hospital, Boston, MA; 8) Harvard Medical School, Boston, MA.

Autosomal dominant tubulo-interstitial kidney disease (ADTKD) encompasses a group of genetic disorders characterized by renal tubular and interstitial abnormalities, leading to slow progressive loss of kidney function requiring dialysis and kidney transplantation. This condition has been identified in almost 1000 families world-wide. Genetic studies revealed causal mutations in *UMOD*, *REN*, *MUC1* and *SEC61A1* encoding uromodulin, renin, mucin-1 and translocan subunit SEC61A, respectively. ADTKD-*MUC1* is caused by a cytosine duplication within a seven-cytosine tract in the GC rich variable number of tandem repeats (VNTR) region of the *MUC1* gene. This duplication produces a frameshift during translation, resulting in a new protein, MUC1fs. Cytosine duplication in VNTR of *MUC1* is the most frequent cause of ADTKD. Sequencing of GC rich VNTR of *MUC1* is extremely difficult. We performed MUC1fs immunostaining on urinary cell smears and various tissues in a group of positive and negative controls as well as in individuals from 37 ADTKD families that were negative for mutations in known ADTKD genes. Novel analytic methods were used to identify *MUC1* frameshift mutations. The sensitivity and specificity for MUC1fs immunostaining of urinary cell smears were 94.2% and 88.6%. Further genetic testing on 17 families with positive MUC1fs immunostaining revealed 6 families with 5 novel *MUC1* frameshift mutations that all predict production of the identical MUC1fs protein. We developed a noninvasive immunohistochemical method to detect MUC1fs in urinary cell smears that may be useful in the future for diagnostic testing after further validation. Production of the MUC1fs protein may be central to the pathogenesis of ADTKD-*MUC1*.

**1314W**

**Whole exome sequencing is essential for defining emerging phenotypes and providing diagnoses in underserved populations.** S. Rego, R. Gallagher, B. Mendelsohn, P-M. Martin, U. Hodoglugil, D. Belefrod, M. Sabbadini, J. van Ziffle, N. Risch, P-Y. Kwok, A.M. Slavotinek. University of California San Francisco, San Francisco, CA.

There are many barriers to health care, including genetic testing, in underserved and underrepresented minority (US/URM) patients, among them cost and lack of insurance coverage. However, genetic testing, including whole exome sequencing (WES), has great potential to provide diagnoses in US/URM patients and also contributes data that may help to better characterize variants that have not been previously described. Here we present three US/URM patients (as defined by type of insurance, self-identification with an ethnic/racial minority group, or residence in a medically underserved area) who had clinical WES as part of an NIH-funded project to study the utility of WES in US/URM populations. An 8 year-old female with intellectual disability (ID) presented with acute weakness and fatigue and creatine kinase levels suggestive of rhabdomyolysis. She had a history of an abnormal newborn screen with inconclusive follow-up testing. She had low T4 and no history of seizures. Her parents are consanguineous. WES showed homozygosity for p.Arg86\* in *TANGO2*—a newly identified cause of rhabdomyolysis, ID, seizures, abnormal thyroid studies and life-threatening cardiac arrhythmias. A 17 year-old female with a history of mild ID, hypotonia, macrocephaly, and supraventricular tachycardia was found to be heterozygous for the recurrent variant, p.Gln406\* in *MECP2*. This patient has a learning disability rather than classical Rett syndrome. X-inactivation studies were normal. A 10 year-old male born with cryptorchidism and micropenis had a clinical course including abnormal hair texture, neonatal hypoglycemia, refractory epilepsy, and failure to thrive. WES revealed a hemizygous variant, p.Gln302fs\*12, in *RNF113A*. This is the third patient described with a variant in *RNF113A* and establishes it as the cause of an emerging trichothiodystrophy syndrome. Two of the three genes (*RNF113A* and *TANGO2*) described above were either absent or uncommon on commercial gene panels, highlighting the need for WES in the diagnostic process. A third patient's results support a broader understanding of the phenotype for patients with *MECP2* variants. We conclude that all three patients required WES for a diagnosis due to the variable and emerging nature of many genetic syndromes, and that access to WES was the limiting factor in establishing a diagnosis. Such evidence is essential for acquiring insurance coverage in disadvantaged populations. .

**New strategies for analyzing exomes from patients with rare and unknown disorders.** K. Schmitz-Abe<sup>1,2,3</sup>, P. Agrawal<sup>1,2,3</sup>. 1) The Manton Center for Orphan Disease Research, Boston Children's Hospital, Boston, MA, USA; 2) Division of Newborn Medicine, Boston Children's Hospital, Boston, MA, USA; 3) Harvard Medical School, Boston, MA, USA.

The Gene Discovery Core (GDC) of The Manton Center for Orphan Disease Research at Boston Children's Hospital (BCH) has been enrolling families, mostly trios, with rare and unknown disorders for the last seven years. Of those enrolled patients, whole exome sequencing (WES) has been performed on 1738 individuals from 721 families without an initial clinical diagnosis. We aim to determine the genetic and molecular basis on those by re-analyzing the WES data. Reportedly, WES is able to determine the cause of disease in a third to half of the patients with genetic rare diseases. One of the reasons for the relatively low yield may be that we are missing important variants in the non-coding regions or copy number variants not detected by WES. Another important reason is the high number of rare coding pathogenic variants in candidate genes per family with scant information about them in the literature. This makes linking the genetic variant with phenotype extremely challenging, especially when we try to determine the functional effects using cellular or animal modeling. To overcome this issue, a) we re-processed the entire WES data using our own in-house bioinformatics and analysis pipeline (Variant Explorer Pipeline); b) we use 55 databases with important genetic discoveries to rank and filter variants (Roadmap, OMIM, Clinvar, MGI, PolyPhen-2, SIFT, Encode project, Roadmap, gnomG, etc); c) we use artificial neural network to optimize (weight) our inputs. The model was trained using reliable results of families with clinical diagnosis; and d) we sub-grouped the families with similar phenotypes and interrogate the data for candidate genes. Genes carrying mutations in several non-overlapping phenotypes were likely to be non-pathogenic and were removed from the candidate gene list. Using this approach, we have reduced the number of potential candidate genes by 73%. We are currently reviewing the reanalyzed data to determine the true candidates that can go for the functional determination and Matchmaker stage. We highly recommended processing all WES data from patients using the same pipeline, use adequately all the important genetic information available online and compare the results within families with variable phenotype.

**Novel gene discovery through an undiagnosed disease program in East Asian.** C. Law, C. Lam. Department of Pathology, The University of Hong Kong, Hong Kong, China.

**Introduction:** We had encountered numerous undiagnosed diseases in Hong Kong over the past decades and the disease spectrum is heterogeneous. With the advance of next-generation sequencing (NGS) techniques, it is now within our reaches to solve these undiagnosed cases using Clinical Whole Exome Sequencing (CWES) and Clinical Whole Genome Sequencing (CWGS). In this regard, we set up the first Undiagnosed Diseases Program (UDP) in Hong Kong and aim to end the diagnostic odyssey for patients suffering from rare conditions. **Methodology:** Proband-only CWES/CWGS approach was performed after consent over 100 cases and the subsequent bioinformatics analysis was done using our in-house algorithm. The CWES/CWGS findings, together with the clinical, biochemical and radiological features of the patients were interpreted by Pathologists qualified in Genetics. **Results:** Majority of the cases were contributed by known disease genes. Of-noted, some "rare diseases" were actionable. In addition, we also discovered novel genes, for example, *AK9* in congenital myasthenic syndrome (CMS), *EBF3* in Moebius syndrome, *CDC25B* for a syndrome with cataract, dilated cardiomyopathy and multiple endocrinopathies (CDCME), and *TTC21A* for Joubert syndrome. **Conclusions:** We recommended a proband-only CWES/CWGS approach for patients with undiagnosed disease for more than 3 months. The clinical interpretation of CWES/CWGS is would require understanding in clinical medicine, laboratory medicine and genetics. Therefore, the interpretation and clinical reporting should be handled by experience and qualified persons in clinical genomics.

Betting<sup>7</sup>, T.K. Truong<sup>5</sup>, I.A. Holm<sup>2,5</sup>, P.B. Agrawal<sup>1,5</sup>, R.B. Parad<sup>2,8</sup>, K. Machini<sup>1,2,4</sup>, K.D. Christensen<sup>2,7</sup>, J. Krier<sup>2,7</sup>, J.L. Vassy<sup>2,7,9</sup>, O. Ceyhan-Birsoy<sup>1,10</sup>, A.H. Beggs<sup>2,5</sup>, H.L. Rehm<sup>1,2,3,4,11</sup>, R.C. Green<sup>1,2,3,7</sup>. 1) Partners HealthCare Personalized Medicine, Cambridge, MA; 2) Harvard Medical School, Boston, MA; 3) Broad Institute of MIT and Harvard, Cambridge, MA; 4) Pathology, Brigham and Women's Hospital, Boston, MA; 5) Division of Genetics and Genomics, The Manton Center for Orphan Disease Research, Boston Children's Hospital, Boston, MA; 6) Department of Neurology, Boston Children's Hospital, Boston, MA; 7) Department of Medicine, Brigham and Women's Hospital, Boston, MA; 8) Department of Newborn Medicine, Brigham and Women's Hospital, Boston, MA; 9) VA Boston Healthcare System, Boston, MA; 10) Department of Pathology, Memorial Sloan Kettering Cancer Center, New York, NY; 11) Center for Genomic Medicine, Massachusetts General Hospital, Boston, MA.

**Background** Identification and reporting of unanticipated findings from genome or exome sequencing (GS) is increasing, among both those who present with a suspected genetic condition and as a predispositional screen in apparently healthy individuals. Population analyses of the ACMG list of 59 genes (ACMG59, recommended as a minimum for secondary findings) reveal pathogenic or likely pathogenic (P/LP) variants in 1-3% of individuals. However, the implications of searching for unanticipated variants in disease-associated genes beyond the ACMG59 are less well understood. **Methods** In the MedSeq and BabySeq Projects, we analyzed ~5000 disease-associated genes to identify monogenic disease risk variants (MDR, defined as P/LP variants in genes associated with dominantly inherited monogenic disease or bi-allelic P/LP variants in genes associated with recessively inherited monogenic disease). Detailed phenotyping and family history analyses were conducted among those identified with MDRs through EHR review, questionnaires, clinical visits, and follow-up testing. **Results** GS was done on 269 individuals (110 adults and 159 infants), including 50 adults and 31 infants with a prior medical indication. Unanticipated MDRs were found in 16/110 (14.5%) adults and 18/159 newborns (11.3%), with 1 adult and 4 newborns having a finding in the ACMG59. Within the adult cohort, 4 MDRs (*EYA4*, *PPOX*, *RDH5*, *HFE*) prompted discovery of clinical features suggestive of a previously unrecognized genetic condition. Among the newborn cohort, 1 MDR (*ANKRD11*) provided an unsuspected molecular diagnosis for an observed phenotype, and 4 (*ELN*, *BTD*, *G6PD*, *GLMN*) prompted discovery of clinical features suggestive of a previously unrecognized genetic condition, including 3 with highly effective interventions. **Discussion** In this, the largest sample to date in which P/LP variants were extensively curated for the entire medical exome, unanticipated MDRs were discovered in 11-15% of individuals. Phenotyping of participants with MDRs revealed previously unrecognized but related clinical features in 9/34 (26.5%) of those in whom MDRs were detected. The remainder of those with MDRs in whom clinical features of the related condition were not seen may benefit from enhanced surveillance or have medical resources expended needlessly if they never develop the condition. Replication of these observations in larger sample sizes may inform the clinical advantage of broad screening in GS to reveal subclinical phenotypes.

**1318T**

**Mutations in the CFAP-coding genes lead to male infertility with multiple morphological abnormalities of the sperm flagella.** *W. Li, F. Zhang.* Obstetrics and Gynecology Hospital, State Key Laboratory of Genetic Engineering, Fudan University, Shanghai 200011, China.

**Background:** Sperm motility is vital to human reproduction. Malformations of sperm flagella can cause male infertility. Men with multiple morphological abnormalities of the flagella (MMAF) have abnormal spermatozoa with absent, short, coiled, bent and/or irregular-caliber flagella, which impair sperm motility. Genetic factors are involved in pathogenesis of MMAF. **Main Questions:** The known MMAF-associated genes are only responsible for approximately half of human cases. Novel pathogenic mechanisms still remain to be elucidated in MMAF. **Experimental Design:** We conducted genetic analyses using whole-exome sequencing and genome-wide comparative genomic hybridization microarrays in a multi-center cohort of 80 Chinese men affected by MMAF. Furthermore, the genome editing technology of CRISPR-Cas9 was employed to generate knockout mouse models for further functional investigations on our identified novel genes for MMAF. **Main Results:** Biallelic mutations in the genes encoding cilia and flagella associated proteins (CFAPs) were identified in 15 (19% out of 80) cases with MMAF, including seven in *CFAP43*, two in *CFAP44*, four in *CFAP65* and two in *CFAP69*. These CFAP-coding genes are specifically or preferentially expressed in testis. Knockout mouse models of these four genes manifest short, coiled flagella and other phenotypes consistent with human MMAF. **Conclusions:** Our experimental observations on human subjects and mouse models strongly suggest that biallelic mutations in *CFAP43*, *CFAP44*, *CFAP65* and *CFAP69* can cause sperm flagellar abnormalities and impair sperm motility.

**1319F**

**Expanded analysis of Lyso-Gb3 and Lyso-Gb3 analogs for the diagnosis of Fabry disease.** *M. Schultz, B. Netzel, D. Gavrilov, D. Matern, D. Oglesbee, S. Tortorelli, P. Rinaldo, K. Raymond.* Biochemical Genetics Laboratory, Department of Laboratory Medicine and Pathology Mayo Clinic, Rochester, MN 55905.

**Background:** Fabry disease (FD) is an X-linked lysosomal disorder caused by alpha galactosidase deficiency. We investigated the biomarker globotriaosylsphingosine (Lyso-Gb3) and related species (Lyso-Gb3 analogs) in a cohort of Fabry patients tested at the Mayo Clinic Biochemical Genetics Laboratory. Biomarkers can address challenges in the diagnosis of affected females with normal enzyme activity and in the interpretation of novel genetic variants. **Methods:** Lyso-Gb3 and eight analogs (mass differences -28, -12, -2, +14, +16, +18, +34, and +50amu) were measured by LC MS/MS from the serum of 59 FD patients (9 female, 50 male, 18 pediatric), and 214 normal control subjects (86, 128, 48). Patients were confirmed as having FD through enzyme testing and either mutation status, urine ceramide trihexosides, clinical presentation, or family history. **Results:** The median Lyso-Gb3 level in FD affected males was 64.05 ng/ml (1.49-113.82; 1<sup>st</sup>-99<sup>th</sup> percentile) and in FD females was 11.05 ng/ml (0.81-80.63; 1<sup>st</sup>-99<sup>th</sup> percentile); reference population was 0.38 ng/ml (0.16-0.73 ng/ml; 1<sup>st</sup> -99<sup>th</sup> percentile). No significant difference was noted between male and female Lyso-Gb3 levels in the non-FD, reference population. During analysis, several peaks were noted in the chromatogram for each analog mass. A total of 23 analogs were measured, (28(2), -12(3), -2(2), +14(4), +16(4), +18(3), +34(2), +50(3)) and analyzed. 22/23 analogs were elevated in all FD specimens, regardless of sex. Notably, in six patients with the p.A143T variant the Lyso-Gb3 analog values were slightly elevated, but in a pattern distinct from affected Fabry males. Three patients with the p.N215S late onset mutation had an elevated Lyso-Gb3 level and a pattern of analogs consistent with FD. **Conclusions:** In our cohort, the Lyso-Gb3 concentration and analog ratios clearly distinguished affected males and females from controls. This study adds to a body of work suggesting the Lyso-Gb3 biomarker can aid in the evaluation of genetic variants of unknown significance, especially in females where other biochemical testing can be normal.

### Identification of protein features associated with Mendelian disease

**variants.** S. Iqbal<sup>1,2</sup>, E. Perez-Palma<sup>3</sup>, J. Jespersen<sup>4,5</sup>, P. May<sup>6</sup>, H. Heyne<sup>1,2</sup>, K. Lage<sup>1,4</sup>, A. Palotie<sup>1,2,7</sup>, J. Cottrell<sup>1</sup>, F. Wagner<sup>1</sup>, M. Daly<sup>1,2,7</sup>, A. Campbell<sup>1</sup>, D. Lal<sup>1,2,3,8,9</sup>. 1) Stanley Center for Psychiatric Research, Broad Institute of MIT and Harvard, Cambridge, MA; 2) Analytic and Translational Genetics Unit, Massachusetts General Hospital, Boston, MA; 3) Cologne Center for Genomics, University of Cologne, Cologne, Germany; 4) Department of Surgery, Massachusetts General Hospital, Boston, MA, USA; 5) Department of Bio and Health Informatics, Technical University of Denmark, Lyngby, Denmark; 6) Luxembourg Centre for Systems Biomedicine, University of Luxembourg, Esch-sur-Alzette, Luxembourg; 7) Institute for Molecular Medicine Finland, University of Helsinki, Helsinki, Finland; 8) Epilepsy Center, Neurological Institute, Cleveland Clinic, Cleveland, USA; 9) Genomic Medicine Institute, Lerner Research Institute Cleveland Clinic, US.

For Mendelian Disorders, a single genetic variant can cause the phenotype. While the variant discovery is progressing fast, elucidating the molecular consequences of variants is still a slow process. Although each protein has a specific role in the organism, related proteins have similar functions; thus, are likely to share variant intolerant and functionally essential sites. We explore whether automated variant annotation by features derived from three-dimensional (3D) protein structures can identify protein-class-specific features associated with patient variants. This approach can advance our understanding of how a single variant changes the protein and leads to etiology of monogenic disorders. For 1,331 disease-associated genes (>80%, 1,078/1,331 annotated in OMIM), we collect missense variants from the general population (gnomAD database, N=164,915) and patients (ClinVar and HGMD databases, N=32,924), and *in silico* transfer the variants onto >15k human protein 3D structures using an in-house mapping framework. We annotate the protein positions of variants with >40 structure-based features. We then group the genes into 24 protein classes based on their molecular function and perform association analyses of the structural features to population and patient variants. Our analyses show that in general, patient variants are less exposed to solvent ( $p < 2.2 \times 10^{-16}$ ), perturb disulfide bonds ( $p < 2.2 \times 10^{-16}$ ), hit ligand binding sites ( $p = 1.5 \times 10^{-92}$ ), and stay at close proximity to phosphorylation sites ( $p < 2.2 \times 10^{-16}$ ). Besides finding the shared features, we test the association of patient variants to all the structural features for each protein class and use the association signature to study the similarity and divergence of variant pathogenicity across protein classes. We show that patient variants of nucleic acid binding and transcription factor proteins obtain similar properties; however, these properties are different than that of receptor proteins. Only in the class of signaling molecules, patient variants are enriched in amino acids of flexible structure ( $p = 8.0 \times 10^{-6}$ ), whereas the intra-protein hydrogen bond is specifically associated with variants in kinases ( $p < 2.2 \times 10^{-16}$ ). In summary, we study the shared and unique protein features associated with patient variants across 24 protein classes which provide novel biological and mechanistic insights. Our protein-class-specific features can be annotated at scale, and can guide variant classification and targeted drug development.

## 1321T

### Stratifying loss-of-function variants in genome sequencing cohort.

A.E. Katz<sup>1</sup>, X. Liu<sup>2</sup>, H. Shiferaw<sup>1</sup>, J. Dudley<sup>1</sup>, J.J. Johnston<sup>1</sup>, W.S.W. Wong<sup>2</sup>, J.E. Niederhuber<sup>2</sup>, L.G. Biesecker<sup>1</sup>, *The Genomic Ascertainment Cohort (TGAC)*. 1) National Human Genome Research Institute, NIH, Bethesda, MD; 2) Inova Translational Medicine Institute, Inova Health Systems, Falls Church, VA.

Predicted loss of function (pLOF) variants are common in human genomes and determining their effect, if any, on phenotype can be challenging. Individuals who have undergone genome sequencing and can participate in subsequent studies represent an opportunity to investigate the phenotypic spectrum associated with select pLOF variants. We sought to characterize the pLOF variants in a large dataset for the purpose of targeted clinical evaluation. We restricted our search to genes for which haploinsufficiency has plausible phenotypic consequence by examining the 3,230 genes for which ExAC data suggest evolutionary constraint with a loss of function intolerance (pLI) >0.9. In our genome sequenced cohort (N=3,817) of individuals unselected for any phenotype from Inova Translational Medicine Institute's Childhood Longitudinal Cohort Study, we queried these genes for nonsense, canonical splice site disrupting, and frameshift variants. A variant allele frequency cutoff of 0.005 in both gnomAD and our cohort was applied to remove common variants. The resulting 2,704 pLOF variants were stratified for known disease-gene association using NHGRI's Clinical Genomic Database. 491 variants were in genes associated with autosomal dominant, X-linked or autosomal recessive disease, 170 variants were in genes associated exclusively with autosomal recessive disease, and the remaining 2,043 variants were in genes with no known disease association. Among these 2,043 variants, we found 105 variants were located in exons present in every transcript of its gene (as defined by Gencode's comprehensive annotation) and 475 variants in at least 50% of that gene's transcripts. None of the 475 prioritized variants were found in a homozygous state. Our filtering strategy represents a computational method by which variants with plausible clinical manifestations can be identified without using phenotypic information. Because individuals in our cohort are eligible for downstream secondary studies, next steps include clinical evaluation of individuals carrying rare pLOF variants of interest. Variants in genes with no known disease association represent an opportunity for novel gene-phenotype correlation discovery. Thus, ascertainment of study participants by genotype can be used to guide clinical research aiming to broaden our understanding of the phenotypic consequence of genomic variation.

**Initiative on Rare and Undiagnosed Diseases in Pediatrics (IRUD-P) in Japan: Statistics of 1<sup>st</sup> stage for three years.** *Y. Matsubara<sup>1</sup>, K. Hata<sup>1</sup>, T. Kaname<sup>1</sup>, K. Kosaki<sup>2</sup>, IRUD-P consortium.* 1) Research Institute, National Center for Child Health and Development, Tokyo, Tokyo, Japan; 2) Center for Medical Genetics, Keio University School of Medicine, Tokyo, Japan.

The Initiative on Rare and Undiagnosed Diseases (IRUD) is a national consortium designed to help patients and their families suffering from rare and undiagnosed disease conditions in Japan. The project started in July 2015. The pediatric version of IRUD (IRUD-P) is coordinated by dual centers, the National Center for Child Health and Development (NCCHD) and Keio University. The IRUD-P developed a nation-wide network for patient recruitment involving 17 regional core clinical centers, and mainly performed whole exome sequencing on children with undiagnosed diseases and their parents. For three years, more than 3,500 patients, who passed the first screening in the core clinical centers, were consulted to the IRUD-P centers in total. Specimens accompanied with medical information (n=7,100) were collected from patients and their families, mainly in trios, and sent to the centers. In NCCHD, of 881 patients analyzed, genetically confirmed diagnosis in 330 patients (diagnostic yield was 37.5%). Of the confirmed patients, 18.6%, 76.5% and 3.5% were found in known gene with reported variants, known gene with novel variants, and novel genes, respectively. Patient cohort represents children with a wide range of undiagnosed disorders (malformation syndromes 37.4%, neuromuscular disorders 17.4%, skeletal and connective tissue diseases 8.7%, endocrine disorders 7.4%, cardiovascular diseases 7.4%, renal and/or liver diseases 6.4%, immunologic or hematologic disorders 3.0%, otolaryngologic/ophthalmologic diseases 1.5%, others 10.9%). For the next turn, IRUD-P has combined with adult version of IRUD and the consortium started disease model analysis for the remaining undiagnosed patients. The IRUD also built international collaboration and data sharing on rare and undiagnosed diseases.

**The Rare Genomes Project: Improving our ability to diagnose rare genetic conditions through a nationwide partnership with families.** *C.E. Williamson, A.H. O'Donnell-Luria, A. Kern Lovgren, M. O'Leary, E. England, L. Pais, Z.M. Valivullah, K.R. Chao, L. Xu, J.K. Goodrich, M.H. Wojcik, J. Chang, M. Getaneh, I. Ndon, G. VanNoy, K. Blakeslee, H. Snow, N. Lopez Zalba, S. Maiwald, E.O. Baker, J. Hendry, A. Zimmer, S. Baxter, B. Weisburd, D.G. MacArthur, H.L. Rehm.* Broad Center for Mendelian Genomics, Program in Medical and Population Genetics, Broad Institute of MIT and Harvard, Cambridge, MA.

A majority of patients in the US with a suspected rare genetic disease do not yet have a molecular genetic diagnosis. A diagnosis can have many medical implications including management strategies, prognoses, and family planning using preimplantation genetic diagnosis and, in rare instances, can even identify effective treatments. Many families reach the end of their clinical diagnostic odyssey without answers, typically after exome sequencing or when their insurance will not cover further genetic testing options. The Rare Genomes Project (RGP; raregenomes.org), launched in June 2017, is a direct-to-families research study leveraging online participation and partnerships with patient advocacy groups to dramatically increase the reach of rare disease genomic research by engaging families as stakeholders at each step. English-speaking families who live in the United States and have an undiagnosed suspected monogenic disease are eligible for the study. We enroll families by phone or video consent, mail kits for blood collection and perform whole genome sequencing followed by standard variant and structural variant analysis. Despite advances in electronic health medical systems, it is challenging to efficiently extract the pertinent information from medical records. In our pilot, we are focusing on patient- and family-provided medical information through surveys with linked Human Phenotype Ontology terminology. We describe results from our primary analysis where we are able to make accurate diagnoses based on participant-provided information, and these diagnoses are confirmed through secondary review of medical records. In cases where we identify the genetic cause of the participant's condition, we performed clinical (CLIA) validation in coordination with a current treating physician identified by the family and provide a genetic testing report to the participant and their doctor. A central goal of this project is broad data sharing, so sequence and phenotype data will be rapidly shared through the Broad's Data Use Oversight System (DUOS, duos.broadinstitute.org) and other means. Our goal is to provide a proof of principle of the value of a patient-engaged approach to diagnosis and gene discovery in rare disease while creating a shared genomic dataset of undiagnosed families to empower the rare disease community.

**1324T****Duarte galactosemia: Shedding new light on an old problem.** *J.L.*

*Fridovich-Keil<sup>1</sup>, G. Carlock<sup>1</sup>, S.T. Fischer<sup>1</sup>, M.E. Lynch<sup>2</sup>, N.L. Potter<sup>3</sup>, C.D. Coles<sup>2,4</sup>, M.P. Epstein<sup>1</sup>, J.G. Mulle<sup>1</sup>, J.A. Kable<sup>2</sup>.* 1) Department of Human Genetics, Emory University School of Medicine, Atlanta, GA; 2) Department of Psychiatry and Behavioral Sciences, Emory University School of Medicine, Atlanta, GA; 3) Department of Speech and Hearing Sciences, Washington State University, Spokane, WA; 4) Department of Pediatrics, Emory University School of Medicine, Atlanta GA.

Duarte galactosemia (DG) is a variant form of the potentially lethal disorder classic galactosemia (CG). For decades, infants with DG have been identified by newborn screening but there has been no uniform standard of care regarding diet. Specifically, it has been unknown (1) whether infants with DG experience increased risk of developmental complications later in childhood, and (2) whether milk exposure in infancy, which causes elevated galactose metabolites, is associated with outcome severity and therefore should be contraindicated. To address this question we conducted a study of infant diet and developmental outcomes of 206 children with DG and 144 unaffected sibling controls. We recruited children with DG and their siblings, ages 6-12, in 18 states where they were identified as newborns. Diet in infancy was ascertained by retrospective parent survey and diagnosis was confirmed by DNA testing. Child developmental outcomes were assessed directly by a team of trained professionals using established instruments. Following testing, data sets were divided randomly into independent discovery (n=87) and validation (n=263) cohorts for analysis. We tested a total of 73 outcome measures for possible association with DG status in the discovery set, and then tested the top 10 of these outcomes for possible association with DG status in the validation set. We also tested the top 10 outcomes from the discovery set for possible association with milk exposure in infancy among children with DG in the validation set. We found no significant associations in any of these tests. Our results demonstrate no significant difference in developmental outcomes tested between children with DG and controls, or among children with DG as a function of exposure to milk in infancy. This study provides a robust and long-needed foundation to empower evidence-based decisions by healthcare providers and families of newborns with Duarte galactosemia choosing what to feed their baby.

**Oligogenic obesity: An explanation for apparent variable penetrance of an *SH2B1* mutation.** *S. Almansoori<sup>1,2</sup>, Al. Blakemore<sup>1,2</sup>, N. Lessan<sup>3</sup>.* 1) Imperial College, London; 2) Brunel University London; 3) Imperial College London Diabetes Centre.

Obesity is a complex, heterogeneous disorder: including a number of monogenic or syndromic subtypes. Here, we present the case of a 22 year old man of South Asian origin, with a history of progressive weight gain starting in his mid-teens, coupled with poor school performance. He had generalised obesity (BMI 38.6 kg/m<sup>2</sup>) with profound hyperinsulinaemia and prominent acanthosis nigricans, but with normal blood pressure and no Cushingoid features. There was no family history of note. The proband was found to carry a mutation in *SH2B1*, C539T/p.S180F, which was predicted to be deleterious, with a CADD score of 23.6, and, at first considered likely to be causative. On investigation, however, the non-obese father was revealed to carry the same mutation, raising questions about penetrance. Examination of exome sequencing data from the proband revealed two further potentially causative mutations A3539T/p.D1180V in *MBO5* and C3022T/p.L1008F in *POGZ*. These variants are also predicted to be deleterious with CADD scores of 22.9 and 24.2, respectively. These findings suggest that an oligogenic inheritance model might be responsible for the phenotype. We urge caution in interpretation of sequencing results from individual genes which, in this case, could have given rise to inaccurate genetic counselling.

**1326W**

**Interallelic interactions in autosomal recessive disorders: A population-genetic and a molecular approach.** A. Miko<sup>1,2</sup>, A. Kaposi<sup>1</sup>, G. Schay<sup>1</sup>, E. Balogh<sup>1,2</sup>, D. Seidl<sup>1</sup>, K. Schnabel<sup>1</sup>, D.K. Menyhard<sup>3</sup>, K. Tory<sup>1,2</sup>. 1) MTA-SE Lendület Nephrogenetic Laboratory, Budapest, Hungary; 2) Semmelweis University, 1st Department of Pediatrics, Budapest, Hungary; 3) MTA-ELTE Protein Modeling Research Group, Budapest, Hungary; 4) Semmelweis University, Department of Biophysics and Radiation Biology, Budapest, Hungary.

We recently identified the first variant (*NPHS2*, R229Q), that is pathogenic only when trans-associated to specific mutations in an autosomal recessive (AR) disorder. We aimed to identify other incompletely penetrant variants (IPV), and to characterize the R229Q podocin. We collected clinical and genotype data from 9,109 Caucasian patients with biallelic HGMD mutations in 17 genes (*ASL*, *ATP7B*, *CAPN3*, *CFTR*, *CTNS*, *DHCR7*, *GAA*, *GALNS*, *GALT*, *IDUA*, *MUT*, *NPHS1*, *NPHS2*, *PAH*, *PKHD1*, *PMM2*, *SLC26A4*) from the medical literature. The penetrance of each pathogenic variant (n=2141) was calculated as its enrichment in the patient population vs. the general population as compared to that of the loss-of-function (LOF) mutations. Out of the 78 variants that were frequent enough to assess their penetrance, we found 23 (28%) to be incompletely penetrant, including the three known IPVs (*NPHS2* R229Q, *CFTR* R117H and L997F). Based on the associated phenotype, most of the IPVs are hypomorphic (16/22, 73% vs. 19/56, 34% of completely penetrant variants, p=0.002). Only the *NPHS2* R229Q variant was significantly associated to specific mutations in the patient population, indicating interallelic interaction as the cause of incomplete penetrance. In order to understand how R229Q makes prone podocin to be subject of a dominant negative effect, we compared the binding capacity of R229Q and wt podocin. Podocin variants with and without dominant negative effect (n=11 types) were transiently expressed in HEK293 cells, extracted, eluted and stained by either Alexa 488 and 555 maleimides. Podocin variants were mixed with wt and R229Q podocin to allow heterooligomer-formation and FRET was measured by fluorescence lifetime spectrometer. We found a significantly higher FRET efficiency in the R229Q (34% [30-36%], median [quartiles]) than in the wt heterooligomers (13% [4%-22%], p=0.01), indicating a higher binding capacity of R229Q podocin. The highest FRET efficiencies were found in the pathogenic R229Q heterooligomers (A284V, R291W, A297V). In conclusion, among the variants with a high allele frequency, we found 23 to be incompletely penetrant, but only one (R229Q) to be subject of interallelic interactions. We found an increased binding capacity of the R229Q podocin which can partially explain its intracellular retainment in the pathogenic associations. Supported by MTA-SE Lendület Research Grant (LP2015-11/2015), NKFI/OTKA K109718, K116305, KH125566 and MedinProt Synergy grant VII.

**Residual function of cystic fibrosis mutants predicts therapeutic response.** S.T. Han<sup>1</sup>, A. Rab<sup>2</sup>, M.J. Pellicore<sup>1</sup>, E.F. Davis<sup>1</sup>, A.F. McCague<sup>1</sup>, T.A. Evans<sup>1</sup>, A.T. Joynt<sup>1</sup>, Z. Lu<sup>1</sup>, Z. Cai<sup>3</sup>, K.S. Raraigh<sup>1</sup>, J.S. Hong<sup>2</sup>, D.N. Sheppard<sup>3</sup>, E.J. Sorscher<sup>2</sup>, G.R. Cutting<sup>1</sup>. 1) Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, MD; 2) Department of Pediatrics, Emory University School of Medicine, Atlanta, GA; 3) School of Physiology, Pharmacology and Neuroscience, University of Bristol, United Kingdom.

Treatment of individuals with cystic fibrosis (CF) has been transformed by modulator therapies that target select molecular mechanisms affecting function of the CF transmembrane conductance regulator (CFTR). However, allelic heterogeneity and low frequency of alleles present significant challenges to therapeutic classification of pathogenic variants. Approximately 1,650 variants have been identified in individuals with CF; most variants have been observed in fewer than 10 individuals worldwide and only 39 genotypes are FDA approved for CFTR modulator therapy. To generate data useful for expansion of treatment eligibility, we stably expressed 43 *CFTR* variants from a single integration site in the genome of CF Bronchial Epithelial (CFBE) cells and evaluated CFTR function by measuring transepithelial ion transport. We found that most variants demonstrated a modest elevation of CFTR function in response to all treatments tested. Importantly, we found that the magnitude of therapeutic response was highly correlated with residual CFTR function for the potentiator ivacaftor (r = 0.96), the corrector lumacaftor (r = 0.83), and the ivacaftor-lumacaftor combination (r = 0.93). Response of a partially overlapping set of 16 variants studied in a similar manner using Fisher Rat Thyroid (FRT) cells, a robust system for studying CFTR biology, showed nearly identical correlations. As expected, only a small subset of variants demonstrated statistically significantly greater response to specific treatments, presumably due to direct interaction between modulator action and molecular mechanism of disease. Furthermore, 40/43 variants studied in CFBE cells and 13/16 variants studied in FRT cells demonstrated highest response to combination therapy. The variants studied here represent 87% of individuals in the CFTR2 database who carry at least one missense variant, indicating that most individuals with CF caused by missense variants are likely to demonstrate modest response to currently available modulator therapy while a small fraction will show significantly elevated responses. Additionally, our results indicate that most individuals with missense variants should derive greatest benefit from combination therapy and we found no variant for which monotherapy was more effective than combination therapy. These findings provide a path to expanding modulator therapy to a significant number of individuals with CF who have rare genotypes that cannot be studied by clinical trials.

**Reassessing the pathogenicity of *RYR1* autosomal dominant variants with modified ACMG criteria.** *D. Ng<sup>1</sup>, S.G. Gonsalves<sup>1</sup>, J.J. Johnston<sup>1</sup>, L.G. Biesecker<sup>1,2</sup>*. 1) Medical Genomics and Metabolic Genetics Branch, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD; 2) NIH Intramural Sequencing Center, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD.

*RYR1* is one of the 59 genes recommended by the American College of Medical Genetics and Genomics/Association for Molecular Pathology (ACMG-AMP) for opportunistic screening. *RYR1* variants (n=289) listed in the European Malignant Hyperthermia Group (EMHG), Human Gene Mutation Database (HGMD), or ClinVar and designated as a disease-causing mutation, pathogenic or likely pathogenic and associated with malignant hyperthermia susceptibility (MHS), central core disease or a dominant *RYR1*-associated phenotype(s) were assessed for pathogenicity using modified ACMG-AMP criteria and the Bayesian calculator of Tavtigian et al. Select criteria were modified to better fit MHS, i.e., BS1 criteria was invoked if the minor allele frequency (maf) >0.0004. PVS1 was not used as there is no evidence for *RYR1* loss of function as a mechanism for MHS. We used the Bayesian calculator to give a posterior probability for pathogenicity: pathogenic  $\geq 0.99$ , likely pathogenic  $\geq 0.90 - < 0.99$ , and VOUS to benign  $< 0.90$ . Among the 289 variants analyzed, 52 were designated pathogenic, 75 were designated likely pathogenic, and 162 were in the VOUS to benign category. Of the 42 *RYR1* "diagnostic mutations" listed on the EMHG website, 34 were designated pathogenic, 5 were likely pathogenic, and 3 were in the VOUS to benign category per modified ACMG-AMP criteria. Of the 3 EMHG variants in the VOUS to benign category, p.Arg530His scored in the high VOUS (posterior probability 0.82), while p.Glu2348del and p.Ile403Met scored low (posterior probability 0.05) because of published functional evidence indicating no damaging effect (BS3). We tailored existing ACMG-AMP criteria to MHS for reassessing *RYR1* variants as an initial step in developing a disease-specific set of guidelines so that assessment for pathogenicity can be standardized and to facilitate secondary findings analysis. We used the Bayesian analysis as a mathematical basis of the pathogenicity scoring. This is a first attempt to make judgement of *RYR1* variant pathogenicity more explicit and scientifically rigorous.

**1329W**

**Preliminary findings from the Colorado Center for Personalized Medicine Biobank.** *N. Rafaels<sup>1</sup>, T. Brunetti<sup>1</sup>, A. Roff<sup>1</sup>, S. Wicks<sup>1</sup>, K. Barnes<sup>1</sup>, K. Crooks<sup>1,2</sup>*. 1) Colorado Center for Personalized Medicine, University of Colorado Anschutz Medical Campus, Aurora, CO; 2) Department of Pathology, School of Medicine, University of Colorado, Aurora, CO.

The Colorado Center for Personalized Medicine (CCPM), established in 2014, has created a CLIA-certified Biobank that, to date, has enrolled over 65,000 adult subjects from across the University of Colorado Health (UCHealth) system and collected blood samples from over 28,000 subjects. CCPM has developed an automated pipeline that enables high-throughput processing of the Illumina Infinium CU Custom MEGA-Ex genotyping array with 45,000 custom variants added with input from 32 principal investigators from the Anschutz Medical Campus, including over 200 additional pharmacogenetic variants. We present preliminary findings from the first 4,230 samples genotyped. Genotyping was performed on 47 96-well custom plates on the Illumina iScan, with 6 controls each, selected from Coriell to maximize genotype diversity of clinically relevant variants for validation. GTC files and sample manifests were then automatically uploaded into BC|Platforms, BC|PIPE, where genotype calling and quality control (QC) analysis was performed, bypassing Illumina GenomeStudio. We employed the following QC cutoffs for this analysis: callrate < 98.5%; 10% GC score < 0.39; LOGR\_DEV > 0.4; F(inbreeding on X chromosome) for males > 0.7 and females < 0.3; and  $-0.2 < F(\text{inbreeding autosomes}) < 0.3$ . In addition, any subjects identified to have a bone marrow transplant were also removed. In total, 4,161 samples passed our QC metrics. In summary, 65.0% of subjects identified as female, and 75.4% of subjects identified as non-Hispanic and Caucasian. From the list of 59 ACMG genes, 36 individuals have a pathogenic or likely pathogenic variant confirmed by multiple submitters or expert panel in CLINVAR for autosomal recessive diseases in OMIM, 14 of which were in BRCA1 or BRCA2 genes. Also, we discovered poor and intermediate metabolizers of CYP2C9 (3, 452); CYP2C19 (109, 1085); CYP3A5 (114, 696); DPYD (0, 4); and SLCO1B1 (80, 1064), based on PharmGKB guidelines. Finally, we found 326 subjects with either Factor V Leiden or Prothrombin thrombophilia mutations and 1408 subjects with either C282Y or H63D hemochromatosis mutations. Genotyping at the CCPM Biobank is ongoing with the first 30,000 subjects to be genotyped on the current Illumina chip. Additional samples will be run on a new custom Illumina MEGA Global chip with additional custom content. Work to return clinical and pharmacogenetic results to patients, and connecting genotype data to patients' electronic health records is underway.

**1330T**

**Discovery of URAT1 and GLUT9 novel variant in hypouricemia subjects using whole exome sequencing analysis.** S. Cho, C.A. Winkler. Molecular Genetic Epidemiology Section, National Cancer Institute (NCI) / NIH, Frederick, MD.

**Objective.** Renal hypouricemia is a rare disorder associated with genetic mutant of renal transporters. Two types are currently reported (Type 1 (OMIM: 220150) and Type 2 (OMIM: 612076)). Because of the low prevalence and asymptomatic presentation in the initial stage, genetic studies are lacking. Here, we investigated the genetic background of renal hypouricemia using whole exome sequencing. **Methods.** Korean cases (N= 31) with extreme hypouricemia (<1.2mg/dl) were selected from an urban cohort of 179,381 subjects; selection criteria included 1) abstinence from alcohol or smoking and 2) an absence of underlying conditions (i.e., hypertension, diabetes and taking anti-hypertensive medication). Whole-exome sequencing was performed for the discovery of diagnostic markers. Two known genetic marker (*SLC22A12* c.774G>A (p.Trp258Stop) and *SLC22A12* c.269G>A (p.Arg90His) were identified, explaining 90.32 % (28/31) renal hypouricemia in Koreans. We used SNaPshot for the 2 *SLC22A12* SNPs and screened 50 additional hypouricemia subjects from the Korean Cancer Prevention Study. 47 carried known *SLC22A12* markers; the unexplained three hypouricemic cases were whole-exome sequenced (WES). **Results.** In total, we conducted WES of 34 individuals with extreme hypouricemia. 82.35 (28/34)% carried known hypouricemia variants. 844~1238 missense variants were identified after filtering out common variants (>1%) in each subject. 5 novel variants of *SLC22A12* (c.408C>A (p.Asn136Lys), c.674C>A (p.Thr225Lys), c.851G>A (p.Arg284Gln), c.1253T>G (p.Leu418Arg) and c.1285G>A (p.Glu429Lys) were found. 1 novel variant c.463A>G (p.Met155Val) of *SLC2A9* were identified. Only one compound heterozygote of *SLC2A9* was identified (c.1138C>T (p.Arg380Trp) and c.463A>G (p.Met155Val)). Homology modeling confirmed that all newly discovered variants are functionally related to uric acid transport. After filtering out known genes of renal hypouricemia (*SLC22A12* and *SLC2A9*), 6 unsolved patients remained. *ASB12*, *NEB* and *LRCH2-RBMXL3* were overlapping genes for 6 unsolved patients. **Conclusion.** This is the first attempt to determine the value of genetic diagnostic screening of patients for hypouricemia in the clinical setting. Screening of just 2 SNPs (p.Trp258Stop and p.Arg90His) identified 75/81 (92.6%) of patients with hypouricemia. Early identification and intervention of hypouricemia (hydration and cautious exercise) may prevent acute kidney injury.

**Inherited retinal dystrophy (IRD) pedigrees with complex genetic causality.** P. Biswas<sup>1</sup>, A. Soto Hermida<sup>1</sup>, K. Branham<sup>2</sup>, H. Matusi<sup>3</sup>, A. Chekuri<sup>4</sup>, A. A. Gurur<sup>5</sup>, A. Alapati<sup>6</sup>, B. Huang<sup>7</sup>, A. L. Villanueva<sup>4</sup>, S. Riazuddin<sup>5,6</sup>, J. R. Hecklively<sup>8</sup>, P. A. Sieving<sup>9</sup>, J. L. Duncan<sup>8</sup>, S. Amer Riazuddin<sup>9</sup>, K. A. Frazer<sup>10</sup>, R. Ayyagari<sup>1</sup>. 1) University of California San Diego, La Jolla, CA, USA; 2) Kellogg Eye Center, University of Michigan, Ann Arbor, MI, USA; 3) Institute for Genomic Medicine, University of California San Diego, San Diego, CA, USA; 4) Mejora Vision MD/Virtual Eye Care MD, Mérida, Yucatán, México; 5) National Centre of Excellence in Molecular Biology, University of Punjab, Lahore, Pakistan; 6) National Centre for Genetic Diseases, Shaheed Zulfiqar Ali Bhutto Medical University, Islamabad, Pakistan; 7) National Eye Institute, NIH, Bethesda, MD, USA; 8) Ophthalmology, University of California San Francisco, San Francisco, CA, USA; 9) Department of Ophthalmology, The Wilmer Eye Institute, Johns Hopkins University School of Medicine, Baltimore, MD, USA; 10) Department of Pediatrics and Rady Children's Hospital, Division of Genome Information Sciences, University of California, San Diego, La Jolla, CA, USA.

**Purpose:** To identify genetic causality of retinal degeneration by using whole genome sequencing (WGS). **Methodology:** Whole genome sequencing was performed on 213 members of 55 pedigrees, using Illumina HiSeqX10. The reads were aligned to hg19 and variant calling was performed using GATK. The genotyping quality of single nucleotide variants (SNVs) and indels was assessed using the variant quality score recalibration approach implemented in GATK. The annotation was done using SnpEff, PolyPhen2 and CADD score and copy number variations (CNVs) were called using GenomeSTRIP and SpeedSeq. Segregation analysis of the candidate variants was carried out using Sanger sequencing followed by functional evaluation of identified novel gene variants. Mutations found in a novel gene *IFT88*, were introduced in mammalian cells using CRISPR-Cas9 system to evaluate the impact of the identified variants. **Results:** Analysis of 55 pedigrees identified 30 novel and 11 reported variants in IRD associated genes in 23 pedigrees (42%). Among these, 10 structural variants were detected in 9 pedigrees and a de-novo variant was found in one pedigree. IRD due to more than one gene involvement was noted in eight large pedigrees with multiple consanguineous marriages. A novel causative variant was found in the promoter region of *TMEM216* in a single pedigree. Interestingly, affected individuals from four additional pedigrees inherited causative mutations in multiple genes. Potential candidate causative variants were detected in 9 novel genes segregating with disease (16%). One of the novel candidates, *IFT88* is known to be localized to the cilium in photoreceptors. Two heterozygous causal variants, p.R266\* and p.A568T in *IFT88* segregated with the phenotype. HeLa cells with *IFT88* mutations introduced using CRISPR-Cas9 system demonstrated nonsense-mediated decay of the mutant p.R266\*-*IFT88* transcript, mis-localization of p.A568T-*IFT88* and abnormal ciliogenesis. **Conclusion:** WGS of 55 pedigrees found causative mutations in 32 pedigrees (58%). The findings reveal the involvement of CNVs, de-novo mutation, mutations in multiple genes and novel gene involvement as the underlying cause of IRD in our cohort. Functional evaluation demonstrated the potential mechanism underlying IRD due to mutations in the novel ciliary protein *IFT88*. Potential involvement of novel genes, non-coding region mutations or structural variants in known genes may be responsible for IRD in the remaining 23 pedigrees.

**1332W****Challenges to increasing the rate of Mendelian disease gene discovery.**

*J.X. Chong<sup>1</sup>, J.C. Carey<sup>2</sup>, A. Hamosh<sup>3,4</sup>, D.A. Nickerson<sup>5</sup>, M.J. Bamshad<sup>1,5</sup>, Baylor-Hopkins Center for Mendelian Genomics, University of Washington Center for Mendelian Genomics.* 1) Department of Pediatrics, University of Washington, Seattle, WA; 2) Department of Pediatrics, University of Utah, Salt Lake City, Utah; 3) McKusick-Nathans Institute of Genetic Medicine; 4) Department of Pediatrics, Johns Hopkins University School of Medicine, Baltimore, MD; 5) Department of Genome Sciences, University of Washington, Seattle, WA.

The introduction in 2010 and rapid adoption of exome sequencing (ES) to identify genes for Mendelian conditions (MCs) was a disruptive innovation that replaced incumbent processes for gene discovery and syndrome delineation. Prior to ES, gene discovery was driven by positional cloning, which requires information about the genomic location and function of a candidate gene, the phenotype, or both. Computational approaches based on ES required neither. Accordingly, application of ES increased the rate of gene discovery for MCs by ~50% and from 2013 to 2018, genes underlying ~1,500 MCs were reported, 40% of which were newly-delineated MCs. Moreover, ~40% (~1,500/3,520) of all the genes now known to underlie a MC have been reported since 2010. Yet, the overall number of MCs for which the genetic basis was reported peaked between 2012-2015 and has declined slightly each year thereafter. Prior to 2010, delineation of new MCs was virtually always "phenotype-driven," that is, a MC was characterized prior to the discovery of a "causal gene." In contrast, among 266 newly delineated MCs added to OMIM in 2013, for only 17 (6%) was the genetic basis unknown. For the vast majority of new MCs reported in 2013 (249 or 94%), syndrome delineation was driven by gene discovery (i.e. "genotype-driven"). By 2017, genotype-driven syndrome delineation accounted for 100% of new MCs added to OMIM. If, as is widely accepted, perturbation of most human genes results in a MC and given that only ~3520 (18%) genes are, to date, known to underlie a MC, delineation of MCs associated with the majority of human genes will be genotype-driven. These observations suggest that even if the current rate of gene discovery for MCs remained constant, it would take up to five decades to identify genes underlying the ~3000 remaining unexplained, known MCs and for genotype-driven delineation to discover ~10,000 new MCs. The factors limiting the rate of MC gene discovery are myriad. Major reasons are the much slower co-evolution of the infrastructure and regulatory framework to share genomic data openly and at scale worldwide (hundreds of putative gene discoveries are unreported), limited access to high-throughput functional validation of candidate variants, and the challenges (insufficient resources, lack of organized efforts) of ascertaining and deeply phenotyping families with high priority candidate genotypes. We discuss various ways to maintain, if not increase, the rate of gene discovery for MCs.

**1333T****Stratification by organ systems and phenotypes in rapid genomic testing results in differences in diagnostic rates.**

*T. Wong, M. Wright, M. Tokita, K. Ellsworth, S. Chowdhury, S. Nahas, D. Dimmock, S. Kingsmore.* Rady Children's Institute for Genomic Medicine, San Diego, CA.

Rapid genomic testing in neonatal and pediatric intensive care units has resulted in improved diagnostic rates compared to current standard of care, and has the potential to impact healthcare management and decision making. The diagnostic rates from genomic testing can range from 10% to 50%, dependent on the study and patient population. In this study, we sought to investigate the diagnostic rates of rapid genomic testing by organ system and phenotype. Peripheral blood DNA from 391 consenting families were characterized by whole genome sequencing (WGS) or whole exome sequencing (WES). Variant prioritization was performed using manually curated Human Phenotype Ontology (HPO) terms that were used for analysis via the Fabric Genomics Interpretation Platform. Cases were classified by affected organ systems (e.g., cardiovascular, nervous, digestive, etc.) and by phenotype (e.g., seizures, respiratory distress, hypotonia, etc.). The overall diagnostic rate across the entire cohort was 32.7%. When parsed by affected organ system, the diagnostic rate ranged from 20% for cases with a reproductive or growth phenotype to over 40% for cases reporting an immune or muscular phenotype. Diagnostic rate also varied by phenotype, including conditions such as congenital diaphragmatic hernia (9.1%, n=11), epilepsy/seizures (31.0%, n=58), and immunodeficiency (75.0%, n=8). These findings highlight the difference in diagnostic rates across disease populations in this rapid genomic testing cohort, and an exploration of how automated phenotyping methods may enhance this process will be explored.

## 1334F

**FMR1 premutation women: High rate of reported co-morbid health conditions with an earlier onset among those with FXPOI.** E.G. Allen<sup>1</sup>, K. Charen<sup>1</sup>, H. Hipp<sup>2</sup>, L. Shubeck<sup>1</sup>, A. Amin<sup>1</sup>, W. He<sup>1</sup>, S.L. Sherman<sup>1</sup>. 1) Human Genetics, Emory University, Atlanta, GA; 2) Department of Gynecology and Obstetrics, Emory University, Atlanta, GA.

Fragile X-associated primary ovarian insufficiency (FXPOI) is seen in about 20% of women who carry an *FMR1* premutation (PM) allele (55-200 CGG repeats). These women develop hypergonadotropic hypogonadism with amenorrhea before the age of 40. A non-linear association with repeat size in the PM range and risk for FXPOI has been documented: those with a mid-range repeats are at highest risk (~70-100 CGG repeats). Importantly, not all female carriers with 70-100 repeats experience FXPOI. We have collected general medical history information along with reproductive histories on 337 women with a PM to test the hypothesis that co-morbid conditions are more frequent among PM carriers with FXPOI compared with those without FXPOI. Of the 337 women, 81 were classified as having FXPOI (amenorrhea < age 40) and 159 were classified as non-FXPOI (still cycling or onset of menopause after age 40). The table below lists conditions that were reported among all PM carriers at the highest frequencies. Notably, anxiety, depression, tension headaches, and migraines were reported by about one-third of all of the women. Greater than 29% of women reported at least one autoimmune disorder (specifically fibromyalgia, Raynaud's, Sjogren's, Lupus, multiple sclerosis, type 1 diabetes, rheumatoid arthritis, or psoriasis). Anxiety was the only condition seen at a higher frequency among women with FXPOI, unadjusted for age at evaluation. Using survival analysis to examine the age of diagnosis of FXPOI, adjusting for the age at evaluation, women with FXPOI compared with women without FXPOI had an earlier age at onset for anxiety, depression, tension headaches, hypothyroidism, fibromyalgia, and autoimmune disorder (see table). The age of diagnosis for anxiety was significantly associated with age at FXPOI or menopause ( $p=0.001$ ;  $r^2=0.22$ ). Overall, our data indicate that women with a PM report a high rate of multiple co-morbid medical conditions, and the age of onset is frequently earlier for women with FXPOI.

Condition	All women (337) %	FXPOI (81) %	No FXPOI (159) %	Difference in frequency between groups ( $\chi^2$ p-value)	Difference in age of onset between groups (survival analysis p-value)
Anxiety	38.1	45.7	31.4	0.03	0.005
Depression	35	33.3	34.6	NS	0.033
Tension headache	31.8	33.3	28.3	NS	0.023
Migraines	32.6	33.3	26.4	NS	NS
Hypothyroidism	17.8	24.7	18.2	NS	0.027
Fibromyalgia	12.2	17.3	10.1	NS	0.005
Inflammatory Bowel Syndrome	20.5	21	18.2	NS	NS
Sleep problems	28.5	33.3	30.2	NS	NS

## 1335W

**A systematic analysis of De Novo mutations in 837 trios with clinical suspicion of Mendelian phenotypes.** Z.H. Coban Akdemir<sup>1</sup>, X. Song<sup>1</sup>, S.N. Jhangiani<sup>2</sup>, T. Gambin<sup>3</sup>, D.M. Muzny<sup>2</sup>, E. Boerwinkle<sup>2,4</sup>, R.A. R.A.<sup>1,2</sup>, J.E. Posey<sup>1</sup>, C.M.B. Carvalho<sup>1</sup>, J.R. Lupski<sup>1,2,5,6</sup>, Baylor-Hopkins Center for Mendelian Genomics. 1) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX 77030, USA; 2) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX 77030, USA; 3) Institute of Computer Science, Warsaw University of Technology, Warsaw 00-665, Poland; 4) Human Genetics Center, University of Texas Health Science Center at Houston, TX 770530, USA; 5) Texas Children's Hospital, Houston, TX 77030, USA; 6) Department of Pediatrics, Baylor College of Medicine, Houston, Texas 77030, USA.

Widespread availability of whole exome sequencing (WES) has enabled systematic identification of *de novo* mutations in personal genomes in both research and the clinic. Recent studies applying clinical WES show that 60-75% of the molecular diagnostic rate in sporadic cases could be attributed to *de novo* mutations. Moreover, in the research setting, *de novo* variants have been shown to contribute extensively to multiple Mendelian phenotypes. However, there remains a lack of systematic identification of *de novo* variants in child-parent trios wherein the sample of sporadic probands presents with a wide range of Mendelian phenotypes. To systematically assess the association of *de novo* variants with Mendelian phenotypes, we examined data from ~8000 exomes presenting with a wide variety of Mendelian disease traits generated at Baylor College of Medicine through Baylor-Hopkins Center for Mendelian Genomics. Our analysis in 837 trios resulted in identification of 3,043 *de novo* coding SNVs/indels (~3.63/trio) detected by an in-house developed tool, DNM-Finder. Out of those, 387 (12.41%) were annotated as truncating variants present in 319 genes, of which ~23% were defined as loss-of-function (LoF)-intolerant in ExAC (pLI score  $\geq 0.9$ ). We identified 91 genes with more than 1 potentially damaging *de novo* variant in unrelated individuals. Those include recently published novel disease genes: *DVL1* (MIM 616331), *NALCN* (MIM 616266) and *PURA* (MIM 616158). Computational detection of *de novo* CNVs ( $>=100$  Kb) in 837 trios using XHMM revealed 102 (~0.12/trio) and 182 (~0.217/trio) *de novo* deletions and duplications, respectively. Those deletions and duplications include 71 and 107 distinct genes, respectively, of which ~30% (21) and ~28% (30), respectively, were defined as LoF-intolerant. Taken together, *de novo* variant analyses in the Baylor-CMG enable novel disease gene discovery and improved understanding of the genetic basis of Mendelian phenotypes and gene function allowing insight into the biology of disease.

**Using phenome risk scores to systematically test the hypothesis that genetically determined expression of Mendelian genes associate with Mendelian phenotypes.** J. Brown<sup>1</sup>, E. Gamazon<sup>1</sup>, J.C. Denny<sup>1</sup>, L. Basterache<sup>1</sup>, H. Im<sup>2</sup>, X. Zhong<sup>1</sup>, N. Cox<sup>1</sup>. 1) Vanderbilt University, Nashville, TN; 2) University of Chicago, Chicago, IL.

In order to conduct a more systematized test of whether the genetically predicted expression of Mendelian genes is associated with features of the Mendelian phenotype, we have combined two relatively novel methods, PrediXcan, a method to predict gene expression based on the cis-regulatory component of variation, and phenotype risk scores (PheRS), a method to quantify clinical features of Mendelian disease from its associated phenome. PheRS is calculated by adding up the number of phenotypes within a set phenome an individual has, after weighting each phenotype by prevalence in a population. Phenome definitions of each Mendelian disease use an established HPO-phenocode map using the HPO terms linked to a Mendelian disease created from OMIM. Previously when using PrediXcan to study associations between predicted gene expression and a phenome suggested to be associated with the gene, decisions regarding enrichment for particular phenotypes depended on qualitative support. A quantitative approach is more reliable and allows for better comparisons across genes. An initial study using just over 10,000 patients from Vanderbilt's biobank, BioVU, focused on cystic fibrosis (*CFTR*), phenylketonuria (*PAH*), and acrodermatitis enteropathica (*SLC39A4*). For each of these Mendelian diseases, a regression was run to test the association of predicted gene expression for the disease-associated gene and the PheRS calculated from the HPO terms that summarize the disease features, while adjusting for sex and the first three principal components. In whole blood, the coefficient on the *CFTR* gene expression term is significant. Neither predicted gene expression for *PAH* or *SLC39A4* was significant with this sample size. This result was expected for phenylketonuria, as previous research showed no differentiation in PheRSs between cases and controls. Moving forward, all Mendelian diseases with HPO-linked terms will be studied in a larger patient sample. In addition, PheRS will be built more directly from ICD codes rather than from OMIM, and then applying those codes to subjects with genotyped data. Ultimately, this will measure for each gene, how much of a pre-specified phenome is associated. This will allow systematic comparisons among genes and flexible extensions, such as being used to identify new associations with genes that appear to be associated with a particular phenome, allowing us to better understand the relationship of Mendelian disease genes to more common complex diseases.

**Identification of rare-disease genes from whole blood RNA-seq of diverse undiagnosed cases.** L. Fresard<sup>1</sup>, C. Smail<sup>2</sup>, K.S. Smith<sup>1</sup>, N.M Ferraro<sup>3</sup>, N.A. Teran<sup>3</sup>, K. Kernohan<sup>4</sup>, X. Li<sup>1</sup>, S. Marwaha<sup>5</sup>, Z. Zappala<sup>6</sup>, B. Balliu<sup>1</sup>, J.R. Davis<sup>7</sup>, B. Liu<sup>8</sup>, D. Bonner<sup>9</sup>, J. Kohler<sup>9</sup>, D. Zastrow<sup>9</sup>, D. Fisk<sup>10</sup>, M.E. Grove<sup>11</sup>, J. Davidson<sup>5</sup>, T. Hartley<sup>4</sup>, R. Joshi<sup>7</sup>, B. Strober<sup>8</sup>, S. Utiramerur<sup>8</sup>, A. Battle<sup>8</sup>, G. Bejerano<sup>10</sup>, J. Bernstein<sup>11</sup>, E.A. Ashley<sup>2,8</sup>, K. Boycott<sup>4</sup>, J.D. Merker<sup>11</sup>, M.T. Wheeler<sup>3,8</sup>, S.B. Montgomery<sup>1,3</sup>, Care4Rare Canada Consortium, Undiagnosed Diseases Network. 1) Department of Pathology, School of Medicine, Stanford, CA; 2) Biomedical Informatics Program, Stanford, CA; 3) Department of Genetics, School of Medicine, Stanford, CA; 4) Children's Hospital of Eastern Ontario, Ontario, Canada; 5) Stanford Center for Undiagnosed Diseases, Stanford, CA; 6) Department of Biology, School of Humanities and Sciences, Stanford, CA; 7) Stanford Medicine Clinical Genomics Program, Stanford, CA; 8) Division of Cardiovascular Medicine, School of Medicine, Stanford, CA; 9) Department of Computer Science, Johns Hopkins University, Baltimore, MD; 10) Departments of Computer Science, Stanford, CA; 11) Department of Pediatrics, Stanford School of Medicine, Stanford, CA.

RNA sequencing (RNA-seq) has demonstrated its potential as a complementary tool for Mendelian disease diagnosis. For both rare mitochondrial and muscle disorders, its application has improved genetic diagnoses. However, despite these successes, there still remains a lack of information on the generalizability of this approach to solve diverse undiagnosed Mendelian disorders. We sequenced whole blood RNA from 56 cases with undiagnosed rare diseases spanning 11 diverse disease categories to study the general application of RNA-seq as a diagnostic tool. We developed a robust approach to compare rare disease cases to existing large sets of RNA-seq controls (N=974 external and N=31 family-based controls). We demonstrate how comparison to a large cohort of healthy controls enables identification of gene expression outliers in loss-of-function intolerant genes. We next demonstrate the utility of whole blood- RNA-seq in diagnosing two separate neurological cases; intuitively, blood would not be viewed as a relevant tissue for these disorders. In the first case, two sisters presented with profound global developmental delay, seizures, microcephaly, hypotonia, and progressive scoliosis. We identified *RARS2* as an under-expression outlier, a gene which had previously been associated with neurodegenerative disorders. Whole exome sequencing further revealed compound heterozygous pathogenic variants in the *RARS2* gene in both sisters. In another example, a female presented with global developmental delay, loss of milestones, tremors and seizures. We identified a new splicing junction in *KCTD7*, a gene previously associated with the symptoms presented. A synonymous mutation is responsible for the aberrant splicing event. Across diverse cases in our cohort, we report that blood RNA-seq matches the 10% diagnostic rate obtained from disease matched targeted tissue approaches. This opens the door to a diagnostic tool for clinicians considering more routine application of blood RNA-seq to help unravel undiagnosed rare disease cases.

**1338W**

**Mild Canavan disease presenting with ocular migraines and atypical brain MRI.** *P. Tanpaiboon<sup>1</sup>, R. Sharma<sup>1</sup>, D. Salazar<sup>1</sup>, R. Bonilla-Guerrero<sup>1</sup>, FL. Lacbawan<sup>1,2</sup>, SM. Asai<sup>3</sup>.* 1) Advanced Diagnostics, Biochemical Genetics, Quest Diagnostics, 33608 Ortega Highway San Juan Capistrano, CA. 92675 USA; 2) Advanced Diagnostics, Molecular Genetics, Quest Diagnostics, 33608 Ortega Highway San Juan Capistrano, CA. 92675 USA; 3) Child And Adolescent Neurology, Sutter health, 2825 Capital Ave Sacramento, CA 95816 USA.

Canavan disease (CD) is a rare neurodegenerative disease characterized by spongy degeneration of the white matter. CD is caused by mutations in ASPA gene, which encodes an enzyme that hydrolyzes N-acetyl-L-aspartic acid (NAA): aspartoacylase (ASPA). ASPA deficiency causes accumulation of NAA, which is the biochemical hallmark of CD. In the majority of patients, the first symptom occurs within the first year of life (neonatal/infantile form). The characteristic features are macrocephaly, head lag, and developmental delay. Classic brain MRI findings for CD include diffuse symmetrical white matter degeneration in the subcortical areas, cerebral cortex, and brain stem. Atypical findings, such as basal ganglia hyperintensity, have also been reported. A milder form or juvenile CD is characterized by a mild developmental delay or learning disability with the normal head circumference. Herein, we present findings for an adult patient with a mild CD phenotype: nonspecific neurological problems without abnormal neurological findings. This 22-year old female was initially evaluated by neurology for chronic headaches at 17-years of age. Cognitive function, neurological, and fundus examination were normal. Brain MRI showed symmetrical hyperintensity in bilateral caudate and anterior putamen in T2 and FLAIR images, and asymmetrical bilateral high signal intensity of cortical gray matter. The patient was diagnosed with a migraine with persistent visual aura. A few years later, she developed new episodes of visual field defect and syncope. The repeat brain MRI findings were unchanged from the previous study and mimicking mitochondrial diseases. Consequently, biochemical testing was ordered. Urine organic acid testing revealed marked elevation of NAA consistent with CD. In summary, the patient presented with mild and nonspecific symptoms that first appeared as a teenager and caused a delay in diagnosis. To our knowledge, this is the oldest age of onset for CD reported to date; the previous was ~7 years old. Although atypical, similar brain MRI findings have been reported previously in mild CD phenotypes. Our report is an example of the wide spectrum of phenotypes in genetic conditions and demonstrates the importance of testing for metabolic disorders in differential diagnosis. A definitive diagnosis leads to appropriate treatment, end of the diagnostic odyssey, genetic appropriate counseling, and support for clinical trial eligibility.

**1339T**

**Clinical naming of genetic phenotypes provides unique insights into molecular mechanisms and disease etiology.** *A. Hamosh, C. Bocchini, A.L. Stumpf, M.J.F. O'Neill, C. Arnold, J.S. Amberger.* McKusick-Nathans Institute of Genetic Medicine, Johns Hopkins University, Baltimore, MD.

Since 1969, OMIM (omim.org) has been at the forefront of the nosology and naming of genetic disease. In the same way that grouping genes of similar function or structure by name opens a window to clinical medicine, grouping similar phenotypes using clinical naming provides a clinical view of the human genome. Clinical naming as an organizing principle of OMIM permits collection and comparison of underlying genes, which opens the possibility of revealing clinically related pathways and disease mechanisms. New disease names are given within the context of existing OMIM phenotypes and are organized and classified first by clinical features and then numbered if genetically heterogeneous (Phenotypic Series). To accommodate necessary evolution in nosology, alternative names are retained under a unique, stable MIM number. The value of clinical naming is seen in the following examples. The MSX1 gene underlies 3 distinct phenotypes - selective tooth agenesis, orofacial cleft, and ectodermal dysplasia - that are also caused by 9, 13, and 15 other genes as represented in their respective Phenotypic Series. Clinical naming highlights the relationship of MSX1 mutations to its phenotypes as well as the relationship of MSX1 to the other causative genes in each Phenotypic Series. Conversely, the Ehlers-Danlos syndrome has been classified into 13 different clinical subtypes. Some of the subtypes have been found to be genetically heterogeneous, for a total of over 20 different EDS syndromes. Arraying the genes responsible for these subtypes reveals etiologic relationships that are not apparent without the clinical naming structure. OMIM has over 415 Phenotypic Series comprised of over 3,400 disorders that can be leveraged accordingly. Naming disorders after genes is ill advised because (1) one third of known disease genes cause more than one disorder; (2) using the same name for a gene and phenotype hinders text mining and machine learning; and (3) phenotypes and genes are distinct concepts whose names should evolve appropriately and independently. Clinical naming of genetic disorders enhances analysis of the relationship between phenotypes and their molecular basis and provides new avenues of research through increased molecular understanding. .

**1340F**

**VariantMatcher: Community-based genomic variant matching to identify new Mendelian disorders.** E. Wohler<sup>1</sup>, F. Schiettecatte<sup>2</sup>, R. Martin<sup>1</sup>, A. Hamosh<sup>1</sup>, J. Posey<sup>3</sup>, C. Akdemir<sup>3</sup>, Z. Hande<sup>3</sup>, S. Jhangiani<sup>3</sup>, J.R. Lupski<sup>1</sup>, D. Valle<sup>1</sup>, N.L.M. Sobreira<sup>1</sup>. 1) McKusick-Nathans Institute of Genetic Medicine, Johns Hopkins University, Baltimore, MD; 2) FS Consulting LLP, Seattle, WA; 3) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX.

The Baylor-Hopkins Center for Mendelian Genomics (BHCMG) seeks to understand the genetic causes of rare Mendelian phenotypes. We have sequenced more than 8394 samples and identified more than 256 novel disease genes, more than 288 known genes, and 190 known genes associated with phenotypic expansion. Sharing phenotypic and genomic information is a pivotal step in elucidating the genes responsible for these phenotypes as we learned from our 5 years' experience with GeneMatcher ([genematcher.org](http://genematcher.org)). As a step further, to share more of the genomic data generated by the BHCMG, we have created a new web-based tool, VariantMatcher ([variantmatcher.org](http://variantmatcher.org)), with the goal of connecting users in the community and participants of the BHCMG project that are interested in the same variant. VariantMatcher is a freely accessible website that can be used by researchers, clinicians or other healthcare providers. To comply with strict patient privacy and safety codes users of the site must register and be approved by site administrators. Users upload the genomic coordinates of interest to the site (up to 10 coordinates per day) and are notified if there is a match or not. The VariantMatcher database contains the rare (MAF <1%), coding, single nucleotide variants (SNVs) identified in the VCF files of the affected and unaffected individuals sequenced by the BHCMG. When there is a match, both parties will be notified by a simultaneous email that contains the email address of both parties so they can connect and exchange further information about the variant, mode of inheritance, phenotype, etc. If a match is not made, the user will be notified but the queried coordinates will not be stored in the database. The coordinates may be uploaded again later if the user chooses. The full dataset is not searchable by users. Data from 251 VCF files are already available for matching in the database. Matching on genomic location should be more specific than matching on features and/or gene name but incomplete penetrance, variable expressivity of the phenotype, age of onset, and zygosity are some of the factors that should be considered when the phenotypes under investigation are being compared. We expect that this tool will facilitate new collaborations among researchers and/or clinicians around the world and improve the next-generation solve rate allowing the discovery of novel disease genes and novel phenotypes.

**2115W**

**Pilot gene expression profiles of surgical weight loss in adipose and blood.** D.C. Croteau-Chonka<sup>1</sup>, A.M. Weigl<sup>2</sup>, R.P. Chase<sup>1</sup>, E.J.M. Rudge<sup>3</sup>, T. Lo<sup>3</sup>, S. McNutt<sup>1</sup>, L. Farnam<sup>1</sup>, A. Tavakkoli<sup>3</sup>, E.G. Sheu<sup>2</sup>, B.A. Raby<sup>1</sup>. 1) Channing Division of Network Medicine, Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, MA; 2) Center for Clinical Investigation, Brigham and Women's Hospital, Boston, MA; 3) Center for Metabolic and Bariatric Surgery, Department of Surgery, Brigham and Women's Hospital and Harvard Medical School, Boston, MA.

Laparoscopic sleeve gastrectomy (LSG) is a highly effective surgical procedure for inducing weight loss in obese individuals. There is robust epidemiological evidence that substantial weight loss dramatically improves asthma symptoms. Our interest is in the biology behind why and how surgical weight loss positively impacts asthma. We hypothesize that the effects of this intervention are reflected in longitudinal gene expression profiles that represent coherent biological pathways. From among 16 enrolled subjects undergoing LSG, we performed a pilot RNA-sequencing study of 24 samples from the first six subjects (two men and four women, of whom two had asthma). Each subject had two adipose tissue biopsies (subcutaneous (SAT) and omental (OAT)) collected at the time of surgery. Whole blood (WB) was also collected at the time of surgery and at three months afterwards. In these six subjects, body mass index (BMI) significantly decreased from the pre-operative timepoint (44.5 kg/m<sup>2</sup> (std. dev. = 6.3)) to the post-operative timepoint (35.7 (6.0)) (paired *t*-test  $P = 1.8E-05$ ). Percent predicted forced expiratory volume in one second (FEV<sub>1</sub>), a measure of lung function, also significantly increased from pre-op (93.2% (12.7)) to post-op (102.0% (11.4)) ( $P = 0.007$ ). We performed univariate differential gene expression analyses using the DESeq2 R package. Our longitudinal study design allowed us to make two initial exploratory comparisons. We identified 8,823 genes differentially expressed (adjusted  $P < 0.05$ ) cross-sectionally between pre-op SAT and OAT. We identified 208 genes differentially expressed (adj.  $P < 0.05$ ) in pre-/post-op WB across three months of weight loss. We then performed gene set enrichment analyses to identify biological pathways underlying these expression profiles using 50 curated hallmark gene sets from the Molecular Signatures Database. The strongest gene set enrichments in the cross-sectional adipose comparison were for mTOR signaling and adipogenesis (false discovery rate (FDR)  $< 0.0001$ ). The strongest gene set enrichments in the longitudinal blood comparison were for heme metabolism and downregulation in response to ultraviolet radiation (FDR  $< 0.001$ ). These preliminary results from three tissues relevant to obese asthma suggest that gene expression profiles implicate pathways with plausible disease connections. Future analyses will include a larger sample size and additional expression and phenotype data at six, nine, and twelve months post-op.

**2116T**

**Person-specific analysis of HLA-presented peptide repertoires reveals novel epitopes associated with type 1 diabetes.** J. Arora<sup>1</sup>, S. Onengut-Gumuscu<sup>2</sup>, W.M. Chen<sup>2</sup>, A. Lernmark<sup>3</sup>, S. S. Rich<sup>2</sup>, S. Raychaudhuri<sup>2</sup>, T. L. Lenz<sup>1</sup>. 1) Research Group for Evolutionary Immunogenomics, Max Planck Institute for Evolutionary Biology, Plön, SH., Germany; 2) Center for Public Health Genomics, University of Virginia, Charlottesville, Virginia, USA; 3) Department of Clinical Sciences, Lund University/CRC, Skåne University Hospital, Malmö, Sweden; 4) Division of Rheumatology, Brigham and Women's Hospital, Harvard Medical School, Boston, Massachusetts, USA.

The increasing incidence of Type 1 Diabetes (T1D), along with a poor understanding of its immune-pathology and no available cure to date, represents a major health challenge. Extensive research on T1D consistently indicate that both environmental triggers and genetic predisposition account for disease initiation and progression. A significant proportion of the genetic risk is associated with the Human Leukocyte Antigen (HLA) locus, recently genetically mapped and analyzed, resolving the majority of the T1D-HLA risk to 3 amino acid residues in the peptide-binding groove of HLA-DQ and -DRB1 molecules that together account for 29.6% of familial T1D risk. This finding implicates a major role of DQ- and DR-bound epitopes for disease risk. Although a number of candidate proteins have been proposed to contain potential self-antigens, the exact T1D-relevant epitopes remain elusive. We used the established Peptidome-wide Association Study (PepWAS) approach on 6,651 T1D cases and 9,378 controls in order to screen for T1D-relevant HLA-bound peptides from the large pool of all possible 15-mer peptides (preferred epitope size for DQ/DR molecules) derived from 17 T1D candidate self-proteins (N = 8,018 peptides). This approach identifies disease-associated peptides by integrating HLA genotype, computationally predicted individual self-peptide repertoires, and disease status. Using PepWAS, we identified 347 and 222 potential T1D-relevant epitopes bound by HLA-DQ and DR alleles, respectively. We also simulated deamidation of the candidate proteins and predicted 136 and 113 T1D-relevant deamidated epitopes bound by DQ and trans-encoded DQ alleles, respectively. Inter-individual variation in T1D case-specific epitope repertoires bound by their HLA-DQ and DR variants additively accounted for 34.2% disease risk, significantly exceeding the T1D risk associated with genetic variants. Notably, identified epitopes varied substantially in the strength of their disease association, allowing for prioritization in experimental assays. Additionally, molecular mimicry between predicted T1D-relevant self-epitopes and specific pathogen-derived peptides provides a potential mechanism for a potential environmental trigger of T1D. Results from experimental assays to validate the predicted T1D-relevant epitopes will also be shown. Overall, our PepWAS-based approach promises a novel strategy to identify and prioritize disease-relevant epitopes for targeted therapy in HLA-associated complex diseases.

**Association analysis of type 1 diabetes in >56,000 ancestrally diverse subjects identifies novel risk loci.** C.C. Robertson<sup>1</sup>, J.R.J. Inshaw<sup>2</sup>, S. Onengut-Gumuscu<sup>1</sup>, W.M. Chen<sup>1</sup>, J.A. Todd<sup>2</sup>, S.S. Rich<sup>1</sup>, *Type 1 Diabetes Genetics Consortium*. 1) Center for Public Health Genomics, University of Virginia, Charlottesville, VA; 2) JDRF/Wellcome Diabetes and Inflammation Laboratory, Wellcome Centre for Human Genetics, University of Oxford, UK.

**Background:** Type 1 diabetes (T1D) is a complex disease driven by diverse genetic and environmental factors. Approximately 60 genomic regions are implicated in T1D, yet ~20% of familial clustering in Europeans remains unexplained by known T1D alleles and little is known about the contribution of risk alleles in non-European populations. To address these gaps, we analyzed genetic association with T1D in an ancestrally diverse cohort twice the size of previous studies. **Methods:** DNA samples were provided to the Type 1 Diabetes Genetics Consortium (T1DGC) and genotyped on the custom Illumina ImmunoChip, which provides dense SNP coverage in 186 regions associated with immune-mediated disease. After stringent quality control, genotypes were imputed using the 1000 Genomes Project Phase 3 reference panel applying SHAPEIT for phasing and Minimac3 for imputation. Imputed variants were filtered for imputation quality ( $r^2 > 0.5$ ). Association analyses with T1D status were performed in seven matched case-control series and one affected-family collection. Case-control association was analyzed using logistic regression, adjusting for population stratification using the first five genetic principal components. Family-based analyses used transmission disequilibrium tests. Fixed effect meta-analysis was used to combine summary statistics from case-control and family-based analyses. **Results:** After sample and variant QC, there were 130,335 genotyped ImmunoChip variants in 56,693 participants, including 15,258 cases, 19,071 controls, and 6,475 affected parent-offspring trios, from diverse ancestry groups (3,194 African, 1,733 Asian Pacific, and 51,766 European or other admixture). After imputation and filtering for high-confidence imputed variants, 1,665,998 variants were analyzed for association with T1D. Forty loci previously associated with T1D are represented on the ImmunoChip. In meta-analysis, we replicated 36/40 of these associations at  $p < 5 \times 10^{-8}$  and all 40 at  $p < 5 \times 10^{-6}$ . We also identified 24 novel T1D-associated regions at genome-wide significance ( $p < 5 \times 10^{-8}$ ), with the strongest associations at 19q13.31 (OR=1.22), 8q12.1 (OR=1.19), 11q12.2 (OR=0.81), and 3q28 (OR=0.82). **Conclusion:** Leveraging our improved power for discovery, we identified novel T1D-associated chromosome regions. Characterization of these additional T1D loci will permit detection of candidate causal genes, elucidate mechanisms underlying disease biology, and improve genetic risk prediction.

**2118W**

**Mitochondrial DNA copy number is a heritable trait that is significantly associated with multiple metabolic phenotypes.** L. Ganer<sup>1,2</sup>, L. Chen<sup>1,2</sup>, H.J. Mitochondrial DNA copy number (mtDNA-CN) varies among individuals and tissues and has tentatively been associated with a range of metabolic traits. However, prior reports of these associations have been inconsistent and often underpowered. To study the association between mtDNA-CN and metabolism, we leveraged deep (>20x) whole genome sequencing (WGS) data in 4,163 Finnish individuals with extensive phenotypic information for >100 metabolic traits. To increase power, we obtained imputed GWAS array genotype data from 17,718 Finnish individuals (including 3,923 that overlap with WGS samples), for which we also had whole exome sequencing (WES) data. We estimated mtDNA-CN from the WGS and WES data by normalizing the mitochondrial genomic coverage to that of the nuclear genomic coverage and controlling for sex, age, and age<sup>2</sup>. Across the 4,163 WGS samples, mtDNA-CN exhibits substantial inter-individual variation and follows an approximately normal distribution (mean=235.3; std=66.6). mtDNA-CN heritability was 31%, similar to previous estimates. In the WGS data, we observed significant associations between mtDNA-CN and several metabolic phenotypes, including fasting insulin ( $p=2.0 \times 10^{-27}$ ), fat mass ( $p=4.5 \times 10^{-16}$ ), and body mass index ( $p=5.7 \times 10^{-12}$ ). In a subset of 2,453 non-diabetic individuals, mtDNA-CN was significantly associated with insulin sensitivity ( $p=7.3 \times 10^{-17}$ ) and disposition index ( $p=0.023$ ) after adjusting for fat mass. We identified one genome-wide significant association ( $p=1.26 \times 10^{-10}$ ) in the *MYB-HBS1L* locus, a region previously associated with blood monocyte and platelet counts. Conditional analysis reveals that this known association is located on the same haplotype as our mtDNA-CN association. We also performed rare variant association analyses using the WES data and found a statistically significant association between mtDNA-CN and rare, predicted high-impact variants in *TMBIM1*, a gene whose expression has recently been reported to be protective against non-alcoholic fatty liver disease. Our results suggest that mtDNA-CN is significantly associated with multiple metabolic phenotypes related to obesity and glucose metabolism. Furthermore, we have confirmed mtDNA-CN as a heritable trait and identified one quantitative trait locus and one gene with a significant association of rare variants.

**2119T****Association study between gene expression and body mass index for middle aged Danish twins using weighted correlation network analysis.**

W. Li<sup>1</sup>, J. Baumbach<sup>2,3</sup>, L. Christiansen<sup>1</sup>, Q. Tan<sup>1,4</sup>. 1) Department of Public Health, University of Southern Denmark, Odense, Denmark; 2) Department of Mathematics and Computer Science, University of Southern Denmark, Denmark; 3) Chair of Experimental Bioinformatics, TUM School of Life Sciences, Technical University of Munich, Munich, Germany; 4) Department of Clinical Research, University of Southern Denmark, Denmark.

Body mass index (BMI) is generally recognized as an indication for underweight and obesity. As a multifactorial trait, BMI is influenced by both genetic and environment factors. Multiple genome-wide association studies have been performed to identify the genetic variants with limited success. Understanding the molecular basis that mediates environmental exposure and BMI can be more important for prevention of metabolic disorders. In this study, we focus on gene expression changes associated with BMI using monozygotic twins. Monozygotic twins that discordant for BMI are perfect subjects for transcriptomics studies where the genetic variants, age and sex are controlled. Twins are selected from The Middle Aged Danish Twins Study with BMI measured and their gene expression profiles obtained using gene expression microarray. Gene expression was summarized to gene level and weighted gene-expression correlation network analysis (WGCNA) was used to cluster correlated genes into modules and test their association with BMI. We applied pair-wised analysis in testing both module-trait and gene-trait associations. There were 4 out of 24 modules found significantly associated with BMI with  $p < 0.036$ , and gene ontology enrichment analysis of 919 genes in one modules suggested that these genes are highly related to several metabolic and cellular processes (cellular metabolic process, FDR  $9.3e-7$ ; organic substance metabolic process, FDR  $1.0e-5$ ; primary metabolic process, FDR  $3.7e-5$ ). Our results suggested differential gene expression regulation involved in multiple metabolic and biological processes that lead to differential BMI. Moreover, we show that the discordant twin design in combination with WGCNA, is an efficient and powerful approach in transcriptomic studies.

**2120F****A single-cell transcriptomics roadmap to investigate diabetes remission induced by the central action of fibroblast growth factor 1 (FGF1).**

T.H. Pers<sup>2</sup>, M.A. Bentsen<sup>1</sup>, D. Rausch<sup>2</sup>, J. Scarlett<sup>1,3</sup>, K. Alonge<sup>1</sup>, Z. Mirzadeh<sup>1</sup>, A. Secher<sup>1</sup>, R. Jorgensen<sup>2</sup>, M.W. Schwartz<sup>1</sup>. 1) UW Medicine Diabetes Institute, University of Washington, WA, USA; 2) Novo Nordisk Foundation Center for Basic Metabolic Research, University of Copenhagen, DK; 3) Department of Pediatric Gastroenterology and Hepatology, Seattle Children's Hospital, Seattle, WA, USA; 4) Barrow Neurological Institute, Phoenix, AZ, USA; 5) Global Research, Novo Nordisk A/S, Måløv, DK.

Recently, lasting remission of hyperglycemia was achieved in rodent models of type 2 diabetes (T2D) by a single intracerebroventricular (icv) injection of FGF1. While the mechanism underlying this effect is unknown, the lack of association with changes of body fat mass or risk of hypoglycaemia raises the possibility that icv FGF1 normalizes the defended level of glycemia, rather than simply lowering blood glucose levels. Recent work from our lab has identified gluco-regulatory neurocircuits in the mediobasal hypothalamus (MBH) as targets for this FGF1 effect. To investigate the mechanism underlying FGF1 action in this brain area, we used large-scale single cell RNA-sequencing to identify and characterize FGF1-responsive cells in mouse MBH. Based on >70,000 single cell MBH transcriptomes from diabetic ob/ob mice harvested 5d after a single icv injection of either FGF1 or vehicle, we identified >20 cell clusters and >900 cell type-specific differentially expressed genes ( $p < 0.01$ ). Among these potential targets of the MBH response to FGF1 in diabetic mice, we found that FGF1 treatment robustly increased the proportion of newly formed oligodendrocytes, a response that can be predicted to yield new mature oligodendrocytes and associated myelination of axons. These preliminary results demonstrate that transcriptional identification and characterisation of icv FGF1-responsive cell clusters may both advance our understanding of brain control of glucose homeostasis and identify novel targets for diabetes prevention and treatment.

**Screening the telomeric regions and a rare variant in the development of DN in the North Indian population.** A.J.S. Bhanwer<sup>1</sup>, G. Singh<sup>1,2</sup>, P. Raina<sup>1</sup>, H.S. Sandhu<sup>1</sup>, V. Kilotra<sup>1</sup>, V. Sharma<sup>2</sup>, I. Sharma<sup>2</sup>, I. Sethi<sup>2</sup>, V. Singh<sup>3</sup>, A. Marwaha<sup>4</sup>, E. Rai<sup>2</sup>, S. Sharma<sup>2</sup>. 1) Human Genetics, Guru Nanak Dev University, AMRITSAR, Punjab, India; 2) Human Genetics Research Group, School of Biotechnology, Shri Mata Vaishno Devi University, Katra, J&K, India; 3) Kidney Clinic and Dialysis Centre, Opposite GMC Amritsar; 4) Joshi Hospital and Trauma Centre, Jalandhar.

Diabetic nephropathy (DN) is the leading cause of end stage renal disease (ESRD) worldwide. In population based studies and registry analyses, DN has emerged as the most common cause of ESRD in India. Both genetic and environmental factors likely to contribute to its development and progression, but the precise mechanisms underlying are still unknown. Different epidemiological studies suggest that genetic susceptibility plays an important role in the pathogenesis of DN, leading to extensive efforts to identify the novel gene(s) involved or replicate the known genes in different populations to uncover the role of genetics in the development and progression of this condition. Unfortunately, telomeric regions and rare variants were overlooked in most of the previous studies either on T2D or its secondary complications, so in this study two SNPs from telomeric regions and one from rare variants were included. In the present study, three SNPs from three susceptible genes of T2D viz. rs7675998 (*NAF1*), rs74019828 (*CSNK2A2*) and rs61741902 (*SGSM2*) were selected to reveal their contribution in the development of the secondary complication of T2D. A total of 1740 samples from North India were included [374 DN cases and 1366 Non-DN controls (1056 Non-DN & Non-T2D controls and 310 T2D without DN controls)] and were genotyped using Sequenom MassArray platform. All these genes were found to be significantly associated with DN, but first two of these were providing protection towards DN, when compared with three control groups i.e. NDN, NDNT and T2D without DN, except rs7675998 which conferred risk when compared with T2D without DN control group. This study concludes that neither telomeric regions nor rare variants can be disregarded, instead should be replicated in other populations with more polymorphisms from these genes to corroborate their role in DN as well as T2D development.

**2122T**

**Whole-genome sequence analysis of body mass index in the trans-omics for precision medicine (TOPMed) program.** J.A. Brody<sup>1</sup>, J.R. O'Connell<sup>2</sup>, J.A. Perry<sup>2</sup> on behalf of the TOPMed Anthropometry Working Group. 1) University of Washington, Seattle, WA; 2) University of Maryland, Baltimore MA.

While genetic analyses of common variants for body mass index (BMI) have leveraged huge sample sizes, relatively few studies have examined rare non-coding variation in relation to BMI. Through whole-genome sequencing (WGS) in TOPMed we have a unique opportunity to examine BMI genetics in a large multi-ethnic sample of deeply sequenced individuals. Analyses were performed in a sample of 45,159 individuals from 20 cohorts and 6 ancestry groups. Age-, study- and PC-adjusted BMI residuals were created within ancestry and sex strata, then rank-normal transformed and rescaled by strata standard deviation. Pooled residuals were analyzed with linear mixed models including a variance component for empirical kinship plus separate residual variance components for each sex-ancestry group. Single-variant analyses were performed using MMAP on all variants (N=87,683,863) with a minor allele count of  $\geq 5$ . Analyses identified single variant associations at six loci that surpassed a suggestive significance threshold of  $p < 1e-8$ : in addition to known loci at *FTO*, *MC4R* and *SEC16B*, three novel rare variant associations were identified (*ARHGAP24*, rs546474633, MAF 0.11%, B=-4.3, p=8.4E-9; *ISPD*, rs757499854, MAF=0.02%, B=10.8 kg/m<sup>2</sup>, p=3.7E-9 and *FRMD5*, rs897162855, MAF=0.01%, B=16.6 kg/m<sup>2</sup>, p=9.6E-9). Complete WGS coverage also allows a better understanding of the genetic architecture of previously identified loci. For example, we identified an independent rare variant signal (rs62106258, MAF=3.2%, B=-0.77 kg/m<sup>2</sup>, P=3.5E-8) in the known intergenic region upstream of *TMEM18* (rs2867125, B= 0.33 kg/m<sup>2</sup>, MAF=15, P=1.4E-5). Rare variants (minor allele frequency < 1%) were aggregated into gene-based units utilizing strategies that infer the target gene for enhancer regions along with variants that fell within the FANTOM5 promoter regions and nonsynonymous coding variants. Enhancer regions and their inferred target gene were identified using GeneHancer and EnhancerAtlas neuronal data sets. Gene-based tests were analyzed using SKAT in the GENESIS R package. No genes surpassed a Bonferroni correction for multiple testing. These findings require further investigation and we are seeking performing replication using the next set of samples (50K) soon to be released by TOPMed.

**2123F**

**Large trans-ethnic discovery identifies novel loci, and differing genomic and expression signatures between glyceic traits.** *J. Chen, Meta-Analyses of Glucose and Insulin-related traits Consortium (MAGIC) Investigators.* Wellcome Sanger Institute, Hinxton, Cambridge, United Kingdom.

Glyceic traits are used to diagnose and monitor diabetes and can inform pathophysiology in type 2 diabetes (T2D). Within MAGIC we analyzed large-scale trans-ethnic genetic data (imputed to 1000Genomes) in up to 281,416 individuals without diabetes across five ancestries (71% European, 13% East Asian, 7% Hispanic, 6% African-American and 3% South Asian) relating to fasting glucose (FG), fasting insulin (FI), 2hour glucose (2hGlu) and glycat-ed hemoglobin (HbA1c). Within-ancestry meta-analyses were conducted in METAL (fixed-effects), followed by trans-ethnic meta-analyses in MANTRA. We identified 242 genome-wide significant loci, of which 99 have not been previously associated with any glyceic trait or T2D. We detected ancestry-driven associations, e.g. two African-American signals for FI (rs12056334) and FG (rs61909476), and a Hispanic signal for FG (rs12315677). In addition, 22 trans-ethnic loci have a  $p > 1 \times 10^{-5}$  in the European meta-analysis, and their discovery was enabled by the different ancestries and not just overall sample size. Combining genetic results with additional genomic resources has provided insights into genomic and expression signatures of each glyceic trait. FG-associated loci were enriched for genes expressed in pancreas/islets and liver, FI-associated loci with adipose and skeletal muscle, and HbA1c-associated loci with all these plus blood/immune system. These expression signatures were corroborated by corresponding enrichment of cell-type specific stretch enhancers. Furthermore, HbA1c expression and genomic signatures were consistent with the likely mode of action of HbA1c-associated loci, based on lookups of association results in glyceic, red blood cell and iron traits and using fuzzy clustering for locus classification. Overall, 36.6% of loci principally affect HbA1c via erythrocytic effects, ~22.8% via glyceic effects, and 29.1% were pleiotropic. T2D risk was 1.05 times higher in loci affecting HbA1c through glyceic mechanisms than others ( $p = 2.2 \times 10^{-6}$ ). In DEPICT pathway analyses, FG-associated loci were enriched for insulin sensitivity, glucose tolerance and pancreas development pathways; FI-associated loci were enriched for pathways involved in glucose homeostasis, embryogenesis, growth and cancer; and HbA1c-associated loci were enriched for hematopoiesis and glucose metabolism pathways. Overall, this effort identified 99 novel loci and provides distinct expression, genomic and pathways signatures for each glyceic trait.

**2124W**

**Uncovering the genetic architecture of data-driven dietary habits in UK Biobank.** *J.B. Cole<sup>1,2,3</sup>, J.C. Florez<sup>1,2,4</sup>, J.N. Hirschhorn<sup>1,3,4</sup>.* 1) Broad Institute, Cambridge, MA; 2) Massachusetts General Hospital, Boston, MA; 3) Boston Children's Hospital, Boston, MA; 4) Harvard Medical School, Boston, MA.

Unhealthy dietary habits are among the leading risk factors for several life-altering metabolic diseases such as obesity, type 2 diabetes, and coronary artery disease, which substantially increase mortality and decrease quality of life worldwide. There has been limited success in the use of traditional summary measures of diet (i.e. macronutrient composition) in genetic and epidemiological studies, emphasizing the potential for data-driven approaches to derive biologically meaningful and genetically based dietary habits for nutrigenomic research that might be easily harmonized across cohorts. We derived novel and data-driven dietary traits from two complementary and comprehensive diet questionnaires in UK Biobank, the largest cohort of complex dietary variables and genetics collected to date ( $N \sim 500K$ ). We employed statistical approaches that leverage repeated measures and correlated traits, including Empirical Bayes and principal components analysis. Preliminary heritability results of our derived dietary habits surprisingly found that 89.3% of dietary habits were significantly heritable ( $P < 0.05/309$  traits analyzed to date =  $1.6 \times 10^{-4}$ ), with milk type (soy milk vs. never drinks milk = 28.3%; full cream vs. never drinks milk = 22.8%), alcohol intake (with meals = 16.5%; overall frequency = 12.1%), and water intake (glasses per day = 11.7%) being the most heritable. Additional dietary habits with moderate heritabilities include pieces of fresh fruit per day (10.8%), coffee type used (10.6%), and amount of salt added to food (10.2%). Preliminary GWAS of these eight heritable traits have identified 394 genome-wide significant loci with minor allele frequency  $> 0.05\%$  ( $P < 5 \times 10^{-8}$ ), with 137 of them meeting study-wide significance ( $5 \times 10^{-8}/309$  traits =  $1.6 \times 10^{-10}$ ). The strongest association is the well-known *ADH1B* variant, rs1229984, associated with overall alcohol frequency ( $P = 5.9 \times 10^{-179}$ ), but we also identified other novel and highly significant associations including rs4410790 with glasses of water per day ( $P = 3.3 \times 10^{-79}$ ), rs10249294 with fresh fruit intake ( $P = 4.4 \times 10^{-65}$ ), rs11336847 with overall alcohol frequency ( $P = 3.0 \times 10^{-63}$ ), and rs2736748 with amount of salt added to food ( $P = 1.4 \times 10^{-27}$ ). In summary, these preliminary findings not only highlight the importance of using wider dietary information but also represent novel dietary habit genetic discoveries, laying the groundwork for future investigation into the biology of diet and its impact on human health and medicine.

**2125T**

**Socioeconomic status associates with gene expression and DNA methylation profiles within genes of the hypothalamic-pituitary-adrenal axis in Mexican Americans.** V.P. Diego<sup>1</sup>, J.M. Peralta<sup>1</sup>, M. Almeida<sup>1</sup>, T.E. Howard<sup>1</sup>, E. Manusov<sup>1</sup>, M. Johnson<sup>1</sup>, J.E. Curran<sup>1</sup>, S. Williams-Blangero<sup>1</sup>, M.A. Carless<sup>2</sup>, J. Blangero<sup>1</sup>. 1) Department of Human Genetics, School of Medicine, University of Texas Rio Grande Valley, Brownsville, TX; 2) Department of Genetics, Texas Biomedical Research Institute, San Antonio, TX.

Low socioeconomic status (SES) is a potent determinant of morbidity and mortality worldwide, particularly in Mexican Americans living close to the US-Mexico border. While this epidemiological relationship is well established, its underlying physiological mechanisms are poorly understood. It is thought that the hypothalamic-pituitary axis (HPA) axis, which is the main physiological stress response system, links SES stress in a causal manner with pathophysiology leading to increased morbidity and mortality. To investigate the effect of SES variables on genetic regulation within the HPA axis, we examined gene expression data for 206 genes in the HPA axis and DNA methylation sites for 249 genes in the HPA axis (including those for which gene expression data was available) in peripheral blood samples obtained from up to 710 individuals. We examined three dichotomized (high versus low) SES variables, namely Duncan's socioeconomic index (SEI), education years (EDU), and household income (INC). These variables are moderately correlated, with tetrachoric correlation coefficients of 0.53, 0.42, and 0.43 for SEI-EDU, SEI-INC, and EDU-INC, respectively. To test if gene expression and/or DNA methylation differ substantially between low and high SES states, we used a vector subspace comparison approach, which is a method of systematically comparing the dominant eigenvectors explaining most of the variation in gene expression and DNA methylation. Under this approach, the null hypothesis of interest is that the subspace distance is 0. We tested this hypothesis by a permutation approach to generate an empirical distribution against which the observed subspace distance was compared in order to compute an associated p-value for formal inference. For the gene expression SES comparisons, the SEI, EDU, and INC contrasts all yielded significantly different subspaces ( $p < 0.0001$ ). Similarly, for the epigenetic SES comparisons, all contrasts yielded significantly different subspaces ( $p < 0.0001$ ). As these inferences are based on comparisons of the dominant eigenvectors, our results show that such high versus low SES contrasts are associated with significantly different genetic/epigenetic effects. We are currently investigating the unique and shared genes associated with SES across the 249 gene expression and DNA methylation data.

**Using genetics to test the birth weight effects of higher maternal body fat uncoupled from its adverse metabolic consequences.** R.M. Freathy<sup>1,2</sup>, W.D. Thompson<sup>1</sup>, N.M. Warrington<sup>2</sup>, R.N. Beaumont<sup>1</sup>, Y. Ji<sup>1</sup>, M.C. Borges<sup>2</sup>, J. Tyrrell<sup>1</sup>, A.R. Wood<sup>1</sup>, D.M. Evans<sup>3</sup>, T.M. Frayling<sup>1</sup>, H. Yaghootkar<sup>1</sup>, D.A. Lawlor<sup>2</sup>. 1) Institute of Biomedical and Clinical Science, University of Exeter, Exeter, United Kingdom; 2) MRC Integrative Epidemiology Unit, University of Bristol, Bristol, United Kingdom; 3) University of Queensland Diamantina Institute, University of Queensland, Brisbane, Australia.

Maternal obesity is associated with high offspring birth weight (BW) and consequent obstetric problems and later-life disease. An improved understanding of this association would offer the potential to reduce the risk. We previously showed, using genetic instruments, that higher maternal BMI is causally associated with higher offspring BW, but the mechanisms underlying this effect are poorly understood. Recently genetic variants associated with higher adiposity but lower cardio-metabolic risk ("favourable adiposity" variants) were identified. We aimed to estimate the causal effect of maternal adiposity on offspring BW using two genetic instruments: one that captures adiposity using BMI-related variants, and one that couples adiposity with favourable metabolic effects. We performed 2-sample Mendelian randomization using summary data on genotype-BMI (76 SNPs) and genotype-favourable adiposity (14 SNPs) associations, and maternal SNP-offspring BW associations from 190,406 UK Biobank women. We calculated effects using Wald ratios and used MR-Egger to adjust for pleiotropic effects. Since maternal and offspring genotypes are correlated ( $r = 0.5$ ), we used a structural equation model (SEM) to estimate the independent maternal and offspring genetic effects using data on own BW ( $n = 215,444$ ) and offspring BW ( $n$  as above) from the UK Biobank. A 1 SD (4 kg/m<sup>2</sup>) genetically higher maternal BMI was associated with a 54g (95%CI: 40, 68) higher offspring BW, but there was evidence that pleiotropic effects contributed to this (MR Egger estimate 14g (-22, 49)). Without controlling for offspring genotype, a 1 SD (8.5%) higher maternal body fat percentage (captured by favourable adiposity variants) appeared to cause a 25g lower offspring BW (-25g (-82, 32)), with similar results using MR Egger. However, adjusting for the maternal-fetal genotype correlation dramatically changed the results to a 150g lower BW (-232, -69). In contrast, a 1 SD higher offspring body fat percentage (captured by favourable adiposity variants) was associated with a 229g (151, 307) higher BW. Using genetic variants that couple maternal adiposity with favourable metabolic consequences, we found a BW-lowering effect, suggesting that fetal growth is not influenced by the amount of maternal body fat per se, but by metabolic correlates. The contrasting effects of maternal and fetal favourable adiposity on BW point to a fetal insulin-related mechanism, which will require investigation in further studies.

**2127W**

**Using genetics to understand the ethnic differences in adiposity and diabetes risk.** J. Harrison, Y. Ji, S.E. Jones, R.N. Beaumont, A.R. Wood, J. Tyrrell, M.N. Weedon, T. Frayling, H. Yaghootar. University of Exeter Medical School, Exeter, United Kingdom.

Studies of non-Europeans are particularly important because they develop obesity related diseases at a lower body mass index (BMI). This additional risk is strongest for people of South Asian ancestry. To investigate the genetic aetiology behind this, we tested the hypothesis that variants associated with higher adiposity but lower risk of disease – “favourable adiposity” – would have different frequencies and different effects in South Asians. We used 10,203 South Asians and 451,000 Europeans from UK Biobank. We generated a genetic score based on 14 favourable adiposity variants and assessed the collective effect of these variants on measures of adiposity including body fat percentage and BMI, and risk of type 2 diabetes (1,150 cases in South Asians and 14,371 in Europeans) and heart disease (1,387 cases in South Asians and 37,741 in Europeans). Favourable adiposity alleles were less common in the South Asian population than in the European population (average number of alleles 10.5 vs 11.6;  $P < 0.0001$ ) despite having similar effects on adiposity and risk of type 2 diabetes. In the South Asian population, carrying an additional favourable adiposity allele was associated with higher body fat percentage (0.148%, 95% confidence interval (CI) [0.0986, 0.197]) and higher BMI (0.062 Kg/m<sup>2</sup> [0.027, 0.10]) but lower risk of type 2 diabetes (0.95 Odds Ratio (OR) [0.92, 0.97]) and heart disease (0.97 OR [0.95, 0.99]). In the European population, an additional favourable adiposity allele was associated with higher body fat percentage (0.128% [0.119, 0.136]) and higher BMI (0.038 Kg/m<sup>2</sup> [0.034, 0.043]), but lower risk of type 2 diabetes ((0.97 OR [0.94, 0.97]) and heart disease (0.98 OR [0.98, 0.99]). Our study demonstrates that favourable adiposity alleles have similar effects in South Asians and Europeans, lowering the risk of type 2 diabetes and heart disease for a given BMI, but these alleles are less frequent in South Asians. The “favourable adiposity” alleles are associated with higher subcutaneous but lower liver fat in Europeans. The lower frequency of these favourable adiposity alleles in South Asian populations suggests a potential mechanism for some of the ethnic differences in adiposity and diabetes risk.

**2128T**

**Obesity revisited: Is there a genetic basis to obesity with favorable cardiometabolic profile?** L.O. Huang<sup>1</sup>, U. Schick<sup>2</sup>, N. Yang<sup>3</sup>, T.O. Kilpeläinen<sup>1,3</sup>, R.J.F. Loos<sup>2,4,5</sup>. 1) Section for Metabolic Genetics, Novo Nordisk Foundation Center for Basic Metabolic Research, København N, København, Denmark; 2) The Charles Bronfman Institute for Personalized Medicine, Icahn School of Medicine at Mount Sinai, New York, New York, United States of America; 3) Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, New York, United States of America; 4) The Genetics of Obesity and Related Metabolic Traits Program, The Icahn School of Medicine at Mount Sinai, New York, New York, United States of America; 5) The Mindich Child Health and Development Institute, Icahn School of Medicine at Mount Sinai, New York, New York United States of America.

Worldwide obesity has nearly tripled since 1975 and is described as a global pandemic. Obesity is often associated with cardiometabolic comorbidities such as insulin resistance, hypertension, dyslipidemia, and increased risk of cardiovascular disease and type 2 diabetes (T2D). However, a substantial fraction of obese individuals retain a cardiometabolically healthy profile, also called the metabolically healthy obese (MHO). While the biological mechanisms that underlie MHO are poorly understood, a number of recent single-trait GWAS have shown that there are genetic variants that predispose to increased adiposity, yet are associated with a favorable cardiometabolic profile. To identify novel adiposity-increasing variants with protective cardiometabolic effects, we performed pairwise analyses -- using the CPASSOC method -- of adiposity and cardiometabolic traits using available summary statistics from 11 GWAS, including three adiposity traits [body fat percentage (BFP), body mass index (BMI), and waist-to-hip ratio (WHR)] and eight cardiometabolic traits [high-density lipoprotein cholesterol (HDL-C), low-density lipoprotein cholesterol (LDL-C), triglycerides, fasting glucose and insulin, blood pressure, and incident coronary artery disease (CAD) and T2D]. We identified genome-wide significant associations ( $P < 5 \times 10^{-8}$ ) with any of the 24 trait pairs consisting of one of three adiposity traits and one of the eight cardiometabolic traits. This resulted in the discovery of 62 independent loci residing in gene regions such as *COBLL1*, *PPARG*, *VEGFB* and *VEGFA*. Results of tissue and cell enrichment analyses using DEPICT implicate strongest enrichment in adipose tissue, adrenal cortex, liver, and arteries. Gene set enrichment analyses using DEPICT highlighted several pathways ( $P < 5 \times 10^{-4}$ ), such as “abnormal muscle cell glucose uptake”, “decreased percent body fat”, and “response to insulin stimulus”. Our results provide insights into biological pathways that may underlie MHO and could shed light on future drug development targeting improvement in cardiometabolic profile of unhealthy obese individuals.

**2129F****Exome-wide association study reveals missense variants associated with diabetic retinopathy in Koreans.**

*B. Kim<sup>1</sup>, S. Moon<sup>1</sup>, J. Ahn<sup>2</sup>, J. Kong<sup>1</sup>, Y.G Kim<sup>1</sup>, M.Y Hwang<sup>1</sup>, S. Han<sup>1</sup>, K.H Park<sup>3</sup>.* 1) Korea National Institute of Health, Cheongju-si, Chungcheongbuk-do, Korea, Republic of; 2) Department of Ophthalmology, Seoul National University, College of Medicine, SMG-SNU Boramae Medical Center; 3) Department of Ophthalmology, Seoul National Bundang Hospital.

Diabetic retinopathy (DR) is the most common diabetic complication and a leading cause of blindness in Korean. According to the Korea National Health and Nutrition Examination Surveys (KNHANES) of the Korean Center for Disease Control and Prevention, the weighted prevalence of DR was 0.9% (95% confidence interval (CI), 0.7-1.1) in the whole adult population and 11.0% (95% CI, 8.9-13.6) in Korean adults with diabetes. With the prevalence of diabetes expected to be increased, the prevalence of DR in Korea will have the highest prevalence of diabetes among OECD countries by the year 2030. DR is associated with the combination of genetic and environmental factors. In particular, progression of DR is closely related to the longer duration of Type 2 Diabetes (T2D) and poor glycemic control. With technological advances of genome-wide association study (GWAS), many risk factors associated with T2D have been identified. However, the aetiology of this complication still remains unclear. Here, we aimed to find functional relevance between variation and phenotype. To achieve this, we conducted exome-wide association analysis using Illumina Infinium HumanExome BeadChip comprising >250,000 markers. After sample quality control process, a total of 538 exome data were used (460 DR and 78 T2D patients). In addition, 97,300 markers were used for logistic regression analysis adjusting age, gender, and body mass index. From the regression analysis between case-control samples, we identified 11 genetic variants including 8 missense variants with statistical cut-off of  $P < 10^{-4}$ . In particular, among genes encompassing identified variants, *SOAT1* at chromosome 1 ( $P = 3.9 \times 10^{-5}$ ) is known that this gene has been implicated in the formation of beta-amyloid and atherosclerotic plaques by controlling the equilibrium between free cholesterol and cytoplasmic cholesteryl esters. Moreover, *RHBDF1* at chromosome 16 ( $P = 7.95 \times 10^{-5}$ ) were reported that this gene regulates the secretion of several ligands of the epidermal growth factor receptor. The functions of these genes are deeply connected with pathogenic mechanism of DR. In conclusion, our findings suggest new candidate genes contributing to DR.

**2130W****Global, multi-ethnic genome-wide association meta-analysis of body mass index.**

*A.E. Locke<sup>1</sup>, S. Vedantam<sup>2,3</sup>, E. Marouli<sup>4</sup>, S. Berndt<sup>5</sup>, L. Yengo<sup>6</sup>, A.R. Wood<sup>7</sup>, T. Ferreira<sup>8</sup>, S. Graham<sup>9</sup> on behalf of the Genetic Investigation of ANthropometric Traits (GIANT) Consortium.* 1) Department of Medicine, Division of Genomics and Bioinformatics, Washington University School of Medicine, Saint Louis, MO; 2) Center for Basic and Translational Obesity Research, Division of Endocrinology, Boston Children's Hospital, Boston, MA; 3) Broad Institute of MIT and Harvard, Cambridge, MA; 4) Heart Centre, William Harvey Research Institute, Barts & the London Medical School, Queen Mary University of London, Charterhouse Square, London, UK; 5) National Cancer Institute, Bethesda, MD; 6) Program in Complex Trait Genomics, Institute for Molecular Bioscience, University of Queensland, St Lucia, Brisbane, Australia; 7) Genetics of Complex Traits, University of Exeter Medical School, University of Exeter, Exeter, UK; 8) Big Data Institute, Li Ka Shing Center for Health and Health Information and Discovery, Oxford University, UK; 9) Department of Internal Medicine, Division of Cardiovascular Medicine, University of Michigan, Ann Arbor, MI.

Obesity is a health crisis affecting more than 1/3 of the US population and contributing to increased risk for other serious health conditions such as heart disease, diabetes, and numerous cancers. Using body mass index (BMI) as a proxy for overall obesity (heritability estimated at ~40-60%), GIANT and other groups have committed substantial effort to understand the genetic basis and underlying biology of obesity. The nearly 200 loci that have been associated with BMI show strong signal enrichment in brain tissues and the central nervous system. However, the BMI-associated loci discovered to date account for <3% of phenotypic variance. Here, we describe our continuing efforts to identify genetic factors contributing to overall obesity through GWAS meta-analyses of BMI. We combined published results from previous GIANT GWAS meta-analyses of BMI ( $n \sim 250,000$ ) with a BOLT-LMM association analysis of a recent UK Biobank release ( $n = 456,426$ ) for a combined total of 681,275 European-descent participants. We limited fixed effects meta-analysis to the ~2.4M HapMap2 variants common to both studies. Through meta-analysis and approximate conditional and joint analysis using GCTA-COJO we identified 941 loci at a stringent threshold of  $P < 1 \times 10^{-8}$ , including 656 primary associations and 285 secondary signals. These associations account for 6.0% of the BMI phenotypic variance. In tandem, we initiated a global GWAS meta-analysis of BMI based on 1000 Genomes and HRC reference panels covering >40M imputed variants. To date, we have received association summary statistics from >170 studies across six ethnic groups totaling >820,000 individuals, nearly half of whom are from non-European ancestry studies. The upcoming final meta-analysis of BMI including all these studies plus UK Biobank and several other large-scale GWAS efforts will comprise a sample size of >2 million individuals. Our analytical pipeline, built to deal with this sample size, will enable us to perform flexible and adaptable *ad hoc* meta-analyses, including full conditional meta-analysis and rare variant group-wise testing of both coding and non-coding regions. This large-scale multi-ethnic endeavor provides an unparalleled opportunity for fine-mapping associations to pinpoint candidate functional variants, which will speed the translation of genomic discoveries to the clinic by providing insight into functional biology of obesity.

**2131T**

**Analysis of whole-exome sequence data to identify variants which influence Body Mass Index (BMI) via a role in adipogenesis.** Y.L. Muller<sup>1</sup>, S. Day<sup>1</sup>, C. Koroglu<sup>1</sup>, G. Elson<sup>1</sup>, S. Kobes<sup>1</sup>, R.L. Hanson<sup>1</sup>, W.C. Knowler<sup>1</sup>, H.I. Kim<sup>2</sup>, C. Van Hout<sup>2</sup>, N. Gosalia<sup>2</sup>, A.R. Shuldiner<sup>2</sup>, C. Bogardus<sup>2</sup>, L.J. Baier<sup>1</sup>. 1) Phoenix Epidemiology and Clinical Research Branch, Phoenix, AZ; 2) Regeneron Genetics Center, Regeneron Pharmaceuticals, Tarrytown, NY.

Body fat is regulated by changes in adipogenesis. To identify variants that potentially impact human body weight via an effect on adipogenesis, we analyzed whole-exome sequence data from a population-based sample of 6809 American Indians with longitudinal measures of BMI. ~180,673 analyzed exonic variants that met the following criteria were prioritized for functional screening 1) non-synonymous, stop-gain or frameshift and occurred in  $\geq 5$  individuals 2) a Combined Annotation Dependent Depletion (CADD) score  $\geq 10$  (probability of being the top 10% of deleterious variants) 3) evidence for association with maximum BMI recorded during adulthood ( $n=6002$ ) or maximum BMI z-score recorded during childhood ( $n=4882$ ) ( $P < 0.001$ , adjusted for age, sex, birth year and the first five genetic principal components) and 4) mapped to a gene highly expressed in adipose tissue with literature support for a possible role in adipogenesis. Twenty variants met these criteria. To date 11 variants have been functionally assessed *in vitro* for roles in lipid accumulation in OP9 cells, and 2 of them showed functional evidence. A variant P891L (rs748552530) in *PTPRF* with a CADD score of 28 was identified in 7 subjects. Heterozygous carriers had a higher BMI in adulthood (54.2 vs. 36.3kg/m<sup>2</sup>,  $P=0.02$ ) and BMI Z-score in childhood (3.0 vs. 0.33SD,  $P=0.0006$ ) as compared to non-carriers. *PTPRF* encodes Protein Tyrosine Phosphatase, Receptor Type F, which inhibits phosphorylation of the insulin receptor. Prior studies have shown that knockdown of *PTPRF* increased adipogenesis in human mesenchymal stem cells and 3T3-L1 preadipocytes. Another variant E37K (rs144101476) in *LAMTOR1* with a CADD score of 24 was identified in 5 subjects. Heterozygous carriers had a higher BMI in adulthood and Z-score in childhood as compared with non-carriers (BMI 51.6 vs. 36.4kg/m<sup>2</sup>,  $P=0.0006$ ; Z-score 1.5 vs. 0.33SD,  $P=0.01$ ). *LAMTOR1* encodes Late Endosomal/Lysosomal Adaptor, which is involved in activation of the mTORC1 pathway during adipogenesis. Analyses of both variants in OP9 cells support their roles in adipogenesis, where cells expressing the BMI-risk allele 891L in *PTPRF* or 37K in *LAMTOR1* had an increase in triglyceride content compared to the wild type allele (20% with  $P=0.007$ ; 51% with  $P=0.02$ , respectively). In conclusion, whole-exome sequencing followed by *in vitro* high-throughput analysis of lipid accumulation in OP9 cells has identified coding variants that may impact body weight via a role in adipogenesis.

**2132F**

**Cardiometabolic GWAS variants colocalize with subcutaneous adipose tissue cis-eQTLs.** C.K. Raulerson<sup>1</sup>, A. Ko<sup>2</sup>, T.S. Furey<sup>1,3</sup>, M. Laakso<sup>4</sup>, P. Pajukanta<sup>2,5</sup>, K.L. Mohlke<sup>1</sup>. 1) Department of Genetics, University of North Carolina, Chapel Hill, NC; 2) Department of Human Genetics, David Geffen School of Medicine at UCLA, Los Angeles, CA; 3) Department of Biology, University of North Carolina, Chapel Hill, NC; 4) Department of Medicine, University of Eastern Finland and Kuopio University Hospital, Kuopio, Finland; 5) Molecular Biology Institute at UCLA, Los Angeles, CA.

Genome-wide association studies (GWAS) have identified hundreds of loci for cardiometabolic traits such as type 2 diabetes (T2D), cholesterol, triglyceride levels, body fat distribution, and adiposity traits. However, the variants, genes, and mechanisms that underlie these signals are not well understood. To investigate genetic variants that influence the expression of nearby genes, we used genotypes and subcutaneous adipose tissue RNA-seq data from 434 Finns from the METabolic Syndrome in Men (METSIM) study. We tested for association between 7.8M variants and levels of 21,735 expressed genes using FastQTL. We identified 14,028 genes associated with  $\geq 1$  variant  $\pm 1$  Mb of the TSS at  $FDR < 5\%$  (local eQTLs). Among these, we focused on genes near 3,015 cardiometabolic GWAS loci from the NHGRI-EBI catalog and a recent DIAMANTE T2D GWAS preprint. We identified 200 local eQTLs targeting 241 genes for which (1) the eQTL variant is in LD ( $r^2 \geq 0.8$ ) with the lead GWAS variant; and (2) after conditioning on the GWAS variant, the conditional p-values were no longer significant. Within the colocalized signals, 79 genes corresponded to lipid loci, 68 genes to BMI loci, and 53 genes to T2D loci. GO biological process analysis of eQTL genes at GWAS loci corresponding to lipid traits showed enrichment for 8 categories, including cholesterol efflux, lipid biosynthetic process, and cholesterol homeostasis. We further conditioned on the lead eQTL variant at each significant gene and identified 2<sup>nd</sup> eQTL signals for 2,689 genes, 24 of which were colocalized with a nearby GWAS variant. For 17 loci, only a 2<sup>nd</sup> eQTL signal, and not a 1<sup>st</sup> eQTL signal, colocalized with the GWAS variant. At these 17 GWAS loci, analysis of second eQTL signals was required to identify a colocalized gene. At another 6 loci, a GWAS variant colocalized with the 1<sup>st</sup> eQTL signal for one gene and a 2<sup>nd</sup> eQTL signal for a different gene. For example, T2D GWAS variant rs3111316 colocalized with the 1<sup>st</sup> eQTL signal for *FARSA* ( $p\text{-val}=2E-14$ ,  $\beta=-0.558$ ) and the 2<sup>nd</sup> eQTL signal for *GCDH* ( $p\text{-val}=1E-06$ ,  $\beta=0.471$ ). *FARSA* encodes a tRNA synthetase and *GCDH* encodes a dehydrogenase involved in degrading lysine, hydroxylysine, and tryptophan. The GWAS signal may affect one or both of these genes to contribute to T2D. Taken together, these results suggest that careful analysis of conditionally distinct eQTL signals can aid with the identification of target genes and the interpretation of pathways and mechanisms at GWAS loci.

## 2133W

**Understanding how natural genetic variation alters the ER stress**

**response.** N.D. Russell<sup>1</sup>, K.G. Owings, C.Y. Chow. Department of Human Genetics, University of Utah, Salt Lake City, UT.

The phenotypic expression of a disease can vary greatly between individuals and can manifest as differences in age-of-onset, severity, and other disease associated phenotypes. Differences in genetic background between patients can be a major contributor to these differences in disease outcomes. We are studying how natural genetic variation between individuals contributes to differences in disease outcomes by incorporating inter-individual genetic variation in my experimental design in the context of endoplasmic reticulum (ER) stress. The ER is a large eukaryotic organelle involved in protein folding. ER stress is the result of the accumulation of misfolded proteins in the lumen of the ER. If left unresolved, this can lead to cell death and disease. ER stress is an important component to many diseases and can impact disease outcomes. We hypothesize that inter-individual genetic variation in the ER stress response pathway is an important contributor to variable disease phenotypic expression. We have previously shown, in *Drosophila* and mouse, that the ER stress response is highly variable across different genetic backgrounds. Our goal is to uncover how genes and genetic variants of the ER stress response contribute to this variable phenotype. To achieve this goal, we are performing an *in vivo* study that will allow us to determine how the *cis*- and *trans*- regulatory landscape drives variation in the ER stress response in a tissue-specific manner. We are using two mouse strains, C57BL/6J (B6) and CAST/EiJ (CAST), which are very genetically divergent. B6 and CAST strains are crossed to produce F1 mice. For each response gene, we can identify *cis*- and *trans*- regulatory effects by comparing the relative allelic expression in the F1 to that of the ratio of expression between the parental strains. In each mouse, we are inducing ER stress and performing RNA-seq on multiple tissues. This will allow us to analyze the regulatory landscape and allele specific expression after the induction of ER stress in a strain and tissue dependent manner. In addition, we are using the *Drosophila* model to functionally test and validate putative genetic modifiers of the ER stress response. A modifier gene of the ER stress response could potentially be used as a therapeutic target in a number of diseases with a strong ER stress component.

DKD is a heritable, common and devastating complication affecting ~40% of those with type 1 diabetes (T1D) and is the leading cause of end-stage renal disease (ESRD). Despite strong evidence for a genetic component in DKD (heritability ~35% in persons with T1D), few DKD loci have been discovered and replicated. We performed the largest GWAS to date for T1D DKD in 19,406 European ancestry participants drawn from 17 cohorts genotyped on the Illumina HumanCoreExome BeadChip. Our GWAS identified 16 novel loci attaining genome-wide significance ( $p < 5 \times 10^{-8}$ ) with at least one DKD-related phenotype. Four of the 16 lead variants were common (minor allele frequency [MAF] > 5%), eight were low frequency ( $5\% \geq \text{MAF} \geq 1\%$ ) and four were very low frequency (MAF < 1%). The variant with strongest association is rs55703767 ( $p = 5.3 \times 10^{-12}$ , MAF = 21%, missense) in the collagen type IV alpha 3 chain (*COL4A3*) gene, which encodes a major structural component of basement membranes implicated in Alport Syndrome. The *COL4A3* association has a protective effect of the minor allele for macroalbuminuria and/or ESRD (OR = 0.78;  $p = 5.3 \times 10^{-12}$ ); genome-wide significance was also reached for three other DKD subphenotype definitions. Stratified analyses in the FinnDiane cohort showed that variants near *COL4A3*, *SNCAIP*, and *ALLC-COLEC11* loci were more strongly associated with DKD in individuals with HbA1c  $\geq 7.5\%$  (chronically high glucose levels) than in those with HbA1c < 7.5%, suggesting that these loci may be related to DKD rather than general renal disease. Similarly, the *COL4A3* effect was stronger among those with longer T1D duration and those randomized to conventional treatment (with resulting higher HbA1c) in the DCCT-EDIC cohort. In sex-stratified meta-analysis of all studies, the *COL4A3* rs55703767 association was stronger in men than women (OR<sub>men</sub> = 0.73,  $p = 1.3 \times 10^{-11}$ , OR<sub>women</sub> = 0.85,  $P = 1.4 \times 10^{-3}$ ). *COL4A3* expression in renal biopsy samples was also positively correlated with the degree of fibrosis in tubules ( $p = 3.2 \times 10^{-9}$ ). Four other loci are in or near genes with known or suggestive connections to renal biology (*BMP7*, *COLEC11*, *DDR1*, and *TAMM41*). Our results implicate determinants of glomerular basement membrane function as playing a key role in DKD, suggesting that this aspect of kidney biology should be a focus of future research on the pathology, prevention, and treatment of DKD.

**2135F**

**Deconstructing the genetic architectures Of BMI and eating behavior phenotypes.** J.F. Shelton, J.R. Ashenhurst, R.I. Tennen, P. Fontanillas, 23andMe Research Team. 23andMe, Mountain View, CA.

Seventy-one percent of Americans over the age of 20 are overweight or obese. A wide range of behavioral and genetic factors contribute to high body mass index (BMI), and a significant number genes related to higher BMI act on neurological rather than metabolic pathways, highlighting the importance of addressing behavioral and emotional factors with regard to the encouragement of achieving or maintaining a healthy weight. To better understand the genetic basis of eating behaviors and their relationship with BMI, we fielded a web-based survey to over 300,000 consented 23andMe research participants covering phenotypes related to restrictive eating, emotional eating, situational eating, disinhibition, preoccupation with food, satiety, snacking behaviors, and mealtime atmosphere. Principal components analysis (PCA) of the 21 survey items yielded two broad constructs (i.e. two first principal components) that we describe as situational eating and food avoidance behavior. Regressing BMI on situational eating resulted in a model that explained 8.6% of the variance in BMI. Food avoidance behavior, on the other hand, explained very little of the variance in BMI ( $r^2 = 0.2\%$ ). Genome-wide association analyses (GWAS) on situational eating scores showed, as expected, a strong signal in *FTO* ( $\beta = -0.135$ , P-value =  $6.6e-53$ ), and others genes associated with BMI including *TMEM18* ( $\beta = 0.083$ , P-value =  $9.7e-13$ ) and *MCR4* ( $\beta = -0.069$ , P-value =  $1.3e-13$ ). On the other hand GWAS on sub-constructs showed that anger and irritability during hunger were associated with *ERI1* ( $\beta=0.031$ , P-value= $7.2e-10$ ) and *VRK2* ( $\beta=0.03$ , P-value= $7.4e-10$ ), genes involved in neuropsychiatric pathways. .

**2136W**

**T2D disease status alters the effects of genetic variation on molecular phenotypes: A direct study.** A. Viñuela<sup>1</sup>, J. Fernandez<sup>2</sup>, A. Kurbasic<sup>3</sup>, MG. Hong<sup>4</sup>, S. Sharma<sup>5</sup>, C. Brorsson<sup>6</sup>, J. Adamski<sup>6</sup>, JM. Schwenk<sup>6</sup>, ER. Pearson<sup>7</sup>, S. Brunak<sup>6</sup>, PW. Franks<sup>3</sup>, MI. McCarthy<sup>2</sup>, ET. Dermitzakis<sup>1</sup>, DIRECT Consortium. 1) Department of Genetic Medicine and Development, University of Geneva, Geneva, Switzerland; 2) WTCHG, University of Oxford, Oxford, UK; 3) University of Lund, Malmö, Sweden; 4) SciLifeLab, Karolinska Institutet, Solna, Sweden; 5) Genome Analysis, Helmholtz Zentrum, Munich, Germany; 6) Systems Biology, DTU, Lyngby, Denmark; 7) Molecular & Clinical Medicine, University of Dundee, Dundee, UK.

Despite the success of GWAS and other studies in identifying genomic regions implicated in T2D, we still lack an understanding of the cellular processes which underline this increased disease risk. To better understand how genetic variants perturb molecular networks, and how these perturbations influence disease progression and status, we present data from the DIRECT consortium cohort of 3,029 subjects. This comprised of 2,234 prediabetic and 795 newly diagnosed T2D subjects, with genotype information deep clinical data and molecular phenotypes such as RNAseq, targeted and untargeted metabolite quantifications and protein (immunoassays) measurements. To explore the effects of genetic variation in cellular phenotypes, we looked for evidence of eQTLs in blood identifying 59,704 independent eQTLs associated with 94.2% genes (FDR 1%), with 78.7% genes having more than one eQTL. Compared to the eQTLs in 44 tissues produced by GTEx, we observed that 81% (testis) to 98% (brain) of the eQTLs were also active in blood, demonstrating the value of large studies in accessible tissues to uncover genetic effects in other tissues. Co-localization analysis between eQTLs and 153 GWAS variants for T2D identified 47 candidate genes with shared genetic effects. Of those, the CaVEMaN fine-mapping method proposed 13 specific causal variants (Probability > 0.9). For example, the T2D associated GWAS variant at the RREB1 locus (rs35742417) co-localized with the eSNPs for the same gene (RTC score 0.95) and the variant showed a high probability of being causal (P = 0.99). Adding information on 116 targeted metabolites and 263 proteins, we found that 67.2% of the expressed genes (10,905) were significantly correlated (FDR 1%) with at least one metabolite, while 71.4% of the genes (11,577) were associated with at least one protein. Finally, to investigate how the molecular network responds to T2D progression, we looked for evidence of T2D specific genetic regulation. We identified 182 significant genotype-by-T2D interactions (FDR 1%), including rs11235825 for ARHGEF17. We are currently further exploring the relationship between variants, gene expression, metabolites, and disease status to understand how they are mediated. Our results will increase the understanding on the complex ways genetic regulation affects multiple cellular phenotypes and leads to disease development.

**Multi-ethnic genotyping in the GENNID study: Elucidating metabolic syndrome etiology underlying linkage regions.** J. Y. Wan<sup>1</sup>, E. L. Willemms<sup>2</sup>, T. M. Norden-Krichmar<sup>1</sup>, S. A. Santorico<sup>2,3,4</sup>, K. L. Edwards<sup>1</sup>, American Diabetes Association GENNID Study Group. 1) Epidemiology Dept, University of California, Irvine, NC; 2) Mathematical and Statistical Sciences Dept, University of Colorado, Denver, CO; 3) Human Medical Genetics and Genomics Program, University of Colorado, Denver, CO; 4) Biostatistics & Informatics Dept, University of Colorado, Denver, CO.

Metabolic Syndrome (MetS) is characterized by a collection of impaired quantitative metabolic traits, including weight, waist circumference, triglyceride (TG) levels, high-density lipoprotein (HDL) cholesterol, fasting glucose and insulin levels, and systolic and diastolic blood pressure. The GENetics of NonInsulin-dependent Diabetes mellitus (GENNID) is a resource of multiplex families across diverse ethnic groups which includes African-American (73 families, 288 individuals), European-American (79 families, 519 individuals), and Mexican-American (113 families, 610 individuals). Previous linkage analyses using microsatellite markers identified several regions on multiple chromosomes harboring variants influencing variation among MetS traits. All samples were genotyped using the Illumina Infinium Multi-Ethnic Global array for follow-up by fine mapping of these regions. These dense markers were analyzed using both variance components linkage and association testing under the previously identified linkage peaks to identify quantitative trait nucleotides (QTNs) for individual MetS traits and combinations of traits. Our genome-wide analysis focuses on both genotyped and imputed common and rare variants and their genetic association with MetS in the presence of linkage. The results show evidence of heterogeneity among underlying QTNs and different clustering of MetS traits across ethnic groups. Further, association analysis detected QTNs in only a subset of the previously identified linkage regions and also identified putative QTNs outside these linkage regions. These results suggest that although both linkage and association testing are useful tools in family-based analyses, further work is needed to resolve the basis of these different results.

**Trans-ancestral fine-mapping and causal inference of variants within urate- and gout-associated loci *SLC2A9* and *ABCG2*.** W. Wei<sup>1</sup>, R. Takei<sup>1,2</sup>, C. Li<sup>3,4</sup>, Z. Li<sup>5,6</sup>, H. Hu<sup>7</sup>, M. He<sup>7</sup>, H. Guo<sup>8</sup>, Y. Shj<sup>3,4,5,6</sup>, T. Merriman<sup>2</sup>. 1) Department of Women's and Children's Health, University of Otago, Dunedin, Otago, New Zealand; 2) Department of Biochemistry, University of Otago, Dunedin, New Zealand; 3) Shandong Gout Clinical Medical Center, Qingdao 266003, China; 4) Shandong Provincial Key Laboratory of Metabolic Disease, The Affiliated Hospital of Qingdao University, Qingdao 266003, China; 5) Bio-X Institutes, Key Laboratory for the Genetics of Developmental and Neuropsychiatric Disorders (Ministry of Education), Shanghai Jiao Tong University, Shanghai 200030, China; 6) Institute of Social Cognitive and Behavioral Sciences, Shanghai Jiao Tong University, Shanghai 200240, China; 7) Department of Occupational and Environmental Health and the Ministry of Education Key Lab of Environment and Health, School of Public Health, Tongji Medical College, Huazhong University of Science & Technology, Wuhan 430030, Hubei, China; 8) Center for Biostatistics, School of Health Sciences, The University of Manchester, Manchester, UK.

Gout is a type of complex inflammatory arthritis affecting a quarter of people with elevated serum urate levels. The prevalence of gout varies widely across ancestral groups, from 6-8% in NZ Māori and Pacific (Polynesian) people, to 3% in Europeans, 1 ~ 2% in East Asians, and 0.4% in South Americans. Genome-wide association studies (GWASs) of gout have identified two major urate-regulating loci *ABCG2* and *SLC2A9* in European and Asian samples. Identification of causal variant(s) in these loci, however, is challenging because of extensive linkage disequilibrium and / or different haplotype structures. We hypothesised that leveraging multiple ancestral genetic backgrounds will enhance fine-mapping of *ABCG2* and *SLC2A9* and inference of causal variants. We used the MANTRA software package to perform trans-ancestral meta-analysis to fine map the two loci in gout and urate separately, and then the coloc package to identify likely causal variants colocalised in associations with urate and gout. Using European (gout: 5,712 cases, 105,569 controls; urate: 110,347) and East Asian (gout: 1,255 cases, 1,848 controls; urate: 36,547) samples, we fine mapped the associations to a single variant resolution for both loci: rs4697701 in both urate and gout for *SLC2A9*, and rs2622621 in gout and rs4148155 in urate for *ABCG2*. The MANTRA fine-mapping results were confirmed in the colocalisation analysis of European samples where only rs4697701 in *SLC2A9* was identified as a common causal variant of urate and gout. These results are consistent with a previous inference of causal variants for urate in Europeans (Farh et al. *Nature* 518:337-43), where rs12498742 was claimed to be a causal variant in *SLC2A9* that is adjacent (2043 bases away) and in linkage disequilibrium ( $r^2 = 0.77$ ) with rs4697701, whereas no causal variants in *ABCG2* were reported. The fine-mapping and colocalisation analyses of East Asian samples might be underpowered but suggested different causality.

**Association of adiponectin gene polymorphism (-3971A/G and +276G/T) with type 2 diabetes in North Indian Punjabi population.** V. Bains, B. Badaruddoza, H. Kaur. Human Genetics, Guru Nanak Dev University, Amritsar, India.

Adiponectin is the most abundant circulating adipocytokine in human that plays important role in regulation of glucose and lipid metabolism and positively regulates insulin actions. Human adiponectin is encoded by the ADIPOQ gene is located on the chromosomal locus 3q27 and spans approximately 16 kilobases (kb) of DNA in a region identified as a susceptibility locus for type 2 diabetes. Previous studies have shown that the Adiponectin gene polymorphisms are associated with insulin resistance and an increased risk of type 2 diabetes mellitus in several ethnic populations. The present study was aimed to investigate the association of adiponectin gene polymorphisms (ADIPOQ-3971A/G and +276G/T) with type 2 diabetes in North Indian Punjabi population. The study comprised of 510 unrelated (300 type 2 diabetics T2D and 310 normal controls) subjects from North Indian Punjabi Population. Anthropometric and physiometric measurements were taken from all the study participants under standardized protocols. Biochemical analysis including glucose and lipid profile was done for all the participants. The ADIPOQ variants were screened by polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) and for the validation of genotyping 10% samples of each polymorphism were confirmed by Sanger sequencing method. The differences of overall genotype distribution for ADIPOQ (-3971A/G and +276G/T) gene polymorphisms are statistically significant ( $p=0.021$  and  $0.046$ , respectively) in cases and controls. Risk genotype (3971GG) had significantly higher TC, TG, LDL-C and VLDL-C. However, +276TT genotype had significantly higher TG and HDL-C levels only. Under genetic models, -3971A/G (rs822396) were significantly associated with T2DM under the co-dominant (OR:1.32, CI-1.04-1.68,  $p=0.021$ ) and recessive (OR:2.05, CI-1.21-3.46,  $p=0.006$ ) genetic models. whereas, +276G/T (rs1501299) was found to be associated with T2DM under recessive model (OR:2.00, CI-1.14-3.49,  $p$ -value=0.013) only. Results of present study supported that the ADIPOQ gene polymorphism (ADIPOQ-3971A/G and +276G/T) plays an important role in type 2 diabetes susceptibility in North Indian Punjabi Population.

**Fine mapping of T2D linked 12q24 region in Finnish families.** O. Dwivedi<sup>1</sup>, T. Tuomi<sup>2</sup>, L. Groop<sup>1,3</sup>. 1) Institute for Molecular Medicine Finland FIMM, University of Helsinki, Finland, Helsinki, Finland; 2) Folkhälsan Institute of Genetics, Folkhälsan Research Center, Helsinki, Finland; 3) Department of Clinical Sciences, Diabetes and Endocrinology, Lund University, Malmö, Sweden.

**Aim:** Previously, a linkage for type 2 diabetes (T2D) was reported at the 12q24 (104-133Mb, b37) region in Finnish families participating in the Botnia Study (Mahtani M et al., Nat Genet. 14: 90-94, 1996). The linkage was observed after stratification for a low 30-minute insulin (INS 30) level, thus suggesting that genetic variation in this region could result in impaired insulin secretion and T2D. We here aimed to fine-map the linkage peak in order to identify the putative causal variant/haplotype in the region. **Material and Methods:** The linkage study included 34 individuals (20 affected and 14 non-diabetics) from six families. All family members underwent a dense GWAS (2.5 millions markers) and whole genome sequencing (WGS) for at least two affected member per family. We first identified identity by descent (IBD) shared haplotypes among families (present in  $\geq 2$  families) using high dense phased data. We used 253 Finnish individuals with genotype data as population controls to allow identification of family specific IBD haplotypes. We further filtered the variants present in shared IBD haplotype and looked their effect on T2D risk, insulin secretion and expression of nearby genes in 191 human islets. **Results:** Analysis of haplotype sharing revealed only one long (>3Mb) IBD haplotype (126 to 130 Mb) under the linkage peak spanning 104 to 133 Mb; two families with the lowest INS 30 levels contributed most to the linkage. We further refined this shared haplotype to a 500kb region (128 to 128.5 Mb, b37) using population controls and high density marker data (2.5 M and WGS data as available). IBD sharing in this region was rarely seen in the population controls whereas the most severely affected patients shared both haplotypes in the region. The shared IBD haplotype contains variants (frequency 0.2% to 5%) that are associated with T2D risk (OR=1.5,  $P=0.044$ ), reduced trend of INS30 ( $P=0.09$ ) levels and increased islet expression of nearest gene *TMEM132C* ( $P=0.01$ ), which is negatively correlated with insulin secretion in human islets (Ottosson-Laakso E. et al. Diabetes 66:3013-3028, 2017). **Conclusion:** The *TMEM132C* gene is a plausible candidate to explain linkage of impaired insulin secretion and T2D to chromosome 12q in these families.

**Phenome-wide prediction of additional effects of antidiabetic therapies using human genetics: The UK Biobank.** S.M. Figarska<sup>1,2,6</sup>, S. Gustafsson<sup>3</sup>, D. Lindholm<sup>1,4,5</sup>, T. Quertermous<sup>1,2</sup>, T. Fall<sup>3</sup>, J.W. Knowles<sup>1,2,6</sup>, E. Ingelsson<sup>1,2,6</sup>. 1) Department of Medicine, Division of Cardiovascular Medicine, Stanford University School of Medicine, Stanford, CA 94305, USA; 2) Stanford Cardiovascular Institute, Stanford University, Stanford, CA 94305; 3) Department of Medical Sciences, Molecular Epidemiology and Science for Life Laboratory, Uppsala University, Uppsala, Sweden; 4) Department of Medical Sciences, Cardiology, Uppsala University, Uppsala Sweden; 5) Uppsala Clinical Research Center, Uppsala University, Uppsala, Sweden; 6) Stanford Diabetes Research Center, Stanford University School of Medicine, Stanford, CA 94305, USA.

**Background:** For several type 2 diabetes (T2D) drugs, it is uncertain whether they have other potentially adverse or beneficial outcomes, including influencing risk for cardiovascular disease (CVD). **Methods:** We investigated downstream effects of functional variants in genes encoding T2D drug targets: dipeptidyl peptidase 4 (*DPP4*), glucagon-like 1 receptor (*GLP1R*), sodium-glucose cotransporter 2 (*SGLT2*), sulfonylurea receptor 1 (*ABCC8*), lysosomal alpha-glucosidase (*GAA*), and peroxisome proliferator-activated receptors- $\gamma$  (*PPARG*) to predict possible additional effects of T2D therapies. For each gene, we tested associations of two variant sets: a) functional variants according to VEP and b) all variants in the gene (MAF<0.05) in a hypothesis-driven set of 16 phenotypes and a hypothesis-free set of 259 phenotypes comprising blocks of ICD-10 codes, groups of procedures (OPCS4) and self-reported variables in 337,536 unrelated individuals of white British ancestry from the UK Biobank. Analyses were performed using Sequence Kernel Association Test (SKAT), as well as single variant tests adjusting for age, sex, array and first ten principal components reflecting ancestry. A Bonferroni correction for multiple testing was applied. **Results:** Variations in all examined genes, except for *SGLT2*, were nominally associated with T2D in the SKAT test. In the hypothesis-driven approach, a loss of function (LoF) variant in *DPP4* was associated with lower T2D risk, BMI, total body fat percentage and heart rate. A LoF variant in *GLP1R* was associated with lower T2D risk and higher risk of acute pancreatitis. An intronic variant in *PPARG* was associated with higher T2D risk and lower body fat percentage, whereas another intronic variant in *PPARG* was associated with higher T2D risk and treatment with lipid-lowering medications. In addition to the phenotypes selected *a priori*, the LoF variant in *DPP4* was associated with lower leukocyte count, a 3' UTR variant in *GLP1R* was associated with higher risk of unspecified mental disorder, and the intronic variants in *PPARG* associated with higher T2D risk were associated with higher use of blood pressure medication and higher platelet count. **Conclusions:** In addition to confirming expected associations of variation in genes encoding T2D drug targets with T2D, we also observe associations with other phenotypes, predicting several previously suggested and some previously unknown potential additional beneficial or adverse effects of T2D drugs.

**Rare variant discovery in type 2 diabetes using extremely low-coverage sequencing in large multigenerational pedigrees.** S.G. Frodsham<sup>1</sup>, J. Laza-ro-Guevara<sup>1,2</sup>, M.H. Pezzolesi<sup>1</sup>, C.A. Zaffino<sup>1</sup>, M.G. Pezzolesi<sup>1,2,3</sup>. 1) Division of Nephrology and Hypertension, Department of Internal Medicine, University of Utah School of Medicine, Salt Lake City, UT; 2) Department of Human Genetics, University of Utah School of Medicine, Salt Lake City, UT; 3) Diabetes and Metabolism Research Center, University of Utah School of Medicine, Salt Lake City, UT.

Type 2 diabetes (T2D) is a common complex metabolic disease with genetic underpinnings. Over the past decade, T2D genome-wide association (GWAS) and sequencing studies have advanced our understanding of the genetic basis of T2D by identifying more 100 loci that impact its risk. Variants at these loci, however, explain only a minority (~10%) of the heritability of T2D; these data suggest that alternative approaches are needed to fully elucidate the residual genetic variance of T2D. While deep coverage (>30X) whole-genome sequencing (WGS) offers the most comprehensive assessment of rare, low-frequency, and common variants, at scale, this approach remains cost prohibitive. Recently, extremely low-coverage (~0.5X) WGS (XLC-WGS) coupled with imputation has been shown to be a cost-effective alternative to deep WGS that increases the power of association studies by allowing for new/rare variant discovery. Here, we apply this approach in the context of large multigenerational pedigrees identified using the Utah Population Database (UPDB), a unique population-based genealogy resource of Utah pioneers and their descendants that is linked to electronic health record data from the University of Utah Health Sciences Center. Using the UPDB, we identified 20 large multigenerational pedigrees enriched for T2D. These pedigrees span as many as 10 generations and range in size from 1,450 to >15,000 members. To date, we have performed XLC-WGS in more than 150 T2D members of these pedigrees. Following XLC-WGS, these data were imputed using 1000 Genomes (Phase 3) to obtain variant calls across the genome. Among these samples, we identified an average of 3.3 million high-quality variants per genome, including 5,500 rare variants (minor allele frequency <0.01). These data show high concordance with GWAS chip data from these same individuals, validating the utility of this approach. Linkage and family-based association analyses are currently underway. Preliminary analyses suggest that XLC-WGS coupled with family-based analyses is a promising approach to identify novel rare variants associated with T2D.

**Influence of vitamin D receptor gene polymorphisms and three autoantibodies on susceptibility to type 1 diabetes mellitus in Kuwaiti Arabs.** *M.Z. Haider<sup>1</sup>, M.A. Rasoul<sup>1,2</sup>, M. Al-Mahdi<sup>2</sup>, H. Al-Kandari<sup>3</sup>, G.S. Dhaunsi<sup>1,4</sup>.* 1) Pediatrics Department, Kuwait University, Jabriya, Kuwait; 2) Pediatrics Department, Al-Adan Hospital, Kuwait; 3) Pediatrics Department, Farwania Hospital, Kuwait; 4) Medical Laboratory, Mubarak Al-Kabeer Hospital, Kuwait.

Type 1 diabetes mellitus (T1DM) is highly prevalent in Kuwait and its incidence has increased considerably during the past four decades. T1DM is thought to result from a complex interplay between genetic and environmental factors and the immune system of susceptible individuals. Vitamin D deficiency is widely spread around the world and is considered to be involved in immune modulation and contribute to autoimmune destruction of insulin producing beta cells in pancreas of T1DM patients. Vitamin D has been shown to exert its effects via a nuclear vitamin D receptor (VDR) and therefore, VDR gene has become a candidate for T1DM susceptibility. We have determined the genotypes of four VDR gene polymorphisms by PCR-RFLP analysis in 261 Kuwaiti Arab T1DM patients and 214 healthy controls in order to investigate their role in susceptibility to T1DM. Statistically significant differences were detected between the genotypes of two VDR gene polymorphisms (*FokI*, C/T, rs10735810 and *TaqI*, C/T, rs731236) between T1DM patients and controls ( $P < 0.0001$ ). In the case of both these polymorphisms, the variant alleles were significantly associated with T1DM. In contrast, the VDR gene *Apal* (G/T, rs7975232) and *BsmI* (A/G, rs1544410) polymorphisms did not show an association with T1DM in Kuwaiti Arabs. The frequency of variant genotype ff, of the *FokI* VDR gene polymorphism was significantly higher in T1DM patients with late age-of-onset (>6y) compared to the early-age-of-onset (<4y). The same pattern was observed in VDR gene *Apal* polymorphisms with the higher frequency of variant genotype detected in late age-of-onset (>6y) patients. For VDR gene polymorphisms, *TaqI* and *BsmI*, no age-of-onset related variation was detected. Three autoantibodies, ICA (Islet cell), GADA (glutamate decarboxylase) and INS (insulin) autoantibodies were positively associated to, varying degrees, with T1DM in Kuwaiti Arabs harboring different VDR gene polymorphism genotypes. Our results support the role of two VDR gene polymorphisms (*FokI* and *TaqI*) in conferring susceptibility to T1DM in Kuwaiti Arabs.

**Genome-wide screen for parent-of-origin effects in the association with type 2 diabetes in American Indians.** *R.L. Hanson, W.C. Hsueh, S. Kobes, Y.L. Muller, S. Day, P. Piaggi, A. Nair, W.C. Knowler, L.J. Baier.* PEICRB/NID-DK, Phoenix, AZ., USA.

Genome-wide association studies (GWAS) have identified multiple variants associated with type 2 diabetes; although some of these variants are subject to parent-of-origin effects, few GWAS have accounted for the parental origin of alleles. We analyzed GWAS data from 7659 Pima Indians (2571 with diabetes), consisting of 4719 nuclear families, with allowance for parent-of-origin effects. Genotypic data were derived from a custom Axiom array (Affymetrix, Santa Clara, CA) designed to capture common variation in Pima Indians, and constituted 474,196 autosomal variants with minor allele frequency  $\geq 0.05$ . Genotypic data were available for  $\geq 1$  parent for 65% of individuals. Parental origin of alleles was assigned probabilistically using a family-based likelihood method. A mixed model, which accounted for empirical genetic-relatedness estimates among all individuals, was used to analyze association with diabetes, with estimation of the odds ratio conferred by a risk allele inherited from the mother ( $OR_m$ ), that conferred by a risk allele inherited from the father ( $OR_f$ ), and the P-value for the null hypothesis  $OR_m = OR_f$  ( $P_{diff}$ ). Since the full likelihood method is computationally intensive, we first used a logistic regression model to analyze the difference in diabetes prevalence according to parental origin of alleles among perfectly informative heterozygous individuals ( $\geq 1$  parent homozygous) across all variants, and applied the full method to the 1000 SNPs with the strongest evidence for parent-of-origin effects; it was also applied to 5529 SNPs in 6 regions containing clusters of genes known to be imprinted in humans. We identified SNPs from 8 different regions with evidence for parent-of-origin effects ( $P_{diff} < 3.0 \times 10^{-5}$ , corresponding to a false discovery rate  $P < 0.05$  across the known imprinted regions). These included established diabetes-susceptibility variants in *KCNQ1* (rs2237895, risk allele=C,  $OR_m = 1.72$ ,  $P = 2.7 \times 10^{-11}$ ,  $OR_f = 0.99$ ,  $P = 0.90$ ,  $P_{diff} = 2.3 \times 10^{-5}$ ), and additional variants near *LINC00670* (rs1460319, G,  $OR_m = 0.76$ ,  $P = 6.7 \times 10^{-4}$ ,  $OR_f = 1.39$ ,  $P = 3.3 \times 10^{-5}$ ,  $P_{diff} = 4.2 \times 10^{-6}$ ), *LOC105378522* (rs7896335, T,  $OR_m = 1.56$ ,  $P = 2.7 \times 10^{-6}$ ,  $OR_f = 0.79$ ,  $P = 0.01$ ,  $P_{diff} = 5.0 \times 10^{-6}$ ) and *LINC00250* (rs12443418, T,  $OR_m = 1.58$ ,  $P = 2.0 \times 10^{-5}$ ,  $OR_f = 0.77$ ,  $P = 0.02$ ,  $P_{diff} = 1.7 \times 10^{-5}$ ). In addition to the established imprinted variants in *KCNQ1*, these analyses identify variants with potential parent-of-origin effects in the association with type 2 diabetes.

**2145W****Genome-wide association study of diabetes progression in Chinese patients with type 2 diabetes.**

Chow<sup>1</sup>, W.Y. So<sup>1,2</sup>, J.C. Chan<sup>1,2,3,4</sup>, R.C. Ma<sup>1,2,3,4</sup>, 1) Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Hong Kong, China; 2) Hong Kong Institute of Diabetes and Obesity, The Chinese University of Hong Kong; 3) Li Ka Shing Institute of Health Sciences, The Chinese University of Hong Kong; 4) Integrated Bioinformatics Laboratory for Cancer and Metabolic Diseases, The Chinese University of Hong Kong.

Disease progression and glycaemic deterioration in type 2 diabetes (T2D) are highly heterogeneous. Identification of genetic risk factors that affect disease progression may facilitate precision medicine in diabetes. We performed a nested case-control study from the Hong Kong Diabetes Register (HKDR), which includes more than 8,000 patients with T2D and prospective follow-up. We excluded patients with type 1 diabetes, those on insulin treatment, those requiring insulin within 1 year, or patients considered oral drug failure at baseline (defined as 2 consecutive HbA1c  $\geq 8.5\%$ , more than 3 months apart, when on two or more oral anti-hyperglycemia drugs). Disease progression was defined as progression to continuous insulin treatment during follow-up (up to 30<sup>th</sup> June 2014), or oral drug failure, whichever came first. Samples were genotyped using the Illumina Omni 2.5+ exome array and genotype data was imputed using minimac 3 (1000G phase 3v5). After standard quality control procedures pre- and post-imputation, ~8.0 million genetic variants (MAF  $\geq 1\%$ ) were included in the study. Association analysis was performed using the Cox proportional hazards regression, adjusted for age, gender, BMI and principal components. Among 4,208 patients included in the genome-wide association analysis for diabetes progression, 1,991 (47.3%) progressed to oral drug failure or insulin treatment during median follow-up of 9.1 years (IQR 4.6-13.9). We identified 61 variants with suggestive association ( $p < 10^{-5}$ ) with disease progression, with the top association signal located at 22q12.3 (MAF=0.19, HR [95% CI]=1.27 [1.17-1.38],  $P=6.5 \times 10^{-8}$ ). Our study has identified a number of novel regions associated with disease progression in T2D. Replications and extension of these findings are currently in progress. **Acknowledgement:** This work was supported by the Research Grants Council Theme-based Research Scheme (T12-402/13N), the Focused Innovation Scheme, Vice-Chancellor One-off Discretionary Fund, and the Postdoctoral Fellowship Scheme of the Chinese University of Hong Kong.

**2146T****Association of adiponectin levels and *AdipoQ* gene variants with T2D in females from Northwest Indian population.** K. Kaur, A.J.S Bhanwer. Human Genetics, Guru Nanak Dev University, Amritsar, India.

Adiponectin is an important cytokine with anti-inflammatory and insulin sensitizing effects. Lower adiponectin levels have been associated with parameters of metabolic syndrome and Type 2 diabetes (T2D) and are further known to exhibit sexual dimorphism. In the present study, Adiponectin protein levels and five polymorphisms in the adiponectin gene (*AdipoQ*) were studied to determine their association with T2D in females (370 cases and 323 controls) from the North-West Indian population of Punjab. Protein levels were determined through ELISA; and SNPs *rs17300539*, *rs266729*, *rs2241766* and *rs1501299* were genotyped using PCR-RFLP method while *rs17846866* was typed through ARMS-PCR. Adiponectin levels were observed to be significantly different ( $p < 0.001$ ) among T2D cases (13.84 $\pm$ 4.39) and controls (18.16 $\pm$ 6.62). Nearly 2-3 folds increased risk for T2D was observed with the T allele of *rs1501299* [ $p = 1.55 \times 10^{-9}$ , OR=2.04(1.61-2.57)], and A allele of the promoter polymorphism *rs17300539* [ $p = 4.96 \times 10^{-5}$ , OR=3.38(1.82-6.31)]. In haplotype analysis, the haplotypes: GCTTG [ $p = 0.002$ , OR=1.41 (1.13-1.75)], GGTTG [ $p = 0.022$ , OR=1.45 (1.06-1.99)] and GCGTG [ $p = 0.024$ , OR=1.70 (1.07-2.7)] significantly associated with increased risk of T2D. Two haplotypes GCTTT [ $p = 1.20 \times 10^{-5}$ , OR=0.56 (0.43-0.73)] and ACTTG [ $p = 0.006$ , OR=0.23 (0.07-0.78)] appeared to have protection against the development of T2D. Association of protein levels in the background of genotypes using one way ANOVA revealed a significant difference in the mean protein levels in cases ( $p = 0.01$ ) controls ( $p = 0.01$ ) for *rs17300539* and *rs17846866*, respectively. Overall, the observations are suggestive of association of reduced adiponectin levels with T2D in females from the North-West Indian population of Punjab. The association of promoter polymorphism *rs17300539* with increased risk of T2D and adiponectin levels, indicate the importance of regulatory region variants in modulating the protein levels and disease etiology. Association of intronic variant *rs1501299* reflects the role of non-coding polymorphisms in regulation of gene expression; however, the findings need to be exemplified through functional validations. In conclusion, the regulatory and structural region *AdipoQ* variants seems to dictate the adiponectin protein levels and hence T2D susceptibility in females from the North-West Indian population. The financial assistance was provided by DST-WOS(A) through Grant No.SR/WOS-A/LS-150/2009. There is no conflict of interest.

**2147F**

**Exome-wide analysis in American Indians identifies an association between rare variants in *TGM2* and type 2 diabetes.** H. Kim<sup>1</sup>, R.L. Hanson<sup>2</sup>, N. Gosalia<sup>1</sup>, B. Ye<sup>1</sup>, C. Koroglu<sup>2</sup>, W.C. Hsueh<sup>2</sup>, W.C. Knowler<sup>2</sup>, L.J. Baier<sup>2</sup>, A.R. Shuldiner<sup>1</sup>, C. Bogardus<sup>2</sup>, C.V. Van Hout<sup>1</sup>. 1) Regeneron Genetics Center, Regeneron Pharmaceuticals, Inc., Tarrytown, NY; 2) Phoenix Epidemiology and Clinical Research Branch, National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, Phoenix, AZ.

Whole exome sequencing in founder populations with unique allelic architecture can lead to the discovery of novel disease-associated genes. To identify rare coding variants that are associated with type 2 diabetes (T2D), we sequenced exomes in American Indians including 2248 T2D cases and 4585 controls. The top gene-based association was with *TGM2*, in which 29 variants are either predicted loss-of-function or missense variants with minor allele frequency lower than 1% (SKAT:  $p = 3.0e-7$ , burden test: OR = 2.21,  $p = 2.1e-5$ ). Further evaluation of the locus showed that two coding variants of *TGM2* that are enriched in American Indians were associated with T2D risk in opposite directions: variant p.Arg76His, c.227G>A, MAF = 0.9%, was associated with increased risk (OR = 3.05,  $p = 2.3e-7$ ), while variant p.Arg476Gln, c.1427G>A, MAF = 1.3%, was associated with reduced risk (OR = 0.61,  $p = 0.010$ ). Furthermore, variant p.Arg76His was associated with earlier T2D age of onset (beta = -4.9yr,  $p = 1.07e-3$ ), while variant p.Arg476Gln was associated with later onset (beta = +3.8yr,  $p = 0.017$ ). *TGM2* [MIM 190196] encodes transglutaminase 2 protein (TGM2) with enzymatic activity mediating protein cross-linkages. Published literature has implicated TGM2 in the regulation of glucose stimulated insulin secretion from pancreatic islets and glycemic control in mice. We hypothesized that genetic variants at the locus might modulate the expression or activity of TGM2, leading to the observed T2D association. We first tested whether p.Arg76His and p.Arg476Gln alter the enzymatic activity of TGM2 by in vitro enzymatic assays using wildtype and mutant recombinant TGM2 proteins. Enzymatic activity of TGM2 is activated by calcium and inhibited by GTP/GDP. TGM2-p.Arg476Gln protein exhibited elevated IC50 for GTPgS compared to wildtype protein (2.1uM versus 0.1uM), indicating that its enzymatic activity is more resistant to GTPgS inhibition; there was no difference in EC50 for calcium. This result suggests that variant p.Arg476Gln may increase the enzymatic activity of TGM2, which in turn, may reduce T2D risk. On the other hand, TGM2-p.Arg76His showed no difference in EC50 for calcium, or IC50 for GTPgS, which suggests that different mechanisms or potentially linkage disequilibrium with another variant in or near *TGM2* might be responsible for the association with T2D. Further studies are ongoing to characterize the potential impact of *TGM2* and its genetic variation on glycemic regulation.

**2148W**

**Pancreatic islet specific long non-coding RNAs variants nominally associate with insulin secretory function and type 2 diabetes in American Indians.** P. Kumar, P. Piaggi, S. Kobes, C. Bogardus, R.L. Hanson, L.J. Baier. Phoenix Epidemiology and Clinical Research Branch, National Institute of Diabetes and Digestive and Kidney Diseases, National Institute of Health.

Long non-coding RNAs (lncRNAs) are increasingly recognized as contributors to metabolic processes and disease pathogenesis. Therefore, we sought to determine common variation in lncRNAs that may increase risk for type 2 diabetes (T2D). Recent genome-wide transcriptome and regulome studies have identified nearly 2,600 intergenic and antisense lncRNAs in human islets. Several of these affect beta-cell differentiation and maturation. We merged the positions of known islet lncRNAs with whole-genome sequence data from 335 Pima Indians, who are at high risk for T2D, to identify common SNPs that mapped to lncRNAs. Tags for these SNPs constituting 11,447 variants, were genotyped in 7,700 Pima Indians informative for T2D, where a subset of this sample (N = 404) was also informative for insulin secretory function as assessed by an intravenous glucose tolerance test when the subject had normal oral glucose tolerance. We identified 16 variants in lncRNAs that nominally associated ( $P$ -value < 0.05) with both a reduced acute insulin response and increased risk for type 2 diabetes. The two strongest associations were rs2210585 which mapped to lncRNA HI-LNC4502 ( $P$ -value, T2D =  $1.11 \times 10^{-4}$ , OR [95%CI] = 1.20 [1.10-1.32];  $P$ -value, insulin secretion =  $4.75 \times 10^{-3}$ , beta = -0.065) and a novel SNP chr6:147389391 which mapped to lncRNA HI-LNC292 ( $P$ -value, T2D =  $5.01 \times 10^{-4}$ , OR = 1.30 [1.12-1.50];  $P$ -value, insulin secretion =  $2.05 \times 10^{-3}$ , beta = -0.103). The risk allele for rs2210585 (A) and a novel chr6:147389391 (A) had a frequency of 64% and 89% respectively in Pima Indians. These lncRNAs mapped to genes SNAP25-AS1 and STXBP5-AS1, respectively and anti-sense to their respective coding genes that belong to the soluble N-ethylmaleimide-sensitive factor attachment protein (SNAP) receptor (SNARE) dependent exocytosis pathway. SNARE proteins have a physiological role in insulin exocytosis in pancreatic beta-cells. Another variant, rs7732130 of lncRNA HI-LNC2744 nominally associated with T2D ( $P$ -value = 0.027, OR = 1.11 [1.01-1.22], risk-allele frequency = 35%) and insulin secretion ( $P$ -value = 0.047, beta = -0.047) in Pima Indians. This lncRNA variant mapped to the ZBED3-AS1 gene, associates with type 2 diabetes previously (T2D Portal,  $P$ -value =  $3.49 \times 10^{-7}$ , OR = 1.16, GoT2D+replication dataset) with a similar direction to our study. In summary, studying islet lncRNAs variants that associate with insulin secretion and type 2 diabetes may uncover novel pathways that modify risk for type 2 diabetes.

**2149T****Dysregulation of microRNAs in DR patients in Chinese Han population.**

Z. Li<sup>1</sup>, Q. Guo<sup>2</sup>, Y. Dong<sup>3</sup>, Q. Wang<sup>1\*</sup>, P. Chen<sup>2\*</sup>. 1) Department of Endocrinology, China-Japan Union Hospital of Jilin University, Changchun, Jilin, China; 2) College of Basic Medical Sciences of Jilin University, Changchun, Jilin, China; 3) Department of Radiotherapy, The Tumor Hospital of Jilin Province, Changchun, Jilin, China.

**Background:** Type 2 diabetes (T2D) can induce many severe complications. Diabetic retinopathy (DR) is one of the most common and severe complications and considered as the major cause of blindness among young adults. MicroRNAs (miRNAs) are a group of small noncoding RNAs regulating the expression of target genes. Several miRNAs have been reported to play a critical role in the development of DR via a variety of molecular mechanisms such as cell proliferation, angiogenesis, and inflammatory response modulation. In this study, we sought to identify miRNAs that are differentially expressed in DR patients, in the hope of unveiling the differentially regulated genes and pathways. **Methods:** We recruited T2D inpatients in China-Japan Union Hospital of Jilin University. All the patients were subjected to a detailed medical examination and retinopathy diagnosis. DR patients with duration of diabetes less than 5 years were selected as DR group (N = 10), while non-DR group was consist of retinopathy-free participants with duration of diabetes more than 10 years (N=11). Fasting peripheral serum samples were obtained at the end point. MiRNA transcription level was evaluated by next-generation sequencing. Differential expression of miRNA in DR group as compared with non-DR group was analyzed by miRDeep2 and DESeq2, adjusted for age. Target genes of miRNAs were predicted by miRDB. **Results:** There was no significant difference in BMI and sex between DR and non-DR groups. Twenty-seven miRNAs were differentially expressed in DR group with p value less than 0.01. Eight genes were found to be jointly targeted by these miRNAs, including KCNMA1, NEAT, MIAT, which has been reported closely correlated with the dysfunction of vascular endothelium. **Conclusion:** Serum circulating miRNAs may resemble the pathogenic changes in retina tissue. Using an extreme case-control study, we identified miRNAs that are differentially expressed in the serum of DR patients and the genes that are apparently regulated by these miRNAs. Our study provided evidences for future mechanical studies. However, studies with larger cohorts are needed to validate our preliminary findings.

**Advanced identification of novel genetic variants for type 2 diabetes, childhood obesity and their pleiotropic loci.** X. Lin<sup>1,3</sup>, C. Zeng<sup>2</sup>, J. Greenbaum<sup>1</sup>, Y. Chen<sup>3</sup>, C. Peng<sup>3</sup>, R. Liu<sup>3</sup>, Z. Feng<sup>3</sup>, L. Peng<sup>3</sup>, J. Shen<sup>3</sup>, H. Deng<sup>1,4</sup>. 1) Department of Biostatistics and Data Science, Tulane University, New Orleans, LA; 2) Department of Endocrinology and Metabolism, The Fifth Affiliated Hospital of Guangzhou Medical University, Guangzhou, China; 3) Department of Endocrinology and Metabolism, The Third Affiliated Hospital of Southern Medical University, Guangzhou, China; 4) School of Basic Medical Sciences, Central South University, Changsha, China.

Type 2 diabetes (T2D) has become a serious global public health issue and caused severe health and economic burden. Numerous studies have demonstrated that childhood obesity (CO) is associated with increased risk of developing T2D in later life. In this study, we aim to identify some novel single-nucleotide polymorphisms (SNPs) associated with T2D and CO. In particular, we are especially interested to identify their pleiotropic loci. We integrated the summary statistics for two independent genome-wide association studies (GWASs) of T2D (n = 149,821) and childhood body mass index (CBMI) (n = 35,668) using the pleiotropy-informed conditional false discovery rate (cFDR) method. By leveraging the information of different levels of association for CBMI, we observed a strong enrichment of genetic variants associated with T2D based on the conditional QQ plot. We identified 139 T2D-associated SNPs including 125 novel ones (cFDR < 0.05). Conditioned on T2D, we identified 37 significant SNPs for CBMI (cFDR < 0.05), including 25 novel ones. It is noteworthy that, the conjunctive cFDR (ccFDR) analysis showed ten novel pleiotropic loci for T2D and CBMI (ccFDR < 0.05). Interestingly, the novel SNP rs1996023 is located at protein coding gene *GNPDA2* (ccFDR = 1.28E-02). Variations of this gene have been reported to influence the risk of T2D and CO through processes in the central nervous system. By integrating GWAS data from related phenotypes, we reported several pleiotropic loci shared by both T2D and CO. Our findings may help to explain a greater proportion of the heritability for human traits and advance the understanding of the common pathophysiology between T2D and CO. This work was partially supported by grants from the National Institutes of Health [U19AG05537301, R01AR057049, R01AR059781, D43TW009107, P20GM109036, R01MH107354, R01MH104680, R01GM109068], the Edward G. Schlieder Endowment fund to Tulane University.

**Process-specific genetic risk scores for type 2 diabetes reveal differential effects on mechanism, phenotype, and disease course.** A. Mahajan<sup>1,2</sup>, N. Robertson<sup>1,2</sup>, M.I. McCarthy<sup>1,2,3</sup>. 1) Wellcome Centre for Human Genetics, Nuffield Department of Medicine, University of Oxford, Oxford, UK; 2) Oxford Centre for Diabetes, Endocrinology and Metabolism, Radcliffe Department of Medicine, University of Oxford, Oxford, UK; 3) Oxford NIHR Biomedical Research Centre, Oxford University Hospitals Trust, Oxford, UK.

Over 400 type 2 diabetes (T2D) risk loci have been identified. However, most map to non-coding sequence and mechanisms of action are often unclear. One strategy for defining the physiological processes through which these variants act is to examine patterns of association to metabolic and anthropometric traits. Here, we extend such analyses to an expanded set of T2D signals. We considered lead variants at 177 loci with the strongest T2D-risk effects and widest availability of relevant GWAS data. From multi-trait association patterns generated from a set of 10 core traits, we used fuzzy clustering to define six genetic clusters (GCs), made up of variants with similar phenotypic consequences. We characterize these clusters as capturing variants with primary effects on: adiposity (GC1-BMI); insulin action (GC2-IA: low BMI and HDL, high TG); beta-cell function (GC3-BCF, GC4-BCF); and mixed features (GC5-MIX, GC6-MIX). Based on GC membership, we created a series of process-specific genetic risk scores (psGRS), and used these as instruments to explore their relationships to the heterogeneity in T2D phenotypes. Across GWAS data for 355 other traits/outcomes not used in the initial clustering, we observed GC-specific patterns of association ( $p < 2 \times 10^{-8}$ ), consistent with the proposed mechanisms. We could also characterize the phenotypes driving membership of related GCs: for example, GC3-BCF and GC4-BCF showed differential association with insulin secretion/processing traits (reduced insulin secretion response  $p = 7 \times 10^{-14}$  vs 0.005; high vs low proinsulin,  $p = 7 \times 10^{-16}$  and  $9 \times 10^{-5}$ , respectively). We observed GC-specific associations with diverse phenotypes. Increased T2D-risk mediated by GC1-BMI was exclusively associated with renal failure ( $p = 6 \times 10^{-9}$ ) and arterial fibrillation ( $p = 5 \times 10^{-9}$ ). Hypertension and coronary artery disease risk were more strongly associated with T2D-risk mediated through GC1-BMI and GC2-IA ( $p < 1 \times 10^{-32}$ ) vs other GCs ( $p > 3 \times 10^{-14}$ ). Branched-chain amino acid levels were related exclusively to T2D-risk mediated through GC1-BMI and GC2-IA ( $p < 1 \times 10^{-7}$  vs  $> 0.05$  for other GCs). These findings demonstrate that process-specific GRSs capture the aetiological heterogeneity that contributes to overall T2D-risk, and that psGRS-differential effects can be detected across diverse clinical phenotypes. As well as enhancing understanding of the pathophysiological basis of T2D, these psGRSs provide a basis for a more personalised approach to the management of T2D.

**Leveraging T2D specific omics data in rare variant association analysis in TOPMed.** T.D. Majarian<sup>1</sup>, P.S. de Vries<sup>2</sup>, D. Jain<sup>3</sup>, B.E. Cade<sup>4,5,6</sup>, A.K. Manning<sup>1,7,8</sup>, TOPMed Diabetes Working Group. 1) Diabetes Research Group, Broad Institute of MIT and Harvard, Cambridge, MA; 2) Human Genetics Center, Department of Epidemiology, Human Genetics, and Environmental Sciences, School of Public Health, The University of Texas Health Science Center at Houston, Houston, TX, USA; 3) Department of Biostatistics, University of Washington, Seattle, Washington; 4) Division of Sleep and Circadian Disorders, Brigham and Women's Hospital, Boston, MA; 5) Division of Sleep Medicine, Harvard Medical School, Boston, MA; 6) Program in Medical and Population Genetics, The Broad Institute of MIT and Harvard, Cambridge, MA; 7) Clinical and Translational Epidemiology Unit, Massachusetts General Hospital, Boston, MA; 8) Department of Medicine, Harvard Medical School, Boston, MA.

In whole genome sequencing (WGS) studies of rare variants, multiple variants must be aggregated into units to have sufficient statistical power for association tests with type 2 diabetes (T2D). We incorporated T2D-relevant functional annotations in generating three separate gene-centric aggregation strategies as an alternative to agnostic, sliding window-based approaches. Using TOPMed WGS (44,732 individuals in 23 studies), T2D was defined by fasting glucose  $\geq 7$  mmol/L or HbA1c  $\geq 6.5\%$  or 2-hr OGTT  $\geq 11.1$  mmol/L or non-fasting glucose  $\geq 11.1$  mmol/L or treatment, physician diagnosis, self-report, resulting in 9,651 T2D cases and 35,081 controls from 4 ancestries: African American, Asian, European, and Hispanic. We tested association of each aggregation unit using sequence kernel association tests (SKAT) as implemented in the GENESIS package. P-value based meta-analyses of summary statistics were also performed. We used Bonferroni correction to determine statistical significance within each of 3 gene-centric grouping strategies. We defined aggregation units with islet-specific expressed genes from previously published RNA-seq data of 89 individuals with and without T2D (aggregation 1). Each unit included regulatory or high-impact, protein truncating variants. Promoter and enhancer regions were derived from chromatin state predictions, filtered by predicted transcription factor binding sites, and linked to genes by distance and publicly available databases. Two gene-centric coding variant aggregation strategies were also used: high-impact, protein truncating variants (2) and high to moderate-impact variants, protein truncating and missense variants (3). Our results show 8,922 islet expressed genes with cumulative minor allele count greater than 10, comprised of 1 million variants. The *TMEM35B* aggregation unit was associated with T2D in the Asian ancestry analysis ( $P = 1.3 \times 10^{-6}$ , (1)). High impact variant aggregation (2) yielded 18,420 tests. *DNASE1* and *EXOC6B* units were associated with T2D in the Asian ancestry ( $P = 1.4 \times 10^{-6}$ , (2)). The *ZNF454* aggregation unit was significant in meta-analysis ( $P = 1.6 \times 10^{-7}$ , (2)). 19,048 units were identified in high- and moderate-impact aggregation. *MC4R* was associated with T2D ( $P = 2.6 \times 10^{-6}$ , (3)) in the Asian ancestry analysis. In conclusion, with islet-specific rare variant aggregation, we identified sets of variants that were likely to be both functional and act on common gene targets in the setting of T2D.

Paterson<sup>11</sup>, C. Piccirillo<sup>4,5,12,13</sup>, C. Polychronakos<sup>2,6</sup>, J.B. Richards<sup>1,2,3,4,14</sup>. 1) Lady Davis Institute for Medical Research, Montreal, Quebec, Canada; 2) Department of Human Genetics, McGill University, Montreal, Quebec, Canada; 3) Department of Epidemiology and Biostatistics, McGill University, Montreal, Quebec, Canada; 4) Department of Medicine, McGill University, Montreal, Quebec, Canada; 5) Department of Microbiology and Immunology, McGill University, Montreal, Quebec, Canada; 6) Department of Pediatrics, McGill University, Montreal, Quebec, Canada; 7) Human Genetics Center, University of Texas School of Public Health, Houston, Texas, USA; 8) The Center for Applied Genomics, The Children's Hospital Philadelphia, Philadelphia, Pennsylvania, USA; 9) Department of Pediatrics, University of Pennsylvania School of Medicine, Philadelphia, Pennsylvania, USA; 10) Division of Human Genetics, Abramson Research Center, The Children's Hospital of Philadelphia, Philadelphia, Pennsylvania, USA; 11) The Hospital for Sick Children Research Institute, The Hospital for Sick Children, Toronto, Ontario, Canada; 12) Program in Infectious Diseases and Immunology in Global Health, Centre for Translational Biology, Research Institute of McGill University Health Centre, Montreal, Quebec, Canada; 13) FOCiS Centre of Excellence in Translational Immunology (CETI), Montreal, Quebec, Canada; 14) Department of Twin Research and Genetic Epidemiology, King's College London, London, UK.

The genetic etiology of type 1 diabetes (T1D) has been extensively studied, with 57 loci identified to date, mainly through genome-wide association studies (GWAS). Most of these known genetic associations involve common variants, while a sizable portion of the missing heritability of T1D may be attributed to unidentified rare single nucleotide polymorphisms (SNPs) (minor allele frequency (MAF) < 5%). The recent availability of large human whole genome sequencing datasets enables the interrogation of rare genetic variation by imputation from directly genotyped data, in search of large genetic effects by rare alleles. Here, through deep imputation, GWAS, and meta-analysis of 12 European cohorts totaling of 9,684 T1D cases and 15,743 controls, we identified 47 independent genome-wide significant variants outside the major histocompatibility complex, among which 23 were common and 24 had MAF < 5%. All 24 rare SNPs had large effects ( $OR_{discovery} > 1.5$ ), and only 5 mapped in previously described autoimmune loci. Six low-frequency variants successfully replicated at  $p < 0.05$  and with  $p_{combined} < p_{discovery}$  in a separate cohort (4,329 T1D cases from the T1DGC sibling pairs/9,543 controls from UK Biobank), 5 of which were novel. After combining discovery and replication results, all of them had an  $OR \geq 1.5$ , and 3 achieved an  $OR \geq 2$ . *In silico* analysis using topological domains and proximity to functional elements prioritized a low-frequency variant at 2q24.3 (rs60587303 (C), MAF 1.8%) within the first intron of *STK39*, with an  $OR_{combined}$  of 1.97 (95% CI 1.58-2.47,  $P_{combined}$   $2.9 \times 10^{-9}$ ), an effect comparable to those of the insulin (*INS*) and *PTPN22* loci. Additional analysis showed that admixture did not unduly bias results for this SNP. This variant overlaps a DNase I hypersensitivity cluster in 68 cell types and a cluster of transcription factor bindings sites including *FOS*, *JUN* and *STAT3*. Pharmacological blocking of *Stk39* in murine T-cells lines increased activation and proliferation of effector T cells and secretion of interferon gamma from CD4+ T cells. Thus, we identified 5 novel rare T1D variants, which have effect sizes larger than most previously described common SNPs. Our findings highlight *STK39* as a protein, with no previously known role in T1D, which appears to influence T-cell activation and effector functions. These findings add to the knowledge of the genetic architecture of T1D and demonstrate *STK39* as a new T1D gene with potential therapeutic implications.

**2154W**

**Diabetes risk loci regulate the expression of nuclear-encoded mitochondrial genes.** H. Maude<sup>1,2</sup>, F. Tamanini<sup>1</sup>, D. Huntley<sup>2</sup>, M.J Jarvelin<sup>3</sup>, W. Laur<sup>4</sup>, N. Maniatis<sup>4</sup>, T. Andrew<sup>4</sup>. 1) Department of Genomics of Common Disease, Imperial College London, United Kingdom; 2) Department of Life Sciences, Imperial College London, United Kingdom; 3) Department of Epidemiology and Biostatistics, Imperial College London, United Kingdom; 4) Department of Genetics, Evolution & Environment, UCL, London, United Kingdom.

Mitochondrial dysfunction is commonly associated with Type 2 Diabetes (T2D) and has been observed in ostensibly healthy, but insulin resistant offspring of T2D patients. However, there remains a lack of genetic evidence supporting a heritable mechanism, thus supporting competing hypotheses that the observed changes are a consequence of disease, rather than a contributory cause. Since the majority of known T2D genetic risk loci (>200) are non-coding, there remains the possibility that common variants modify mitochondrial function through currently uncharacterised regulatory mechanisms. Given that non-coding variants can regulate the expression levels of local *cis*- (and distal *trans*-) genes in the genome, we hypothesize that individuals at risk of T2D possess an inherent mitochondrial dysfunction, driven by heritable changes in the expression of nuclear- encoded mitochondrial genes (NEMGs). In order to investigate this, subcutaneous adipose eQTL (expression quantitative trait loci) and T2D disease loci were co-located using high-resolution genetic maps, to estimate the location of variants that increase risk of T2D by altering the expression of *cis*-genes (here named Diabetes-eQTL). The current study identifies a number of NEMGs (>80) with evidence of being regulated by variants at Diabetes-eQTL. These *cis*-NEMGs include many which maintain general mitochondrial function, as well as genes which function in common metabolic pathways related to fuel partitioning of lipids, carbohydrates and amino acids, in addition to energy production. Further work has been carried out to validate the altered expression of these *cis*-NEMGs and implicated mitochondrial pathways using independent T2D case-control expression data, and to characterize the functional role of the *cis*-NEMGs in peripheral insulin resistance. We observe enrichment of *cis*-genes involved in branched chain amino acid (BCAA) catabolism and propose a genetic mechanism driving the increased levels of BCAAs, which have been demonstrated to be effective biomarkers for predicting T2D.

**2155T**

**Integration of genome-wide polygenic risk scores from type 2 diabetes and related glyceic traits improves the prediction of the disease in Partners Healthcare Biobank participants.** *J.M. Mercader<sup>1</sup>, A. Leong<sup>3,4</sup>, V. Kaur<sup>2</sup>, B. Porneala<sup>3</sup>, M.S. Udler<sup>2,1,4</sup>, J.B. Meigs<sup>3,4</sup>, J.C. Florez<sup>2,1,4</sup>.* 1) Programs in Metabolism and Medical & Population Genetics, Broad Institute of Harvard and MIT, 02142 Cambridge, Massachusetts, USA; 2) Diabetes Unit and Center for Genomic Medicine, Massachusetts General Hospital, 02114 Boston, Massachusetts, USA; 3) Division of General Internal Medicine, Massachusetts General Hospital, Boston, 02114 Massachusetts, USA; 4) Department of Medicine, Harvard Medical School, 02115 Boston, Massachusetts, USA.

Despite the identification of hundreds of loci associated with type 2 diabetes (T2D), the ability of these genetic markers to predict disease incidence is poor. Recently developed methods allow the generation of genome-wide polygenic risk scores (PRS), which improve prediction over using only genome-wide significant loci. Current PRSs developed for T2D are based on summary statistics from T2D genome-wide association studies (GWAS) and cannot distinguish between individuals who develop T2D due to insulin resistance, impairment of beta-cell function, or both. We hypothesized that combining the PRSs based on GWAS for T2D and related glyceic traits may be an alternative strategy to improve the prediction of T2D. To test this hypothesis we generated a PRS composed of 5.9M variants based on a T2D GWAS (12,931 T2D cases and 57,196 controls), 1.9M variants from a GWAS of homeostasis model assessment of beta-cell function, (HOMA-B, N=46,168) and 1.8M variants from GWAS data from homeostasis model assessment of insulin resistance (HOMA-IR, N=46,168). We computed the PRS for these three traits in 12,938 subjects participants from Partners Healthcare Biobank, a biobank from patients seen at Partners HealthCare-affiliated hospitals in Boston. Genotyping was performed with the Illumina Multi-Ethnic Genotyping Array, and imputation with the Haplotype Reference Consortium panel after applying standard quality control procedures. By combining the PRSs for T2D and both glyceic traits we observed that PRSs for T2D (OR per SD=1.4,  $p=5 \times 10^{-22}$ ), HOMA-IR (OR per SD=1.26,  $p=5 \times 10^{-7}$ ), and HOMA-B (OR per SD=0.8,  $p=6 \times 10^{-4}$ ) were associated with T2D, with the three of them providing orthogonal information. The variance explained by the combination of the three genetic PRSs after accounting for sex, age and body-mass-index improved by 32% compared to the model that used only the T2D PRS. Additionally, we observed that individuals in the intersection of the top 5% percentile for T2D PRS and the top 5% percentile of HOMA-IR had 5.5 fold higher risk for T2D ( $p=1.5 \times 10^{-6}$ ) compared to individuals in the middle of the T2D PRSs distribution, suggesting that intersection of tail-ends of PRS for several related traits can identify individuals with extreme genetic risk for T2D. Overall, we show the advantage of using multiple-phenotype PRSs to improve the prediction of T2D. This approach may be enhanced as data from additional and larger T2D and glyceic traits GWAS become available.

**2156F**

**Distinct polymorphisms in *RNLS* are associated with Type 1 Diabetes (T1D) in European and African ancestry populations and implicate novel functional pathways.** *S. Onengut, R. Pickin, M. Faidas, N. Vogler, E. Gersz, S.S. Rich.* University of Virginia, Charlottesville, VA.

Type 1 diabetes (T1D) is an autoimmune disease that arises from the action of both genetic and environmental factors. Genetic studies of T1D have focused almost exclusively on European ancestry populations and identified more than 50 risk loci. We recently conducted the largest T1D association study in African-ancestry participants and identified variants in the 10q23.31 T1D risk locus in European and in African ancestry populations, suggesting a common genetic contribution to T1D. The T1D risk variants in the 10q23.31 locus are located in the non-coding region of the FAD-dependent amine oxidase gene (*RNLS*). While 10q23.31 appears to be a "shared" T1D risk locus, the T1D-associated variants in European populations are distinct from the African-ancestry T1D risk variants; thus, there may be allelic heterogeneity. Our current understanding of the function of *RNLS* is limited. In previous studies, a positive *RNLS*-STAT3 feedback loop has been suggested. Thus, we evaluated the role of *RNLS* in the immune system, given the T1D association and the importance of JAK-STAT signalling in immune-mediated diseases. RNA-seq was used to compare transcriptomes of Jurkat cells expressing endogenous *RNLS* versus those overexpressing *RNLS*. RNA-seq analysis identified 390 genes that were more than two-fold differentially expressed, of which 74.1% (289/390) of genes were up-regulated and 25.9% (101/390) were down-regulated in cells overexpressing *RNLS*. Tissue-specific gene network analysis revealed that up-regulated genes mainly functioned in pathways related to chromosome segregation and cell division; in contrast, genes that were down-regulated by *RNLS* overexpression were involved in the interferon (IFN) and nuclear factor- $\kappa$ B (NF- $\kappa$ B) signaling pathways. Together, these results suggest a role for *RNLS* in cell-cycle related pathways and immune signaling pathways, providing new mechanistic insights of the role of *RNLS* in risk of T1D.

**Chromatin accessibility patterns of a hiPSC model of islet development and type 2 diabetes risk.** M. Perez-Alcantara<sup>1</sup>, C. Honoré<sup>2</sup>, M. Thurner<sup>1,3</sup>, M. Hansson<sup>4</sup>, A.L. Gloy<sup>1,3,5</sup>, M. van de Bunt<sup>1,3</sup>, N.L. Beer<sup>2</sup>, M. McCarthy<sup>1,3,5</sup>. 1) Wellcome Centre for Human Genetics, University of Oxford, Oxford, United Kingdom; 2) Department of Stem Cell Biology, Novo Nordisk A/S, Maaloev, Denmark; 3) Oxford Centre for Diabetes, Endocrinology & Metabolism, University of Oxford, Oxford, United Kingdom; 4) Department of Stem Cell Research, Novo Nordisk A/S, Maaloev, Denmark; 5) Oxford NIHR Biomedical Research Centre, Churchill Hospital, Oxford, United Kingdom.

Most variants associated with type 2 diabetes (T2D) predisposition in genome-wide association studies (GWAS) act through defects in insulin secretion, which could result from deficiencies in islet development and/or mature islet function. While functional studies have focused on the latter, we have explored the contribution of disturbed islet development to T2D pathogenesis. We used ATAC-seq to characterise patterns of open chromatin in three human fibroblast-derived iPSC lines (from different donors) differentiated along the pancreatic endocrine lineage. We obtained ATAC-seq profiles of 174,379 peaks at eight developmental stages (iPSC to beta-like cells). Chromatin accessibility profiles at each peak were clustered by weighted gene co-expression network analysis (WGCNA). Peaks within the resulting 26 modules (median=558, range=5841) that were highly correlated (Pearson's  $r$   $p$ -value < mode [ $r$   $p$ -value]) with their respective module profile were tested for enrichment in T2D-associated SNPs from the European ancestry DIAMANTE analysis (~900,000 participants) using fGWAS. Six clusters of chromatin accessibility profiles were enriched in T2D-associated signals, reaching maximum ATAC-seq peak counts at varying degrees of developmental maturity, including middle (posterior foregut) and late stages (endocrine and beta-like cells), with log<sub>2</sub> fold enrichment values from 2.49 (95% CI 1.06–3.32) to 3.92 (95% CI 0.15–5.24). Peaks within these modules were tested for enrichment in transcription factor (TF) binding sites with HOMER. Enriched ( $p$ -value  $\leq 10^{-10}$ ) motifs included those bound by TFs implicated in islet development (e.g. *PDX1*, *MAFA*, *FOXA2*; which were expressed at those stages as measured by RNA-seq), confirming the biological relevance of this model. 1007 ATAC-seq peaks contained at least one variant from the 99% credible set, 47 with an individual posterior probability of association (PPA) above 10%. Several were near known important genes in islet development (*HNF1A* [98%], *HNF4A* [52%]) and less well-known candidates such as *WDR72* (99%) or *SLC2A10* (40%), with ATAC-seq peak counts across stages significantly ( $p$ -value<0.01) correlating with these genes' expression profiles. Integrating ATAC-seq data with epigenetic and gene expression data which have also been obtained from this iPSC-derived differentiation model will allow further exploration of the contribution made by genome regulation to disturbed human islet development and T2D pathogenesis.

## 2158T

**Trans-ethnic meta-analysis of gestational diabetes reveals shared genetic background with type 2 diabetes.** N. Pervjakova<sup>1,2</sup>, J.P. Cook<sup>3</sup>, A.P. Morris<sup>1,3</sup>, T. Ferreira<sup>4,5</sup>, R. Mägi<sup>1</sup>, – on behalf of the GenDip Consortium. 1) Estonian Genome Center, Institute of Genomics, University of Tartu, Tartu, Tartumaa, Estonia; 2) Genomics of Common Disease, Division of Diabetes, Endocrinology and Metabolism, Department of Medicine, Imperial College London, UK; 3) Department of Biostatistics, University of Liverpool, Liverpool, UK; 4) 5 Big Data Institute, Li Ka Shing Center for Health for Health Information and Discovery, Oxford University, Oxford, UK; 5) Wellcome Centre for Human Genetics, University of Oxford, Roosevelt Drive, Oxford OX3 7BN, UK.

Gestational diabetes mellitus (GDM), defined as glucose intolerance first recognized in pregnancy, has important implications for both mother and child. Offspring of mothers with GDM have an increased risk of birth complications associated with increased birth weight and adiposity, as well as for developing metabolic syndrome, type 2 diabetes (T2D) and cardiovascular disease in later life. Furthermore, in a 5-10 years perspective, it is estimated that around 50% of the women diagnosed with GDM will develop T2D. To date, the only genome-wide association study (GWAS) for GDM, in 1,399 affected Korean women, revealed associations at two loci: *MNTR1B* and *CDKAL1*. We conducted trans-ethnic meta-analysis of 21 GWAS in 5,374 cases and 346,506 controls of diverse ancestry (62.0% European, 16.5% East Asian, 3.2% Mexican-American and 18.3% Afro-Caribbean), each imputed up to reference panels from the 1000 Genomes Project or Haplotype Reference Consortium. The trans-ethnic meta-analysis, performed with MR-MEGA to allow for heterogeneity in allelic effects between ancestries, included 13,980,490 variants, after excluding those with minor allele count <5 and imputation quality <0.4 in each GWAS. We replicated both known GDM associations at genome-wide significance ( $P < 5 \times 10^{-8}$ ): *MTNR1B* (rs10830963,  $P = 2.3 \times 10^{-9}$ ) and *CDKAL1* (rs9348441,  $P = 9.7 \times 10^{-15}$ ). We also identified three additional novel loci: *TCF7L2* (rs7903146,  $P = 1 \times 10^{-14}$ ), *CDKN2A/B* (rs10811660,  $P = 1.9 \times 10^{-9}$ ) and *LOC105369513* (rs143421658,  $P = 4.1 \times 10^{-8}$ ). Allelic effects of GDM association signals were mostly homogeneous across ethnic groups. The exception was at the *CDKAL1* locus ( $P_{het} = 3.68 \times 10^{-9}$ ), where the association signal was driven by East Asian ancestry GWAS ( $OR_{East-Asian} = 1.67(1.46-1.89)$ ;  $OR_{Europeans} = 1.06(1.01-1.12)$ ). Four of the loci (*MTNR1B*, *CDKAL1*, *TCF7L2*, and *CDKN2A/B*) have also been robustly associated with T2D, and lead variants are identical to those we have identified for GDM, supporting a shared underlying genetic contribution to both diseases.

**Altered expression of *WFS1* & *NOTCH2* genes associated with diabetic nephropathy in T2DM patients.** S.A. Sharaf<sup>1</sup>, N.A. Kantoush<sup>2</sup>, D.F. Ayoub<sup>2</sup>, A.A. Ibrahim<sup>2</sup>, A.A. Abdelaal<sup>1</sup>, R. Abdel Aziz<sup>2</sup>, M.M. ElHefnawi<sup>1</sup>, A.N. Ahmed<sup>2</sup>. 1) Clinical and Chemical Pathology Department-Faculty of Medicine Cairo University, Cairo, Egypt; 2) Clinical and Chemical Pathology Department, National Research Centre, Cairo, Egypt; 3) Internal Medicine, Faculty of Medicine, Cairo University, Cairo, Egypt; 4) Biomedical Informatics and Chemoinformatics Group, Informatics and Systems Department, Division of Engineering Research, National Research Centre, Cairo, Egypt.

**Introduction:** The increased incidence of type 2 diabetes mellitus (T2DM) and the importance of early identification and management of its complications, especially diabetic nephropathy (DN), have spotted the light on genetic factors that increase risk of T2DM and its related nephropathy. The present study aimed at investigating expression of (*KCNJ11*, *ABCC8*, *JAZF1*, *WFS1*, *PPARG*, *NOTCH2* and *EXOSC4*) genes in peripheral blood of T2DM patients. **Materials and Methods:** The study included 30 non-complicated T2DM patients, 30 patients with DN and 40 healthy controls. Quantitative Real Time PCR Array was used to study gene expression. **Results:** *NOTCH2* showed higher expression while *KCNJ11*, *JAZF1*, *WFS1* and *PPARG* genes showed lower expression in DN patients compared to non-complicated patients. *KCNJ11*, *JAZF1*, *WFS1*, *PPARG*, and *EXOSC4* expression showed significant negative correlation with microalbumin, while *NOTCH2* expression was significantly positively correlated with microalbumin. As regard HbA1c and studied genes expression, there was significant negative correlation between *WFS1* expression and HbA1c, while *NOTCH2*, *KCNJ11*, *JAZF1*, *PPARG*, *EXOSC4* expression didn't show significant correlation with HbA1c. Risk ratio of studied genes expression showed that *WFS1* and *NOTCH2* had highest risk ratio (30) and highest sensitivity and specificity, in relation to DN and they were the best predictors in the group of studied genes at cut off value of =0.861 for *WFS1* and =0.678 for *NOTCH2*. **Conclusions:** Altered expression of *WFS1* and *NOTCH2* genes may play a role in pathogenesis and development of DN in patients with T2DM. These results may contribute in early identification and management of DN.

**Association of risk factors and *CAPN10*, *PGC-1α* genes in T2D pathogenesis along with potential microRNA targets: A study from Northwest India.** R. Sharma<sup>1</sup>, R. Kapoor<sup>2</sup>, A.J.S. Bhanwer<sup>1</sup>. 1) Human Genetics, Guru Nanak Dev University, Amritsar, Punjab, India; 2) Heart station and Diabetes Clinic, Amritsar, India.

Diabetes is a cluster of metabolic diseases characterized by hyperglycaemia that results from alterations in either insulin secretion, insulin action, or both. The prevalence of T2D is escalating especially in developing countries like India. Study enrolled 6195 individuals (3762 T2D cases and 2433 healthy controls) from North-West India. Waist circumference, waist-hip ratio, hypertension, Triglycerides, RBS, HbA1c, Percent body fat, SGOT, SGPT levels posed risk towards T2D. The association of *CAPN10* (rs3792267, rs3842570, rs5030952) and *PGC-1α* (rs3736265, rs3755863, rs8192678, rs17574213, rs2970847, rs2946385) polymorphisms were investigated in 1125 samples including 554 T2D cases and 571 healthy controls. Minor allele of *CAPN10* rs3792267 [ $p=2.97 \times 10^{-4}$ , 1.69(1.35-2.13)], rs5030952 [ $p=3.26 \times 10^{-5}$ , 1.59(1.28-2)], *PGC-1α* rs3736265 [ $p=0.006$ , 1.49(1.12-1.96)], rs2970847 [ $p=0.02$ , OR=1.22(3.0-1.43)] conferred risk towards T2D progression. Significant association of *CAPN10* 121 haplotype combination played protective role against T2D [ $p=0.0008$ , 0.75(0.63-0.89)]. Linkage disequilibrium (LD) analysis revealed strong LD for *PGC-1α* rs3736265 and rs2970847 polymorphisms and the haplotypes G-A-G-G-C-A, G-G-G-G-C-C of *PGC-1α* gene played protective role against T2D. Epistatic effect of *PGC-1α* rs3755863, rs8192678, rs2970847 variants was observed to confer 2.48-fold increased T2D risk. MicroRNAs (miRNAs) regulate the expression of protein-coding genes and represent potential biomarkers. In addition, we identified molecular networks and biological pathways, enriched for or targeted by miRNAs. Ingenuity Pathway analysis (IPA) predicted the miRNA targets mir-223, mir-132, mir-103, mir-142, mir-34a and mir-199a for T2D. The discovered miRNAs and their target genes and pathways represent potential clinically actionable biomarkers and therapeutic targets. The financial assistance to Rubina Sharma by UGC, UGC-CPEPA and DBT Scheme is acknowledged. The authors declare no conflict of interest.

**Development and standardization of a type 1 diabetes genetic risk score for use in newborn screening and incident diagnosis.** S.A. Sharp<sup>1</sup>, S.S. Rich<sup>2</sup>, A.R. Wood<sup>1</sup>, S.E. Jones<sup>1</sup>, R.N. Beaumont<sup>1</sup>, J.H. Harrison<sup>1</sup>, D.A. Schneider<sup>3</sup>, J.M. Locke<sup>1</sup>, M.N. Weedon<sup>1</sup>, W.A. Hagopian<sup>2</sup>, R.A. Oram<sup>1</sup>. 1) University of Exeter Medical School, University of Exeter, Exeter, Devon, United Kingdom; 2) PNRI, 720 Broadway, Seattle, WA 98122, USA; 3) University of Virginia, Charlottesville, VA, USA.

Type 1 diabetes (T1D) exhibits strong familial aggregation with ~50% of the genetic risk associated with HLA region genes. A genetic risk score (GRS) is a simple, inexpensive approach to improve prediction of T1D and to distinguish T1D from other diabetes subtypes in research and clinical settings. We aimed to use large cohort studies to improve the capture of genetic variants associated with T1D to maximise the discriminative power of a T1D GRS. We analysed genetic variants from 6481 cases with T1D and 9247 controls of the Type 1 Diabetes Genetics Consortium (T1DGC) in both the HLA region and across the genome. We included interactions of variants with strongly associated HLA haplotypes to create an improved T1D GRS. We validated our findings in the UK Biobank (542 with T1D, 16652 with type 2 diabetes (T2D), and ~374,000 controls). The improved T1D GRS used information from 68 single nucleotide polymorphisms (SNPs) and accounted for interactions between 18 HLA DR-DQ haplotype combinations. T1D discrimination was validated in UK Biobank (ROC AUC=0.922,  $p < 0.0001$  vs previous T1D GRS). The new T1D GRS was most discriminative of early onset T1D (<5 years old, AUC=0.942) but performed well for all T1D (AUC=0.922), including discrimination of T1D vs T2D in adults (AUC=0.918,  $p < 0.0001$ ). We simulated use of the improved GRS in a newborn screening program, demonstrating performance nearly twice as efficient as HLA genotyping alone (reflecting increased familial aggregation captured by the T1D GRS). Those with a T1D GRS in the top 0.01% had over 22.8% increased risk of T1D in childhood, suggesting a future threshold for intervention trials. Simulation experiments showed >78% of childhood T1D occurs in the top 10% of T1D GRS in the population, suggesting targeting parents for education about the presenting symptoms of T1D. Our results demonstrate how an improved T1D GRS is highly useful for both classifying form of diabetes in incident cases, and improving newborn screening efforts. Given the cost-effectiveness of SNP genotyping, this approach has great clinical and research potential in T1D and could be extended to other autoimmune disorders.

**Association study of three single nucleotide polymorphisms (SNPs) of *TERC*- a telomeric gene, in diabetic nephropathy patients.** G. Singh<sup>1,2</sup>, P. Raina<sup>1</sup>, H.S. Sandhu<sup>1</sup>, V. Kalotra<sup>1</sup>, V. Sharma<sup>2</sup>, I. Sharma<sup>2</sup>, I. Sethi<sup>2</sup>, V. Singh<sup>3</sup>, A. Marwaha<sup>4</sup>, E. Rai<sup>2</sup>, S. Sharma<sup>2</sup>, A.J.S. Bhanwer<sup>1</sup>. 1) Department of Human Genetics, Guru Nanak Dev University, Amritsar, India; 2) Human Genetics Research Group, School of Biotechnology, Shri Mata Vaishno Devi University, Katra, J&K, India; 3) Kidney Clinic and Dialysis Centre, Opposite Govt. Medical College, Amritsar, Punjab, India; 4) Joshi Hospital and Trauma Centre, Jalandhar, Punjab, India.

Telomeres are the border region of the chromosomes which continuously loses their bases per cell cycle. Telomere length is regulated by a set of genes and any variations in these genes have been extensively linked with attrition of telomeres in complex and age related disorders, such as Idiopathic pulmonary fibrosis, Cancers, Cardiovascular diseases, Atherosclerosis and Diabetes. Since Diabetic nephropathy (DN) is a major late onset complication of diabetes and affects ~30–40% of all patients with either type 1 or type 2 diabetes (T1D or T2D) and continues to be the leading contributor to end-stage renal disease (ESRD) worldwide. Thus, this effort has been made to identify the role of telomeric gene *TERC* in DN development. In this case-control study, 1740 subjects from North India were included, 374 were DN cases, 1056 were Non-DN & Non T2D controls and 310 were T2D controls (Without DN) and were genotyped for the three SNPs, rs10936599, rs3772190 and rs16847897 from *TERC* telomeric gene using the MassARRAY system. All three SNPs were observed to be associated with DN, but rs10936599 was providing protection, whereas rs3772190 and rs16847897 were conferring risk towards DN development in all the three compared groups i.e. Non-DN, Non-DN & Non T2D and T2D without DN controls. This observation demonstrated that *TERC*, a telomeric gene does play a vital role in the development of the DN and more studies should be carried out to elucidate its contribution in the development of this complication. The financial assistance to GS by UGC-UPE Scheme is acknowledged. Financial Support from DST/SERB, Gol through project grant to SS and project grants from UGC, Gol to SS and ER are acknowledged. Financial support from UGC-CPEPA to AJSB is also acknowledged. The authors declare no conflicts of interest.

To understand genetics of type 2 diabetes (T2D) in Japanese, we conducted meta-analysis of the four genome-wide association studies (GWAS; 36,614 cases and 155,150 controls of Japanese ancestry). We identified 88 T2D-associated loci ( $P < 5.0 \times 10^{-8}$ ) with 115 independent signals ( $P < 5.0 \times 10^{-6}$ ), of which 28 loci with 30 signals were novel. Twenty-eight missense variants were in linkage disequilibrium ( $r^2 > 0.6$ ) with the lead variants. Among the 28 missense variants, previously unreported three variants had distinct minor allele frequency (MAF) spectra between Japanese and Europeans (MAF<sub>JPN</sub> > 0.05 vs. MAF<sub>EUR</sub> < 0.01), such as the missense variants in genes related to pancreatic acinar cells (*GP2*) and insulin secretion (*GLP1R*). Trans-ethnic comparisons of the molecular pathways from the GWAS results highlighted both ethnically shared and distinct impacts of a series of pathways on T2D (e.g., monogenic diabetes). These findings shed light on the etiology of T2D in Japanese and Europeans.

## 2164T

## Discovery of 176 novel loci for type 2 diabetes in 790,275 individuals in a multi-ethnic meta-analysis.

**Background:** The global epidemic of type 2 diabetes (T2D) is projected to reach ~592 million by 2035. To date, genetic studies have uncovered >240 loci associated with T2D, but they only partially explain the genetic heritability of T2D. While the incidence of T2D varies with sex, age, and anthropometry, the genetic relationships have not been fully elucidated. In addition, the genetic mechanisms leading to T2D complications are largely unknown. To characterize the genetic etiology of T2D and its major complications, we performed genome-wide association studies in the Million Veteran Program (MVP), a mega-biobank established by the Veterans Health Administration. **Methods:** The current analyses comprise 790,275 individuals (156,233 with T2D), including 63,051 European, 21,234 African and 7,342 Hispanic T2D cases enrolled in MVP. Stratified by self-reported ethnicity, we conducted primary discovery analyses for T2D in MVP controlling for age, gender and 10 PCA's followed by an overall meta-analysis involving participants from the UK Biobank, DIAGRAM, PROMIS, MDC, RACE, MedStar, PennCath and PHF. Given the availability of individual participant data in MVP, the largest analysis of the X-chromosome to date was performed. SNP-T2D effect decomposition by BMI was done with causal mediation analysis. Stratified analyses for three macrovascular complications of T2D (coronary heart disease, stroke and peripheral vascular disease) and three microvascular complications (retinopathy, nephropathy and neuropathy) were also performed. **Results:** Our preliminary analyses identified 840 autosomal variants of genome-wide significance ( $P < 5 \times 10^{-8}$ ) at 393 distinct genomic regions; of these, 166 were previously not reported. Five of these novel loci were observed in African Americans only, which can be attributed to differences in allele frequencies, LD patterns, and potential effect heterogeneity. Chromosome X analysis identified an additional 10 novel loci, some of which displayed effect heterogeneity by sex. Finally, mediation analysis elucidated several loci that conferred T2D susceptibility through BMI. **Conclusion:** This large-scale multi-ethnic meta-analysis identified 176 novel T2D risk loci. Some T2D loci had effects that differed by African American ancestry, sex, diabetic complications, or obesity.

Identification of human disease signature genes typically requires samples from many donors to achieve statistical significance. Here we show that single cell heterogeneity analysis may overcome this hurdle by significantly improving the test sensitivity. We analyzed the transcriptome of 39,905 single islets cells from 9 donors and observed  $\beta$  cell heterogeneity trajectories associated with obesity or type II diabetes (T2D). We therefore developed RePACT, a general single-cell analysis algorithm to identify both common and specific signature genes for obesity and T2D with high sensitivity. We further mapped both  $\beta$  cell specific genes and disease signature genes to the insulin regulatory network identified from a genome-wide CRISPR screen. Our integrative analysis discovered the previously unrecognized roles of the cohesin loading complex and the NuA4/Tip60 histone acetyltransferase complex in regulating insulin transcription and release. Our study demonstrated the power of combining single-cell heterogeneity analysis and functional genomics to dissect the etiology of complex diseases.

**Subjects at the phenotypic extremes of the baseline T2D phenotype spectrum differ in genetic risk and disease progression over 36 months: a DIRECT study.** A. Wesolowska-Andersen<sup>1</sup>, C. Brorsson<sup>2</sup>, A. Mari<sup>3</sup>, R. Koivula<sup>4</sup>, A. Kurbasic<sup>4</sup>, A. Mahajan<sup>1</sup>, J. Fernandez<sup>1</sup>, A. Viñuela<sup>5</sup> on behalf of the DIRECT Consortium. 1) University of Oxford, Oxford, Oxfordshire, United Kingdom; 2) Technical University of Denmark, Lyngby, Denmark; 3) National Research Council, Padova, Italy; 4) Lund University, Malmö, Sweden; 5) University of Geneva, Geneva, Switzerland.

Type 2 diabetes (T2D) is a complex common disease with heterogeneous presentation and progression. The stratification of patients into more homogeneous subgroups is the foundation of precision medicine: however current T2D diagnosis based purely on a single biomarker - glucose - is not reflective of the disease heterogeneity. Here, we investigated detailed clinical phenotypes from 725 subjects with newly-diagnosed type 2 diabetes from the DIRECT study, comprising anthropometric, biochemical and glycemetic modelling variables. We applied reversed graph embedding to define a principal tree spanning the phenotype spectrum for 30 of these clinical variables. At the extremes of this baseline phenotype spectrum, we find the subjects with the highest involvement of processes underlying T2D etiology: beta-cell dysfunction, insulin resistance, obesity, and dyslipidemia. Using the tree branch points, we identified 5 subgroups of subjects who differ significantly in their clinical presentation at baseline, disease progression at 18 and 36 months, and patterns of genetic predisposition to T2D. We observed significant differences in disease progression between subgroups, evaluated in two ways: the slope of change in glycated haemoglobin (HbA1c) at 18m ( $p=1.14e-03$ ), and the proportion of patients starting or increasing dose of diabetes medication within each subgroup (18m,  $p=1.03e-06$ ; 36m,  $p=7.13e-10$ ). While the overall T2D genetic risk score (GRS) constructed using all 403 reported T2D GWAS loci did not differ between subgroups, we observed significant differences with process-specific GRSs, in particular the insulin secretion GRS ( $p=8.46e-08$ ). Additionally, we sought circulating multiomic signatures of the subgroups, detecting, at baseline, significant differences for 287 genes (RNA expression) and levels of 87 proteins and 192 metabolites at 5% FDR. These signatures can be used to better stratify patients, and to highlight additional underlying mechanisms, such as enrichment of neutrophil gene expression signatures in the fastest progressing subgroup ( $p=1.18e-24$ ). In conclusion, the heterogeneity observed in patients with newly-diagnosed diabetes can be described by different degrees of impairment of underlying biological processes. Identification and characterization of patients at the phenotypical extremes is an important step towards implementation of precision medicine in T2D.

**2167T**

**Type 2 diabetes and osteoporosis: A Mendelian randomization Study.** Q. Zhang<sup>1</sup>, W.D. Zhang<sup>2</sup>, J. Greenbaum<sup>1</sup>, C.Q. Sun<sup>2</sup>, H.W. Deng<sup>1</sup>. 1) Tulane University, New Orleans, LA; 2) Zhengzhou University, Zhengzhou, China.

Traditional epidemiological studies suggest that there is an association between type 2 diabetes (T2D) and bone mineral density (BMD) at the sites of the femoral neck and lumbar spine (FNK and LS BMD), indicating a potentially important relationship between T2D and the development of osteoporosis (OP). However, these findings may be influenced by unmeasured confounding factors that can obscure the true relationship between the phenotypic traits. Therefore, we performed Mendelian randomization (MR) analyses to determine whether there is a causal relationship between T2D and BMD (FNK and LS BMD), where T2D may increase the risk of developing OP. Adopting a two-sample MR approach we incorporated genome-wide association (GWAS) summary statistics from the DIAbetes Genetics Replication And Meta-analysis (DIAGRAM) (a total of 26,488 cases and 83,964 control) consortium and the GEnetic Factors for OSteoporosis (GEFOS) Consortium (n=53,236). Using this MR approach we found that T2D is not causally associated with FNK BMD ( $b = 0.022$ ,  $se = 0.018$ , 95% CI (-0.013, 0.057),  $p = 0.229$ ) and LS BMD ( $b = 0.028$ ,  $se = 0.025$ , 95% CI (-0.021, 0.077),  $p = 0.269$ ), which deviates from the traditional study results. This study demonstrates no causal relationship between T2D and OP etiology and may provide novel insights into the pathophysiology of bone related diseases. **Exome sequencing identifies a nonsense variant in DAO associated with reduced energy expenditure and respiratory quotient in American Indians.** P. Piaggi<sup>1</sup>, C. Koroglu<sup>1</sup>, A.K. Nair<sup>1</sup>, Y.L. Muller<sup>1</sup>, W.C. Hsueh<sup>1</sup>, S. Kobes<sup>1</sup>, A.R. Shuldiner<sup>2</sup>, H.I. Kim<sup>2</sup>, N. Gosalia<sup>2</sup>, C. Van Hout<sup>2</sup>, M. Jones<sup>2</sup>, R.L. Hanson<sup>1</sup>, C. Bogardus<sup>1</sup>, L.J. Baier<sup>1</sup>. 1) NIDDK, Phoenix, AZ; 2) Regeneron Genetics Center, Regeneron Pharmaceuticals, Inc., Tarrytown, NY.

Obesity and energy expenditure (EE) are heritable and genetic variants altering EE and substrate utilization may contribute to the development of obesity. The aim of this study was to identify genetic variants that affect EE in American Indians, an ethnic group with a high prevalence of obesity where lower EE predicts long-term weight gain. Whole-exome sequencing was performed in 373 healthy Pima Indians (224 men, age:  $27 \pm 6$  yr, BMI:  $34 \pm 7$  kg/m<sup>2</sup>, body fat:  $33 \pm 8\%$ ) who underwent a 24-h session in a whole-room indirect calorimeter to measure EE and respiratory quotient (RQ, an index of substrate utilization) during energy balance. Genotypic analyses of 24-h EE were performed for 60,231 exonic variants ( $\geq 5$  carriers) after adjusting for age, sex, body composition, physical activity, the first 5 genetic principal components, and accounting for genetic relatedness among individuals by pairwise identity-by-descent estimates. Due to the limited statistical power for rare variants, only coding variants annotated to be damaging by prediction tools (CADD, SIFT, or PROVEAN) were considered for follow-up studies. A total of 17 exonic variants predicted to be pathogenic by at least one algorithm showed a  $p$ -value  $< 10^{-3}$  for association with 24-h EE (effect sizes ranged from 43 to 268 kcal/day). Rs752074397 (C/A, CADD=35) introduces a premature stop codon (Cys264Ter) in DAO, and demonstrated the strongest association for 24-h EE ( $p = 10^{-5}$ ), where the Ter allele (7 carriers) associated with substantially lower 24-h EE ( $b = -268$  kcal/day) and sleeping EE ( $b = -135$  kcal/day,  $p = 0.01$ ). This variant also associated with lower RQ ( $b = -0.03$ ,  $p = 2 \times 10^{-3}$ ), reflecting markedly reduced carbohydrate oxidation rate ( $b = -197$  kcal/day,  $p = 7 \times 10^{-3}$ ). Analysis of rs752074397 in a population-based sample of 7686 Pima Indians showed that the Ter allele has a frequency of 0.5% and 0.2% in full vs. mixed heritage Pima Indians, while public databases show that this variant is extremely rare in Latinos (ExAC frequency=0.009%) and monomorphic in other ethnic groups. DAO encodes D-amino acid oxidase, which is involved in dopamine synthesis which might explain its role on modulating EE. Functional studies are ongoing to determine the effect of rs752074397 on DAO protein expression and activity. Our results suggest that a nonsense mutation in DAO may influence EE and substrate oxidation in American Indians. Identification of variants that influence energy metabolism may lead to new pathways to treat human obesity.

**Heterozygotes for a founder mutation in SLC12A3 that causes autosomal recessive Gitelman syndrome is associated with lower serum potassium in the Amish.** X. Wan<sup>1,2</sup>, J.A. Perry<sup>1</sup>, H. Zhang<sup>1</sup>, E. Streeten<sup>1</sup>, B.D. Mitchell<sup>1</sup>, A.R. Shuldiner<sup>1,3</sup>, M. Fu<sup>1</sup>. 1) Program in Personalized and Genomic Medicine, and Division of Endocrinology, Diabetes & Nutrition, Department of Medicine, University of Maryland School of Medicine, Baltimore, MD; 2) Department of Endocrinology and Diabetes Center, The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; 3) Regeneron Genetics Center, Tarrytown, NY.

Potassium levels regulate multiple physiological processes, including nerve and muscle function, hormone secretion and action, glucose and insulin metabolism, and fluid and blood pressure homeostasis. To identify functional variants that contribute to normal physiologic variation in serum concentrations of potassium, we performed whole exome sequencing in 5045 Old Order Amish subjects. We identified a cluster of variants spanning ~537 Kb on chromosome 16q13 showing exome-wide significant association with age-, age<sup>2</sup>- and sex-adjusted potassium levels ( $P = 5 \times 10^{-8}$  to  $6.57 \times 10^{-9}$ ). These variants tag a large haplotype block that includes 22 genes. Among the associated variants is a missense variant in *SLC12A3* (rs200697179, R642G), the gene encoding solute carrier family 12 member 3, a renal thiazide-sensitive sodium-chloride cotransporter that is important for electrolyte homeostasis. Mutations in this gene cause autosomal recessive Gitelman syndrome. The mutation, R642G, in its recessive form is a known pathogenic variant. Consistent with a founder effect and genetic drift, the minor allele frequency (MAF) of R642G is 650 times higher in the Amish (MAF: 0.013; 4912 wild type homozygotes and 133 heterozygotes) than in other populations (MAF: 0.0002 in 1000 Genomes). The heterozygous carriers had markedly lower potassium levels than wild type carriers (4.053 mmol/L vs 4.201 mmol/L;  $P = 1.89 \times 10^{-3}$ ). The heterozygous carriers also had slightly lower serum chloride levels, lower blood urea nitrogen (BUN) levels and higher serum CO<sub>2</sub> levels than wild type carriers ( $P = 1.88 \times 10^{-3}$  to  $7.16 \times 10^{-3}$ ). In a subset of 469 wild type homozygotes and 10 R642G heterozygotes subjected to 7 days of a low-salt diet (40 mmol Na/day), carriers had nominally higher resting heart rate (79.7 vs. 74.2 bpm, respectively;  $p = 0.025$ ) but no significant difference in blood pressure or in heart rate or blood pressure in the same subjects subjected to a high salt diet (300 mmol Na/d), suggesting increased heart rate as a compensatory change for mild hypovolemia on a low-salt diet. In summary, we have identified a locus on chromosome 16q13 that is significantly associated with potassium levels and confirmed a heterozygous mutation (R642G), in *SLC12A3* that may influence potassium levels at the population level. These findings support the growing realization that pathogenic variants causing many canonically recessive disorders may manifest an intermediate often sub-clinical phenotype in heterozygotes.

**Phenome-wide patterns of genotype-environment (GxE) interactions.**

R. Moore<sup>1,2</sup>, I. Barroso<sup>1</sup>, O. Stegle<sup>2</sup>. 1) Wellcome Sanger Institute, Cambridge, United Kingdom; 2) European Bioinformatics Institute, Cambridge, United Kingdom.

Phenome-wide association studies (PHEWAS) are a useful tool to study the effect of loci on multiple phenotypes, and have established new links between biological processes or diseases not previously known to be related. However, such pleiotropy for genotype-environment (GxE) interactions has been poorly explored. Phenome-wide GxE analyses may reveal greater aetiological overlap between traits than conventional PHEWAS, or identify loci that are enriched for interaction effects. To explore phenome-wide GxE effects, we used seven cardiometabolic traits from the UK Biobank data ( $N_{\text{min}} = 251,443$ ), focussing on a set of 57,328 variants (1,104 loci, 1MB window, LD  $r^2 < 0.1$ ) significantly associated ( $P < 5 \times 10^{-8}$ ) with basal metabolic rate (BMR), and a set of 64 lifestyle factors, including dietary and physical activity variables. Interaction effects were evaluated using StructLMM (bioRxiv doi: 270611), a computationally efficient method for detection and characterisation of loci interacting with one or more environmental variables. There are two main results from our GxE analysis. First, this analysis detects many interaction loci. Whilst only eight significant interaction loci are identified for BMR (conditional FDR 5%; estimated heritability 0.29), in contrast, for other traits with lower heritability ( $< 0.27$ ), including BMI and hip circumference, we detect  $\geq 30$  distinct interaction loci. We also note that 32% of the detected interaction loci are shared across at least three phenotypes, suggesting that pleiotropic GxE effects are common. Secondly, estimating the proportion of phenotypic variance explained by interaction effects, reveals substantial differences across traits and for some traits, interaction effects explain more of the phenotypic variation than that explained by direct genetic effects. Namely, interaction effects explain 0.20 times the amount of phenotypic variation explained by direct genetic effects for BMR, and 1.35 times for diastolic blood pressure. Together, our results provide first insights of the GxE landscape across multiple phenotypes.

**Genome wide assessment for resting heart rate and shared genetics with type 2 diabetes and metabolic traits.** Y. Guo<sup>1</sup>, W. Chung<sup>1</sup>, Z. Shan<sup>2</sup>, J. Li<sup>3</sup>, S. Liu<sup>4</sup>, L. Liang<sup>1,4</sup>. 1) Program in Genetic Epidemiology and Statistical Genetics, Department of Epidemiology, Harvard School of Public Health, Boston, MA; 2) Department of Nutrition, Harvard T.H. Chan School of Public Health, Boston, MA, USA; 3) Departments of Epidemiology, Medicine, and Center for Global Cardiometabolic Health, Brown University, Providence, Rhode Island, USA; 4) Department of Biostatistics, Harvard T.H. Chan School of Public Health, Boston, Massachusetts, USA.

**Abstract Background:** Resting heart rate (RHR) has recently been related with type 2 diabetes (T2D) and cardio-metabolic traits. However, genetic correlations and shared genetics of RHR with T2D and cardio-metabolic traits were largely unknown. **Methods:** In the current study, we performed large scale cross trait and transcriptome wide association scan (TWAS) analysis to investigate genetic correlations and shared genetics of RHR with T2D and cardio-metabolic traits using UK Biobank data (N~500K), public available GWAS data for T2D and eight cardio-metabolic traits, and GTEx tissue expression data. **Results:** We found significant genetic correlation of RHR with T2D ( $r_g=0.19$ , 95% confidence interval [CI]: 0.13 to 0.24,  $P=2.55 \times 10^{-11}$ ) and five metabolic traits: FI ( $r_g=0.24$  [0.15 to 0.33],  $P=3.08 \times 10^{-7}$ ), WHR (0.15 [0.09, 0.21],  $P=5.81 \times 10^{-7}$ ), FG ( $r_g=0.13$  [0.05 to 0.21],  $P=0.001$ ), TG ( $r_g=0.13$  [0.07, 0.19],  $P=1.60 \times 10^{-6}$ ), and BMI ( $r_g=0.10$  [0.06, 0.14],  $P=2.38 \times 10^{-6}$ ), as well as a marginal significant negative association ( $r_g=-0.09$  [-0.16, -0.02],  $P=0.009$ ) with HDL. No significant genetic correlations were observed with LDL and TC. Cross-trait LD Score regression by eleven functional categories showed similar results. TWAS analysis identified nine unique genes were shared between RHR and T2D in multiple tissues. Three out of these nine unique shared genes: *BMP8A*, *PABPC4*, and *RP11-69E11.8*, were located in the same region at chromosome 1p34.3, indicating important roles of this region in linking RHR to T2D, potentially through vascular calcification. In addition, we further identified 57 unique genes shared between RHR and at least one metabolic trait. **Conclusion:** The current study confirmed significant genetic correlation of RHR with T2D and cardio-metabolic traits, and identified shared genetics between these traits, which would help clarifying mechanisms linking RHR with T2D and cardio-metabolic disorders.

**GWAS of insulin resistance measures in Hispanic/Latino adolescents from the Santiago Longitudinal Study (SLS).** V.L. Buchanan<sup>1</sup>, Y. Wang<sup>1</sup>, E. Blanco<sup>2</sup>, M. Graff<sup>3</sup>, C. Albala<sup>2</sup>, J.L. Santos<sup>4</sup>, B. Angele<sup>5</sup>, B. Lozoff<sup>6</sup>, V.S. Voruganti<sup>6</sup>, S. Gahagan<sup>2</sup>, H.M. Highland<sup>7</sup>, A.E. Justice<sup>7</sup>, K.E. North<sup>1</sup>. 1) Department of Epidemiology, University of North Carolina at Chapel Hill, NC, USA; 2) Division of Academic General Pediatrics, Child Development and Community Health at the Center for Community Health, University of California at San Diego, CA, USA; 3) Department of Public Health Nutrition, Institute of Nutrition and Food Technology, University of Chile, Santiago, Chile; 4) Department of Nutrition, Diabetes and Metabolism, School of Medicine, Pontificia Universidad Católica de Chile, Santiago, Chile; 5) Pediatrics and Communicable Diseases, University of Michigan, Ann Arbor, MI, USA; 6) Department of Nutrition and UNC Nutrition Research Institute, University of North Carolina at Chapel Hill, Kannapolis, NC, USA; 7) Biomedical and Translational Informatics, Geisinger Health, Danville, PA, USA.

**Introduction:** Genetic underpinnings of insulin resistance, which can lead to prediabetes and type 2 diabetes (T2D), have been understudied in Hispanic/Latino (HL) populations and adolescents, despite shouldering an increasing burden of obesity and T2D. We therefore conducted a genome-wide association study (GWAS) of 3 insulin resistance traits—fasting glucose, insulin, and HOMA-IR (homeostatic model assessment of insulin resistance)—in HL adolescents from the Santiago Longitudinal Study (SLS). **Methods:** Participants were genotyped on the Illumina Multiethnic Genotyping Array (MEGA) and imputed using the 1000 Genomes Phase III AMR reference panel. We conducted linear regression, assuming an additive genetic model, adjusting for sex and population substructure. In order to provide a relatively normal distribution for the 3 traits, both fasting insulin and HOMA-IR were natural log-transformed. All participants (n=543) were aged 16-17 years, and because age did not appear to have a meaningful effect on these variables, it was not included in the model. We only included study participants without diabetes, and sensitivity analyses considered adjustment for BMI. Quality control included individual call rate >90%, SNP call rate >95%, imputation quality >0.5, minor allele count >10, gender mismatch, and ancestry outliers. **Results:** For HOMA-IR, we identified a novel GWAS-significant association between rs77465890-C and decreased HOMA-IR on chromosome 8 ( $p < 5 \times 10^{-8}$ , MAF: 0.10,  $\beta$ : -0.32, SE: 0.057) within the *CSMD1* gene, and 14 additional independent signals with suggestive evidence for statistical significance ( $p < 5 \times 10^{-6}$ , +/-500kb). We also generalized several SNP-trait associations previously observed in other study populations. Notably, the novel SNP association we identified is in a locus previously associated with obesity-related traits in Mexican-American participants from the Viva La Familia Study. **Conclusion:** We demonstrated associations between common variants with insulin resistance phenotypes in Chilean adolescents, generalized some loci and reported concordant direction of effects with published findings. Importantly, we observed novel associations indicating possible age- or population-specific genetic effects on insulin resistance. Our findings support the importance of conducting GWAS in ancestrally diverse populations and across life stages to better understand the inherent genetic architecture of complex traits.

Richards<sup>8</sup>, T.E. Robinson<sup>7</sup>, A.A. Palmer<sup>1</sup>, L.C. Solberg Woods<sup>8</sup>. 1) Department of Psychiatry, University of California San Diego, La Jolla, California; 2) Medical College of Wisconsin, Milwaukee, Wisconsin; 3) Molecular and Behavioral Neuroscience Institute, University of Michigan, Ann Arbor, Michigan; 4) Department of Pharmacology, The University of Tennessee Health Science Center, Memphis, Tennessee; 5) Department of Psychology, University at Buffalo, Buffalo, New York; 6) Research Institute on Addictions, University at Buffalo, Buffalo, New York; 7) Department of Psychology, University of Michigan, Ann Arbor, Michigan; 8) Department of Internal Medicine, Wake Forest Baptist Medical Center, Winston-Salem, North Carolina.

Obesity is a global health crisis that is influenced by both genetic and environmental factors. Although many genes have been identified for body mass index (BMI) and obesity in human genome-wide association studies, the majority of genetic drivers remain unknown. Studies in rodents often employ standardized housing conditions that curtail the impact of alleles that alter food consumption, exercise and other factors that are likely to be identified in humans. Our study used 3,184 N/NIH heterogeneous stock (HS) rats from the NIDA Center for GWAS in outbred rats. Although the rats were produced as part of a behavioral genetics project, we also measured numerous physiological traits, including body weight, BMI, fat pad weight (retroperitoneal, epididymal, and parametrial), and fasting glucose levels. We obtained >6 million SNPs per individual by using genotype by sequencing (GBS). We used a linear mixed model to account for complex familial relationship among the HS rats. We estimated the proportion of variance attributable to SNPs (SNP heritability  $h^2$ ) using GCTA-GREML. We used the GCTA Bivariate GREML analysis to estimate genetic correlations ( $r_G$ ). The SNP heritability estimates for these traits ranged from 0.1 to 0.4. We observed strong evidence of pleiotropic effects across multiple phenotypes. For example, body weight and body length showed a genetic correlation of 0.787 and shared overlapping QTLs on chromosomes 3, 7, and 12. A QTL on chromosome 1, which has been previously identified for retroperitoneal fat in rats, showed pleiotropic effects on body weight, BMI, epididymal, retroperitoneal and parametrial fat pad weight. Finally, the genetic correlation between epididymal and retroperitoneal fat weights was high ( $r_G = 0.788$ ) and both had a QTL on chromosome 6. This work underscores the potential of rodent studies to supplement our understanding of molecular genetic factors that contribute to obesity-relevant traits and to provide novel mechanistic insights into the underlying genetic architecture of these traits.

**Targeted metabolomics and genome-wide association study identifies plasma amino acids and genetic variants associated with non-alcoholic fatty liver disease.** A. Huertas-Vazquez<sup>1</sup>, E. Ocampo-Medina<sup>2</sup>, P. Leon-Mimila<sup>2</sup>, L. Macias-Kauffer<sup>2</sup>, H. Villamil-Ramirez<sup>2</sup>, S. Hui<sup>1</sup>, A. Lusic<sup>1</sup>, F. Campos-Perez<sup>2</sup>, N. Mendez-Sanchez<sup>1</sup>, F. Campos-Perez<sup>2</sup>, S. Canizales-Quinteros<sup>4</sup>. 1) University of California, Los Angeles, Los Angeles, CA; 2) National University of Mexico. Mexico City; 3) Clinica Integral de cirugia para la obesidad y enfermedades metabólicas. Hospital Ruben Lenero. Mexico City; 4) Liver Research Unit. Medica Sur Clinic and Foundation. Mexico City.

Background: Non-alcoholic fatty liver disease (NAFLD) manifests as a spectrum of abnormalities ranging from steatosis to non-alcoholic steatohepatitis (NASH). The incidence of steatosis and its progression to NASH varies among different populations, where Mexicans have the highest prevalence. Due to the growing prevalence and lack of FDA approved therapies, increased scientific knowledge of the genetic and molecular factors underlying NAFLD is urgently needed. In this study, we aimed to identify plasma metabolites and investigate the effects of genetic variation modulating metabolite levels and risk of NAFLD in mice and humans. Methods: A total of 43 plasma metabolites were measured in 425 morbidly obese Mexican subjects who underwent bariatric surgery using a targeted mass-spectrometry based platform. We investigated the correlation between metabolites and histological features of NAFLD using the Kleiner scoring system that includes steatosis grade, hepatocellular ballooning, lobular inflammation and NAFLD activity score (NAS). Genome-wide association analysis was performed to identify genetic variants associated with plasma metabolites using a Multi-ethnic genotyping array. To investigate the potential causal role of identified variants, we performed correlations with existing liver and adipose tissue gene expression and clinical data from the Hybrid Mouse Diversity Panel (HMDP) including liver fibrosis, insulin resistance, HOMA-IR and liver triglycerides. Correlation p-values were generated from the bcor coefficient implemented in R. Results: We observed that plasma levels of tyrosine, alanine, proline and methionine were associated with NAFLD and its components including hepatocellular ballooning and lobular inflammation. In addition, we identified a population-specific missense variant in the proline dehydrogenase 1 (*PRODH*) gene, to be significantly associated with proline levels ( $P < 5 \times 10^{-6}$ ) and NAS score ( $r = 0.83$ ,  $p = 0.0002$ ) after Bonferroni correction. In the HMDP, *Prodh* liver expression was strongly correlated with liver triglycerides and fibrosis. Conclusions: We identified several plasma metabolites associated with NAFLD and its components and identified a population specific genetic variant in the *PRODH* gene to be associated with proline levels and risk of NAFLD.

**2175W**

**Identification of 12q24 locus strongly associated with sweet taste preference in Japanese populations by genome-wide meta-analysis.** *K. Kawafune<sup>1</sup>, T. Hachiya<sup>1,2</sup>, S. Nogawa<sup>1</sup>, K. Saito<sup>1</sup>, S. Takahashi<sup>1</sup>.* 1) Genequest Inc., Tokyo, Japan; 2) Genome Analytics Japan Kabushikikaisha, Tokyo, Japan.

Sweet taste preference is important for human to get carbohydrates as energy source, while it can be a risk factor for diseases such as obesity and diabetes. It is known to be strongly influenced by ethnicity, but its genetic background remains unclear. Here we performed a genome-wide meta-analysis of 12,312 Japanese participants recruited via the direct-to-consumer genetic testing service of Japan, who completed internet-based questionnaires on sweet taste preference. Their genomic DNA was extracted from saliva and was genotyped for ca. 300,000 SNPs. The participants were divided into eight groups by the residential area, and for each group the association between SNPs and sweet taste preference scale was tested by a linear regression model. Genome-wide meta-analysis of the results from all regional groups was performed using a fixed-effect model and the inverse-variance weighting method. P-value  $<5 \times 10^{-8}$  was regarded as genome-wide significance. The genome-wide meta-analysis revealed a strong association between 12q24 locus and sweet taste preference scale ( $P = 2.8 \times 10^{-79}$ ). The lead variant rs671 for this locus which is located at a coding exon of the aldehyde dehydrogenase gene (*ALDH2*), is known for its association with alcohol drinking and commonly found in East Asian populations. The association between minor allele of rs671 and sweet taste preference scale was attenuated when additionally adjusted for alcohol consumption ( $P = 7.8 \times 10^{-27}$ ) or frequency of alcohol drinking ( $P = 6.5 \times 10^{-16}$ ), suggesting the mediation by drinking habits at least partially. The subgroup analysis stratified by sex showed that the effect of rs671 on sweet taste preference scale of males was greater than females ( $P$  for interaction  $<0.001$ ). Our data suggested that alcohol drinking was inversely associated with sweet taste preference, which was inconsistent with a previous study that reported that alcohol drinking was positively associated with sweet taste preference in non-Asians. In conclusion, we found the association between the 12q24 locus and sweet taste preference. Our findings may provide new clues to understand the difference among ethnicities as well as to shed light on mechanisms influencing personal food preference in Japanese.

**2176T**

**HRC-based genome-wide association study of uric acid in the Korean population.** *B. Kim<sup>1</sup>, SK. Cho<sup>1,3</sup>, W. Myung<sup>2</sup>, S. Kim<sup>1</sup>, HH. Won<sup>1,3</sup>.* 1) Samsung Advanced Institute of Health Sciences and Technology (SAIHST), Sungkyunkwan University., Seoul, Republic of Korea.; 2) Department of Neuropsychiatry, Seoul National University Bundang Hospital, Seongnam, Republic of Korea; 3) Co-corresponding authors.

**Background** Abnormal level of serum uric acid (SUA) is an important marker and risk factor for complex diseases such as gout and chronic kidney disease. Although SUA level is heritable, most genetic determinants of SUA are not known in East Asians, particularly for hypouricemia. Since genome-wide association studies (GWAS) were designed to examine common variants, the differential effect between common and lower-frequency variants has yet to be fully explored. In the present study, we conducted GWAS of SUA using the Haplotype Reference Consortium (HRC)-based imputation to identify novel common and lower-frequency variants in the Korean population. **Method** We measured SUA levels of 6,881 individuals and performed a meta-analysis of GWAS of SUA in two different cohorts from the Korean Genome and Epidemiology Study; a nation-wide cohort from urban areas (3,585 individuals) and a nation-wide cohort from rural areas (3,296 individuals). Genotyping was conducted on the Affymetrix 6.0 array and the Illumina Omni1 array for the urban cohort and the rural cohort, respectively. After quality control, genotype data was phased by using Eagle 2.3 and imputed on the reference panel of the HRC (HRC r1.1 2016) by using Minimac3. We performed GWAS using linear regression adjusted for sex, age, BMI, eGFR, diabetes, hypertension, systolic blood pressure, total cholesterol, HDL cholesterol, LDL cholesterol, and triglycerides. The inverse variance-weighted fixed-effects meta-analysis was conducted using METAL. **Results** We identified 16 independent genetic variants (2 lower-frequency and 14 common) that reached a level of genome-wide significance ( $P < 5 \times 10^{-8}$ ). Of note, a rare, nonsense variant in the *URAT1* gene (*SLC22A12*) showed the strongest association with SUA ( $P = 7 \times 10^{-9}$ ;  $\beta = -1.15$ mg/dl;  $SE = 0.07$ mg/dl). Although it was reported as a pathogenic variant of familial renal hypouricemia (RHUC1, OMIM #220150), this variant has not been identified in previous GWAS of the general population. Other significant genetic variants were found to be located near genes, including *ABCG2*, *SLC2A9*, *NRXN2*, *PYGM*, *SF1*, *NAA25*, *PCNX3*, *EHBP1L1*, *SLC17A3*, *SLC17A2*, and *BCAS3*. **Conclusions** In this study, we identified novel variants, including one rare variant, that were significantly associated with SUA in the Korean population. We also demonstrated the utility of the large-scale, high-density imputation panel to identify novel lower-frequency variants from GWAS array data.

Obesity has reached pandemic proportions: 25% of adults worldwide are either overweight (body mass index, BMI $\geq$ 25 kg/m<sup>2</sup>) or obese (BMI $\geq$ 30) and >10% of children meet obesity criteria. While obese individuals are at higher risk of some cancers, infertility, and cardiometabolic disease, epidemiological studies show that the location of fat storage, rather than general adiposity, is more informative for predicting disease risk. Independent of BMI, individuals with higher central adiposity have higher cardiometabolic disease risk and Mendelian randomisation studies indicate a putative causal effect of higher central adiposity on cardiometabolic disease. To pinpoint genetic variants associated to fat distribution, we performed a meta-analysis of waist-hip ratio adjusted for BMI (WHRadjBMI). WHR is an easily-measured fat distribution phenotype well-correlated with imaging-based fat distribution measures. Implementing a linear mixed model to account for relatedness and ancestral heterogeneity, we performed genome-wide association studies (GWAS) of WHRadjBMI in UK Biobank, followed by meta-analysis with publicly-available data. The meta-analysis comprised 694,649 samples and ~27.4M SNPs and identified 346 associated loci ( $p < 5 \times 10^{-9}$ ) containing 463 independent signals. Given the known sex-dimorphism of fat distribution in humans, we also performed sex-specific meta-analyses. We identified ~3x more loci associated in women (266 loci) than men (91) and found SNP-based heritability to be strikingly different between the sexes ( $h^2_{\text{women}} = 25.6\%$ ,  $h^2_{\text{men}} = 16.7\%$ ,  $p = 9 \times 10^{-8}$ ). Of all index SNPs ( $p < 5 \times 10^{-9}$  in the combined or sex-specific analyses), 105 were sex-dimorphic (Bonferroni  $p < 3.3 \times 10^{-4}$ ) and 97 of these 105 showed stronger effects in women than men. In the combined analysis, index SNPs in 12 loci correlated with nearby loss-of-function variants, including stop gains in an insulin like growth factor binding protein (*IGFBP3*) and a gene expressed in testis (*AKR1E2*). Pathway analyses mapping associated SNPs from the combined analysis to eQTLs in 53 tissues revealed enrichment of association signal in adipose tissue, while analysis of associated SNPs in women revealed an enrichment not only for adipose but also in female reproductive tissues including uterus, cervix and vagina. Additional work, including fine-mapping and further tissue and cell-enrichment analyses, will help elucidate the causal mechanisms and biological interplay underlying fat distribution and its comorbidities.

**Genetic study of birth weight resolves maternal and fetal genetic effects and provides insight into the role of the intrauterine environment on future risk of offspring cardiometabolic health.**

N.M. Warrington<sup>1</sup>, R.N. Beaumont<sup>2</sup>, M. Horikoshi<sup>3,4,5</sup>, F.R. Day<sup>6</sup>, K.K. Ong<sup>6,7</sup>, M.I. McCarthy<sup>3,4,8</sup>, J.R.B. Perry<sup>6</sup>, D.M. Evans<sup>1,9</sup>, R.M. Freathy<sup>2,9</sup>, EGG Consortium Birth Weight Collaborators. 1) Diamantina Institute, University of Queensland, Brisbane, Australia; 2) Institute of Biomedical and Clinical Science, University of Exeter, Exeter, UK; 3) Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, UK; 4) Oxford Centre for Diabetes, Endocrinology and Metabolism, University of Oxford, Oxford, UK; 5) RIKEN, Centre for Integrative Medical Sciences, Laboratory for Endocrinology, Metabolism and Kidney diseases, Yokohama, Kanagawa, 230-0045, Japan; 6) MRC Epidemiology Unit, University of Cambridge School of Clinical Medicine, Cambridge, UK; 7) Department of Pediatrics, University of Cambridge, Cambridge, UK; 8) Oxford National Institute for Health Research (NIHR) Biomedical Research Centre, Churchill Hospital, Oxford, UK; 9) MRC Integrative Epidemiology Unit, University of Bristol, Bristol, UK.

Birth weight (BW) is influenced by both fetal and maternal factors, and has been reproducibly associated with adult cardiometabolic health. These associations are hypothesised to reflect lifelong consequences of an adverse intrauterine environment. We previously demonstrated that genetic effects contribute to the negative correlation between BW and adult cardiometabolic traits. However, no previous study has systematically distinguished the direct fetal genetic effect on BW and cardiometabolic health from the indirect effects of their mother's correlated genotype, mediated by the intrauterine environment. We aimed to (1) discover novel BW loci, (2) distinguish between fetal and maternal genetic contributions to BW, using a statistical method based on structural equation modelling (SEM) and (3) use the fetal- and maternal-specific genetic effects to elucidate BW-later health relationships. We report a large genome-wide association meta-analysis (GWAS) of BW using fetal (N=321,223) and maternal (N=230,069) genotypes from 50 studies including the UK Biobank and studies in the EGG Consortium. We identified 305 lead SNPs at 274 loci (210 novel) associated with BW ( $P < 5 \times 10^{-9}$ ). We decomposed the direct fetal and indirect maternal genetic influences on BW using SEM, and were able to categorize lead SNPs at the majority of loci into those with fetal genetic effects only (N=83), maternal effects only (N=45), directionally-concordant (N=36), or directionally-opposing maternal and fetal effects (N=24). Our findings implicate several fetal-specific or maternal-specific mechanisms/tissues involved in the regulation of BW. We used Mendelian randomization to explore the causal relationships between BW and cardiometabolic traits using the fetal- and maternal-specific genetic effects. These analyses indicated that the inverse genetic correlation between BW and systolic blood pressure (SBP) can be explained by a combination of (1) the indirect effects of maternal SBP-raising alleles reducing BW and (2) the direct effects of SBP-raising alleles inherited by the offspring increasing their own SBP. Conversely, direct fetal genotype effects dominate the inverse relationship between BW and type 2 diabetes risk. This work represents a significant advance in GWAS of perinatal outcomes by using novel methods to separate fetal from maternal genetic effects, and has set a precedent for future analyses interrogating the causal role of the maternal environment on offspring outcomes.

**Whole-exome sequencing identifies rare coding variants associated with erythrocyte membrane fatty acids.** X. Yin<sup>1,2</sup>, A. Locke<sup>3</sup>, A. Jackson<sup>1,2</sup>, H. Stringham<sup>1,2</sup>, M. Laakso<sup>4</sup>, M. Boehnke<sup>1,2</sup>. 1) Biostatistics, University of Michigan, Ann Arbor, MI; 2) Center for Statistical Genetics, University of Michigan, Ann Arbor, MI; 3) McDonnell Genome Institute, Washington University School of Medicine, Saint Louis, MO, 63108, USA; 4) Institute of Clinical Medicine, Internal Medicine, University of Eastern Finland and Kuopio University Hospital, Kuopio, Finland.

**Introduction:** Erythrocyte membrane fatty acids (EMFAs) are circulating biochemical compounds that are associated with the risk for a wide spectrum of human diseases including type 2 diabetes and neurological disorders. Recent EMFAs genome-wide association studies have detected > 60 associations within > 20 genetic loci; most of them are common non-coding variants. The role of rare coding variants has not been studied. **Methods:** We measured 20 EMFAs (six saturated, five mono-unsaturated, and nine poly-unsaturated), three summed measures of saturated, mono-unsaturated, and poly-unsaturated fatty acids, and six ratios of EMFA concentrations using gas chromatography technology in 2,223 Finnish men from the METabolic Syndrome In Men (METSIM) study. These study participants have been exome sequenced on the HiSeq2500. We performed single variant and gene-based association analyses for each of the 29 EMFA traits under the linear mixed model framework to account for population structure and sample relatedness. **Results:** We validated known single-variant associations at *ELOVL5*, *AGPAT4*, *AGPAT5*, *FADS1*, *CPT1A*, *LPCAT3*, *PDXDC1*, and *CERS4*. We also identified significant novel associations ( $P < 5 \times 10^{-6}$ ) at two rare missense variants (MAF=0.045%) within *CSMD2* and *ATP11A*. In gene-based association analysis, we constructed four gene masks of putative coding variants. We found the *CERS4* gene attained significance even after conditioning on known *CERS4* variants. We also discovered novel significant gene-level association evidence in *ABHD3* ( $P_{\text{gene}} = 8.37 \times 10^{-10}$ ), *CPSF1* ( $P_{\text{gene}} = 1.70 \times 10^{-6}$ ), *FAM83E* ( $P_{\text{gene}} = 1.69 \times 10^{-6}$ ), *TRPV1* ( $P_{\text{gene}} = 2.42 \times 10^{-10}$ ), and *AKR1E2* ( $P_{\text{gene}} = 2.20 \times 10^{-6}$ ), due to the aggregated effect of rare coding variants. These genes newly-implicated for EMFAs have been previously suggested for multiple human diseases/traits, for example *ABHD3* in the hemostasis of plasma phospholipid levels.

**Systematic identification of genes underlying obesity risk in adipocytes.** G.T. Hansen, Y.I. Li, D.R. Sobreira, A.C. Joslin, L.E. Montefiori, M.A. Nobrega. University of Chicago 920 E 58th St, Chicago IL, 60637.

Obesity is a highly heritable condition affecting a third of individuals in the United States. Over 700 loci have been previously associated to obesity risk from genome-wide association studies (GWAS), yet like many other diseases, the total identified heritability is distributed over many variants, each of which contribute a miniscule amount to overall disease risk. Because the vast majority of obesity risk variants identified in GWAS are located in non-coding regions of the genome, it has been challenging to pinpoint exactly which genes drive obesity. Here, we performed a transcriptome-wide association study (TWAS) using GTEx gene expression data in subcutaneous adipose tissue to identify genes whose expression underlies obesity risk. We used summary statistics from a GWAS meta-analysis on obesity in ~750,000 individuals (Yengo et al., 2018) and identified 113 genes whose expression is associated with increased obesity risk. Interestingly, these genes show functional enrichment for responses to oxidative stress and protein localization. To systematically validate the link between obesity-associated variants and genes nominated by our TWAS, we collected ATAC-seq and promoter capture HiC data in a primary human adipocyte cell culture. We investigated the chromatin state and physical interactions between GWAS SNPs and identified genes. ATAC-seq and promoter-capture HiC show colocalization between chromatin accessibility and interactions at the promoters of TWAS-identified genes. Thus, our TWAS identified genes represent promising targets for further research, and potential new targets of therapies for the prevention and treatment of obesity.

**Looking beyond the nearest gene: A high throughput functional approach using tissue-specific RNAi knockdowns to move from “statistical loci” to “functional genes”.** M.A. Province<sup>1</sup>, J.L. Fink<sup>2</sup>, P.A. Lenzi<sup>3</sup>, I.B. Borecki<sup>4</sup>, C.T. Liu<sup>5</sup>, L.A. Cupples<sup>6</sup>, K.E. North<sup>7</sup>, T.J. Baranski<sup>8</sup>. 1) Department of Genetics, Division of Statistical Genomics, Washington University School of Medicine, SAINT LOUIS, MO; 2) Department of Internal Medicine, Division of Endocrinology, Metabolism and Lipid Research, Washington University School of Medicine, SAINT LOUIS, MO; 3) Department of Biostatistics, University of Washington, Seattle, WA; 4) Department of Biostatistics, Boston University School of Public Health, Boston, MA; 5) Department of Epidemiology, University of North Carolina, Chapel Hill, NC.

GWAS have identified thousands of novel complex trait loci but knowledge of function is lagging. The loci are undeniably tagging real biology with overwhelming statistical significance, and independent replication, but effect sizes are clinically trivial. Few loci seem to tag coding variation (perhaps only 12%), making identification of the gene of action difficult. Regulome databases are helpful but much of the annotation is either lacking, insufficient, or not specific enough to allow definitive gene mapping. Functional experiments in high order organisms is daunting, expensive, and time consuming. We chose a high throughput *Drosophila* system, to efficiently functionally screen the set of nearby human genes that have fly orthologs for many loci simultaneously. Starting with 50 known Waist-Hip Ratio GWAS loci, we identified all human genes within 250kb of the most significant tag SNP (442 genes). 140 of these had *Drosophila* orthologs. We crossed RNAi knock down (KD) lines for each gene with *cg-GAL4* tissue-specific driver line to obtain brain and fat body KD crosses. We measured adult percent body fat compared to wild type (WT), using Dunnett's multiple comparison test in ANOVA to assess significance. For 17 of the 50 WHR loci (34%), we found at least one -fat functional gene in the fly whose human ortholog was near the GWAS locus. All of these significant KDs were fatter than WT. For 12 of the 17, GTEx validated that the index SNP was an eQTL for the same nearby genes in human tissue corresponding to the fly brain or fat body. For 5 loci, more than one nearby gene was fat-functional in the fly, suggesting that the initial GWAS locus was tagging the influence of multiple nearby genes. The significant, GTEx validated SNP-human gene pairs are: *RS10804591*→*IFT122*, *RS11231693*→*ESRRA*, *RS11231693*→*FERMT3*, *RS17819328*→*MKRN2*, *RS17819328*→*SYN2*, *RS303084*→*NUDT6*, *RS3805389*→*TMEM165*, *RS4765219*→*ATP6V0A2*, *RS6090583*→*EYA2*, *RS6090583*→*TP53RK*, *RS6784615*→*NT5DC2*, *RS6784615*→*TWF2*, *RS714515*→*SUCO*, *RS7917772*→*SUFU*, *RS905938*→*DCST1*, *RS905938*→*SCAMP3*, *RS9991328*→*HERC3*. For only 2 of the 17 loci was the nearest human gene the fly-functional one (*EYA2* and *FGFR4*). For all others, other nearby genes were the functional in the fly and validated in GTEx. This “low hanging fruit” approach will not work for every locus or trait, but it may substantially help move the field from “statistical loci” to “functional genes.”.

**Role of *FAM13A* in insulin resistance: *FAM13A* gene expression in human and mice demonstrates tissue specific activity.** A. Rao<sup>1</sup>, M. Fathzadeh<sup>2</sup>, N. Cook<sup>3</sup>, J. Li<sup>2</sup>, I. Chennamsetty<sup>2</sup>, M. Gloudemans<sup>4</sup>, N. Abell<sup>5</sup>, S. Montgomery<sup>6,8</sup>, M. Shin<sup>7</sup>, D. Reilly<sup>9</sup>, J. Yang<sup>9</sup>, T. Quertermous<sup>2</sup>, E. Ingelsson<sup>2</sup>, J. Knowles<sup>2</sup>. 1) Department of Bioengineering, Stanford University, Stanford, CA, USA; 2) Division of Cardiovascular Medicine, Cardiovascular Institute and Diabetes Research Center, Stanford University School of Medicine, Stanford, CA, USA; 3) Department of Medical Sciences, Molecular epidemiology, Uppsala University, Sweden; 4) Department of Biomedical Informatics, Stanford University, Stanford, CA, USA; 5) Department of Genetics, Stanford University, Stanford, CA, USA; 6) Department of Pathology, Stanford University, Stanford, CA, USA; 7) Genetics & Pharmacogenomics, Merck & Co Inc., Boston, MA, USA; 8) Translational Medicine at Merck, Kenilworth, NJ, USA; 9) Department of Comparative Biosciences, College of Veterinary Medicine, University of Illinois at Urbana-Champaign, Urbana, IL, USA.

Insulin resistance (IR) is a major driver of T2D and results in increased cardiovascular risk partly due to IR-associated dyslipidemia (e.g. high plasma triglyceride and low plasma HDL-cholesterol levels). Increases in indices of body fat distribution (e.g. waist-hip-ratio adjusted for BMI, WHRadjBMI) are correlated with IR. Large genome-wide association studies (GWAS) of fasting insulin adjusted for BMI (FladjBMI), a proxy for intravenously assessed IR, and WHRadjBMI showed a significant positive association at the *FAM13A* locus. These findings suggest that *FAM13A* might regulate insulin and fat distribution even in normal-weight individuals, a “lipodystrophy-like” phenotype. We characterized the role of *FAM13A* across human tissues by integrating GWAS data with tissue-specific gene expression, and analyzed tissue specific gene expression from *Fam13a* knockout (KO) mice. **Humans:** We performed colocalization analysis of *FAM13A* gene expression in subcutaneous adipose (SAT), visceral adipose (VAT), liver and skeletal muscle from the Genotype Tissue Expression project (v7) with 7 IR-related GWAS traits using eCAVIAR. Using a modified colocalization posterior probability (mCLPP) computed in eCAVIAR, we observed colocalizations (mCLPP > 0.8) between SAT *FAM13A* expression and FladjBMI, WHRadjBMI, triglycerides and HDL-cholesterol. We did not observe similar colocalizations in the other tissues, suggesting that *FAM13A* plays an active and differential role in SAT. **Mice:** To evaluate the biological effect of *Fam13a*, we performed differential expression (DE) analysis in VAT and SAT tissue between wild-type and KO male mice on both chow and high fat diet (total n = 32 tissue samples). After adjustment for the effects of diet and type of adipose tissue, we observed 255 differentially expressed genes at 5% FDR. Pathway analysis showed a strong enrichment of oxidative phosphorylation and a depletion of immunodeficiency pathways in KOs. To understand the differential impact of *Fam13a* KO across tissues, we performed a DE analysis stratified by adipose tissue type adjusted for sex and diet. We observed a much more pervasive effect of the KO on the transcriptome in SAT (96 DE genes) compared to VAT (0 DE genes) at 5% FDR. In conclusion, our results establish *FAM13A* as the causal gene in the locus; indicate that the primary effect is in SAT; and highlight oxidative phosphorylation and immunodeficiency as key biological pathways underlying the association with IR.

**Togetherness of lysinuric protein intolerance and HOIP deficiency in a boy: SLC7A7 and RNF31 gene disruptions.** L. Aliyeva<sup>1</sup>, S. Erdol<sup>2</sup>, O. Gorukmez<sup>3</sup>, H. Gurkan<sup>4</sup>, Y. Yerali<sup>5</sup>, B. Baytan<sup>6</sup>, H. Saglam<sup>7</sup>, K. Terali<sup>8</sup>, S. Kilic<sup>9</sup>, S.G. Temel<sup>1</sup>. 1) Uludag University, Faculty of Medicine, Department of Medical Genetics, Bursa, Turkey; 2) Uludag University, Faculty of Medicine, Department of Pediatric Metabolism; 3) Sevket Yilmaz Government Research Hospital, Department of Medical Genetics, Bursa, Turkey; 4) Trakya University, Faculty of Medicine, Department of Medical Genetics, Edirne, Turkey; 5) Uludag University, Faculty of Medicine, Department of Pediatric Immunology, Bursa, Turkey; 6) Uludag University, Faculty of Medicine, Department of Pediatric Haematology, Bursa, Turkey; 7) Uludag University, Faculty of Medicine, Department of Pediatric Endocrinology & Metabolism, Bursa, Turkey; 8) Near East University, Faculty of Medicine, Department of Biochemistry, Nicosia, Cyprus.

Lysinuric protein intolerance (LPI) is a rare autosomal inherited disease caused by defective cationic amino acid at the basolateral membrane of epithelial cells in the intestine and kidney. LPI is a multisystemic disease with a variety of clinical symptoms such as hepatosplenomegaly, osteoporosis, hypotonia, developmental delay, pulmonary insufficiency or end-stage renal disease, anemia, bone marrow may show hemophagocytosis. Inherited, complete deficiency of human HOIP, a component of the linear ubiquitination chain assembly complex (LUBAC), underlies autoinflammation and infections. Here we report on a 8 months old boy with LPI and HOIP deficiency a third child born to a consanguineous couple and delivered via caesarian section. The main clinical findings developmental delay, pulmonary insufficiency, hepatosplenomegaly and hypotonia. Laboratory findings anemia, thrombocytopenia, hypertriglyceridemia, high serum ferritin (35.000) and lactate dehydrogenase levels. Bone marrow morphology is compatible with hemophagocytosis. During follow-up respiratory distress was progressively increased, HSM was not regressed, recurrent infections and autoinflammation findings were observed. Whole exome and targeted sequencing in the proband revealed the presence of one homozygous missense variant c.1573C>T, this variant leads to a p. Arg525Cys change in *RNF31* and deletion of exome 4-11 of *SLC7A7* gene, respectively. Heterozygous *RNF1* variants were confirmed in both mother and father. This variant was found in ExAC (#9) and in CentoMD (#1) databases as heterozygote manner not reported as homozygote manner and regarded as disease causing and damaging based on the in-silico prediction tools (mutation taster, SIFT, Provean). As far as we know our case is the first reported case of homozygous *SLC7A7* deletion and homozygous *RNF31* variation seen together, and the second reported case of HOIP deficiency.

**2184W**

**Prediction of metabolic syndrome in Korean females by a genetic risk score combining SNPs for female specific metabolic syndrome-related quantitative traits.** Y. Cho. Hallym University, Chuncheon, Korea, Republic of.

Metabolic Syndrome (MetS) has plagued the many lives of human worldwide and females have been reported to be relatively more vulnerable to this cluster of risks. In order to elucidate genetic variants underlying MetS specifically in females, we performed gender stratified genome-wide association study (GWAS) for metabolic traits, obesity and blood pressure in a total of 13,485 Korean subjects. Our analyses detected female-specific association of rs38796 in *NECTIN2* ( $P_{\text{meta}} = 1.95 \times 10^{-9}$ ) for low density lipoprotein cholesterol (LDLC) and of rs848652 in *MYL10* ( $P_{\text{meta}} = 2.19 \times 10^{-9}$ ) for blood gamma-glutamyltransferase level (GTP). To facilitate the prediction of MetS in females, we calculated a genetic risk score (GRS) combining top 7 SNPs detected from our GWA analyses for MetS-related traits and conducted logistic regression analyses between the GRS and the increased prevalence of MetS in females. A total of 645 MetS cases and 598 controls were grouped in the study populations according to the International Diabetes Federation (IDF) criteria. Our results showed that GRS was associated with the increased prevalence of MetS in females ( $P = 1.28 \times 10^{-6}$ ) but not in males ( $P = 0.714$ ). The area under the curve (AUC) in the receiver operating characteristics (ROC) analysis was higher in GRS prediction of MetS in females (AUC = 0.858) than that in males (AUC = 0.577). In total, this study identified new female-specific genetic variants associated with metabolic traits and suggested that GRS of variants showing compelling association with MetS-related traits is a likely useful predictor of MetS in females.

**2185T**

**Genetic polymorphisms association with the neutrophil-lymphocyte ratio and their clinical implications for metabolic risk factors.** *E. Choe<sup>1</sup>, B. Park<sup>2</sup>, H. Kang<sup>2</sup>, S. Won<sup>2</sup>.* 1) Seoul National University Hospital Healthcare System Gangnam Center, Seoul, South Korea; 2) Department of Public Health Science, Seoul National University, Seoul, Korea; 3) Department of Internal Medicine, Seoul National University Hospital Healthcare System Gangnam Center, Seoul, Korea.

**Background:** The neutrophil-lymphocyte ratio (NLR) is valuable as a prognostic or predictive biomarker in various diseases, but the genetic factors underlying the NLR have not been studied. We attempted to investigate the genetic polymorphisms related to the phenotypic NLR and to determine whether they have the power to predict metabolic syndrome or metabolic risks in addition to impacting the phenotypic NLR. **Methods:** A genome-wide association study (GWAS) was carried out for log-transformed NLR among 7,257 healthy Koreans using the Affymetrix Axiom™ KORV1.1-96 Array. Prediction models for metabolic risk status were designed using significant single nucleotide polymorphisms (SNPs). **Results:** We detected 4 SNPs near the TMEM116, NAA25 and PTPN11 genes associated with the NLR. The top SNP associated with the log-transformed NLR was rs76181728 in the TMEM116 gene (P value, discovery set=1.68×10<sup>-20</sup>, validation set=0.00749). A case-control study was performed for the presence of metabolic risks according to the respective SNPs after adjusting for age, sex and body mass index (BMI). All four SNPs displayed significant odds ratios (ORs) with increased blood pressure and increased waist circumference. In the prediction model for metabolic syndrome, rs76181728 showed a significant association (OR=1.465, 95% confidence intervals (CI)=1.091-1.969, P=0.011) after adjustment for the phenotypic NLR. **Conclusions:** This was the first GWAS with which we identified four novel SNPs associated with the NLR in healthy Koreans. Thus, SNPs in the relevant genes at locus 12q24 might be used as biomarkers for diseases that have previously been predicted by the phenotypic NLR.

**2186F**

**Reassessing the significance of the PAH c.158G>A (p.Arg53His) variant in Korean patients with hyperphenylalaninemia.** *J. Kim<sup>1</sup>, D. Lee<sup>2</sup>, J. Lee<sup>2</sup>.* 1) Department of Pediatrics, Chungbuk National University H, South Korea; 2) Department of Pediatrics, Soonchunhyang University H, South Korea.

**Background:** The accurate interpretation of sequence variation is critical for successful molecular diagnoses. It is also fundamental to the accurate diagnosis and treatment of phenylketonuria (PKU). This study aims to evaluate the significance of the c.158G>A (p.Arg53His) variant in the PAH gene, which was previously reported to be a pathogenic mutation that results in decreased phenylalanine hydroxylase enzyme activity in hyperphenylalaninemia (HPA) patients. **Methods:** Seven unrelated Korean patients with HPA genotyped with the c.158G>A variant were included in this study. The variant c.158G>A was classified by the standards and guidelines for the interpretation of sequence variants by the American College of Medical Genetics and Genomics and the Association for Molecular Pathology. **Results:** By both directly collecting genetic data and comprehensively reviewing the existing literature, we found that this variant is more appropriately classified as "Likely benign" rather than pathogenic. The allele's frequency is 2.57% in the general Korean population, which was greater than expected for PKU. This variant was observed to be homozygous in healthy subjects and was also observed in cis with other pathogenic variants. It is common in East Asian populations (especially in Koreans) compared to Western populations. There is a possibility that it causes decreased enzyme activity without leading to the full pathology of PKU. **Conclusions:** This study expands our understanding of the consequences of variation in PAH and its relationship to HPA.

**2187W**

**Whole-exome sequencing of Emirati population and high-risk genetic susceptibility to type 2 diabetes in Abu Dhabi.** D. Simpson<sup>1,2</sup>, A. Pandya<sup>1,2</sup>, C. Inman<sup>3</sup>, M. Vogelsang<sup>2</sup>, A. Abdulle<sup>3</sup>, R. Ferguson<sup>1,2</sup>, D. Galani<sup>3</sup>, M. Haji<sup>3</sup>, A. Al Hamiz<sup>3</sup>, A. Al Hosani<sup>3</sup>, J. Ahn<sup>1,2</sup>, R. Ramasamy<sup>4</sup>, A. Schmidt<sup>4</sup>, S. Sherman<sup>1</sup>, R. Ali<sup>3</sup>, R. Hayes<sup>1,2</sup>, H. Alsafer<sup>5</sup>, T. Kirchhoff<sup>1,2</sup>, *UAE Healthy Future Study*. 1) Department of Population Health, NYU School of Medicine, New York, NY; 2) NYU Perlmutter Cancer Center, New York, NY; 3) Public Health Research Center, NYUAD, Abu Dhabi, UAE; 4) Diabetes Research Program, Division of Endocrinology, NYU School of Medicine, New York, NY; 5) Center for Biotechnology, Khalifa University, Abu Dhabi, UAE.

In the United Arab Emirates (UAE), the increasing incidence of type 2 diabetes (T2D) and other metabolic traits draws an interest to the role of population-specific germline genetic risk factors. While next-generation sequencing (NGS) initiatives for mapping the genetic risk of metabolic disease have been established in some countries in the Arabian Peninsula, no NGS efforts have yet been expended in UAE. In this study, we present a first whole-exome sequencing (WXS) analysis of 96 subjects from a recently initiated UAE cohort study to elucidate etiological and genetic factors associated with metabolic disease. We sought to generate preliminary data on genetic population structure and exome variation for their relationship to high-risk forms of T2D in the UAE population. We performed WXS on 96 UAE nationals residing in Abu Dhabi, 30 of whom had T2D. By analyzing the structure of the UAE population, we show that there is an admixture from proximal ancestries, in particular European, African and South Asian populations. We furthermore report a first catalogue of exonic variation in the UAE. While our data show no significant differences in the overall distribution of identified rare or common variants compared to other populations, we noted the differences in the distribution of novel indel variants, and an increase of pathogenic deleterious variants. Importantly, we found a significant enrichment of high-risk pathogenic mutations associated with Mendelian forms of T2D. Our study represents a first NGS effort towards the genetic mapping of metabolic disease in the UAE. Using WXS data from 96 UAE nationals in Abu Dhabi, we show the presence of admixture of regional ancestries in the Emirati population. While our study did not detect overall differences in exonic variation distribution compared to other global populations, some differences in structural variation suggest population-specific genetic features to be explored in future analyses. Importantly, enrichment of pathogenic variants associated with Mendelian traits strongly suggests that consanguinity shapes the Emirati genome and, pending future validation on a genome-wide level, may contribute to the genetic susceptibility of metabolic disease in UAE.

**2188T**

**Studies of liver tissue identifies functional gene regulatory elements associated to gene expression, type 2 diabetes and other metabolic diseases.** C. Wadelius<sup>1</sup>, M. Cavalli<sup>1</sup>, N. Baltzer<sup>2</sup>, G. Pan<sup>1</sup>, J.R. Bårceñas-Walls<sup>1</sup>, C. Kumar<sup>3,4</sup>, S. Skrtic<sup>5,6</sup>, J. Komorowski<sup>7,8</sup>. 1) Science for Life Laboratory, Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden; 2) Science for Life Laboratory, Department of Cell and Molecular Biology, Computational Biology and Bioinformatics, Uppsala University, Uppsala, Sweden; 3) Translational Sciences, Cardiovascular Metabolic and Renal Diseases, IMED Biotech Unit, AstraZeneca, Gothenburg, Sweden; 4) Karolinska Institutet/AstraZeneca Integrated CardioMetabolic Center (KI/AZ ICMC); 5) Translational Medicine Unit CVRM, Early Clinical Development, IMED Biotech Unit, AstraZeneca, Gothenburg, Sweden; 6) Institute of Medicine at Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; 7) Institute of Computer Science, Polish Academy of Sciences, Warszawa, Poland.

Genome wide studies of diseases and traits have been effective in finding association to gene regions but not the functional SNP or the gene mediating the effect. A fraction of functional variants are coding but the majority are predicted to be located in gene regulatory elements and mediate differential binding of transcription factors (TF) and thereby expression from the alleles. Difference in gene regulatory signals can be detected genome wide using ChIP-seq of TFs or histone modifications by aligning reads to known polymorphisms in individual genomes. Gene regulatory mechanisms are often studied in cell lines derived from cancer cells, which have single nucleotide and copy number variants that drive the cancer and additional aberrations acquired during prolonged culturing. It is important to study gene regulation in native conditions so we obtained normal human liver tissue and sequenced the genome using 10x genomics technology to reliably call all polymorphic positions and found 4 588 678 SNPs out of which 2 331 202 were heterozygous and used further in the analysis. We then performed ChIP-seq for H3K4me3, H3K27ac and CTCF, aligned the reads to the two phased personal genomes, and used an established pipeline to detect sites with a genome-wide significant difference in signal between the alleles. We only considered regions predicted to bind TFs and after removing SNPs in black list regions we detected 2,329 allele specific (AS-)SNPs. From the GWAS catalogue we extracted diseases and traits that can be attributed to liver biology and took the top SNP and those in LD  $r^2 > 0.8$  and intersected with the AS-SNPs. We found 26 AS-SNPs that are likely candidates to mediate the effect. One of them is rs655185 with genome-wide corrected binomial test p-value  $3.1 \times 10^{-4}$  is candidate to explain the signal for rs622217 which is associated with type 2 diabetes (T2D). The effect may be mediated by the nearby *LPA* which has previously been associated to familial hyperlipidemia and T2D. Environmental and gene regulatory signals acting on rs655185 may now be studied further to clarify the pathways. We also investigated top SNP and highly associated SNPs from GTEx eQTLs in the liver and found 314 AS-SNPs that are putative candidates to mediate the effect.

**Polygenic susceptibility underlies trajectories of weight and severe obesity from birth to adulthood.** *M. Chaffin<sup>1</sup>, A.V. Khera<sup>1,2,3</sup>, K.H. Wade<sup>4</sup>, S. Zahid<sup>1</sup>, J. Brancale<sup>5</sup>, M.E. Haas<sup>1</sup>, A. Bick<sup>1</sup>, K.G. Aragam<sup>1,2,3</sup>, G.D. Smith<sup>4</sup>, N.J. Timpson<sup>4</sup>, L.M. Kaplan<sup>5</sup>, S. Kathiresan<sup>1,2,3</sup>*. 1) Cardiovascular Disease Initiative of the Broad Institute of Harvard and MIT, Cambridge, MA, USA; 2) Center for Genomic Medicine, Massachusetts General Hospital, Boston, MA, USA; 3) Cardiology Division of the Department of Medicine, Massachusetts General Hospital, Boston, MA, USA; 4) MRC Integrative Epidemiology Unit (IEU), Bristol Population Health Science Institute, University of Bristol, United Kingdom; 5) Obesity, Metabolism, and Nutrition Institute, Massachusetts General Hospital, Boston, MA, USA.

Obesity is an epidemic attributed largely to a rapidly changing environment; yet, obesity is highly heritable, with much of that heritability due to common DNA sequence variants. Here, we use large studies and improved algorithms to define a new polygenic predictor for severe obesity that incorporates a genome-wide set of 2.1 million common DNA variants. Applying this genome-wide polygenic score to 288,016 middle-aged adults in the UK Biobank (mean age 57 years), we find that those in the top decile of polygenic score are 29 pounds heavier than those in the bottom decile. Remarkably, the polygenic score identified both subsets of the population at substantial risk of severe obesity (BMI>40), and those that enjoyed considerable protection. Among 2,177 non-obese young adults (mean age 30 years) in the Framingham Heart Study who were followed for 26 years with serial weight measurements, 40 of 218 (18%) of those in the top decile of the polygenic score distribution went on to develop severe obesity as compared with 0 of 218 (0%) of those in the bottom decile. In the ALSPAC longitudinal birth cohort, we noted minimal gradient in weight at time of birth across polygenic score deciles, but this gradient increased to 8 pounds by age 8 years and 27 pounds by age 18 years. A genome-wide polygenic score identifies subsets of the population at high risk or near complete protection from severe obesity. Weight trajectories across strata of polygenic risk diverged starting at a very young age suggesting that clinical prevention needs to start in early childhood.

**Harnessing longitudinal data to derive a new genetic risk score for childhood obesity.** *S.J.C. Craig<sup>1,2</sup>, J. Lin<sup>3</sup>, A.M. Kenney<sup>6</sup>, I.M. Paul<sup>2,4</sup>, L.L. Birch<sup>5</sup>, J.S. Savage<sup>6,7</sup>, M.E. Marini<sup>7</sup>, F. Chiaromonte<sup>2,3</sup>, M. Reimherr<sup>2,3</sup>, K.D. Makova<sup>1,2</sup>*. 1) Biology Department, Penn State University, University Park, PA; 2) Center for Medical Genomics, Penn State University, University Park, PA; 3) Department of Statistics, Penn State University, University Park, PA; 4) Department of Pediatrics, Penn State College of Medicine, Hershey, PA; 5) Department of Foods and Nutrition, University of Georgia, Athens, GA; 6) Department of Nutritional Sciences, Penn State University, University Park, PA; 7) Center for Childhood Obesity Research, University Park, PA.

The childhood obesity epidemic affects one in three children in the United States. Obesity has a complex etiology with 40 to 70% of the interindividual variability attributed to genetics. However, only 5% is explained by known genetic variants. Here we exploit the longitudinal structure of the growth data to estimate the relationship between genetics and infant weight gain patterns during the first three years after birth. We genotyped 225 first-born children from the Intervention Nurses Start Infants Growing on Healthy Trajectories (INSIGHT) study on the Affymetrix Precision Medicine Research Array. Weight and length/height were collected at five time points between birth and one year, and at two and three years, and used to build growth curves from these participants. Utilizing functional data analysis techniques we identified 24 SNPs associated with the growth curves. Rapid infant weight gain genetic risk score (GRS) was calculated as the weighted sum of these SNPs' effect sizes. This risk score is highly predictive in the first three years after birth, after which GRS defined by SNPs identified in GWAS with adult obesity becomes effective. Our results suggest that predisposition to rapid infant weight gain and to adult obesity might be determined, at least in part, by different genetic variants. This information, along with other 'omic' and environmental factors (e.g. microbiome, methylome, diet, etc.) can aid in identifying at-risk children who will benefit most from very early-life obesity intervention programs.

**2191T**

**Association of adiponectin gene variants (+276G/T and -3971A/G) with obesity susceptibility in Punjabi population of North India.** *H. Kaur, B. Badaruddoza, V. Bains.* Human Genetics, Guru Nanak Dev University, Amritsar, India.

Human obesity is a worldwide health epidemic which is widely accepted as an important risk factor for metabolic syndrome and other non-communicable diseases. The etiology of obesity is multifactorial and involves complex interactions among genetic and environmental factors. Visceral fat accumulation is associated with dysregulation in the secretion of adipocytokines that participate in the development of obesity and its related disorders. The *ADIPOQ* gene spans 16kb consisting of three exons and two introns on chromosome 3q27 and *ADIPOQ* variants have been proved to be a promising markers for understanding the genetic basis of obesity in different study populations. The present study was aimed to investigate the association *ADIPOQ* variants +276G/T and -3971A/G with obesity in North Indian Punjabi population. The present case control study included a total of 520 unrelated adult subjects comprising of 240 obese (BMI >25 kg/m<sup>2</sup>) cases and 280 non obese (BMI <23 kg/m<sup>2</sup>) healthy controls. Biochemical analysis including fasting glucose and lipids was done for all the participants. Anthropometric parameters were measured using standard protocol. The variants were screened by polymerase chain reaction based restriction fragment length polymorphism method and was confirmed using sanger sequencing. It was revealed from the analysis that minor allele frequencies for both the polymorphisms were significantly higher among the obese cases than controls. It was also evidenced that both the variants of *ADIPOQ*-3971GG and +276TT significantly increases the risk towards the development of obesity (OR= 2.23(1.17-4.26), p=0.01, OR= 1.69(1.01-2.82) p=0.04 respectively) in our study population. All anthropometric and biochemical parameters except triglycerides and very low-density lipoproteins cholesterol have shown significant association with both -3971A/G and +276G/T genotypes. The *ADIPOQ* polymorphisms were significantly associated to increased susceptibility to obesity under the recessive genetic model and were shown to provide two fold risk (OR=2.21(1.19-4.12), p=0.011 and OR=1.64(CI: 1.0-2.7), p=0.04 respectively for -3971A/G and +276G/T polymorphism) in developing obesity. This study reveals that the adiponectin gene variants -3971A/G and +276G/T contributes to the genetic risk towards the development of obesity and related traits, and clinically helpful to estimate the disease risk in North Indian Punjabi population.

**2192F**

**Identification of pleiotropic waist-to-hip ratio SNPs using the NHGRI-EBI catalog of published genome-wide association studies.** *Y. Kaur<sup>1,2</sup>, D.X. Wang<sup>1,3</sup>, H.Y. Liu<sup>1,3</sup>, D. Meyre<sup>1,4</sup>.* 1) Health Research Methods, Evidence, and Impact, McMaster University, Hamilton, Canada; 2) Faculty of Medicine, University of Toronto, Toronto, Canada; 3) Schulich School of Medicine and Dentistry, University of Western Ontario, London, Canada; 4) Department of Pathology and Molecular Medicine, McMaster University, Hamilton, Canada.

Visceral obesity is associated with a wide array of health conditions, some of which share a genetic overlap with obesity. In order to assess pleiotropic associations, we conducted a hypothesis-free cross-trait analysis for waist-to-hip ratio adjusted for body mass index (WHR<sub>adjBMI</sub>) loci derived through genome-wide association studies (GWAS). Summary statistics from 12 previously published GWAS were used to capture all WHR<sub>adjBMI</sub> SNPs, and proxy SNPs were identified. These SNPs were used to extract cross-trait associations between WHR<sub>adjBMI</sub> SNPs and other traits using the NHGRI-EBI GWAS catalog. Pathway analysis was conducted for pleiotropic WHR<sub>adjBMI</sub> SNPs. We found 159 WHR<sub>adjBMI</sub> SNPs and 3,674 proxy SNPs. Cross-trait analysis identified 239 associations, of which 100 were for obesity traits (e.g. BMI). The remaining 139 associations were grouped into 12 phenotypic categories: lipids, red blood cell traits, white blood cell counts, inflammatory markers and autoimmune diseases, type 2 diabetes-related traits, adiponectin, cancers, blood pressure, height, neuropsychiatric disorders, electrocardiography changes, and urea measurement. The highest number of trait associations were found for triglycerides (n=10), HDL-C (high-density lipoprotein cholesterol; n=9), and reticulocyte counts (n=8). Pathway analysis for WHR<sub>adjBMI</sub> pleiotropic SNPs found immune pathways (e.g. crosstalk between dendritic cells and natural-killer cells, antigen presentation pathway, dendritic cell maturation) as the top canonical pathways. Our results point to a possible genetic association between reticulocyte counts and WHR<sub>adjBMI</sub>, which has not yet been reported. We also highlight the interplay between immune pathways and body fat distribution, and their relationships with other traits at a genetic level. Our original and hypothesis-free methodology is a powerful tool to decipher genetic correlation between complex human traits and diseases.

**Identification of novel genes whose expression in adipose tissue is causally associated with obesity traits.** S. Konigorski<sup>1</sup>, J. Janke<sup>1</sup>, G. Patone<sup>2</sup>, D. Drogan<sup>3</sup>, M.M. Bergmann<sup>4</sup>, J. Hierholzer<sup>5</sup>, N. Hübner<sup>2,6,7</sup>, R. Kaaks<sup>8</sup>, H. Boeing<sup>1</sup>, T. Pischon<sup>1,6,7</sup>. 1) Molecular Epidemiology Research Group, Max Delbrück Center for Molecular Medicine in the Helmholtz Association (MDC), Berlin, Germany; 2) Genetics and Genomics of Cardiovascular Diseases Research Group, Max Delbrück Center for Molecular Medicine in the Helmholtz Association (MDC), Berlin, Germany; 3) AOK Research Institute (WIdO), AOK Bundesverband, Berlin, Germany; 4) Department of Epidemiology, German Institute of Human Nutrition Potsdam-Rehbrücke (DIfE), Nuthetal, Germany; 5) Department of Diagnostic and Interventional Radiology, Clinic Ernst-von-Bergmann, Potsdam, Germany; 6) DZHK (German Center for Cardiovascular Research) partner site Berlin, Germany; 7) Charité Universitätsmedizin Berlin, Germany; 8) Department of Cancer Epidemiology, German Cancer Research Center (DKFZ), Heidelberg, Germany.

Obesity has continuously increasing prevalence between 10–30% world-wide and is a major risk factor for chronic disease. Adipose tissue (AT), whose amount is used to define obesity, is stored in different body compartments and acts as an endocrine organ, so understanding the association of adiposity with metabolic imbalance is of interest. In this study, our aim was to identify novel genes whose gene expression in subcutaneous AT (SAT) is causally related to the obesity traits of body fat mass and body fat distribution. The study sample consisted of 160 probands from the population-based European Prospective Investigation into Cancer and Nutrition (EPIC) Potsdam substudy. Gene expression in SAT of 30,917 genes was quantified by sequencing total mRNA from abdominal SAT biopsies. SAT mass and the ratio of SAT and total AT (TAT) were obtained from whole-body MRI scans as measures of fat mass and fat distribution. In the analysis, we first investigated the association of gene expression with SAT and SAT/TAT in joint copula models, and followed-up the results with a gene ontology (GO)-term enrichment analysis, and a Mendelian Randomization (MR) study to investigate the causal association of genetically-determined gene expression with SAT and SAT/TAT, using single nucleotide variants (called from the RNA-Seq data with 6.6X) in the respective gene as instruments. The analysis identified 607 obesity-associated autosomal (430 for SAT, 215 for SAT/TAT, of which 38 overlap) and 18 sex-chromosomal genes after multiple testing corrections. 531 of them encode a known protein and 518 are novel candidate genes for obesity. Enrichment analyses indicated that SAT-associated genes are characterized by their higher than expected involvement in cellular, regulatory and immune system processes, and SAT/TAT-associated genes by their involvement in cellular, metabolic, and regulatory processes. MR analyses suggested that the gene expression of 35 (out of the 430) genes was causally related to SAT and the gene expression of 28 (out of the 215) genes to SAT/TAT. The gene expression of these 35 and 28 genes explained 70% and 69% of the variance of SAT and of SAT/TAT, respectively. 29 and 23 of them are novel. In summary, we identified 52 novel genes, 29 for body fat mass and 23 for body fat distribution, whose up/down-regulated gene expression might causally contribute to obesity, and might help to explain the role of obesity and metabolic imbalance in chronic disease in more detail.

**2194T**

**Association between SNPs in *FTO* and *IRX3* and metabolic traits in population of Colombian Caribbean Coast.** G.J. Mora-Garcia<sup>1</sup>, M.S. Ruiz-Diaz<sup>1</sup>, D. Mena-Yé<sup>2</sup>, D. Gomez-Camargo<sup>1</sup>. 1) Doctorado en Medicina Tropical, Facultad de Medicina, Universidad de Cartagena, Cartagena de Indias, Colombia; 2) Facultad de Medicina, Universidad de Cartagena.

*FTO* gen has been widely associated with obesity, type 2 Diabetes Mellitus (DM2) and related metabolic disorders. Recently, single nucleotide polymorphisms (SNPs) in *FTO* have been linked with the *IRX3* gen. Some authors have revealed high linkage disequilibrium (LD) between *FTO* and *IRX3* SNPs. In Latin America *FTO* has been also associated with these conditions, however there is little evidence about *IRX3-FTO* relationship. Since this is an admixed population, LD between both genes could show different behavior. Therein, this study aimed to describe the possible *FTO-IRX3* LD, and to estimate the association between these genes, obesity and related disorders in a Latin-American population. A cross-sectional genetic association study was carried out (n=805). Body weight excess (BWE), obesity, abdominal obesity, hypertension, hyperglycemia, DM2 and dyslipidemia were evaluated. Four SNPs were genotyped: 3 at *FTO* locus (rs17817449, rs8050136, rs9939609) and 1 at *IRX3* locus (rs3751723). LD between these SNPs was estimated. Data were analyzed through generalized regression models, including genotype additive and haplotypic models. Associations were adjusted by genetic stratification assuming a three-hybrid substructure (k=3) using a Bayesian approach (Markov Chain Monte Carlo). SNP rs3751723 (*IRX3*) was not in LD with *FTO* SNPs ( $D' \leq 0.03$ ;  $r^2 \leq 0.03$ ). But it was found for *FTO* SNPs ( $D' \geq 0.97$ ;  $r^2 \geq 0.93$ ); therefore, only one of these three *FTO* polymorphisms (rs9939609) was employed in further single-gene [GM2] association analyses. TT genotype (rs9939609) was found to be associated with waist circumference ( $p=0.04$ ;  $adj-p=0.01$ ); Interestingly, no association between this *FTO* SNP and BWE was found ( $adj-p=0.13$ ). *IRX3* SNP was found to be associated with BWE (OR=1.06,  $adj-p=0.03$ [GM3]). Also, it was found one *FTO-IRX3* combination associated with BWE (G-A-A-T, rs17817449-rs8050136-rs9939609-rs3751723; OR=0.67,  $p=0.04$ ). *FTO* was related with waist circumference and *IRX3* was associated to BWE. In spite that these genes were not in LD, findings of a haplotype involving *FTO-IRX3* suggest a gene-gene interaction associated with increased risk of obesity. Results from the current study partially agree previous findings of a long-range functional connection between these genes. Further studies on this phenomenon might contribute to a better understanding of *FTO-IRX3* role in obesity pathogenesis. .

**2195F**

**Candidate gene analyses in families with discordance for extreme obesity.** M.H. Preuss<sup>1</sup>, C. Schurmann<sup>2</sup>, W.D. Li<sup>3</sup>, R.A. Price<sup>4</sup>, D.R. Reed<sup>5</sup>, R.J.F. Loos<sup>1,6,7</sup>. 1) The Charles Bronfman Institute for Personalized Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; 2) Regeneron Genetic Center, Regeneron Pharmaceuticals, Inc, Tarrytown, NY; 3) Department of Genetics, College of Basic Medical Sciences, Tianjin Medical University, Tianjin, China; 4) University of Pennsylvania, Philadelphia, PA; 5) Monell Chemical Senses Center, Philadelphia, PA; 6) The Mindich Child Health and Development Institute, Icahn School of Medicine at Mount Sinai, New York, NY; 7) Genetics of Obesity and Related Metabolic Traits Program, Icahn School of Medicine at Mount Sinai, New York, NY.

Obesity in the general population is a common multifactorial disease that results from an intricate interplay of genes and environment. On the other hand, extreme and early-onset forms of obesity are rare, typically caused by a single gene mutation, and environment has little impact. Recent genome-wide association studies have shown that genes that play a role in monogenic and syndromic obesity, also may play a role in common obesity (e.g. *MC4R*, *SH2B1*, *POMC*). Here, we examine the role of rare and low frequency coding variants in 119 candidate genes in 393 families (n = 1,501 individuals) discordant for extreme obesity. Families had at least one offspring with extreme obesity (BMI  $\geq 40$  kg/m<sup>2</sup>), who had at least one sibling or parent with no history of overweight or obesity (lifetime BMI < 25 kg/m<sup>2</sup>). DNA samples were genotyped using the Illumina MEGA array and the 1000G reference panel was imputed using a pedigree-phased approach. Analyses focused on 119 genes known to play a "definite" or "likely" role in monogenic forms of extreme and early-onset obesity in humans and/or animal models. We performed single-variant (additive/recessive) and gene-based association analyses of rare (MAF < 1%) and low-frequency (MAF < 5%) missense variants. Case (BMI  $\geq 40$  kg/m<sup>2</sup>) vs control (BMI < 30 kg/m<sup>2</sup>) or extreme control (BMI < 25 kg/m<sup>2</sup>) status were used as outcomes. All analyses were adjusted for age and sex. Bonferroni corrected *P*-values at  $\alpha = 0.05$  correspond to  $10^{-4}$  for single-variant analyses and  $4 \times 10^{-4}$  for gene-based analyses. None of the single-variant or gene-based results reached Bonferroni-corrected significance, but for 15 variants ( $P < 0.01$ ) and 8 genes ( $P < 0.05$ ) associations were promising. For example, missense variants in *ALMS1* (rs45608038, p.Asn1786Asp,  $P = 0.002$ ), *ATXN2* (rs7969300, p.Ser248Asn,  $P = 0.0015$ ), *BBS1* (rs77298332, p.Ser410Phe,  $P = 0.004$ ) and *BDNF* (rs66866077, p.Glu6Lys,  $P = 0.003$ ) were found to be associated with increased risk of extreme obesity. Gene-based analyses highlighted *SH2B1* ( $P_{\text{burden}} = 0.004$ ), *GLUCY2C* ( $P_{\text{burden}} = 0.01$ ), *TLR5* ( $P_{\text{burden}} = 0.01$ ), among others. Despite a family design with discordance in extreme obesity, our study had insufficient statistical power to identify significant associations with rare and low-frequency variation in candidate genes. Nevertheless, our analyses have prioritized a number of genes and variants for further follow up analyses to elucidate the mechanisms through which they affect human obesity.

**Genome-wide association study of body fat distribution identifies novel adiposity loci and sex-specific genetic effects.** M. Rask-Andersen, T. Karlsson, W.E. Ek, A. Johansson. IGP, Uppsala University, Uppsala, Uppsala, Sweden.

Body mass and body fat composition are of clinical interest due to their links with cardiovascular- and metabolic diseases. Fat stored in the trunk has been suggested as more pathogenic compared to fat stored in other compartments of the body. In this study, we performed genome-wide association studies (GWAS) for the distribution of body fat to the arms, legs and trunk. Proportions of fat, distributed to these compartments were estimated from segmental bio-electrical impedance analysis (sBIA) for 362,499 individuals from the UK Biobank. A total of 97 loci, were identified to be associated with body fat distribution, 40 of which have not previously been associated with an anthropometric trait. A high degree of sex-heterogeneity was observed and associations were primarily observed in females, particularly for distribution of fat to the legs and trunk. Interaction with sex was tested for with GWAMA and showed sex-heterogeneous effects at 42 loci. Enrichment analysis with DEPICT indicated involvement of mesenchyme derived tissues and cell types: the musculoskeletal system, chondrocytes, mesenchymal stem cells and adipocytes; female gonadal and endocrine tissues, as well as arteries. Our findings also highlight several enzymatically active members of the ADAMTS family of metalloproteinases, which are involved in extracellular matrix maintenance and remodeling. In conclusion, GWAS of sBIA-determined body fat distribution revealed a genetic architecture that influences the distribution of body fat throughout the human body. Analyses showed genetic variation to have a stronger influence on the proportion of fat stored in the trunk and legs in females, as compared to males. The capacity for peripheral adipose storage has been highlighted as a potential factor underlying the lower risk of cardiovascular and metabolic disease in women of middle age. Determining the genetic determinants and mechanisms that lead to a favorable distribution of body fat may help in risk assessment and in identifying novel venues for intervention to prevent or treat obesity-related disease.

**2197T****Association of longitudinal body mass index (BMI) trajectories with genetic risk score in children with severe early childhood obesity (SECO).**

V.V. Thaker<sup>1</sup>, K. Qian<sup>2</sup>, M. McDonald<sup>3</sup>, S. Christensen<sup>3</sup>, A. Lage<sup>3</sup>, S. Challa<sup>3</sup>, B. Weaver<sup>4</sup>, S. Vedantam<sup>3</sup>, S. Lopez-Pintado<sup>2</sup>, J. Hirschhorn<sup>3,4,5</sup>. 1) Columbia University Medical Center, New York, NY; 2) Mailman School of Public Health, New York, NY; 3) Boston Children's Hospital, Boston, MA; 4) Harvard Medical School, Boston, MA; 5) The Broad Institute, Boston, MA; 6) Boston University Medical School, Boston, MA.

**Background:** SECO, BMI > 120% of 95th percentile for children under 6 years of age, is a serious threat to our future health. While childhood BMI has been shown to track into adulthood, limited data are available on the association of childhood BMI trajectory and genetic risk. The objectives of the study were: 1) To identify the differences in the BMI trajectory of children with SECO compared to those with normal BMI. 2) To study the association between the functional BMI trajectories with polygenic risk score for obesity in children with severe obesity. **Methods:** Lifetime height and weight data of children attending outpatient clinics at Boston Children's Hospital were obtained from 2012-2017 for Genetics of Early Childhood Obesity (GECO) study by a validated electronic algorithm from the electronic health records (PMID: 27452794) and from growth charts using Plot Digitizer v3.12. A functional data analysis approach was used to model the BMI data measured at sparse time points using functional principal component decompositions and a mixed model approach. A functional depth-based global envelope test was used to compare the differences in the BMI trajectory patterns. We studied the association between the BMI smoothed functions and the additive polygenic risk score generated with BMI loci identified in population-based studies, in a subset of children. **Results:** A total of 332,250 observations in 28,554 children of mixed ethnicity (31% African Americans, 22% Hispanic); 52% girls, 22% with severe obesity, were obtained, with min. 2 BMI readings/child. Of the children with BMI available at age < 6 years (n=16,683), 7.6% had severe obesity. The global functional envelope test identifies differences in the BMI trajectory of children with SECO compared to those with normal BMI. No adiposity rebound is seen in the children with SECO, while their trajectories cross the percentiles predicted by the extension of the CDC 2000 BMI charts, stratified by gender. The polygenic risk score is associated with the BMI trajectory patterns. **Conclusions:** A novel functional data analysis approach can be used to analyze sparse longitudinal clinical anthropometric data. These methods can test and visualize the differences in BMI trajectories between different groups of children with SECO. The association of polygenic risk score with BMI trajectories of children with obesity may help in profiling those with higher genetic risk for severe obesity with a goal of personalized therapy.

**2198F****Obesity and personality are genetically intertwined.** U. Vainik<sup>1,2</sup>, R.

Mõttus<sup>3,2</sup>, A. Realo<sup>4,2</sup>, J. Allik<sup>2,5</sup>, T. Esko<sup>6,7</sup>, A. Dagher<sup>1</sup>. 1) Montreal Neurological Institute, Montreal, Quebec, Canada; 2) Institute of Psychology, University of Tartu, Tartu, Estonia; 3) University of Edinburgh, Edinburgh, UK; 4) University of Warwick, Warwick, UK; 5) Estonian Academy of Sciences, Estonia; 6) Estonian Genome Centre, University of Tartu; 7) Broad Institute, Cambridge, Massachusetts.

Obesity-related genes mostly express in the brain and obesity is related to personality. However, it is unclear how genetic propensity for obesity translates into observable behaviour. Here, we assessed overlap between genetic risk for obesity and personality traits. We relied on genomic and NEO-PI-3 personality data (240 items) in 3445 Estonian adults with a wide age range (18-91). Obesity polygenic score (OPGS) constructed from GWAS weights obtained from GeneAtlas (UK Biobank, 452,264 individuals) comprising 4,759,748 single nucleotide polymorphisms (SNPs) predicted body mass index in this sample ( $R^2=0.034$ ,  $p<0.001$ ). When correlating OPGS with individual personality items, the analysis highlighted items known to be related to obesity from previous meta analysis. Namely, the personality item-OPGS correlation profile tracked with the meta-analytic personality item-BMI profile ( $r=0.35$ ;  $p<0.001$ ). On an individual item level, OPGS associated positively with behaviours, such as overeating, sociability, and joyfulness, and negatively with deliberation, straightforwardness, and compliance. Together, current analysis shows a systematic overlap between personality and genetic propensity for obesity, which may inform intervention efforts.

**2199W**

**Genetic architecture of human obesity traits in the rhesus macaque.** A. Vinson<sup>1,2</sup>, M.J. Raboin<sup>1</sup>, J. Letaw<sup>1</sup>, A.D. Mitchell<sup>1</sup>, D. Toffey<sup>1</sup>, C. Roberts<sup>2</sup>, J.E. Curran<sup>3</sup>. 1) Oregon National Primate Research Center, Primate Genetics Section, Oregon Health & Science Univ., Beaverton, OR; 2) Oregon National Primate Research Center, Div. of Cardiometabolic Health, Oregon Health & Science Univ., Beaverton, OR; 3) South Texas Diabetes & Obesity Institute, Dept. of Human Genetics, Univ. of Texas Rio Grande Valley School of Medicine, Brownsville, TX.

Rhesus macaques display considerable spontaneous variation in adiposity and susceptibility to dietary challenge. While the physiological consequences of obesity have been studied extensively in this species, corollary genetic studies of obesity do not exist. We aimed to assess genetic contributions to spontaneous adiposity in rhesus macaques. We measured phenotypic variation by age-class and sex for 4 well-studied human obesity traits in 584 chow-fed macaques, including body mass index (BMI), waist-to-height ratio (WHtR), waist-to-thigh ratio (WTR), and circulating ghrelin. We estimated total and sex-specific heritability for all traits, including waist-to-thigh ratio adjusted for BMI (WTRadjBMI), as well as genotypic and phenotypic correlation among all traits. We also assessed functional genetic variation segregating at *ADIPOQ*, *BDNF*, *FTO*, *LEP*, *LEPR*, *MC4R*, *POMC*, and *RETN* in 4 animals with extreme values of BMI, WHtR, or WTR. All measures of adiposity increased with age, and were greater for males than females. Trait heritabilities ranged from 0.13 to 0.43 ( $P=2.6 \times 10^{-2}$  to  $4.0 \times 10^{-7}$ ). When stratified by sex, heritability was greater in females for all traits, with the exception of BMI, for which heritability was greater in males. Sex-stratified heritability estimates for BMI, WHtR, WTR, and ghrelin included confidence intervals that did not overlap between males and females. Phenotypic variation in all traits was robustly correlated, with genetic correlations ranging from 0.63-0.89, indicating substantial pleiotropy. Macaques with extreme adiposity segregated 825 functional genetic variants at 7 of 8 obesity genes, including 6 missense mutations in *ADIPOQ*, *BDNF*, *FTO*, *LEP*, and *LEPR*, and notably, 1 premature stop mutation in *LEPR*. We conclude that there are significant polygenic contributions to adiposity in macaques, and mutations with potentially larger effects in genes known to influence obesity in humans. We find substantial similarity between macaques and humans for traits that are robust indicators of adiposity in humans.

**PheWAS of sub-components of T2D genetic risk in large-scale biobanks reveals clinical outcomes linking to physiological effects.** X. Zhong<sup>1</sup>, A. Mahajan<sup>2</sup>, J. Torres<sup>2</sup>, A.B. Faucon<sup>1</sup>, R. Tao<sup>1</sup>, N.J. Cox<sup>1</sup>, M.I. McCarthy<sup>2</sup>. 1) Vanderbilt Genetics Institute, Nashville, TN, USA; 2) The Wellcome Centre for Human Genetics, University of Oxford, Oxford, UK.

Development of type 2 diabetes (T2D) involves dysfunction of multiple mechanisms. Our primary goal was to comprehensively interrogate clinical phenotypes associated with T2D risk alleles considered to act through different biology. We constructed three genetic risk scores (GRS) according to the physiological classification of T2D risk variants by Mahajan *et al.* (2018 Nat Genet) that capture the primary effect of insulin secretion (IS), insulin action (IA), and BMI and dyslipidemia (BL). We tested these instruments for association across >1600 clinical endpoints in two independent biobanks, with a total of 362,485 samples of European ancestry (23,294 from BioVU and 339,191 from UK Biobank). Despite different ascertainment of subjects in BioVU and the UKBB, the GRS-phenotypes associations were directionally consistent (concordance rate ranged 60%-100% over a range of significance thresholds). We then meta-analyzed the phenome-wide results over 1099 phenotypes shared by the two sites, and identified 42 significant associations (Bonferroni correction,  $p < 4.4E-5$ ) that involved 33 phenotypes in addition to diabetes. For most of these associated phenotypes (88%), the effect size estimates significantly differed across the GRS categories (Cochran's Q,  $p < 0.05$ ), including hypercholesterolemia, coronary artery disease, obesity, chronic nonalcoholic liver disease, renal failure, and osteoarthritis etc. We further carried out association analysis stratified by T2D status, and observed strong associations only in T2D patients but not in patients without diabetes for a variety of phenotypes (e.g., Renal failure ( $p=6.2E-4$ ) and Sleep apnea ( $p=0.0006$ ) in BL, Intestinal obstruction ( $p=0.001$ ) in IA, and Cerebral artery occlusion, with cerebral infarction ( $p=0.004$ ) and Speech disturbance ( $p=0.006$ ) in IS). In conclusion, the GRSs comprised of SNPs associated with different mechanisms of T2D genetic risk were associated at different degrees with clinical outcomes, consistent with the hypothesis that different pathophysiology may contribute to the differentiated T2D comorbidities/complications. Combining results from independent biobanks increased our ability to resolve the patterns of phenome associations with GRS for sub-components of the T2D genetic risk physiology.

Erectile dysfunction (ED) is a common disease, affecting 20-40% of men over 60. The genetic architecture of ED remains poorly understood, owing in part to a paucity of well-powered genetic association studies. We conducted a genome-wide association study (GWAS) for ED using data from 6,175 cases among 223,805 European men from UK Biobank (UKBB), Estonian Genome Center of the University of Tartu (EGCUT) and Partners HealthCare Biobank (PHB). GWAS in UKBB revealed a single genome-wide significant ( $< 5 \times 10^{-8}$ ) locus at 6q16.3 in the intergenic region between *MCHR2* and *SIM1* (lead variant rs57989773, EAF<sub>UKBB</sub> (C-allele) = 0.24; OR 1.23;  $p = 3.0 \times 10^{-11}$ ). Meta-analysis with estimates from PHB (OR 1.20;  $p = 9.84 \times 10^{-6}$ ) and EGCUT (OR 1.08;  $p = 0.16$ ) yielded a pooled meta-analysis OR 1.20;  $p = 5.72 \times 10^{-14}$ . Meta-analysis of all variants yielded no further genome-wide loci. In-silico analysis of the locus revealed enhancer marks in several tissues, including embryonic stem cells, mesenchymal stem cells and endothelial cells, indicating that the ED-associated interval lies within a regulatory locus. Chromosome conformation capture (Hi-C) and Capture Hi-C showed that *MCHR2* and *SIM1* were in the same topologically associated domain as the ED-associated variants, with high contact probabilities between the ED-associated interval and the *SIM1* promoter. A genome-wide association study of rs57989773 found significant associations with 12 phenotypes including adiposity (9 traits), adult height and sleep-related traits. Sex-stratified analyses revealed sexual dimorphism for waist-hip ratio (WHR), systolic and diastolic blood pressure. These associations recapitulate the effects on blood pressure and adiposity seen in patients with rare *SIM1* coding variants. These findings suggest that the ED-associated intergenic region and *SIM1* are functionally connected. *SIM1* encodes a transcription factor that is highly expressed in hypothalamic neurons and Sim1-expressing neurons have recently been implicated in murine male sexual function. LD score regression identified ED to be correlated and share genetic architecture with type 2 diabetes (T2D;  $r_g = 0.40$ , nominal  $p$ -value = 0.0008; FDR-adjusted  $p$ -value = 0.0768). Mendelian randomization identified genetic risk to T2D to be causally implicated in ED: OR 1.11 (95% CI 1.05-1.17,  $p = 3.5 \times 10^{-4}$ ), per 1-log higher genetic risk of T2D, with no causal effects of BMI on ED. Our findings provide novel insights into the biological underpinnings of ED.

**Single nuclei RNA-seq to decipher hypothalamic transcriptional response to chronic topiramate administration.** K. Ushakov<sup>1,2</sup>, M.F. Lopez<sup>1,3</sup>, A. Nelson<sup>4</sup>, G. Gorski<sup>1,2</sup>, E.Z. Macosko<sup>4,5</sup>, J.N. Hirschhorn<sup>1,2,3</sup>. 1) Center for Basic and Translational Obesity Research and Divisions of Endocrinology and Genetics, Boston Children's Hospital, Boston, MA, USA; 2) Metabolism Initiative and Program in Medical and Population Genetics, Broad Institute of Harvard and MIT, Cambridge, MA, USA; 3) Department of Medicine, Endocrine Division, Harvard Medical School, Boston, MA, USA; 4) Stanley Center for Psychiatric Research, Broad Institute of Harvard and MIT, Cambridge, MA, USA; 5) Department of Psychiatry, Massachusetts General Hospital, Boston, MA, USA.

Obesity remains a major global public health problem caused by a combination of environmental and genetic factors. Some progress has been made in our understanding of appetite and body weight regulation, but there are still no highly effective and safe therapies to treat obesity. One recently approved anti-obesity treatment includes topiramate, which can lead to decreased appetite by unknown mechanisms. Genome wide association studies (GWAS) have previously identified numerous common genetic variants that are associated with body mass index (BMI). Computational methods developed by our laboratory and others have strongly implicated these variants with neuronal biology, and specifically glutamate signaling and synaptic plasticity. These findings overlap with one of topiramate's proposed mechanism of action, which is modulation of glutamate signaling. Thus, BMI GWAS loci may contain genes encoding site(s) of action for topiramate's anorectic effect. In the present study, we decided to take an unbiased gene expression approach to dissect the mechanism by which topiramate elicits its effects and also to determine whether there is overlap between genes regulated by topiramate and those implicated by GWAS. Obese mice were injected intraperitoneally with either topiramate (50 mg/kg/day) or vehicle for 14 days. Brain tissue from relevant hypothalamic regions (arcuate and paraventricular nuclei) was collected and single nuclei were isolated. Using a combination of flow cytometry and the 10X Genomics Chromium Platform, we generated gene expression signatures of >8,000 hypothalamic nuclei collected from mice treated with vehicle or topiramate. The data was aligned and clustered to associate nuclei with different cell types. Results show differential expression of several non-coding RNAs such as Malat1, Meg3 and Nrg3os in multiple clusters between topiramate or vehicle treatments. Our data also identifies expression differences in genes underlying obesity or related to proposed mechanisms of topiramate action, including Ksr2, Kcnd3, and Gria2. We are performing gene set analysis to find pathways enriched in differentially expressed genes within cell types. Our results begin to describe a hypothalamic transcriptional signature for the anti-obesity drug topiramate. These studies could lead to a better understanding of processes that regulate body weight and help guide development of more precise and effective therapies for weight loss.

Adipose tissue (AT) is a complex endocrine organ found throughout the body at specific locations including under the skin (subcutaneous, SAT) or around internal organs (visceral, VAT). Visceral adiposity is an important determinant of obesity-linked metabolic complications, but the precise mechanism of association remains unknown. Dysfunctional adipocytes and infiltration of immune cells are proposed mechanisms but the complete cellular landscape remains to be elucidated. To this end, we aimed to characterize the non-adipocyte fraction of AT (i.e. stromal vascular fraction - SVF) derived from both SAT and intra-abdominal VAT from obese (BMI > 35 kg/m<sup>2</sup>) individuals with or without type 2 diabetes (T2D). In total, we obtained 26 tissue samples (T2D = 11) and generated mRNA profiles at single-cell resolution applying the 10x Genomics Chromium platform. On average we sequenced 1,527 cells/sample at a depth that resulted in on average 1,175 genes/cell. We used RNA-Seq from matching bulk samples for validation purpose. After initial QC and filtering we identified 26,350 high quality cells for clustering and further analysis. The majority of the cells (~60%) were stem/progenitor cells, found clustered as six different subpopulations. Among these, three clusters constituted of VAT cells only, with two clusters showing enrichment for the mesothelial marker *MSLN* whereas the other had pronounced expression of the pro-adipogenic factor *CFD* similar to progenitor clusters from SAT. We further noted sub-populations among *MSLN*-expressing cells being derived mainly from T2D patients. We were also able to profile the large number of immune cell subtypes residing in AT in a depot and T2D-specific manner. For instance, we confirmed the notion that AT macrophages are residing to larger extent in VAT compared to SAT including cells at different stages of polarization – a pattern that was further enhanced when analysis was restricted to cells derived from T2D subjects. Finally, we identified the presence of multiple endothelial cell types including AT-microvascular endothelial cells expressing *FABP4* and *CD36* which were recently shown to be involved in obesity-linked AT dysfunction. In conclusion, we have shown that high-throughput single-cell approaches applied to deeply phenotyped cohorts and carefully prepared tissues samples allow the identification of dysfunctional cellular and molecular machineries underpinning complex diseases such as obesity and type 2 diabetes.

## 2204F

**Identification of death associated protein kinase 2 as a novel obesity-induced driver of non-alcoholic fatty liver disease.**

The rising prevalence of obesity has led to a pandemic of non-alcoholic fatty liver disease (NAFLD), affecting almost 25% of adults worldwide. Without intervention or treatment, NAFLD can progress into nonalcoholic steatohepatitis (NASH), cirrhosis or hepatocellular carcinoma, which are often irreversible. To improve our understanding and treatment of NAFLD, we sought to delineate the molecular mechanisms of NAFLD by testing the hypothesis that obesity impairs the function of adipose tissue, which can lead to ectopic fat deposition in the liver. We RNA-sequenced subcutaneous adipose tissue samples collected from 259 morbidly obese individuals during their bariatric surgery and re-profiled their adipose transcriptomes one-year post surgery to understand the effect of weight loss on gene expression. In parallel, liver histology was performed to accurately stage NAFLD and NASH. We discovered that the expression of 17 genes is significantly downregulated in NASH (adjusted  $P < 0.05$ ) and negatively correlated with liver steatosis score and serum triglycerides (TGs). Furthermore, adipose expression of five of the 17 genes was also correlated with diet-induced liver steatosis in a large panel of mouse strains. Notably, the adipose expression of one of the five genes, *DAPK2*, recovered after the weight loss at the one-year follow-up. To infer a causal pathway among obesity, serum TGs, *DAPK2* adipose expression, and NAFLD, we leveraged longitudinal transcriptome information and carried out mediation analyses. The results of our mediation analyses support the causal effect of obesity on NAFLD, mediated by adipose expression of *DAPK2* and serum TGs. To gain insight into the functional consequences of reduced *DAPK2* expression in the adipose tissue, we knocked down *DAPK2* in human primary preadipocytes via siRNA. Five key genes involved in autophagy were significantly downregulated, including *TGM2* and *ULK2*, which also regulate adipocyte differentiation. These data suggest impaired autophagy and adipocyte differentiation due to *DAPK2* reduction in the adipose tissue as a novel pathogenic mechanism of NAFLD. In summary, we present genomic and experimental data to support the causal role of *DAPK2* in NAFLD pathogenesis.

**2205W****Association between hepatic CYP7A1 activity and PGC-1 $\alpha$  polymorphism.**

*T. Inamine<sup>1</sup>, A. Makimoto<sup>1</sup>, K. Ohyama<sup>2</sup>, K. Tsukamoto<sup>1</sup>.* 1) Department of Pharmacotherapeutics, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan; 2) Department of Pharmacy Practice, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan.

**Background** Hepatic cholesterol 7 $\alpha$ -hydroxylase (CYP7A1) is the rate-limiting enzyme in the classical bile acid biosynthesis pathway and transcriptionally induced by HNF4 $\alpha$  and PGC-1 $\alpha$ . We evaluated the effects of CYP7A1, HNF4 $\alpha$ , and PGC-1 $\alpha$  polymorphisms on CYP7A1 enzyme activity in healthy Japanese individuals. **Methods** A study cohort consisted of 42 healthy Japanese students (31 female and 11 male) in School of Pharmacy, Nagasaki University. Blood was drawn from 1 to 3 PM. Serum 7 $\alpha$ -hydroxycholest-4-en-3-one (C4), which is a serum marker of hepatic CYP7A1 activity, and total cholesterol were measured by high performance liquid chromatography-ultraviolet detection and enzymatic colorimetric method, respectively. Four single nucleotide polymorphisms of the 3 genes (rs3808607 within *CYP7A1*, rs6017340 and rs6031587 within *HNF4A*, and rs8192678 within *PPARGC1A*) were genotyped by polymerase chain reaction (PCR)-restriction fragment length polymorphism and PCR-high resolution melting curve analysis. Serum C4 concentration as well as C4/cholesterol ratio were compared among three genotypes of each SNP by Jonckheere-Terpstra trend test. **Results** In our healthy Japanese cohort, serum C4 concentration (35.53 vs 34.92  $\mu$ g/L) and total cholesterol concentration (13.71 vs 14.25 mmol/L) and C4/cholesterol ratio (7.10 vs 6.61  $\mu$ g/mmol) were comparable between female and male subjects. In regards to rs3808607, rs6017340, and rs6031587, there were no significant trend in C4, total cholesterol, and C4/cholesterol ratio among three genotypes of each SNP. With respect to rs8192678 of *PPARGC1A*, C4 level (GG 28.31 vs GA 34.36 vs AA 43.03  $\mu$ g/L) as well as C4/cholesterol ratio (GG 12.25 vs GA 12.32 vs AA 16.99  $\mu$ g/mmol) were increased in A-allele dependent manner ( $P = 0.007$  and  $P = 0.015$ , respectively). **Conclusion** This study demonstrated association between hepatic CYP7A1 activity and a *PPARGC1A* polymorphism for the first time. rs8192678 that is a missense variant of PGC-1 $\alpha$  (p.Gly482Ser) might influence on CYP7A1 activity more than rs3808607 which is a functional promoter SNP of CYP7A1, at least in a healthy Japanese. .

**2206T****Common variants in *NPC1L1* are not associated with response to ezetimibe treatment in the IMPROVE-IT trial.**

*Y. Zhang<sup>1</sup>, G. Kosova<sup>2</sup>, C.T. Ruff<sup>3</sup>, Z. Guo<sup>1</sup>, D.F. Reilly<sup>2</sup>, D.V. Mehrotra<sup>1</sup>, Y. Mitchell<sup>1</sup>, S.H. Shah<sup>5</sup>, M.A. Blazing<sup>5</sup>, E.A. Bohula<sup>3</sup>, R.P. Guigliano<sup>3</sup>, C.S. Fox<sup>2</sup>, M.S. Sabatine<sup>3</sup>, P.M. Shaw<sup>2</sup>.* 1) Biostatistics and Research Decision Sciences, Merck Sharpe and Dohme, Kenilworth, NJ; 2) Genetics and Pharmacogenomics, Merck Sharpe and Dohme, Kenilworth, NJ; 3) TIMI Study Group, Brigham and Women's Hospital, Boston, MA; 4) Clinical Research, Merck Sharpe and Dohme, Kenilworth, NJ; 5) Duke Clinical Research Institute, Durham, NC.

**IM**proved **R**eduction of **O**utcomes: **V**ytorin **E**fficacy **I**nternational **T**rial (IMPROVE-IT) demonstrated a significant benefit of adding ezetimibe to a statin therapy in lowering LDLc levels and reducing the risk of cardiovascular (CV) events. Ezetimibe lowers absorption of dietary cholesterol by inhibiting Niemann-Pick C1-like 1 (*NPC1L1*), a cholesterol transporter found in the intestinal epithelial cells. Previous studies have shown genetic variation in *NPC1L1* to be associated with *NPC1L1* levels, LDLc levels and risk of CV events. Therefore, we hypothesized that variants in *NPC1L1* are likely candidates to explain a portion of inter-individual variability observed in LDLc reduction in response to ezetimibe treatment. We examined the associations between five common, independent *NPC1L1* variants previously shown to be associated with LDLc levels in Global Lipid Genetics Consortium (GLGC) analyses and LDLc levels in the ~6,500 participants of the IMPROVE-IT trial, who were randomized to receive simvastatin monotherapy or simvastatin+ezetimibe combination treatment. There were no significant associations between baseline LDLc levels or percent change in LDLc after 1 month of either treatment and any of the SNPs, tested either as a single variant or as a genetic risk score ( $P > 0.1$ ). Association between rs10234070 (MAF=0.11) and risk of CV events in patients treated with simvastatin+ezetimibe remained significant after correcting for multiple testing ( $P_{\text{corrected}}=0.015$ ). However, the observed direction of effect is opposite to what we predicted, such that the minor ("T") allele associated with increased LDLc levels in GLGC is associated with reduced risk of CV events in our study. While we cannot rule out a potential role for rare, inactivating mutations in *NPC1L1* in response to ezetimibe treatment, we did not find significant associations between common variants and baseline LDLc, LDLc reduction or CV events in the IMPROVE-IT trial in a directionally consistent manner. Therefore, our data suggests that the reduction in LDLc levels by adding ezetimibe to a statin regimen remains consistent regardless of the common variation in *NPC1L1*..

**Genetic susceptibility to low HDL-C among Filipinos.** *E. Cutiongco de la Paz*<sup>1,2</sup>, *R. Sy*<sup>2</sup>, *J. Nevado Jr.*<sup>1</sup>, *P. Reganit*<sup>2</sup>, *F. Punzalan*<sup>2</sup>, *L. Santos*<sup>2</sup>, *R. Tiongco II*<sup>2</sup>, *E. Llanes*<sup>2</sup>, *D. Ona*<sup>2</sup>, *J. Magno*<sup>2</sup>, *J. Aherrera*<sup>2</sup>, *L. Abrahan IV*<sup>2</sup>, *C. Agustin*<sup>2</sup>, *A. Aman*<sup>2</sup>, *A. Bejarin*<sup>2</sup>. 1) Institute of Human Genetics, National Institutes of Health, University of the Philippines Manila, Philippines; 2) Philippine Genome Center, University of the Philippines; 3) Section of Cardiology, Department of Medicine, College of Medicine, University of the Philippines Manila.

High density lipoprotein cholesterol (HDL-C) is strongly correlated with atherosclerotic cardiovascular disease (ASCVD) risk. Differences in HDL-C levels are seen across ethnic groups with Filipinos having high prevalence of low HDL-C from national nutrition surveys in the Philippines over a ten year period (2003 to 2013). Studies on HDL-C metabolism and heritability estimates suggest that 60-70% of variance in HDL may be due to genetic factors. HDL-C is influenced by genetic variants across entire spectrum of allele frequencies in genes involved in its metabolism. The study aims to validate the important role of common variations at different loci influencing HDL-C levels in the Filipino adult population. This is an observational study with 62 participants having low HDL-C profile and 123 have normal HDL-C profiles. Patients' DNA samples were genotyped using a customized Illumina GoldenGate microarray chips. Polymorphisms in CETP, ABCG8, APOB, GALNT2 and GCKR genes have been found to be associated with low HDL-C profile among Filipinos. This study has provided an opportunity to reveal population-specific genetic determinants of HDL-C.

**GWAS of serum lipids in Africans identifies 4 novel loci.** *A.R. Bentley*, *G. Chen*, *A.P. Doumatey*, *A.A. Adeyemo*, *C.N. Rotimi*, *the AADM Investigators*. National Human Genome Research Institute, Bethesda, MD.

Serum lipids are biomarkers of cardiometabolic disease risk, and understanding the genomic factors contributing to their distribution has been of considerable interest. Large meta-analyses have identified over 150 lipid loci; however, there has not yet been a GWAS of Africans. Given the genomic diversity among those of African ancestry, it is expected that a GWAS in Africans could yield novel lipid loci. While GWAS have been conducted in African Americans (AA), because of the drastically different environmental context, these studies are not proxies for studies in continental Africans. Therefore, we conducted a GWAS of 4,116 Africans enrolled in the AADM study. We used linear mixed models of the inverse normal transformations of covariate-adjusted residuals of lipid traits with adjustment for 3 principal components and the random effect of relatedness. Replication of loci associated at  $p < 10^{-6}$  was attempted in 9,542 AA from the HUF5, ARIC, CFS, MESA, and JHS studies. We also evaluated known lipid loci in Africans using both exact replication and "local" replication, which accounts for interethnic differences in linkage disequilibrium. We identified 3 novel loci: rs4908578 (*CAMTA1*) with TG (MAF 0.06,  $p = 2 \times 10^{-8}$ ) and TG/HDL ( $p = 9 \times 10^{-9}$ ), rs1003611624 (intergenic) with TG/HDL (MAF 0.04,  $p = 1 \times 10^{-8}$ ), and rs142840854 (*TRDN*) with LDL (MAF 0.07,  $p = 3 \times 10^{-9}$ ). None of these replicated in AA despite similar allele frequencies, however, meta-analysis of Africans and AA identified novel locus rs1199578 (intergenic) associated with TG (MAF 0.42,  $p = 4 \times 10^{-8}$ ). Only 14% of previously identified SNP-Trait associations replicated in our data. With additional replications using the local method, the replication rate was 17% (19% for SNPs with  $MAF \geq 0.05$  in our data). In this first GWAS of Africans, we identify 3 novel loci, and discover an additional novel locus upon meta-analysis with AA. Identified variants alter regulatory motifs (rs142840854, rs1199578) and occur in enhancer histone marks (rs142840854, rs1199578) and DNase hypersensitivity sites (rs1199578), and rs1199578 is an eQTL for *SLC22A23* and *ST8SIA2*. Replication of these loci is being sought in a comparable sample of Africans, to reduce the effect of divergent environmental backgrounds observed between Africans and AA. None of these loci have been previously identified in traits or pathways known to influence serum lipids, and if these associations are replicated functional work will be needed to determine their role.

**2209T****Genetics of hypertriglyceridemia: An assortment of polygenic effects.**

J.S. Dron<sup>1,2</sup>, J. Wang<sup>1</sup>, M.A. Iacocca<sup>1,2</sup>, J.R. Menard<sup>3</sup>, H. Cao<sup>1</sup>, A.D. McIntyre<sup>1</sup>, I.G. Movsesyan<sup>4</sup>, M.J. Malloy<sup>4</sup>, C.R. Pullinger<sup>4</sup>, J.P. Kane<sup>4</sup>, R.A. Hegele<sup>1,2,5</sup>. 1) Robarts Research Institute, Schulich School of Medicine and Dentistry, Western University, London ON, Canada; 2) Department of Biochemistry, Schulich School of Medicine and Dentistry, Western University, London ON, Canada; 3) Department of Physics and Astronomy, University of Waterloo, Waterloo ON, Canada; 4) Cardiovascular Research Institute, University of California San Francisco, San Francisco CA, United States; 5) Department of Medicine, Schulich School of Medicine and Dentistry, Western University, London ON, Canada.

Hypertriglyceridemia (HTG) is a complex trait influenced by genetic and non-genetic factors. Genetic determinants include both rare and common single nucleotide variants (SNVs) in triglyceride (TG)-associated genes. However, the individual genetic influences on HTG have so far been examined only in a piecemeal manner. Furthermore, copy-number variants (CNVs) in HTG patients have not been systematically evaluated. Here, we concurrently assessed rare SNVs and CNVs, and the accumulation of common SNPs in a discovery and replication cohort of 377 and 312 Caucasian patients with severe HTG (TG $\geq$ 10 mmol/L), respectively. As a contrast, we studied 503 healthy Caucasians from the 1000 Genomes Project. Patient DNA was subjected to targeted next-generation sequencing (the LipidSeq panel) of >70 genes and 185 SNPs associated with dyslipidemia. We first screened for rare SNVs and CNVs in TG-associated genes. For rare variants with likely large phenotypic effects, 2.7% and 1.3% of subjects had bi-allelic SNVs, 16.7% and 15.0% had heterozygous SNVs, and 0.8% and 0.7% had heterozygous CNVs in the HTG discovery and replication cohorts, respectively. In the normolipidemic controls, 4.0% of subjects had heterozygous SNVs. We then assessed patients for an accumulation of common SNPs using a polygenic risk score. We identified an extreme score (defined as >90th percentile of the general population) in 29.4% and 29.3% of discovery and replication patients, respectively, compared to 10.1% of normolipidemic controls. Taken together, 49.6% and 45.3% of the HTG discovery and replication patients had either a rare variant or high polygenic burden, compared to only 14.1% of controls. Since there was no significant difference in proportions of genetic factors between patient cohorts, we combined them into a single affected HTG cohort to derive global risk ratios. Compared to normolipidemic controls, HTG patients are 5.25-fold (CI 95% 3.22-8.55; P<0.0001) more likely to carry a rare variant, 5.11-fold (CI 95% 3.62-7.20; P<0.0001) more likely to have a polygenic burden, and 5.78-fold (CI 95% 4.30-7.77; P<0.0001) more likely to carry any TG-related genetic factor. We thus report the most in-depth, systematic evaluation of genetic contributors of severe HTG to date. Next steps include: 1) identification of novel genetic determinants in patients negative for genetic determinants studied here; and 2) evaluations of genotype differences in clinical outcomes and intervention response.

**2210F****Low density lipoprotein cholesterol and sepsis: A clinical and genetic approach.**

Q. Feng<sup>1</sup>, W.Q. Wei<sup>2</sup>, S. Chaugai<sup>1</sup>, G. Carranza-Leon<sup>3</sup>, J.D. Mosley<sup>1,2</sup>, L. Jiang<sup>1</sup>, A. Ihegword<sup>1</sup>, C. Shaffer<sup>1</sup>, C. Chung<sup>1,4</sup>, C.M. Stein<sup>1,5</sup>. 1) Division of Clinical Pharmacology, Department of Medicine, Vanderbilt University Medical Center, Nashville, TN; 2) Department of Biomedical Informatics, Vanderbilt University Medical Center, Nashville, TN; 3) Division of Diabetes, Endocrinology and Metabolism, Department of Medicine, Vanderbilt University Medical Center, Nashville, TN; 4) Division of Rheumatology & Immunology, Department of Medicine, Vanderbilt University Medical Center, Nashville, TN; 5) Department of Pharmacology, Vanderbilt University, Nashville, TN.

**Background:** Sepsis is a major global health concern. Lipoproteins, including low-density lipoprotein cholesterol (LDL-C), bind bacterial toxins and facilitate their clearance. In animal models, high LDL-C levels were protective against sepsis, and in patients with sepsis, low LDL-C levels were a marker for poor prognosis. An study of community-dwelling adults showed that low LDL-C levels were associated with increased risk of sepsis, but residual confounding remained a concern. We used a clinical and genetic approach to test the hypothesis that low LDL-C levels are directly associated with increased risk of sepsis and poorer outcomes. **Methods:** Using de-identified electronic health records (EHR) we defined a cohort of patients admitted to Vanderbilt University Medical Center with infection. Patients were older than 18 yrs, had an ICD code indicating infection, and received an antibiotic within 2 days of hospital admission. We used 3 approaches: 1) clinically measured LDL-C levels (excluding measurements <1 year before hospital admission and those associated with acute illness) (N=3961), 2) a genetic risk score (GRS) for LDL-C derived from 81 SNPs reported by the Global Lipid Genetics Consortium (GLGC) (N=7804), 3) a Bayesian sparse linear mixed modeling (BSLMM) GRS for LDL-C (N= 4397) derived from ARIC. For each approach we tested the association with 3 outcomes: (1) development of sepsis (defined using a validated algorithm), (2) admission to the intensive care unit (ICU) and (3) in-hospital death. Analyses were adjusted for age, sex, Charlson/Deyo comorbidity index, HDL-C, triglycerides, EHR length, and BMI. **Results:** In unadjusted analyses, low measured LDL-C levels were strongly associated with increased risk of sepsis (P=0.001) and ICU admission (P=0.008), and weakly with in-hospital mortality (P=0.055). None of these associations was statistically significant after adjusting for covariates (all P values > 0.05). Both the GLGC-based LDL GRS and the BSLMM-based LDL GRS significantly predicted LDL-C levels (all P<2 $\times$ 10<sup>-16</sup>), but neither GRS was significantly associated with any of the outcomes. **Conclusion:** Low measured LDL-C levels were significantly associated with increased risk of sepsis in patients admitted to hospital with infection but this was due to confounding by co-morbidities since adjusted clinical models and genetic models showed no increased risk. LDL-C levels do not directly alter the risk of sepsis or poor outcomes.

**2211W**

**Genetic risk determination of hypercholesterolemia at the individual patient level.** C.F. Ma, M.M Roth, L. Shen. Genben Lifesciences, San Diego, CA.

**Background:** Severe hypercholesterolemia (SHC; >190mg/dL) is a major risk factor for atherothrombotic diseases (ASCVD). The genetic architecture is complex and heterogeneous with monogenic and polygenic causes. Studies show the clinical utility and cost-effectiveness of genetic analysis in assessing SHC risk. We have developed and are testing a comprehensive NGS panel for genetic risk assessment of ASCVD. Our panel analyzes coding and selected non-coding regions identified in GWAS to comprehensively quantify risk. We have developed a 0-100 risk score within major classes of dyslipidemia/vascular disease that weights and adds/subtracts based on the known or predicted effect of a variant and grouped by patient's ancestry. **Methods:** 48 patients with primary cause of SHC (ICD-10 codes: E78.01 or E78.5) from 3 academic-based lipid clinics were analyzed with our GBinsight NGS panel on an Illumina instrument. Laboratory work is performed at CLIA-certified Otagenetics Inc. Salivary DNA was acquired from patients after providing signed consent. **Results:** We identified 5 patients with heterozygous pathogenic/likely pathogenic familial hypercholesterolemia variants: p.Arg3527Gln in APOB and p.Gly219del, p.Cys681Ter, p.Pro685Leu and p.Met652Glyfs within LDLR. We identified 4 patients with heterozygous pathogenic/likely pathogenic variants in LPL that cause combined hyperlipidemia. Separately, 3 family members carried heterozygous ApoE4-Freiburg subtype. We identified several very rare variants (MAF<0.1%) of uncertain significance (VUS) including: p.Asn76Lys and p.Leu127Phe in ANGPTL3, p.Ser934Cysfs and p.Arg989His in ABCA7, p.Ala161Ser and p.Glu185Lys in APOA4, p.Val442Gly in LPL and p.Met2Thr in STAP1. Common variants enriched in our cohort include: p.Ser19Trp APOA5, p.Leu446Pro in GCKR, p.Ile1891Met in LPA, p.Asp19His in ABCG8, p.Asp-2702Gly in SVEP1, APOE4 and an intergenic variant near the ASGR1 gene (rs314253). The median polygenic risk score for hypercholesterolemia in our cohort is 74 (25.7 SD) with a range of 4-100. Median risk score for combined hyperlipidemia is 66.5 (34.7 SD) with a range of 0-100. **Conclusion:** At the individual patient level, a complex mix of monogenic and polygenic variants affect SHC. Combinatorial genetic epistasis may explain the heterogeneity in clinical phenotypes observed at the individual patient SHC level. Risk stratification may help to apply more precise medical management and reduce morbidity, mortality and cost.

**2212T**

**Replication of association between triglyceride level and SLC25A40 in a multi-ancestry sample.** E.A. Rosenthal<sup>1</sup>, A.S. Gordon<sup>1</sup>, I.B. Stanaway<sup>2</sup>, D.R. Crosslin<sup>2</sup>, L. Albertson-Junkans<sup>3</sup>, E.B. Larson<sup>3</sup>, D. Carrell<sup>3</sup>, G.P. Jarvik<sup>1</sup> on behalf of the eMERGE Network. 1) Division of Medical Genetics, Department of Medicine, University of Washington, Seattle, WA; 2) Department of Biomedical Informatics and Medical Education, University of Washington, Seattle, WA, USA; 3) Kaiser Permanente Washington Health Research Institute, Seattle, WA, USA.

Elevated triglycerides (TG) is associated with, and may cause, cardiovascular disease (CVD). Hypo- and hypertriglyceridemia (HTG) have major genetic components (e.g., APOC3 and APOA5, respectively). Other genes (e.g., APOE) have smaller effect on TG. Knowledge of genetic causes for high TG may lead to early intervention and targeted treatment for CVD. We previously identified linkage and association of a rare, highly conserved missense SNV in SLC25A40 with HTG in a large family, as well as an association with rare missense SNVs at highly conserved sites in SLC25A40 in a European American (EA) and African American (AA) sample (PMID: 24268658). SLC25A40 encodes a mitochondrial transmembrane protein. In drosophila, SLC25A40 loss-of-function and missense SNVs were shown to contribute to mitochondrial damage due to excessive oxidation. Here, we replicate the association in a multi-ancestry population (Kaiser Permanente Washington) from the Electronic Medical Records and Genomics (eMERGE) Network phase 3, freeze 1 study. As TG vary widely within individuals, we calculated the median TG (TGmed) over all medical records prior to onset of lipid medication (LRx) (N=4909, TGmed range: 30-1840 mg/dL; median age range: 24-90). For individuals with records only post-LRx (N=397), we imputed pre-LRx TGmed based on post-LRx TG, sex, fibrate use, and onset age of LRx (TGmed range: 61-2532 mg/dL, age range: 41-81). Of these, 963 participants (755 EA, 35 AA, 123 Asian American (AS), 50 mixed ancestry; 54% male) were sequenced on a custom platform, consisting of study-wide nominated genes and SNVs, and the original 56 ACMG medically actionable genes. Five EA individuals were removed due to having a known TG lowering SNV in APOC3 (N=4; TGmed range: 35-78 mg/dL) or a TG elevating SNV in APOA5 (N=1; TGmed=178 mg/dL). Our trait of interest (TGres) was the residuals from the log-transformed TGmed regressed on median age, sex, APOE, and the 1<sup>st</sup> 10 components of ancestry. At SLC25A40, we observed 4 rare (maxpopMAF < 0.001) missense SNVs and 1 rare frameshift. Heterozygotes at the missense SNVs (3 EA, 1 AS) had lower mean TGres than the rest of the sample ( $\beta$ =-0.61, p=0.02). The individual with the frameshift was in the upper 2<sup>nd</sup> percentile of TGmed and of mixed EA/AS ancestry. We replicate an association between rare missense SNVs in SLC25A40 and TG in a multi-ancestry sample and show that the direction of effect may be variable, warranting further study of how SLC25A40 affects TG.

**Best practices for polygenic risk score modeling of laboratory values from biobank data: Application to blood lipid levels.** J. Dennis<sup>1,2</sup>, G. Chen<sup>3</sup>, P. Straub<sup>1,2</sup>, D. Hucks<sup>1,2</sup>, J.D. Mosley<sup>4</sup>, R. Tao<sup>2,5</sup>, W.L. Song<sup>6</sup>, M.F. Linton<sup>6</sup>, D. Ruderfer<sup>1,2</sup>, N.J. Cox<sup>1,2</sup>, L.K. Davis<sup>1,2</sup>. 1) Division of Genetic Medicine, Department of Medicine, Vanderbilt University Medical Center, Nashville, TN; 2) Vanderbilt Genetics Institute, Vanderbilt University Medical Center, Nashville, TN; 3) Department of Biostatistics and Medical Informatics, University of Wisconsin-Madison, Madison, WI; 4) Department of Medicine, Vanderbilt University Medical Center, Nashville, TN; 5) Department of Biostatistics, Vanderbilt University Medical Center, Nashville, TN; 6) Division of Cardiology, Department of Medicine, Vanderbilt University Medical Center, Nashville, TN.

**Background:** Polygenic risk score (PRS) modeling of laboratory values from electronic health records could provide insights into trait architecture, improve trait prediction, and identify novel biomarkers. Optimal strategies for analyzing these data, however, are unclear. Our objectives were to determine how best-fit p-value thresholds (pT) for SNP inclusion in a PRS, as well as the proportion of variability explained ( $R^2$ ) by PRS varied across: (i) a two-stage strategy for PRS validation and testing; (ii) strategies for control of medication and disease; and (iii) models of repeated measures, with and without accounting for trajectories over time. **Methods:** We developed our approach in 25,461 patients (9,259 validation, 16,202 testing) in the Vanderbilt University Medical Center biobank (BioVU) with at least one lipid measurement. Median values were calculated. Discovery GWAS results for PRS weighting and thresholding were obtained from the Global Lipids Genetics Consortium. We constructed PRS for high- and low- density lipoprotein cholesterol (HDL and LDL) and for triglycerides (TG) at discovery GWAS p-value thresholds from  $5 \times 10^{-4}$  to 0.5 in intervals of  $5 \times 10^{-4}$ , and tested these PRS for association with the same trait in BioVU. We defined pT as the threshold that maximized the  $R^2$  of the PRS in the validation set. **Results:** (i) The PRS at pT explained 0.059, 0.019, and 0.043 of testing set variance in HDL, LDL, and TG, and the pT of HDL and LDL were remarkably close to the pT fit independently in the testing set. (ii) Restricting to observations before lipid-lowering medication use (~30% of all observations) lowered the pT, in accordance with the selection of patients in the discovery GWAS, and improved the  $R^2$  for HDL, LDL, and TG by 7.4, 76.8, and 4.3%. Excluding patients with coronary artery disease or type 2 diabetes had marginal consequences. (iii) Preliminary analyses of repeated measures confirmed that only pre-medication LDL levels were strongly associated with a PRS of genome-wide significant SNPs. **Conclusions:** PRS are associated with lipid levels measured in a biobank. However, no tools exist to calculate pT using repeated measures. Therefore, we will next adapt the pT framework to longitudinal data and test whether PRS calculated at different p-value thresholds explain trajectories over time. As biobank data continue to accrue, methods that leverage repeated measures could shed light on the role of genetics in disease progression.

## 2214W

**Identifying genetic determinants of osteoporosis and obesity in postmenopausal women.** S. Zhou<sup>1,2</sup>, L. Laurent<sup>6</sup>, V. Forgetta<sup>2</sup>, J.A. Morris<sup>2,3</sup>, J. Vijay<sup>4</sup>, A. Pramatarova<sup>4</sup>, E. Grundberg<sup>4,5</sup>, J.B. Richards<sup>1,2,3,6</sup>. 1) Department of Epidemiology, Biostatistics and Occupational Health, McGill University, Montreal, Quebec, Canada; 2) Lady Davis Institute, Jewish General Hospital, McGill University, Montreal, Quebec, Canada; 3) Department of Human Genetics, McGill University, Montreal, Quebec, Canada; 4) McGill University and Genome Quebec Innovation Centre, Montreal, Quebec, Canada; 5) Children's Mercy Hospitals and Clinics, Kansas City, Missouri, USA; 6) Department of Twin Research and Genetic Epidemiology, King's College London, London, UK.

**Background:** Osteoporosis is an age-related disease that leads to increased fracture risk, with an increase in waist to hip ratio (WHR) - a clinically relevant obesity marker - are two common public health issues of women after menopause. WHR and bone mineral density (BMD), the major risk factor for osteoporosis have high genetic heritability, yet no shared pathophysiological mechanisms have been identified. A recent finding identified that inhibiting follicle-stimulating hormone (FSH) leads to reduced body fat and bone loss in ovariectomized mice, however, its relevance in humans has not been tested. If this were true, pharmacological manipulation of such biomarkers may be possible. **Methods:** We performed genome-wide association studies (GWAS) of BMD and WHR in the UK Biobank, which include 434,985 individuals and deeply imputed to ~18.6 million genetic variants after QC, stratified by sex and menopausal status of women. The sex and menopausal status heterogeneity were also tested in a large meta-analysis comprised of GIANT and UK Biobank (N=694,649) to determine the genetic etiology differences of BMD and WHR between sex and age. Two-sample Mendelian Randomization (MR) was performed using 1,538 postmenopausal women from TwinsUK and 9,900 individuals from Canadian Longitudinal Study on Aging to identify the genetic instruments for FSH level and its association with BMD and WHR. To further understand the function of FSH, the expression of FSH genes in different stages of mesenchymal stem cell differentiation were measured and the effect of FSH on adipocytes differentiation will also be assessed. **Results:** We found that there was a strong evidence for variants at the *LHCGR-FSHR* locus to be associated with WHR in postmenopausal women (N=193,400,  $p=1 \times 10^{-16}$ ), and this association was attenuated in pre-menopausal women (N=30,493,  $p=1 \times 10^{-4}$ ) and men (N=211,092,  $p=5 \times 10^{-3}$ ). The MR results also showed that a decrease in FSH level was associated with increased BMD in postmenopausal women ( $p=2.99 \times 10^{-6}$ ). In adipocyte culture, *FSHR* expression was absent in un-differentiated and matured adipocytes but reached peak level of expression at one week after adipocyte differentiation. **Conclusion:** These results show that the FSH signaling pathway has an effect on WHR and BMD, which is pronounced in postmenopausal women. We provided further evidence of a role for FSH in osteoporosis and obesity, which could present a tractable drug target to treat these common and costly diseases.

**2215T**

**Genetic polymorphism of LDLR (rs688) and correlation of inflammatory marker with genetic damage in patients with hypercholesterolemia.** *M. Monu, G. Gandhi.* Department of Human Genetics, Guru Nanak Dev University, Amritsar, Punjab, India.

The low density lipoprotein receptor is a cell surface receptor that plays an important role in cholesterol homeostasis by binding and uptaking the plasma LDL particles. LDLR gene variations can lead to unbinding of receptor with LDL particles, thus resulting in high levels of circulating LDL-C which may induce an inflammatory response and its atherogenic effects can cause DNA damage. Alongwith genetic damage, this inflammatory response can induce production of C-reactive protein (CRP) by hepatocytes. Methodology: In this study, the venous blood samples of patients (n=100, 20-40y) from local hospitals and age-, sex- and socioeconomic status- matched healthy controls from general population (n=100, 20-40y) were withdrawn after informed consent and approval by the Institutional Ethical Committee(IEC). Genomic DNA was isolated from venous blood samples and *LDLR*-rs688C > T gene polymorphism was detected using RFLP-PCR. DNA damage using the alkaline Single Cell Gel Electrophoresis(SCGE) assay was investigated in peripheral blood leukocytes of the subjects for damage index, damage frequency and per cent DNA in tail. using comet assay/. Isolated serum was used for assessment of CRP levels. Results: Statistical analyses revealed that CRP levels were significantly higher ( $p=0.000$ ) in patients ( $17.506\pm 0.706\text{mg/L}$ ) as compared to that in controls ( $2.986\pm 0.257\text{mg/L}$ ). Damage frequency ( $95.705\pm 0.461$ ,  $p=0.050$ ), damage index( $144.66\pm 1.117$ ;  $p=0.001$ ) and per cent DNA in tail( $45.836\pm 1.031$ ,  $p=0.000$ ) were also significantly increased in patients. Positive association of LDL-C with damage index( $p=0.050$ ) and with CRP( $p=0.000$ ) while negative association of HDL-C with CRP( $p=0.001$ ) was observed in correlation analysis. The observed frequencies of genotypes CC,CT and TT in patient group were 30%, 65% and 5%, respectively, while all healthy control samples were homozygous wild type. The genetic damage as a function of *LDLR*(rs688) genetic polymorphism revealed no significant differences in patients and controls. Conclusion: In the absence of co-morbidities and/or exposures, the results of this study imply that the hypercholesterolemic condition acts as causal factor for increased inflammation and DNA damage. However dietary and lifestyle management can assist in reducing risk to cardiovascular and hepatocellular diseases. .

**Genome-wide association studies of ezetimibe response in IMPROVE-IT trial.** *G. Kosova<sup>1</sup>, C.T. Ruff<sup>2</sup>, Y. Zhang<sup>3</sup>, Z. Guo<sup>3</sup>, D.F. Reilly<sup>1</sup>, D.V. Mehrotra<sup>2</sup>, Y. Mitchell<sup>4</sup>, S.H. Shah<sup>5</sup>, M.A. Blazing<sup>5</sup>, E.A. Bohula<sup>2</sup>, R.P. Giugliano<sup>2</sup>, C.S. Fox<sup>1</sup>, M.S. Sabatine<sup>2</sup>, P.M. Shaw<sup>1</sup>.* 1) Genetics and Pharmacogenomics, Merck, Kenilworth, NJ; 2) TIMI Study Group, Brigham and Women's Hospital, Boston, MA; 3) Biostatistics and Research Decision Sciences, Merck, Kenilworth, NJ; 4) Clinical Research, Merck, Kenilworth, NJ; 5) Duke Clinical Research Center, Durham, NC.

IMProved Reduction of Outcomes: Vytorin Efficacy International Trial (IMPROVE-IT) demonstrated a significant benefit of Vytorin (ezetimibe [EZ]+simvastatin [simva]) vs. simva alone in lowering LDLc levels and reducing the risk of cardiovascular events. However, inter-individual variability in drug response, as measured by reduction in LDLc levels, has been observed with statin therapy. Previous studies of statin monotherapy have demonstrated common pharmacogenetic variants contribute to variation in drug response. Therefore, we performed a GWAS in ~6,500 participants of the IMPROVE-IT trial to test the hypothesis that genetic variation is associated with EZ efficacy. In total, five independent loci were associated with fold-change in LDLc levels after one month of lipid lowering therapy both in the simva monotherapy arm and in the simva+EZ combination arm at  $P<5\times 10^{-8}$ . Four of these loci (*APOE*, *LPA*, *CELSR2/SORT1* and *SLCO1B1*) have previously been implicated in statin response. However, our study showed a trend for larger effect sizes of these genetic variants in the EZ+simva arm, compared with simva monotherapy. For example, patients receiving simva+EZ showed on average 15.9% additional reduction in LDLc per number of *APOE*- $\epsilon 2$  allele (e.g., if a patient carrying no copies of  $\epsilon 2$  and has a LDLc of 100mg/dL at baseline had a reduction to ~55mg/dL at 1 month of treatment, then a patient carrying 1 copy of  $\epsilon 2$  would have a reduction to ~46mg/dL;  $P=1.2\times 10^{-28}$ ), compared to 8.6% additional reduction per allele in patients treated with simva alone (e.g. from 100mg/dL to 70mg/dL if carrying no  $\epsilon 2$ , and to 64 mg/dL if carrying 1 copy;  $P=9.0\times 10^{-9}$ ,  $P_{\text{tag}}=2.7\times 10^{-4}$ ). When tested as a composite score combining LDLc lowering alleles at these four loci, there was 9.2% additional reduction in LDLc per LDLc reducing allele in the simva+EZ arm ( $P=1.5\times 10^{-37}$ ), compared to 5.2% in the simva alone ( $P=1.2\times 10^{-12}$ ;  $P_{\text{tag}}=2.5\times 10^{-3}$ ). We also identified one novel association with an intronic variant in *NCK1* (MAF=0.02) only in patients receiving simva+EZ, however this association requires a further validation. In conclusion, we replicated the four previously reported "statin-response" associations with in patients receiving simva monotherapy, and simva+EZ combination therapy. The larger effect sizes that we observed in the combination arm suggest that these variants are not statin-specific, and may have distinct roles in influencing the magnitude of LDLc reduction in response to ezetimibe.

**Background:** Genetic investigation of the plasma lipidome, composed of a large number of structurally and functionally diverse lipids species, may elucidate lipid metabolism and its link to diseases beyond traditional lipid measures. **Methods:** We carried out a genome-wide association study of 141 lipid species in 2,045 Finnish individuals with ~9.3 million genetic variants, followed by phenotype-wide scans (PheWAS) with 58 clinical end-points related to cardiovascular, metabolic, psychiatric and gastro-intestinal disorders in >383,000 individuals from the Finnish and UK Biobanks. **Results:** We found that: 1. Lipid species are quite heritable ( $h^2_{SNP}$  ranged 10-54%). Lipids with  $\omega$ -3 and  $\omega$ -6 fatty acids showed highest heritability and shared genetic component, suggesting considerable genetic regulation at acyl chains. 2. 35 genomic loci, including 24 novel, were associated with at least one lipid species ( $P < 5 \times 10^{-8}$ ). 3. Lipidomic profiles could help to identify new disease risk-modifying variants. The PheWAS showed associations for eight of 35 identified loci (*APOA1*, *ABCG5/G8*, *BLK*, *LPL*, *LIPC*, *FADS2*, *MIR100HG*, *DHRS12*) with various diseases (false discovery rate <0.05), including novel disease associations (Table 1). 4. Lipidomic profiles provide clues to new biology, both in new and known lipid loci. The association patterns of novel variants at *SYNGR1*, *MIR100HG*, *PTPRN2*, *VWA3B* and *ABLIM2* suggested their possible involvement in desaturation and/or elongation of fatty acids. At many known lipid loci including *ABCG5/G8*, *MBOAT7*, *FADS2* and *LPL*, our genetic associations provided better understanding of their roles in lipid biology and complex diseases. 5. Traditional lipids used in routine clinical work fail to capture association with lipid species such as LPCs and CEs that are potential disease risk factors.

**Conclusions:** Our study reveals genetic regulation of detailed plasma lipids and highlights the importance of lipidomic profiling in disease gene mapping.

Table 1: Selected novel variants associated with plasma lipid species and diseases (\*reported previously)

## Family-based heritability of statin low-density lipoprotein cholesterol

**response.** A. Oni-Orisan<sup>1,2</sup>, T.J. Hoffmann<sup>2,3</sup>, D. Ranatunga<sup>4</sup>, M.W. Medina<sup>5</sup>, E. Jorgenson<sup>4</sup>, C. Schaefer<sup>4</sup>, R.M. Krauss<sup>5,6</sup>, C. Iribarren<sup>3,4</sup>, N. Risch<sup>2,3,4</sup>. 1) Department of Clinical Pharmacy, University of California, San Francisco, CA; 2) Institute for Human Genetics, University of California, San Francisco, CA; 3) Department of Epidemiology and Biostatistics, University of California, San Francisco, CA; 4) Kaiser Permanente Northern California Division of Research, Oakland, CA; 5) Children's Hospital Oakland Research Institute, Oakland, CA; 6) Department of Medicine, University of California, San Francisco, CA.

The genetic basis of low-density lipoprotein cholesterol (LDL-C) response to statin therapy has not been fully elucidated. In particular, there are no reports describing the heritable component of variability in statin-induced changes of LDL-C. The primary objective of this study was to estimate heritability of statin LDL-C response in a large, multi-ethnic population of statin users. We calculated familial correlations in first-degree relatives from 33,139 statin users of the Kaiser Permanente Genetic Epidemiology Research on Adult Health and Aging (GERA) cohort, which also includes genome-wide genotype data. The effect of statin dosing on LDL-C was determined from electronic health records (EHRs). We first demonstrated the validity of the EHR-derived LDL-response by showing a statin dose-response relationship comparable to that seen in randomized clinical trials. We also identified age, sex, smoking, diabetes and race/ethnicity as significant covariates. Familial first-degree relationships were determined genetically using KING v1.4. First-degree relatives included parent-offspring and sibling pairs. To estimate heritability, we first applied a square-root transformation to the covariate-adjusted statin LDL-C response residuals for trait normalization and calculated an interclass correlation for the parent-child pairs and intraclass correlation for the sib pairs. Heritability was determined from the doubled correlations. Among the 33,139 statin users, we identified 229 parent-offspring pairs and 296 sib pairs. The parent-offspring correlation of statin LDL-C response was 0.060 (SE = 0.067, P = 0.365) and the sibling correlation was 0.054 (SE = 0.059, P = 0.357). The heritability estimate was 0.114 (95% confidence interval -0.06 to 0.286), which was below the threshold of statistical significance. Thus, statin-induced changes in LDL-C were found to be modestly inherited. These results provide novel information about the contribution of genetic factors to statin LDL-C response variation.

**Causal association of lipid fractions with estimated glomerular filtration rate. A multivariable Mendelian randomization analysis of the HUNT Study, Norway.** H. Rasheed<sup>1,2,3</sup>, J. Rees<sup>4</sup>, B. Brumpton<sup>1,2,5</sup>, J. Zheng<sup>6</sup>, G.D. Smith<sup>7</sup>, S. Burgess<sup>4,6</sup>, B.O. Asvold<sup>1,7</sup>. 1) K.G. Jebsen Center for Genetic Epidemiology, Department of Public Health and Nursing, Norwegian University of Science and Technology (NTNU), Trondheim, Norway; 2) MRC Integrative Epidemiology Unit, University of Bristol, UK; 3) Department of Chemistry, University of Engineering and Technology, Lahore, Pakistan; 4) Cardiovascular Epidemiology Unit, University of Cambridge, Cambridge, UK; 5) Department of Thoracic Medicine, St. Olavs Hospital, Trondheim University Hospital, Trondheim, Norway; 6) MRC Biostatistics Unit, University of Cambridge, Cambridge, UK; 7) Department of Endocrinology, St. Olavs Hospital, Trondheim University Hospital, Trondheim, Norway.

**Background:** In observational studies, higher low-density lipoprotein cholesterol (LDL-C), lower high-density lipoprotein cholesterol (HDL-C) and higher triglyceride (TG) levels have been associated with lower estimated glomerular filtration rate (eGFR). We aimed to investigate whether these associations are likely to be causal in the Nord-Trøndelag Health Study (HUNT), using multivariable Mendelian randomization (MR), being advantageous then conventional MR methods, to disentangle the effects of the separate lipid fractions. **Methods:** In a two-sample MR approach, we obtained information on associations of 185 independent lipid-associated genetic variants with serum levels of LDL-C, HDL-C and TG from the Global Lipids Genetics Consortium (n=188,577). Associations of these variants with eGFR were estimated in 69,570 participants from the HUNT. Causal associations of serum lipid levels with eGFR were estimated both using standard inverse-variance weighted (IVW) MR and multivariable MR. Evidence of pleiotropy was evaluated using MR Egger regression. All analyses were adjusted for age and sex. The estimates (b [95% CI]) represent the difference in eGFR (mL/min/1.73 m<sup>2</sup>) per 1 standard deviation higher lipid levels. **Results:** In observational analyses, higher measured LDL-C (-0.0033 [-0.0039, -0.0028], P<10<sup>-16</sup>) and TG (-0.0015 [-0.0018, -0.0013], P<10<sup>-16</sup>) were associated with lower eGFR, and higher HDL-C was associated with higher eGFR (0.0033 [0.0028, 0.0039], P<10<sup>-16</sup>). The IVW method showed no evidence of a causal association of LDL-C (0.441 [-0.100, 0.982], P=0.11) or HDL-C (-0.214 [-0.800, 0.373], P=0.47) with eGFR, but suggestive evidence that TG could influence eGFR (0.663 [-0.057, 1.383], P=0.07). However, using multivariable MR, there was no strong evidence for causal associations of either LDL-C (0.346 [-0.209, 0.901], P=0.22), HDL-C (0.015 [-0.627, 0.657], P=0.96) or TG (0.566 [-0.245, 1.377], P=0.17) with eGFR. MR Egger regression showed no evidence of pleiotropy in any of the analyses. **Conclusion:** Our findings do not support a causal effect of serum lipid concentrations on eGFR. Further research should use Mendelian randomization in larger well-phenotyped cohorts to replicate and extend our findings.

**Regional genomic heritability analysis of waist circumference in a Japanese population.** O. Gervais<sup>1</sup>, K. Misawa<sup>1</sup>, Y. Harada<sup>1</sup>, T. Mimori<sup>1</sup>, Y. Kawai<sup>2</sup>, K. Tokunaga<sup>2</sup>, M. Nagasaki<sup>1</sup>. 1) Tohoku University, Sendai, Miyagi, Japan; 2) The University of Tokyo, Tokyo, Japan.

The obesity epidemic, which was initially mostly conspicuous in high-income countries, has become a worldwide health issue; for instance, it has been reported recently that in Bangladesh, a low-income country, the prevalence of overweight/obesity has reached one-fourth of the population and is higher in younger age groups. Nevertheless, and in spite of fact that regional genetic differences are known to affect obesity, the majority of studies on the underlying genetic factors of obesity are conducted in populations of European descent. To better understand the regional genetic differences of obesity, this study primarily aims to quantify the effect of each genomic region on variation in obesity in a Japanese population of almost 10,000 individuals by using SNP array genotyping data. The trait considered in this study was waist circumference (WC), as it has been suggested in several studies that it may be a better indicator of cardiovascular disease risk than BMI. In this study, several polygenic models were applied to estimate the genetic components of the population considered at three different levels: at the genome-wide level to estimate trait SNP heritability, at the chromosomal level, as well as at the regional level to estimate regional genetic variance. The analysis of each genomic region (a region being represented by a given number of adjacent SNPs) was conducted by using the Regional Heritability Mapping approach. The models were adjusted to account for relevant environmental factors and population structure.

**Genome-wide association study identifies 4 novel loci with metabolites in East Asians.** J.F. Chai<sup>1</sup>, I.W. Khor<sup>2</sup>, F. Torta<sup>3</sup>, D.R. Herr<sup>4</sup>, C.M. Khoo<sup>5</sup>, M.R. Wenk<sup>3</sup>, E.S. Tai<sup>1,2,5</sup>, X. Sim<sup>1</sup>. 1) Saw Swee Hock School of Public Health, National University of Singapore and National University Health System, Singapore; 2) Department of Medicine, Yong Loo Lin School of Medicine, National University Health System, Singapore; 3) Singapore Lipidomics Incubator (SLING), Department of Biochemistry, Yong Loo Lin School of Medicine, National University of Singapore, Singapore; 4) Department of Pharmacology, Yong Loo Lin School of Medicine, National University of Singapore, Singapore; 5) Duke-NUS Medical School, Singapore.

Metabolites are small intermediate products of cellular metabolism, which can serve as biomarkers for understanding complex disorders and to aid in drug development. Here, we genotyped 2,434 Singapore Chinese across three Illumina arrays, and profiled 14 amino acids, 45 acylcarnitines, and 103 sphingolipids in plasma samples to understand the role of genetic variants on these metabolites. We conducted single variant association tests using an additive linear mixed model between 47 million genetic dosages and 232 metabolites (including 70 derived sphingolipid ratios). Association test statistics across arrays were combined using fixed-effects sample-size weighted meta-analysis. At a conservative genome-wide threshold of  $2.16 \times 10^{-10}$  ( $5 \times 10^{-8}/232$ ), we report associations at 17 genetic loci with 64 metabolites. Four of these loci represented novel associations with metabolites. The strongest association among these four loci was between dihexosylceramide/lactosylceramide (DHCer) d18:1/C24:1 and a missense variant at *ABCA7* that has been linked to Alzheimer's disease (rs3752246, MAF=0.37;  $P=3.21 \times 10^{-30}$ ), suggesting a potential mechanism linking glycosylceramides and Alzheimer's disease. Other novel loci included *GSTM2* (rs3587154; associated with acylcarnitine C18:1-DC, MAF=0.24;  $P=8.52 \times 10^{-13}$ ), *CHCHD2* (rs57427081; associated with serine, MAF=0.30;  $P=8.67 \times 10^{-13}$ ), and *A4GALT* (rs77076498; associated with the ratio of monohexosylceramide (MHCer) d18:1/C24:0 to DHCer d18:1/C24:0, MAF=0.43;  $P=4.63 \times 10^{-28}$ ). At the remaining 13 loci, after conditioning on previously reported metabolite associations in Europeans, we identified independent (conditional  $P < 6.49 \times 10^{-6}$ ) signals in each metabolite class. For example, the association between intron *CPT2* variant (rs77466051) and acylcarnitine C5-DC (MAF=0.22;  $P=1.73 \times 10^{-16}$ ; conditional  $P=2.19 \times 10^{-14}$ ), was independent of previously reported European GWAS variant rs13375749. We also observed selectivity for the d16 sphingosine backbone of sphingosine-1-phosphate (S1P) for *SPTLC3* and *SGPP1* variants, which were significantly associated with d16:1 S1P (*SPTLC3*: rs438568, MAF=0.44,  $P=7.84 \times 10^{-21}$ ; *SGPP1*: rs34817779, MAF=0.11,  $P=1.41 \times 10^{-16}$ ), but not d18 S1P. This is consistent with the role of *SPTLC3*, which promotes use of myristoyl-CoA in the production of d16:0 sphingoid bases. Altogether, we replicated 13 known metabolic loci and identified 4 new loci in Chinese that are candidate biomarkers for understanding metabolic and other disorders.

**Differential gene expression and large-scale lipid molecular species quantitation during human macrophage activation.** M.K. Lin<sup>1,2</sup>, A. Moreno-Moral<sup>3</sup>, S. Muralidharan<sup>2,4</sup>, M. Bagnati<sup>5</sup>, M.R. Wenk<sup>1,2</sup>, E. Petretto<sup>4</sup>, J. Behmoaras<sup>5</sup>, F. Torta<sup>1,2</sup>. 1) National University of Singapore, Yong Loo Lin School of Medicine, Department of Biochemistry, Singapore; 2) National University of Singapore, Singapore Lipidomics Incubator, Singapore; 3) DUKE-NUS Medical School, Centre for Computational Biology, Singapore; 4) National University of Singapore, Faculty of Science, Department of Biological Sciences, Singapore; 5) Imperial College London, Centre for Complement and Inflammation Research, London, United Kingdom.

Macrophage activation induced by lipopolysaccharide (LPS) mimics the immune response to bacterial infections. Genes regulating the immune, apoptotic and lipid metabolism pathways have been shown previously to be involved in macrophage activation. In particular, lipid metabolism has been appreciated to be perturbed in a number of clinical pathologies and during inflammation. In this study, we explored gene and lipid molecular species interaction during macrophage activation. Activation of human primary macrophages from 11 individuals was induced with LPS. Cells were harvested before and at 0.5, 3, 8, and 16 hours after activation. Lipids were extracted and quantified using a targeted approach by liquid chromatography-mass spectrometry. Approximately 300 lipid molecular species were measured. RNA of the macrophages across the five time-points were sequenced in four individuals. Gene expression and lipid molecular species levels were corrected for inter-individual variation and correlated. Time series clustering using Gaussian processes was employed to cluster both gene expression and lipid molecular species abundance, followed by functional enrichment annotation for each cluster. The results showed that the sphingolipids and the cholesterol esters pathways are significantly affected after LPS-induced human primary macrophage activation. The sphingolipid pathway can be altered in a number of clinical pathologies, namely cancer progression, cardiovascular and metabolic diseases. However, the clarification of the influence of gene expression on particular lipid molecular species abundance and vice versa, is still an ongoing effort. This study identifies differentially expressed genes previously known to play a role in, and also genes not typically associated with, lipid metabolism during LPS-induced macrophage activation.

**Effects of delivering *SLCO1B1* genotype-informed statin therapy on cholesterol levels: Analysis of commercial laboratory data.** D. Voora<sup>1,2</sup>, E. Perry<sup>3</sup>, M. Mehan<sup>4</sup>, R. Gill<sup>4</sup>, Y.-J. Li<sup>3</sup>. 1) Department of Medicine, Duke University, Durham, NC; 2) Center for Applied Genomics & Precision Medicine, Duke University, Durham, NC; 3) Department of Biostatistics and Bioinformatics, Duke University, Durham, NC; 4) Boston Heart Diagnostics, Boston, MA.

**Background:** HMG-CoA reductase inhibitors (“statins”) lower cholesterol and prevent cardiovascular disease (CVD). A common, reduced function variant (rs4149056, \*5) in *SLCO1B1* that encodes a hepatic statin transporter is a known risk factor for statin side effects, premature statin discontinuation, and higher cholesterol levels and CVD risk. The \*5 variant increases the risk of side effects for simvastatin and possibly atorvastatin but not for rosuvastatin, pravastatin, or fluvastatin – forming the basis of *SLCO1B1* genotype-informed statin therapy (GIST). Commercial laboratory *SLCO1B1* testing and GIST is currently in use. However, outcomes of GIST in a general population are unknown. **Methods:** Based on prior randomized clinical trial findings, we hypothesized that GIST was associated with cholesterol levels. We accessed *SLCO1B1* genetic and longitudinal cholesterol testing data from a single commercial laboratory vendor. We included all patients with >1 cholesterol measurement and excluded patients who received *SLCO1B1* testing after their first cholesterol test. Baseline clinical data including age, sex, lipid-lowering therapy, CVD, and diabetes were used to build a 1:1 propensity score matched dataset for *SLCO1B1* testing. A mixed effects regression model adjusting for sex was used to estimate the effect of *SLCO1B1* testing on cholesterol levels over time. **Results:** Among 143757 patients that met our criteria, 92271 received *SLCO1B1* genetic testing that had, on average, 2.9±1.5 cholesterol measurements over a period of 14.6±10.1 months. Tested patients had more CVD and pre-diabetes and were younger, more likely female, and not using lipid-lowering therapy (p<0.01). After matching, 1907 patients who received *SLCO1B1* testing were similar to those who did not with the exception of sex. Compared to matched, untested controls, patients who received *SLCO1B1* testing had a larger decrease in low-density lipoprotein (-1.8 ± 0.8 mg/dl/year, p = 0.035), non-high density lipoprotein (-2.7 ± 1 mg/dl/year, p = <0.001), and total cholesterol (- 2.7 ± 1.0 mg/dl/year, p = 0.006). In patients receiving GIST, there were no differences in cholesterol levels across *SLCO1B1*\*5 genotypes. **Conclusions:** In a general population, delivery of *SLCO1B1* genotype-informed statin therapy was associated with modest cholesterol reductions that were smaller than reported in prior randomized trials.

Franklin<sup>1</sup>, R.C. Landis<sup>1</sup>, H. Watson<sup>5</sup>, I. Ruczinski<sup>6</sup>, T.H. Beaty<sup>6</sup>, R.A. Mathias<sup>1</sup>, K. Barnes<sup>1</sup>. 1) Department of Medicine, University of Colorado, Aurora, CO, USA; 2) Department of Biostatistics, Bloomberg School of Public Health, JHU, Baltimore, MD, USA; 3) University of West Indies at Cavehill, Barbados, WI; 4) Edmund Cohen Laboratory for Vascular Research, The George Alleyne Chronic Disease Research Centre, The University of the West Indies at Cave Hill, Barbados W.I; 5) Faculty of Medical Sciences, The University of the West Indies, Queen Elizabeth Hospital, Bridgetown, St. Michael, Barbados; 6) Department of Epidemiology, Bloomberg School of Public Health, JHU, Baltimore, MD, USA.

**RATIONALE:** Asthma is a complex disease partly attributable to genetic factors and environmental triggers. CD4+ T helper cells are known to play a role in the pathogenesis of asthma and are therefore good target tissues for elucidating disease mechanisms. One of the main goals of the Barbados asthma genetic study (BAGS) expression quantitative trait loci (eQTL) analysis is to identify cis and trans-effects of variants identified in the transcriptome of CD4+ T cells from atopic asthmatics. **METHODS:** Paired-end RNA-Seq on RNA from CD4+ T-cells isolated from 84 samples was performed on the Illumina HiSeq4000, using the TruSeq Total RNA Ribozero kit for library preparation. Ten samples were removed from further analysis due to high percentages of ribosomal bases (>20%). Low quality RNA-Seq read removal and adapter trimming were performed using BBDOUK. Trimmed reads for all samples were mapped and assembled using the HISAT2 graph aligner and STRINGTIE using the UCSC hg38 reference. Assembled transcripts from all samples were merged using STRINGTIE to create a uniform set of transcripts. Gene/transcript expression tables were created with the Ballgown R package, and genes with median FPKM (fragments per kilobase of transcript per million mapped reads) <=1 across all samples were filtered out. eQTL analysis was then performed on 43 asthmatic cases with Illumina OMNI2.5 GWAS data using a linear model implemented in the MatrixEQTL R package to detect cis and trans eQTLs. FPKM values were log<sub>10</sub> transformed, batch and the first 6 principal components derived from GWAS data were included as covariates. **RESULTS:** There are 10,940 genes with median FPKM>1 in the 43 samples analyzed. eQTL analysis in total identified 275 genes (405 variants) with cis-eQTLs and 137 genes (307 variants) with trans-eQTLs. There were 5 significant trans-eQTLs with false discovery rate (FDR) adjusted p<1x10<sup>-5</sup>. SNPs rs9272219 and rs9273012 appeared as trans-eQTLs for HLA-DQA1 gene, a locus previously associated with asthma, and were the most significant with p=4.9x10<sup>-17</sup>(FDR p=1.8x10<sup>-7</sup>), while SNPs rs2708377, rs2597974 and rs1669424 were identified as trans-eQTLs for the SIMM1OL1 gene with p=3.4x10<sup>-15</sup>(FDR p=5.0x10<sup>-6</sup>). **CONCLUSIONS:** We identified multiple trans-eQTLs that may play a role in asthma pathogenesis. Future work includes incorporating additional subjects into these analyses and identifying eQTLs with effects that differ between atopic asthmatics and non-atopic non-asthmatics.

**2225F**

**Gene co-expression networks are associated with asthma and reveal diverse molecular signatures and disease processes.** *K.M. Magnaye<sup>1</sup>, M.M. Soliai<sup>1</sup>, D.K. Hogarth<sup>2</sup>, E.T. Naureckas<sup>2</sup>, S.R. White<sup>2</sup>, D.L. Nicolae<sup>1,2,3</sup>, C. Ober<sup>1</sup>.* 1) Human Genetics, University of Chicago, Chicago, IL; 2) Medicine, University of Chicago, Chicago, IL; 3) Statistics, University of Chicago, Chicago, IL.

Asthma is a common chronic inflammatory disease of the airways, affecting over 235 million people worldwide. The etiology of asthma is complex, and its diagnosis likely reflects the effects of different molecular pathways. To further dissect the molecular heterogeneity of asthma, we characterized the transcriptome in primary bronchial epithelial cells (BECs) by RNA sequencing from 82 asthmatics and 42 non-asthmatic adults. Technical sources of variation were identified and adjusted using principal components analysis and limma, respectively. Using 16,003 autosomal genes, weighted gene co-expression network analysis (WGCNA) assigned 14,974 genes into 38 co-expression modules (module size ranged from 20-2,924 genes). We tested for associations between the eigengenes in each module and asthma using a linear model, correcting for age, sex, current smoking status, and 3 ancestry PCs. Five of the 38 modules were significantly associated with asthma after adjusting for multiple testing ( $p < 1.32 \times 10^{-3}$ ). The eigengenes for each asthma-associated module were then correlated with clinical phenotypes among the asthmatic cases, and Ingenuity Pathway Analysis (IPA, Qiagen) was used for enrichment studies of genes within each module. One module was positively correlated with both the "Type 2" asthma gene signature ( $p = 5.90 \times 10^{-25}$ ) and fractional exhaled NO ( $p = 7.92 \times 10^{-06}$ ). IL-13 was a significant upstream regulator of genes in this module (by IPA) further suggesting that this module represents the Type 2 asthma endotype. A second module that was negatively associated with asthma was negatively correlated with blood eosinophil count ( $p = 1.83 \times 10^{-04}$ ) and enriched for genes in estrogen-signaling pathways. Two other asthma-associated modules were enriched for genes involved in iCOS-iCOSL signaling and IL-17 signaling but were not associated with any of the measured phenotypes. Overall, these results revealed 5 bronchial epithelial cell molecular signatures that correlated with distinct phenotypes and/or diverse immune and endocrine profiles, potentially reflecting underlying asthma endotypes and discrete mechanistic pathways. Supported by U19 AI095230; KMM and MMS were supported in part by T32GM007197..

**Shared and distinct genetic risk factors for childhood onset and adult onset asthma.** *M. Pividori<sup>1</sup>, N. Schoettler<sup>1,2</sup>, D. Nicolae<sup>1,2,3</sup>, C. Ober<sup>1</sup>, H. Im<sup>1,2</sup>.* 1) Department of Medicine, The University of Chicago, Chicago, IL; 2) Department of Human Genetics, The University of Chicago, Chicago, IL; 3) Department of Statistics, The University of Chicago, Chicago, IL.

**Asthma is the most prevalent chronic respiratory disease worldwide. Childhood onset asthma and adult onset asthma are distinct diseases with respect to sex ratios, triggers of exacerbation, associated co-morbidities, and severity, and potentially also for genetic risk factors. However, it remains unknown as to whether asthma risk loci are associated with age of onset or contribute specifically to childhood onset or adult onset asthma. Our goal was to provide insights into the molecular mechanisms contributing to the different clinical manifestations of asthma that is diagnosed at different ages. Toward that goal, we first determined shared and distinct genetic risk loci for childhood and adult onset asthma to assess the effects of associated loci on the age of onset of asthma. Then we identified candidate genes that may be mediating the effects of associations at shared and age of onset specific asthma loci. Leveraging the data available in the U.K. Biobank, this study is the first GWAS of age of onset in asthma that includes both childhood (9,433 cases, onset prior to 12 years of age) and adult onset asthma (23,395 cases, onset after 25 years), which were compared against participants without an asthma diagnosis (323,376 controls). Individuals with COPD were excluded, and all disease status, age of onset asthma and gender were extracted from self reported questionnaires and hospital records. Stratifying by age of onset revealed 63 independent asthma loci: 17 specific to childhood onset, 3 specific to adult onset, 5 shared but with significantly larger effect sizes in the childhood onset GWAS, and 38 additional shared loci. Among the 63 loci were 32 not reported in previous GWAS. Using a gene-based test, PrediXcan, we identified 120 unique genes associated with asthma, including 33 at 6 childhood onset asthma loci, one gene at an adult onset locus, 76 genes at 19 shared loci, and 10 genes outside the loci identified in the GWASs. Our findings of more childhood onset asthma loci and larger effect sizes of risk alleles in the childhood onset cases are particularly striking given that there were nearly 2.5-times more adult onset than childhood onset cases in this study. Overall, our study indicates that genetic risk for adult onset asthma is largely a subset of risk loci for childhood onset asthma, but with overall smaller effect sizes..**

**2227T**

**QTLs detected in an airway smooth muscle cell model of gene-environment interactions identify functional candidates from bronchial responsiveness and contractile response GWAS.** *E.E. Thompson<sup>1</sup>, Q. Dang<sup>2</sup>, B. Mitchell-Handley<sup>1</sup>, K. Rajendran<sup>2</sup>, S. Ram-Mohan<sup>2</sup>, J. Solway<sup>3</sup>, R. Krishnan<sup>2</sup>, C. Ober<sup>1</sup>.* 1) Human Genetics, The University of Chicago, Chicago, IL; 2) Center for Vascular Biology Research, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA; 3) Department of Medicine, The University of Chicago, Chicago, IL.

Airway hyperresponsiveness (AHR) to inhaled stimulants is a key feature of asthma. We used cell models of AHR to discover functional single nucleotide polymorphisms (SNPs) with direct effects on transcriptional and epigenetic responses to two asthma and AHR-promoting cytokines, IL-13 and/or IL-17, in cultured airway smooth muscle cells (ASMCs) from 71 individuals. We hypothesized that some of these variants will be enriched for small p-values among SNPs included in bronchial responsiveness, contractile responsiveness, and asthma GWAS. Expression and DNA methylation data were obtained using Illumina Human HT-12 v4 arrays and Infinium MethylationEPIC BeadChip, respectively. A GWAS of bronchial responsiveness index (BRI) was performed in 964 Hutterite individuals and a GWAS of contractile response was performed in ASMCs using quantitative measurements of contractile responses to methacholine. We conducted expression quantitative trait locus (eQTL) and methylation (me)QTL mapping using Matrix eQTL in cytokine-treated samples. To maximize our power to identify signals shared across exposures, we used mashr with a local false sign rate (lfsr) <0.01; enrichment testing among GWAS SNPs was performed using GARFIELD. We identified 6,390 eQTLs ( $\pm 250$ Kb of the transcription start site) and 61,207 meQTLs ( $\pm 5$ Kb of the nearest CpG) that are either unique to or shared among IL-13, IL-17, IL-13+IL-17, and vehicle-exposed ASMCs. Both eQTLs (3.91 fold enrichment (FE)) and meQTLs (7.55 FE) were over-represented among asthma GWAS SNPs with small p-values ( $P < 0.01$ ), and eQTLs (3.13 FE) and meQTLs (6.94 FE) were over-represented among BRI GWAS SNPs. Genes with eQTLs shared among exposures are enriched for upregulated expression in smooth muscle cells (Human Gene Atlas;  $P = 0.006$ ). To look for overlap between our *in vitro* cellular assay of ASM contraction and bronchial responsiveness in human subjects, we compared the results of our GWAS of contractile response in ASMCs to the results of a GWAS of BRI in Hutterites. We observed 2,476 unique SNPs across all exposures, which are enriched for positive regulation of calcium ion transport (GO:0010524;  $P = 0.0028$ ) and H3K9ac (active enhancer) marks in smooth muscle ( $P = 0.04$ ). These results indicate that IL-13 and IL-17-exposed cultured ASMCs serve as a model for elucidating the function of asthma-associated SNPs identified in GWAS, and for identifying additional candidates that did not meet stringent criteria for genome-wide significance.

**Detection of new genetic variants associated with eosinophil-derived neurotoxin and eosinophil cationic protein levels using bivariate genome-wide association study.** *R. Verne<sup>1,2</sup>, P. Margaritte-Jeannin<sup>1,2</sup>, R. Matran<sup>3</sup>, F. Zerimech<sup>4</sup>, V. Siroux<sup>5</sup>, M-H. Dizier<sup>1,2</sup>, R. Nadi<sup>6,7</sup>, F. Demenais<sup>1,2</sup>, E. Bouzigon<sup>1,2</sup>.* 1) Inserm, UMR-946, Genetic Variation and Human Diseases Unit, Paris, France; 2) Université Paris Diderot, Paris, France; 3) Université Lille and CHU de Lille, Lille, France; 4) Pôle de Biologie Pathologie Génétique, Laboratoire de Biochimie et Biologie Moléculaire, CHU de Lille, Lille, France; 5) Inserm, CNRS, University Grenoble Alpes, IAB, Grenoble, France; 6) INSERM U1168, VIMA (Aging and Chronic Diseases: Epidemiological and Public Health Approaches), Villejuif, France; 7) Université Versailles St-Quentin-en-Yvelines, UMRS 1168, Montigny-le-Bretonneux, France.

The number of genetic factors identified for asthma remains limited. The study of biological phenotypes involved in the pathophysiological mechanisms of asthma may help understanding the genetic architecture of the disease. To characterize the genetic factors influencing two correlated immunomodulatory enzymes released by eosinophils in the allergic response in asthma: ECP (eosinophil cationic protein) and EDN (eosinophil-derived neurotoxin), we conducted univariate and bivariate genome-wide association (GWA) analyses of these phenotypes in 1,018 subjects from the French Epidemiological study on the Genetics and Environment of Asthma (EGEA) using 1000-Genomes imputed SNPs. The univariate GWA analyses detected two genome-wide significant loci associated with ECP on chromosomes 14q11 (rs7141958, located 36kb downstream of *RNASE3* and 27kb upstream of *RNASE2*,  $P = 1.2 \times 10^{-10}$ ) and 18q21, near *MC4R* (rs8097644,  $P = 2.7 \times 10^{-8}$ ). We also identified one significant locus associated with EDN at 6.5kb downstream of *RNASE2* (rs67049014,  $P = 1.1 \times 10^{-11}$ ). The two 14q11 lead SNPs were not correlated ( $r^2 = 0.03$ ). Overall, the 14q11 EDN-associated SNPs were not associated with ECP and conversely ( $P > 0.16$ ). Moreover, the effect of SNPs detected at the genome-wide significant level did not differ according to the allergy and/or asthma status ( $P > 0.12$ ). The bivariate GWA analysis confirmed the associations with the 14q11 (rs67049014,  $P = 3.8 \times 10^{-14}$ ) and 18q21 regions (rs8097644,  $P = 6.9 \times 10^{-9}$ ) and detected a third region on 1p31 in *AK4* gene (rs12091953,  $P = 3.7 \times 10^{-8}$ ). Fine-mapping of these three regions, based on bivariate conditional analysis, showed that the 14q11 region contained two distinct signals located 76kb apart: the lead SNP rs67049014 (previously associated with EDN) and another SNP, rs76185655 located in the 5' region of *RNASE3*. This latter SNP was in moderate LD with the ECP-associated SNP rs7141958 ( $r^2 = 0.5$ ). Interrogation of eQTL databases showed that the two distinct 14q11 SNPs were strongly associated with expression of *RNASE2* and *RNASE3* in the blood ( $P < 10^{-18}$ ). Functional annotations indicated colocalization of these genetic variants with DNA regulatory elements in blood cells. This study shows that bivariate analysis can increase power to detect new loci and may help refining the associated regions. Further replication of these results are ongoing. Funded: Région Nord-Pas-de-Calais.

Otitis media (OM) is a very common disease in early childhood that can lead to complications such as hearing loss. It remains one of the most common reasons for health care visits and antibiotic use. Despite maximization of public health interventions, the worldwide incidence of OM is increasing, pointing to other risk factors such as genetic predisposition. Previously a synonymous *FUT2* variant that is in linkage disequilibrium with a common *FUT2* variant c.461G>A (p.Trp154\*) was identified as a genome-wide-significant protective locus against childhood ear infections. Non-secretor status or loss of cell surface expression of ABO blood group antigens due to homozygosity for the p.Trp154\* variant is known to be associated with either risk for autoimmune diseases or protection against viral diarrhea and HIV. To determine the role of *FUT2* in familial OM, DNA samples were obtained from 853 multi-ethnic families and patients with OM. Exome and Sanger sequencing, linkage analysis, Fisher exact and transmission disequilibrium tests (TDT) were performed. The common *FUT2* c.604C>T (p.Arg202\*) variant co-segregates with OM in a Filipino pedigree (LOD=4.0), while heterozygosity for a rare variant c.412C>T (p.Arg138Cys) is associated with recurrent/chronic OM in European-American patients (OR=3.3,  $p=8.5 \times 10^{-6}$ ) and US trios (TDT  $p=0.005$ ). A second missense variant c.311C>T (p.Ala104Val) was identified in a European-American OM patient and also co-segregates with OM in a Pakistani family. Moreover 30 middle ear samples from OM patients were submitted for microbiome sequencing and analyses. The p.Trp154\* variant was associated with shifts in middle ear microbiota composition (PERMANOVA  $p<10^{-7}$ ) and increased biodiversity. *Fut2* is transiently upregulated after bacterial inoculation of mouse middle ear, with peak levels (10x) at 24 hours post-infection. To further elucidate the functional effects of *FUT2* variants, COS-7 cells were transfected with human GFP-*FUT2* variant constructs then GFP expression was determined by flow cytometry. GFP levels were decreased in cells with nonsense variants p.Trp154\* and p.Arg202\*, suggesting lower expression or quicker degradation of *FUT2*. On the other hand, expression of A antigen is decreased by all four *FUT2* variants p.Ala104Val, p.Arg138Cys, p.Trp154\* and p.Arg202\*. In conclusion, common and rare *FUT2* coding variants confer OM risk, potentially by modulating the middle ear microbiome through decreased mucosal expression of A antigen.

## 2230T

**Multiple sclerosis genetic risk score distribution and utility across diverse populations.** A. Beecham<sup>1,2</sup>, L. Amezcua<sup>3</sup>, A. Chinea<sup>4</sup>, G. Beecham<sup>1,2</sup>, S. Delgado<sup>5</sup>, D. Conti<sup>6</sup>, J. Oksenberg<sup>7</sup>, J.L. McCauley<sup>1,2</sup>. 1) John P. Hussman Institute for Human Genomics, Miller School of Medicine, University of Miami, Miami, FL; 2) Dr. John T. Macdonald Department of Human Genetics, Miller School of Medicine, University of Miami, Miami, FL; 3) Department of Neurology, Keck School of Medicine, University of Southern California, Los Angeles, CA; 4) San Juan MS Center, Guaynabo, Puerto Rico; 5) Multiple Sclerosis Division, Department of Neurology, Miller School of Medicine, University of Miami, Miami, FL; 6) Department of Preventative Medicine, Keck School of Medicine, University of Southern California, Los Angeles, CA; 7) Department of Neurology, University of California at San Francisco, San Francisco, CA.

Observed differences in multiple sclerosis (MS) prevalence and clinical presentation across populations provide evidence that allele and locus heterogeneity may exist. Currently, 200 non-MHC autosomal risk variants have been identified as conferring risk for MS in >100,000 ancestral Europeans. We computed a genetic risk score of the 200 variants in 1000 Genomes populations of Europe (N=441), Africa (N=323), Asia (N=166), and the Americas (N=258) in order to evaluate the distribution of risk alleles across populations. The mean risk score ranges from 18.8 in Asians to 19.8 in Africans (~13 more risk alleles in Africans), with Europeans and people of the Americas demonstrating intermediate scores of 19.4 and 19.3 respectively. When comparing the mean risk score across the four populations, differences ( $p<0.05$ ) were observed for each of the pairwise combinations except Europeans and people of the Americas; indicating differences in the distribution of MS risk variants across ancestral groups. We further evaluated the genetic risk score in admixed (3 or 2-way European, African, and Native American ancestry) Hispanics (1398 cases; 1386 controls) and African Americans (1305 cases; 1155 controls); in addition to Europeans (1811 cases; 477 controls) for comparison. The mean risk score was 19.4, 20.0 ( $p=8.12E-58$ ); 19.7, 20.03 ( $p=3.51E-23$ ); and 19.4, 20.0 ( $p=2.88E-39$ ) in Hispanic, African American, and European controls, cases respectively. The increase in Hispanic and African American cases versus controls indicates the utility of the risk score in characterizing risk among diverse populations. In each admixed data set, we compared risk scores in the top 5th percentile of the distribution to those in the interquartile range and found that being in the top 5th percentile indicates greater odds of disease in Hispanics than in African Americans (3.16 vs 2.39) despite higher mean risk scores observed in African Americans. Utilizing local ancestry to compute the odds of MS for those with 0, 1, and 2 alleles of European, African, and Native American ancestry (derived from Karitiana, Maya, Pima, and Surui peoples of HGDP) for each risk variant; we find evidence that for some risk loci, haplotype structures differ across populations and the identified risk variant may not be the best tag for the true causal variant in all populations.

**2231F**

**Proteomic profiling of T cells from multiple sclerosis patients and healthy controls.** T. Berge<sup>1,2</sup>, A. Eriksson<sup>2,3</sup>, I.S. Brorson<sup>2,3</sup>, E.A. Høgestøl<sup>2,3</sup>, H.F. Harbo<sup>2,3</sup>, S.D. Bos<sup>2,3</sup>, F. Berven<sup>4</sup>. 1) Institute of Mechanical, Electronics and Chemical Engineering, Oslo Metropolitan University, Oslo, Norway; 2) Neuroscience Research Unit, Oslo University Hospital, Oslo, Norway; 3) Institute of Clinical Medicine, University of Oslo, Norway; 4) Proteomics Unit, Department of Biomedicine, University of Bergen, Norway.

Multiple sclerosis (MS) is an autoimmune disorder affecting the central nervous system. It is one of the most common neurological conditions among young adults, leading to both physical and cognitive impairments. The disease develops in genetic susceptible individuals, triggered by common environmental factors such as reduced serum levels of vitamin D, virus infection and smoking. The exact underlying pathogenesis remains unclear, but T lymphocytes, both CD4<sup>+</sup> and CD8<sup>+</sup> T cells, have long been considered to play pivotal roles in MS. In addition, the genetic architecture of MS susceptibility emerged from genome-wide association studies, indicates an important role for the adaptive immune system, in particular T cells, for MS. To get an insight into immune-cell processes in MS, we evaluated immune dysregulation at the protein level using liquid chromatography combined with mass-spectrometry analyses. We have analyzed the proteomic profile of purified immune-cell subsets, i.e. CD4<sup>+</sup> and CD8<sup>+</sup> T cells, which allows us to disentangle potential cell-subtype specific differences that could not be detected in a heterogeneous cell material such as whole blood, allowing a comprehensive understanding of disease mechanisms. CD4<sup>+</sup> and CD8<sup>+</sup> T cells were purified from blood by magnetic separation from 13 treatment-naïve female patients with relapsing-remitting MS and 14 age and gender-matched healthy controls. More than 2000 proteins were identified above detection threshold, of which 195 and 230 proteins were differentially expressed ( $p < 0.05$ ) in CD4<sup>+</sup> and CD8<sup>+</sup> T cells respectively. In order to identify the true candidate proteins differentially expressed between MS cases and healthy controls, we used a more stringent filter for selection (i.e. fulfilling two of the following criteria; fold change  $> 2$ , area under the curve  $> 0.8$ ,  $p < 0.01$ ). This resulted in 91 and 62 proteins from CD4<sup>+</sup> and CD8<sup>+</sup> T cells, respectively, that were analyzed using the Ingenuity Pathway Analysis software. We were also able to identify two MS risk loci, which genotypes showed correlation with protein expression from neighboring genes. It should be highlighted that a larger verification study is needed to replicate our current findings.

**Generation of humanized MHC knock-in mice to study immune-related phenotypes.** P. Chen<sup>1,2,3</sup>, K. Chen<sup>1</sup>. 1) Graduate Institute of Medical Genomics and Proteomics, National Taiwan Univ., Taipei, Taiwan, Taiwan; 2) Department of Medical Genetics, National Taiwan University Hospital, Taipei, Taiwan; 3) Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan.

Most immune-related human phenotypes actually lack good animal models. Technology advances (such as recombineering, pronuclear injection-based mouse targeted transgenesis (PITT) and CRISPR/Cas9) in recent years would open a new era of excellent humanized animal models. Previously animal models involved in major histocompatibility complex (MHC) were mostly simple transgenic lines. There are syntenic regions between human and mouse MHC loci/genes, but the correlations are far from perfect. More sophisticated humanized MHC knock-in design holds the promise to shed light on the mechanism of human immune-related diseases. In this study, we aimed at generating mouse lines carrying various *HLA-DRB1* alleles. We started with the embryonic stem cells from the C57BL/6N line, thus future backcrossing to the B6 background will not be necessary. We successfully achieved first targeting; the mouse *H2-Aa* was replaced with human *HLA-DRA* gene, which was retrieved from human BAC RF11-379F19. We then accomplished the second targeting by replacing mouse *H2-Ab1* with the human *HLA-DRB1* gene, which was retrieved from human BAC CTD-2510D15. We are introducing various HLA alleles (such as *HLA-DRB1\*03:01* and *HLA-DRB1\*08:03*) into the mouse to better model various human phenotypes (such as Graves' disease and antithyroid drug-induced agranulocytosis). A companion humanized CD4 mouse will also be available soon. Humanized MHC mice could provide important help to study immune-related human diseases/phenotypes.

**2233T****DNA methylation profiles separate clinical subtypes of Sjögren's**

**syndrome.** C. Chi<sup>1,2</sup>, H. Quach<sup>1</sup>, D. Quach<sup>1</sup>, K.E. Taylor<sup>2</sup>, L.F. Barcellos<sup>1</sup>, L.A. Criswell<sup>3</sup>. 1) University of California, Berkeley, Berkeley, CA; 2) Computational Biology Graduate Group, University of California, Berkeley, Berkeley, CA; 3) Russell/Engleman Rheumatology Research Center, University of California, San Francisco.

Sjögren's syndrome (SS [MIM 270150]) is an autoimmune disorder resulting in glandular dysfunction. Clinical heterogeneity of SS presents a challenge in clinical care, therefore it is important to identify disease subtypes and corresponding biomarkers of disease. We performed a genome-wide DNA methylation study of human labial salivary gland biopsy samples obtained from 131 white female subjects from the Sjögren's International Collaborative Clinical Alliance (SICCA; HHSN268201300057C) Registry (67 cases and 64 controls). A total of 402 significant differentially methylated regions associated with SS (DMR-SS) were identified using Bumphunter. Principal component analysis (PCA) of CpGs in the DMR-SS revealed that cases and controls are linearly separable, and a support vector machine (SVM) classifier using the top 10 principal components (PC) was able to achieve 82% ten-fold cross validation accuracy for distinguishing cases from controls. Chromosome 6 accounted for the majority of DMR-SSs and neighborhood genes included *HLA-E* and *TAP*. *TAP* is known to transport MHC class I molecules to form complexes with *HLA-E* for natural killer cell recognition. We next searched for clinical subtypes of SS and their associated DMR (DMR-CS). Since SS is clinically heterogeneous, a large number of phenotypes including antibody serotypes, dry eyes, salivary gland function, and focus score (a quantitative assessment of the severity of focal lymphocytic sialadenitis) were collected for all subjects. PCA together with k-means identified two clusters of SS cases, with one exhibiting severe and the other exhibiting mild phenotypic outcomes. Bumphunter identified 82 significant DMR-CSs associated with severe and mild clinical subtypes, with chromosome 6 accounting for the largest share of DMR-CSs. Using the top 10 PCs from DMR-CS CpGs as predictors, the SVM SS subtype classifier was able to achieve a 92% ten-fold cross validation accuracy. Nearest genes to the DMR-CSs included *HLA-DPA1*, *TAP1*, *HLA-DQB1*, *HLA-DPA1*, *HLA-B*, and *HLA-E*; and pathway analysis with Panther on chromosome 6 genes identified antigen processing and presentation as the most significantly enriched pathway. This work demonstrates that genome-wide DNA methylation can be used to distinguish cases from controls and severe from mild clinical subtypes. Many DMRs are located near immune genes and offers evidence that epigenetic changes affect autoimmunity in SS.

**2234F****Whole exome sequencing of more than 16,500 hypothyroidism cases**

**from a clinical cohort implicates a role for protein altering variants in novel and known autoimmunity genes.** J. Freudenberger, C. Schurmann, L. Gurski, C. O'Dushlaine, A. Li, G. Della Gatta, J. Horowitz, N. Gosalia, J. Staples, A. Marcketta, X. Bai, J. Penn, L. Habegger, K. Praveen, N. Abul-Husn, T. Teslovich, F. Dewey, O. Gottesman, M. Jones, M. Sleeman, A. Shuldiner, J. Overton, J. Reid, S. Haxhinasto, A. Baras, Geisinger-Regeneron DiscovEHR Collaboration. Regeneron Genetics Center, Tarrytown, NY.

Hypothyroidism (HT) is a very common trait among the elderly. In the present study, we analyzed exome sequencing data from 16,819 HT cases and 63,627 controls from the GHS DiscovEHR cohort. 69,604 individuals also had at least one measurement of thyroid stimulating hormone (TSH). In total more than two millions protein altering variants (PAVs) were ascertained, of which more than 300 thousands with a minor allele count greater than eight were separately evaluated. When variants were tested for association under an additive genetic model, twelve independent non-MHC loci were returned under a significance threshold of  $P < 1e-7$ . Implicated novel genes include a common missense variant in *TLR3* (rs3775291, L412F, MAF=29.6%, HT:OR=0.92; P=1.71e-8, TSH:beta=-0.027; P=4.70e-6), which alters a position that is conserved across human *TLR3*, *TLR5*, *TLR7*, *TLR8* and *TLR9* protein sequences. *TLR3* encodes an intracellular endolysosomal dsRNA sensor. Furthermore, we observed novel associations for several rare variants and an infrequent missense variant in *B4GALNT3* (rs149363012, A967V, MAF=1.99% HT:OR=1.12; P=8.30e-3; TSH:beta=0.11; P=1.15e-8). *B4GALNT3* encodes a Golgi-localized glycosylation enzyme expressed in the thyroid and other tissues. Previously recognized autoimmunity genes with common missense variants displaying significant associations comprise *CTLA4* (rs231775, T17A), *PTPN22* (rs2476601, W620R), *SH2B3* (rs3184504, W262R), and *C1QTNF6* (rs229526, P42R). Additionally, the aggregate burden test of all rare (MAF<1%) PAVs in the known autoimmunity gene *IFIH1* displays evidence for protective effects (HT:OR=0.85; P=2.8e-6, TSH:beta=-0.045; P=1.5e-3). Interestingly, *IFIH1* also encodes an intracellular dsRNA sensor, suggesting a shared mechanism with *TLR3*. In conclusion, our whole exome sequencing study finds novel and known associations with hypothyroidism both in the common and the rare variant spectrum. The results support autoimmunity as its major determinant in general, and a role for innate immune responses and type I interferon signaling in particular. The results further point to targets for potential interventions in thyroiditis itself as well as functionally related immunological traits. .

**2235W**

**Characterizing oxysterols as a moderator of inflammation and mediator of remyelination in multiple sclerosis.** S.G. Gregory<sup>1</sup>, S.F. Arvai<sup>1</sup>, S.K. Siecinski<sup>1</sup>, K. Pegram<sup>2</sup>, M. Kanayama<sup>3</sup>, M.L. Shonihara<sup>3</sup>, E.J. Benner<sup>2</sup>. 1) Duke University School of Medicine, Department of Neurology, Durham, NC; 2) Duke University School of Medicine, Department of Pediatrics, Durham, NC; 3) Duke University School of Medicine, Department of Immunology, Durham, NC.

Multiple sclerosis (MS) is the most common neurological disease of young adulthood, affecting an estimated 1 million individuals in the U.S. and 2.3 million worldwide. MS is an autoimmune disease mediated, in part, by T-cell components that trigger demyelination and neuronal damage of the central nervous system (CNS), resulting in debilitating neurological symptoms. While disease-modifying therapies have proven to be efficacious, they only prolong remission, they do not change disease course, and the majority of individuals with MS will likely experience worsening of clinical symptoms during the course of their disease. There is a significant gap in our knowledge with respect to curative therapies for MS that modulate autoimmune response and promote remyelination via mechanisms such as differentiation of oligodendrocyte precursor cells into mature oligodendrocytes (ODs) within the adult CNS. We present data that shows treatment with the oxysterol, 20-HC, modulates CD4+ activated T Helper 17 (Th17) cell differentiation and attenuates the clinical severity of the animal model of MS, experimental autoimmune encephalomyelitis (EAE). We show that 20-HC functions as an agonist of the Liver X Receptor (LXR) pathway and modulates inflammation by preventing polarization in T cells, which suggests that 20-HC blocks the differentiation of Th17 cells *in vitro*. We also establish in a model system that 20-HC treatment triggers remyelination via the differentiation of new ODs from the quiescent pool of oligodendrocyte progenitor cells in the CNS, using *in vivo* and single cell expression data, beyond the limited spontaneous regeneration that occurs during disease course. Our data has significant potential to improve the lives of individuals with MS and establishes the mechanistic foundation for the repair of other neurodegenerative phenotypes in which oxysterol therapy may be efficacious. .

**2236T**

**Epigenomic dissection of multiple auto-immune disorders using H3K-27ac ChIP-seq across 200 individuals.** L. Hou<sup>1,2</sup>, L. He<sup>1,2</sup>, Y. Li<sup>1,2</sup>, L. Wang<sup>1,2</sup>, S. Steelman<sup>2</sup>, C. Nusbaum<sup>2</sup>, M. Kellis<sup>1,2</sup>. 1) Computer Science and Artificial Intelligence Lab, Massachusetts Institute of Technology, 32 Vassar St, Cambridge, Massachusetts 02139, USA; 2) The Broad Institute of Harvard and MIT, 415 Main Street, Cambridge, Massachusetts 02142, USA.

Understanding the molecular basis of complex traits and human disease requires integration of functional genomics data and genetic information from genome wide association studies (GWAS). An increasing number of genome wide enrichment analyses have revealed that >90% of genetic loci associated with complex traits impact noncoding regions. These enrichments make an implicit assumption that changes in gene regulation underlie complex traits, but these changes have thus far been rarely observed directly. To address this challenge, we directly profiled epigenomic alterations in a large cohort of individuals from the MGH biobank, consisting of patients with Crohn's Disease (CD), Ulcerative Colitis (UC), Rheumatoid Arthritis (RA), and healthy controls, according to their electronic healthy records. We focused on autoimmune disorders, given the readily accessible nature of blood enabling us to observe changes directly in disease-relevant cell types. We carried out ChIP-seq for H3K27ac, a mark associated with activated enhancers, and sought to understand whether changes in enhancer activity are linked to genetic variants associated with disease. Given the diversity of blood cell types, we reasoned that the epigenomic alterations may more manifest strongly in specific immune cell types that may not be visible at the bulk level. To recognize those, we developed a deconvolution pipeline that separates bulk samples into each of 8 components, based on epigenomic profiles for sorted cells from ROAD-MAP and BLUEPRINT epigenomic projects, including memory CD4+ T cells, naïve CD4+ T cells, memory CD8+ T cells, naïve CD8+ T cells, monocytes, B cells, Natural killer (NK) cells, and neutrophils. We applied our algorithm to compare individuals between each disease group and healthy group, resulting in differential H3K27ac peaks for each cell type in each disease relative to health controls. Based on Gene Ontologies analysis for genes near differential peaks, we found disease-related terms, including "T helper cell differentiation", "Inflammatory bowel disease (IBD)", "Autophagy", confirming the biological relevance of our findings. Lastly, we used RiVIERA to study the enrichment of GWAS signals in these alterations across traits, and to recognize the most relevant cell types for each. This predict NK cells for CD and RA, memory CD8+ T cells for UC are those with epigenomic alterations more strongly enriched with relevant genetic alterations for further investigation.

**2237F**

**Shared underlying genetic susceptibility to Crohn's disease and leprosy in East Asians.** S. Jung<sup>1</sup>, H.S. Lee<sup>1</sup>, M. Hong<sup>1</sup>, Y. Li<sup>2</sup>, L. Wang<sup>2</sup>, A. Irwanto<sup>2</sup>, B.D. Ye<sup>3</sup>, S.K. Yang<sup>3</sup>, F. Zhang<sup>4</sup>, J.J. Liu<sup>2</sup>, K. Song<sup>1</sup>. 1) Department of Biochemistry and Molecular Biology, University of Ulsan College of Medicine, Seoul, Korea; 2) Human Genetics, Genome Institute of Singapore, Singapore; 3) Department of Gastroenterology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea; 4) Shandong Provincial Institute of Dermatology and Venereology, Shandong Academy of Medical Sciences, Jinan, China.

Genome-wide association studies in Chinese patients with leprosy and European patients with Crohn's disease (CD) have suggested that CD and leprosy might share a common underlying genetic susceptibility related to nonspecific innate immunity. Few studies have investigated the relationship between Asian CD and leprosy susceptibility loci at a genome-wide level. The object of the study was to identify shared susceptibility loci to both diseases in East Asians. We first performed meta-analyses of three Immunochips and a GWAS on CD (3,566 cases and 8,885 controls of Korean, Chinese and Japanese ancestry) and three published GWAS on leprosy (2,960 cases and 3,747 controls of Chinese ancestry) and followed up susceptibility loci at genome-wide significance for shared disease association. In addition, we tested established Asian CD risk SNPs for association with leprosy and vice versa. By testing non-HLA 18 CD risk loci for association with leprosy and 19 leprosy risk loci for association with CD, we identified nine shared susceptibility loci: *IL23R* at 1p31.3, *IL18RAP* at 2q12.1, *IL12B* at 5q33.3, *RIPK2* at 8q21.3, *TNFSF15* at 9q32, *ZNF365* at 10q21.2, *CCDC88B* at 11q13.1, *LACC1* at 13q14.1, and *NOD2* at 16q12.1. Of the nine shared loci, only two loci (*LACC1* at 13q14.1 and *RIPK2* at 8q21.3) showed concordance in allelic effects between CD and leprosy. Our study shows that CD and leprosy share about half of their susceptibility genes in East Asians. The majority of shared susceptibility loci between CD and leprosy showed allelic effects in opposite directions, suggesting complex genetic susceptibility between inflammatory diseases and infection.

**2238W**

**Phenome-wide scan of genetic liability of multiple sclerosis using UK Biobank.** R.E. Mitchell<sup>1</sup>, G. Davey Smith<sup>1</sup>, S.J. Sawcer<sup>2</sup>, L. Paternoster<sup>1</sup>. 1) Medical Research Council Integrative Epidemiology Unit, Population Health Sciences, Bristol Medical School, University of Bristol, Bristol, UK; 2) University of Cambridge, Department of Clinical Neurosciences, Box 165, Cambridge Biomedical Campus, Hills Road, Cambridge, CB2 0QQ.

Multiple sclerosis (MS) is an inflammatory demyelinating disorder of the central nervous system with diverse manifestations and comorbid conditions. Genome-wide association studies (GWAS) have identified MS as a polygenic disease with a large number of genetic variants, contributing to susceptibility. However, limited evidence explains how genetic risk for MS is manifest in a general population. Therefore, we investigated the association of the genetic variants contributing to the susceptibility of MS with a comprehensive set of phenotypic traits within the UK Biobank cohort. A weighted genetic risk score (GRS) was generated on an individual basis using the latest International Multiple Sclerosis Genetics Consortium (IMSGC) GWAS meta-analysis. Regression analyses were used to assess the association between the GRS and phenotypic traits. This analysis was undertaken using PHESANT (Phenome Scan ANalysis Tool), a software package for performing comprehensive phenome scans in UK Biobank. Due to the major contribution of the human leukocyte antigen (HLA) in the genetics of multiple sclerosis, this analysis has been performed excluding and including genetic variants in the HLA region as well as with the HLA variants alone. The non-HLA GRS is associated 15 traits below a stringent Bonferroni p value threshold with a positive association with hypothyroidism (OR per SD increase in GRS 1.07, 95% CI 1.06-1.09,  $p=2.94 \times 10^{-20}$ ) and eosinophil counts ( $10^9$  cells/Litre) ( $\beta$  per SD increase in GRS 0.018, 95% CI 0.015-0.021,  $p=2.49 \times 10^{-29}$ ). The pheWAS using the GRS including independent variants in the HLA region identified 57 associations below a Bonferroni corrected p value, including several autoimmune diseases. Interestingly, hypothyroidism (OR per SD increase in GRS 0.89, 95% CI 0.88-0.91,  $p=4.71 \times 10^{-14}$ ) and eosinophil counts ( $10^9$  cells/Litre) ( $\beta$  per SD increase in GRS -0.014, 95% CI -0.017 - -0.011,  $p=1.55 \times 10^{-17}$ ) are negatively associated with the HLA GRS. These findings suggest polygenic overlap between genetic variants associated with MS and these phenotypes that are a manifestation of MS genetic risk. Increased understanding of the genetic overlap between different conditions helps to understand the underlying mechanisms of these diseases and may also provide useful information into repositioning and off-target effects of current therapies.

**A comprehensive analysis of 94 SLE loci identifies multiple novel functional SNPs and their target genes.** J.E. Molineros<sup>1</sup>, B. Singh<sup>1</sup>, M. Alasti<sup>1</sup>, Y. Uzun<sup>2</sup>, K. Tan<sup>2</sup>, S.K. Nath<sup>1</sup>. 1) Oklahoma Medical Research Foundation, Oklahoma City, OK; 2) Department of Pediatrics, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, 19104,.

Systemic Lupus Erythematosus (SLE) is a complex autoimmune disease with a strong genetic component. Multiple genomewide association and candidate gene studies have identified several susceptibility loci. However, the largest challenge has been to identify causal variants, their cell-specific target genes and associated pathways that explain those association signals. The objectives of this study were to (1) re-assess each of the published association signals; (2) identify functional variants and their target genes within the identified associated regions, and (3) characterize the effect of those genes in SLE involved pathways. We analyzed each of the 308 previously reported genomewide significant (GWS) lead SNPs and all their correlated ( $r^2 > 0.7$  and  $D > 0.9$ ) variants within 1Mb. We incorporated summary SLE GWAS information as well as cell specific epigenetic information to each annotated variant. We used two recently published methods for functional SNP identification and gene prioritization using epigenetic annotations, cell and tissue-specific eQTLs, and network based analyses. SNPs were considered functional if they were in an exon (CADD score  $> 12.37$ ), had enhancer (eSNPs) or promoter function, affected expression of a target gene or were inside anchor points for promoter-capture Hi-C assays. We used epigenetic information from blood cell lines to identify target genes. We performed network and submodule analysis to further link functional SNPs to target genes within pathways as well as to identify core target genes. Finally, we validated some candidate eSNPs using Luciferase assays. We curated previously reported SLE GWS SNPs were located in 94 independent loci/regions. We identified associated functional SNPs in 63 of those loci. There were 14 loci that included coding variants (from 45 genes), 13 of which also included eSNPs or promoter linked SNPs. There were 49 additional SLE regions that had eSNPs and SNPs in chromatin interaction anchors. Target genes extended outside associated regions, yielding 416 target genes implicated through eQTLs, eSNPs or promoter-enhancer chromatin interaction targets. Target genes were enriched in interferon I signaling and response to interferon I stimulus pathways. Luciferase assays confirmed the functional potential and differential allele-specific effect of rs10239000 in *IKZF1*. In conclusion, out of 94 independent SLE associated regions, we identified functional SNPs and their cell-specific gene targets at 63 SLE loci.

**HLA-DQA1\*05 is associated with the development of antibodies to anti-TNF therapy.** A. Sazonovs<sup>1</sup>, N.A. Kennedy<sup>2</sup>, L. Moutsianas<sup>1</sup>, C. Bews-Hea<sup>2</sup>, G.J. Walker<sup>2</sup>, K. de Lange<sup>1</sup>, J. Goodhand<sup>2</sup>, J.C. Barrett<sup>1</sup>, T. Ahmad<sup>2</sup>, C.A. Anderson<sup>1</sup>, PANTS Investigator Consortium. 1) Human Genetics, Wellcome Sanger Institute, Hinxton, Cambridgeshire, CB10 1SA, United Kingdom; 2) The Institute of Biomedical & Clinical Science, Exeter Medical School, University of Exeter, EX1 2LU, United Kingdom.

Anti-TNF therapies are the most common biologic therapies for treating immune-mediated diseases, such as rheumatoid arthritis, psoriasis, and Crohn's disease. Crohn's Disease (CD) is a chronic condition associated with inflammation of the gastrointestinal tract. While there is no cure for it, anti-TNF drugs are effective in treating patients resistant to conventional therapies. However, 10-40% of patients fail to respond to 10-12 weeks of therapy, and a further 25-45% lose response within 12 months. Immunogenicity to anti-TNF therapy is a major cause of loss of response, hypersensitivity reactions, and discontinuation of treatment, and it currently cannot be predicted prior to treatment. A number of factors have been associated with the risk of immunogenicity, but knowledge of the cellular and molecular mechanisms remains limited. Our aim was to investigate genetic susceptibility to immunogenicity. The Personalised Anti-TNF Therapy in Crohn's Disease study is a 3-year prospective UK-wide study of response to anti-TNF drugs. Patients' anti-drug antibodies (ADAs) were serially measured over a period of at least 365 days. Using a Cox proportional hazard model, we carried out a GWAS for time to immunogenicity. We identified a strong association in the HLA region on chromosome 6 (rs2097432;  $P=4.2 \times 10^{-13}$ ; HR=1.69; 95% CI, 1.48 to 1.94). We imputed the HLA alleles and demonstrated that this signal was driven by a dominant effect at HLA-DQA1\*05 ( $P=5.9 \times 10^{-13}$ ; HR=1.90; 95% CI, 1.60 to 2.25). The effect of HLA-DQA1\*05 carriage on immunogenicity is the same for patients treated with infliximab versus adalimumab, on anti-TNF monotherapy versus combination therapy with an immunosuppressant, and for smokers versus non-smokers (heterogeneity of effect  $P > 0.05$ ). We replicated the association in an independent retrospective cohort (N=178,  $P=4.31 \times 10^{-4}$ ; HR=2.00; 95% CI, 1.36 to 2.96). Around 40% of Europeans carry HLA-DQA1\*05 and our data suggest that 95% of these would develop immunogenicity within the first year of infliximab monotherapy treatment (a common anti-TNF treatment regime). Genetic testing prior to treatment might thus allow targeted use of immunomodulatory therapies to deliver more durable, safe and cost-effective anti-TNF therapy. We are currently investigating the impact of HLA-DQA1\*05 carriage on other clinical outcomes following anti-TNF therapy – loss of response and adverse drug reactions, and these results will also be presented at the meeting.

**Functional study of Peptidylarginine Deiminase genes in arthritis model mice.** A. Suzuki, Y. Kochi, K. Yamamoto. RIKEN, Yokohama, Kanagawa, Japan.

Previously, peptidylarginine deiminase type 4 (PADI4) was identified as a susceptibility gene for Rheumatoid arthritis (RA) by genome-wide association studies. Peptidyl citrulline is a target antigen of anti-citrullinated peptide antibodies (ACPAs), and only PADs (translated protein from PADI genes) can provide peptidyl citrulline via modification of protein substrates. PADI4 is highly expressed in bone marrow, macrophages, neutrophils, and monocytes and PADI2 has overlapped distribution with PADI4 in immune cells. The aim of this study was to investigate the relationship between PADI4 gene and PADI2 gene in the progression of RA. Padi4  $-/-$  DBA1J and wild-type mice were immunized with bovine type II collagen (CII) to develop collagen-induced arthritis (CIA). Expression of various inflammatory cytokines and Padi genes in immune cells was detected by real-time TaqMan assay. Cytokine concentration in sera was measured by enzyme-linked immunosorbent assay. Localization of PAD4 and PAD2 protein was indicated by immunohistochemistry. We also generate Padi2  $-/-$  mice and performed experimental arthritis. We demonstrated that the clinical disease score was significantly decreased in Padi4  $-/-$  mice and Padi4 expression was induced by CII immunization. In Padi4  $-/-$  mice sera, serum anti-type II collagen (CII) IgM, IgG, and inflammatory cytokine levels were also significantly decreased compared with those in wild-type mice sera. Interestingly, Padi2 expression was compensationally induced in CD11b+ cells of Padi4  $-/-$  mice. We also demonstrated that the clinical disease score was significantly decreased in Padi2  $-/-$  CIA mice. It appears that Padi4 and Padi2 enhance collagen-initiated inflammatory responses. Our results revealed that PAD4 affected on expression of various cytokines and also controlled Padi genes.

**2242T**

**Molecular analysis of a skin equivalent tissue culture model system of systemic sclerosis using RNA sequencing, epigenetic assays, histology, and immunoassays.** D.M. Toledo<sup>1</sup>, M. Huang<sup>1</sup>, Y. Wang<sup>1</sup>, B.K. Mehta<sup>1</sup>, T.A. Wood<sup>1</sup>, A. Smith<sup>2</sup>, Y. Nesbeth<sup>3</sup>, I. Ivanovska<sup>3</sup>, B.C. Christensen<sup>1</sup>, P.A. Pioli<sup>1</sup>, J. Garlick<sup>4</sup>, M.L. Whitfield<sup>4</sup>. 1) Molecular & Systems Biology, Dartmouth College, Hanover, NH; 2) Tufts University School of Medicine, Tufts University, Medford, MA; 3) Celdara Medical LLC, Lebanon, NH; 4) Biomedical Data Science, Dartmouth College, Hanover, NH.

**Background:** The molecular mechanisms of systemic sclerosis (SSc) have been difficult to study outside of patient samples. Mouse models lack key features of the disease, and fibroblast cultures show inconsistent results. We have developed an innovative skin-like tissue of SSc, self-assembled skin equivalents (sSE), where we study fibroblast behavior in a 3D microenvironment with epithelial-dermal crosstalk. Here we investigate the molecular changes in SSc sSE and show that it is molecularly similar to SSc skin biopsies. **Methods:** Isolated fibroblasts from SSc patient skin (SScDF) and normal skin (NDF) were seeded into transwell chambers +/- monocytes. SSc patient plasma and healthy control (HC) plasma were added into the media during the polarization period. Keratinocytes were seeded at 3 weeks for epithelialization, and tissues were harvested after 5 weeks followed by IHC, RNA-seq, DNA methylation, ATAC-seq, and ELISA analysis. **Results:** We created 136 samples of sSE from one SScDF line and one NDF line. H&E staining of SScDF sSE showed increased dermal thickness compared to NDF. Differential expression of SScDF sSE and NDF sSE with autologous plasma and monocytes showed increased expression of the following pathways in SScDF: immune system response, myeloid-mediated immunity/activation, and leukocyte differentiation. The upregulated pathways in NDF sSE showed typical processes involved in epithelial proliferation and cell growth. Differential expression of SScDF sSE +/- monocytes found that tissues with monocytes had increased immune response, immune cell proliferation/activation, and macrophage migration. Samples without monocytes showed upregulated collagen processes, but the strong immune signal was missing. IL6 and IL13 production increased in SScDF supernatant during tissue development. Also, gene expression in SScDF sSE by RNA-seq data showed molecular similarity to human SSc patient skin samples and NDF clustered with HC skin samples. Lastly, 3D sSE tissues and 2D monolayer fibroblast cultures have distinct DNA methylation patterns. **Conclusion:** There is a hierarchy of drivers in the creation of 3D tissues, with the origin of fibroblasts being the biggest modifier of disease morphology and the addition of monocytes being the next biggest factor in developing the immune response. These 3D sSE tissues consistently replicate the molecular pathways found in SSc skin and allow for a controlled model system of SSc to manipulate and test drug therapy responses.

**Pathway-analysis using datasets of GWAS and mRNA expression array identified IFNG as the most significant upstream-regulator in primary biliary cholangitis in the Japanese population.** K. Ueno<sup>1</sup>, Y. Aiba<sup>2</sup>, O. Gervais<sup>3</sup>, Y. Kawai<sup>1</sup>, Y. Hitomi<sup>1</sup>, K. Kojima<sup>3</sup>, M. Kawashima<sup>1</sup>, N. Nishida<sup>1</sup>, S. Shimoda<sup>1</sup>, M. Nagasaki<sup>3</sup>, K. Tokunaga<sup>1</sup>, M. Nakamura<sup>2,5</sup>. 1) Department of Human Genetics, Graduate School of Medicine, University of Tokyo, Japan; 2) Clinical Research Center, National Hospital Organization (NHO) Nagasaki Medical Center, Japan; 3) Tohoku Medical Megabank Organization, Tohoku University, Japan; 4) Department of Medicine and Biosystemic Science, Kyushu University Graduate School of Medical Sciences, Fukuoka, Japan; 5) Department of Hepatology, Graduate School of Biomedical Sciences, Nagasaki University, Japan.

Primary Biliary Cholangitis (PBC) is an autoimmune liver disease characterized by chronic inflammation and destruction of intrahepatic small bile ducts. So far, genome-wide association studies (GWAS) and the following pathway-analysis have been conducted worldwide and some disease-pathways such as IL12/JAK-STAT, phosphatidylinositol, and hedgehog signaling have been reported operative. However, disease-pathways and their upstream-regulators are still largely unknown in PBC. In the present study, to better understand the disease-pathways and their upstream-regulator, pathway analysis was performed by Ingenuity Pathway Analysis (IPA) using the dataset 1 of GWAS (1920 PBC cases and 1770 controls performed by Affymetrix ASI and Japonica array) and dataset 2 of mRNA microarray of liver biopsy specimens (15 PBC cases and 5 normal controls performed by Agilent Sure Print G3 Human GE 8x60K v3) in the Japanese population. The dataset 1 included 262 annotated genes derived from 6760 SNPs showing  $p$ -value $<0.00001$  in GWAS. The dataset 2 included 2293 genes which showed x2 more or less expression as compared to controls in the microarray. There were 41 genes (HLA, IKZF3, PRKCB, etc.) that were overlapped between the two datasets, while there were more than 22 overlapped pathways (antigen presentation, Th1, Th2 pathways, etc.). Furthermore, upstream regulator-analysis by IPA revealed that IFNG is the most significant upstream regulator shared between the significant pathways identified in each dataset. We propose that causal genes identified by GWAS could affect the genes identified by mRNA array via the common upstream-regulator. Our strategy should be useful for identifying upstream-molecular targets in various complex diseases.

**Subphenotype analysis of systemic lupus erythematosus and identification for loci with lupus nephritis predisposition.** H. Zhang<sup>1</sup>, Y.-F. Wang<sup>1</sup>, Y. Zhang<sup>2</sup>, J. Yang<sup>1</sup>, Y.L. Lau<sup>1</sup>, W. Yang<sup>1</sup>. 1) Department of Paediatrics and Adolescent Medicine, Queen Mary Hospital, The University of Hong Kong, Hong Kong SAR, China; 2) Department of Pediatric Surgery, Guangzhou Institute of Pediatrics, Guangzhou Women and Children's Medical Center, Guangzhou Medical University, Guangdong, China.

Systemic lupus erythematosus (SLE) is a chronic autoimmune disease with heterogeneous clinical manifestations. Among the 11 SLE subphenotypes, lupus nephritis (LN) is one of the major causes of end-stage organ failure. Previous studies have suggested higher rates of renal involvement and more severe nephritis in Asians compared to populations of European origin. In this study, we have performed a subphenotype analysis in two Asian SLE cohorts, with a total of 2661 cases and 3588 controls, for which detailed clinical data have been documented. The cumulative genetic risk scores (GRSs) was calculated based on the known susceptibility loci. GRSs for LN cases are significantly higher than non-LN cases. Preliminary analysis also found that several known genes reported as associated with SLE, such as *STAT4*, *SLC15A4* and *TNFSF4*, showed a higher effect size in LN cases than non-LN cases, suggesting different genetic predisposition in patients with and without renal involvement. Identification for novel loci showed promising results. So far, we have selected 44 novel loci with suggestive disease association signal ( $P < 1 \times 10^{-3}$ ) and lupus nephritis predisposition ( $P < 1 \times 10^{-4}$ ), which awaits further confirmation in the replication cohorts.

**Development of a genetic testing method by next-generation sequencing for screening of Thalassemia mutations.** Y. Cao<sup>1</sup>, S. Ha<sup>2</sup>, C. So<sup>2</sup>, J. Yang<sup>2</sup>, I. Ho<sup>2</sup>, W. Yang<sup>1</sup>. 1) Department of Paediatrics and Adolescent Medicine, Queen Mary Hospital, The University of Hong Kong, Hong Kong SAR, China; 2) Department of Pathology, Queen Mary Hospital, The University of Hong Kong, Hong Kong SAR, China.

Thalassemia is a major health threat in Hong Kong due to its high disease prevalence. The current mutation detection methods for thalassemia rely heavily on a combination of different tests that target various types of mutations. These tests are extremely cumbersome and make it impossible to establish efficient screening solutions that are applicable to the general population. Thus, a more efficient, accurate and universal platform is badly needed for population thalassemia screening. To achieve this goal, we first designed a set of probes to capture the entire regions of alpha and beta hemoglobin gene clusters. To secure continuous coverage, intervals between adjacent probes are minimized to no more than 500bps whenever possible, so as to ensure continuous coverage of sequences between these gaps by off-target sequencing. In the next step, next-generation sequencing (NGS) was performed in large volume to ensure in-depth coverage. We have applied the above method on the first batch of 96 samples with known common thalassemia mutations. Data quality check showed that 85.5% of the sequences in the alpha and beta hemoglobin gene loci were covered with an average depth of 1000 folds. The uncovered regions are mainly interspersed repeats (such as Alu sequence) that contribute little to mutation detection. Due to the complex nature of the sequences in the alpha gene cluster, poor mapping in homologous sequences is the major hurdle for variant calling. To increase sensitivity and specificity of mutation detection, currently, we are developing a tailor-made bioinformatics pipeline by taking sequence specificity in each region into consideration. Furthermore, we are trying to define haplotypes associated with founder thalassemia mutations to help aid mutation detection. Preliminary results showed that by making use of a combination of available tools and reference sequences built in house, we are able to detect the breakpoints for Southeast Asia (SEA) deletion with certainty. We are also able to discover and genotype  $-a^{3.7}$  and  $-a^{4.2}$  deletions with high confidence level through coverage depth analysis. Future work will involve dealing with multiple alignment issues existing within homologous sequences in *HBA1*, *HBA2* and pseudogenes and development of a comprehensive NGS data analysis tool for thalassemia mutation detection.

**Exploration of disease susceptibility HLA alleles for cold medicine-related Stevens-Johnson syndrome with high resolution NGS-based HLA typing.** K. Nakatani<sup>1</sup>, S. Khor<sup>1</sup>, Y. Hitomi<sup>1</sup>, M. Ueta<sup>2</sup>, Y. Okudaira<sup>3</sup>, A. Masuya<sup>3</sup>, Y. Wada<sup>4</sup>, C. Sotozono<sup>5</sup>, S. Kinoshita<sup>5</sup>, H. Inoko<sup>5</sup>, K. Tokunaga<sup>1</sup>. 1) Department of Human Genetics, The University of Tokyo, Tokyo, Japan; 2) Department of Frontier Medical Science and Technology for Ophthalmology, Kyoto Prefectural University of Medicine, Kyoto, Japan; 3) GenoDive Pharma Inc., Kanagawa, Japan; 4) The Center of Medical Innovation and Translational Research, Graduate school of medicine, Osaka university, Osaka, Japan; 5) Department of Ophthalmology, Kyoto Prefectural University of Medicine, Kyoto, Japan.

[Purpose];Stevens-Johnson syndrome (SJS) and its more severe form, toxic epidermal necrolysis (TEN), are diseases characterized by fever and acute inflammatory vesiculobullous reactions of the skin and mucous membranes, often caused by inciting drugs and/or infectious agents. We previously reported that in the Japanese population, cold medicine-related SJS/TEN was associated with *HLA-A\*02:06* and *HLA-B\*44:03* using Luminex HLA typing method. In this study, we performed high resolution typing of *HLA-A*, *HLA-B* and *HLA-C* at the 3 or 4-field level in order to elucidate disease related susceptibility HLA alleles at 3 or 4-field level. [Method];High resolution HLA typing of 123 Japanese SJS/TEN patients and 213 Japanese healthy controls were determined by using NXType HLA typing kit (One Lambda) and Ion PGM System (Thermo Fisher Scientific). Genotype determination was performed automatically using Typestream Visual software. For the ambiguous HLA alleles, Sanger sequencing were used to determine the key SNP genotypes and final HLA alleles were finally assigned manually. Finally, we performed the case-control association test by comparing the allele frequency of individual HLA alleles in the patients and controls with the  $\chi^2$ -test. [Result];Among the HLA alleles in HLA class I genes, *HLA-A\*02:06:01* at the 3-field resolution showed significant associations in the patients group ( $P = 4.11 \times 10^{-11}$ , OR=4.39). *HLA-A\*02:06* is previously reported to be associated with cold medicine related SJS/TEN and consistent with previous study, *HLA-A\*02:06* is the single 3-field level HLA alleles that exhibited significant association. We are currently in the phase of conducting analysis with more samples, and in this presentation, we will also report new findings utilizing whole genome sequencing data in the HLA region.

**2247W**

**Genome-wide association study of shellfish allergy in Japanese population.** K. Saito<sup>1</sup>, H. Jia<sup>2</sup>, S. Nogawa<sup>1</sup>, K. Kawafune<sup>1</sup>, S. Takahashi<sup>1</sup>, H. Kato<sup>2</sup>. 1) Genequest Inc. , 5-29-11. Siba, Minato-ku, Tokyo 108-0014, Japan; 2) Laboratory of Health Nutrition, Department of Applied Biological Chemistry, Graduate School of Agricultural and Life Sciences, The University of Tokyo, 1-1-1, Yayoi, Bunkyo-ku, Tokyo 113-8657, Japan.

**[Background and Objective]** Food allergy is caused by an antigen-specific immune reaction to the ingestion of food, and the number of affected patients is increasing, particularly in developed countries. Its diagnosis relies on the detection of immunoglobulin E (IgE) antibodies specific to food allergens using invasive blood and skin tests. In recent years, genome-wide association studies (GWAS) advanced the analysis of single-nucleotide polymorphisms (SNPs) of peanut allergy-related genes commonly occurring in European populations. On the other hand, there has been no report on the shrimp and crab allergies often found in Asian populations, particularly among the Japanese. Therefore, this study conducted a comprehensive search for SNPs related to shrimp and crab allergies using a GWAS of a Japanese population. **[Method]** We administered a Web-based questionnaire to assess the presence or absence of shrimp and crab allergies in 10,000 healthy men and women living in Japan. In addition, respondent DNA was extracted from saliva samples, collected through the direct-to-consumer genetic testing service of Japan, and then subjected to genome-wide genotyping with SNP arrays. A GWAS was performed on the acquired data using PLINK, and statistically significant SNPs were extracted with the genome-wide significance level ( $p < 5.0 \times 10^{-8}$ ). **[Results and Discussion]** In the shrimp allergy group, we were able to identify genetic loci in the region of an antigen-recognition gene (*HLA-DOB*) encoding human leukocyte antigen (HLA), a product of major histocompatibility complex (MHC), and in the region of MHC class II-related genes (*HCG23*, *BTNL2*). On the other hand, in the crab allergy group, although we were able to detect a genetic locus showing significant genome-wide associations, we were unable to elucidate the function of the neighboring gene (*C6orf10*). These findings suggest that the genetic backgrounds of shrimp and crab allergies may differ. In the future, we believe that it will be necessary to confirm the reproducibility of these results and carry out more detailed studies towards their diagnostic application.

**2248T**

**Disease-specific regulation of gene expression in a comparative analysis of juvenile idiopathic arthritis and inflammatory bowel disease.** A. Mo<sup>1</sup>, UM. Marigorta<sup>1</sup>, D. Arafat<sup>1</sup>, LHK. Chan<sup>2</sup>, L. Ponder<sup>2</sup>, SR. Jang<sup>2</sup>, J. Prince<sup>2</sup>, S. Kugathasan<sup>2</sup>, S. Prahalad<sup>2</sup>, G. Gibson<sup>1</sup>. 1) Georgia Institute of Technology, Atlanta, GA; 2) Emory University School of Medicine and Children's Healthcare of Atlanta, Atlanta, GA.

The genetic and immunological factors that contribute to differences in susceptibility and progression between sub-types of inflammatory and auto-immune diseases continue to be elucidated. Inflammatory bowel disease and juvenile idiopathic arthritis are both clinically heterogeneous and known to be due in part to abnormal regulation of gene activity in diverse immune cell types. Comparative genomic analysis of these conditions is expected to reveal differences in underlying genetic mechanisms of disease. We performed RNA-Seq on whole blood samples from 202 patients with oligoarticular, polyarticular, or systemic JIA, or with Crohn's disease or ulcerative colitis, as well as healthy controls, to characterize differences in gene expression. Gene ontology analysis combined with Blood Transcript Module and Blood Informative Transcript analysis was used to infer immunological differences. Comparative eQTL analysis was used to quantify disease-specific regulation of transcript abundance. A pattern of differentially expressed genes and pathways reveals a gradient of disease spanning from healthy controls to oligoarticular, polyarticular, and systemic JIA, CD, and UC. Transcriptional Risk Scores also provide good discrimination of controls, JIA, and IBD. Most eQTL are found to have similar effects across disease sub-types, but we also identify disease-specific eQTL at loci associated with disease by GWAS.

**Background.** Human immunodeficiency virus (HIV) infection is associated with a substantially increased risk of developing both Hodgkin lymphoma and non-Hodgkin lymphoma (NHL), with NHL being the most common malignancy. High HIV plasma viral load, low CD4+ T cell counts and absence of antiretroviral treatment (ART) are known predictive factors for NHL, but even in the era of suppressive ART, individuals infected with HIV still remain at increased risk of developing NHL compared to the general population. **Methods.** To search for human genetic determinants of HIV-associated NHL, we performed case-control genome-wide association studies (GWAS) in two cohorts of HIV+ patients of European ancestry (Swiss HIV Cohort Study + French Primo ANRS and ANRS CO16 Lymphovir cohorts). In total data were collected on 206 cases (NHL+/HIV+) and 1652 matched controls (NHL-/HIV+). To reduce the confounding effect of severe immunosuppression due to lack of suppressive ART before 1996, we restricted the analysis to cases with an NHL diagnosis post-2000. After genotype imputation, ~7 Million variants were tested for association with development of NHL using linear mixed models implemented in GCTA (mlma-loco) including sex as a covariate. Results were combined across cohorts using a weighted Z-score-based meta-analysis. Potential physical interactions between variant loci and promoters were assessed through analysis of publicly available promoter capture Hi-C data in GM12878 lymphoblastoid cells. **Results.** After meta-analysis, we identified 2 significantly associated variants; rs7919208 ( $p=1.04e-9$ ) and rs12264354 ( $p=2.27e-8$ ) ( $r^2=0.4$ ). Both variants are on chromosome 10, downstream of *CXCL12*. Analysis of promoter capture Hi-C data revealed a significant interaction between the region of rs7919208 and the active TSS of *CXCL12*, suggesting a possible functional impact of rs7919208 on transcription of *CXCL12*. No variants reported in previous GWAS of NHL in the general population were replicated, even at nominal significance ( $p<0.05$ ), indicating that distinct genetic mechanisms might be at play in HIV-related NHL. **Discussion.** We have identified a novel NHL risk locus in the HIV+ population with a possible link to the chemokine *CXCL12*. *CXCL12* is highly relevant in HIV+ patients, as it is known to modulate infection by X4 tropic HIV strains. Furthermore, increased *CXCL12* mRNA levels has previously been correlated to NHL development in HIV+ kids, underlining its relevance in HIV-related NHL.

**2250W**

**Development and validation of *NUDT15* and *TPMT* genotyping kit based on real-time PCR method for dosing recommendation of thiopurine drugs.** W. Lee, H.-K. Kim, D. Chu, S. Ahn, S. Chun, W.-K. Min. Laboratory Medicine, Asan Medical Center, Seoul, Korea.

**Background:** Thiopurines, widely prescribed anti-cancer and immunosuppressive drug in acute lymphoblastic leukemia and inflammatory bowel disease, have severe myelosuppressive toxicity caused by active thioguanine nucleotide (TGN) metabolites. Thiopurine methyltransferase (TPMT) methylates mercaptopurine and thioguanine, causing an inverse relationship between TPMT activity and concentrations of active TGN metabolites. Nudix hydrolase 15 (*NUDT15*) is hypothesized to dephosphorylate activate TGN metabolites, thus preventing their incorporation into DNA and negatively affecting the cytotoxic effects of thiopurines. Variants in these genes result in decreased activities, are associated with thiopurine-induced side effects. In Korean population, *NUDT15* variant allele frequency is about 10-15%, and *NUDT15* genotyping, in addition to *TPMT* genotyping, could be very informative. **Methods:** We established genotyping kit (SolGent Co., Ltd., Daejeon, Korea) to identify three types of *NUDT15* alleles including \*2 or \*3 (c.415C>T), \*4 (c.416G>A), and \*5 (c.52G>A), and three types of *TPMT* alleles, \*3B (c.460G>A), \*3C (c.719A>G), and \*6 (c.539A>T) using hydrolysis probe based real-time PCR method based on differential amplification by allele-specific primers for each variant. Testing was performed in cobas z480 (Roche Diagnostics Ltd. Rotkreuz, Switzerland). In *TPMT* genotyping, \*3A allele was designated, when c.460G>A and c.719A>G variants were both detected. We tested one hundred specimens using the real-time PCR method and compared its results with those from Sanger sequencing method for coding region and its flanking regions of two genes. **Results:** All the samples genotyped by the real-time PCR method showed successful amplification patterns for each variant. In comparison with Sanger sequencing method, the real-time PCR method showed 100% concordance in all six targeted variants. There was one case with *TPMT* \*1/\*38 genotype. Of course, \*38 (c.514T>C, p.Ser172Pro; unknown functional status) allele detected by Sanger sequencing method was not detected by real-time PCR method. **Conclusions:** *NUDT15* and *TPMT* genotyping by the real-time PCR method successfully detected all the six targeted variants. The advantage of the real-time PCR method is short turn-around time (TAT), but it could miss rare alleles which are not tested for. A clinical laboratory should choose a method for *NUDT15* and *TPMT* genotyping, considering TAT required and allele frequency in a population.

**Non-HLA celiac disease susceptibility loci are associated with early disease onset and the severity of clinical symptoms.** J.X.M. Cerqueira<sup>1</sup>, K. Lindfors<sup>1</sup>, K. Kurppa<sup>2</sup>, P. Laurikka<sup>1</sup>, L. Koskinen<sup>3</sup>, D. Yohannes<sup>3</sup>, K. Kaukinen<sup>1,4</sup>, P. Saavalainen<sup>3</sup>. 1) Celiac Disease Research Center, Faculty of Medicine and Life Sciences, University of Tampere, Tampere, Finland; 2) Tampere Center for Child Health Research, University of Tampere and Tampere University Hospital, Tampere, Finland; 3) Research Programs Unit, Immunobiology, Haartman Institute, Department of Medical and Clinical Genetics, University of Helsinki, Helsinki, Finland; 4) Department of Internal Medicine, Tampere University Hospital, Tampere, Finland.

**Background:** In celiac disease (CeD), dietary gluten leads to the development of small bowel mucosal damage of varying degree and the appearance of serum disease-specific autoantibodies. The clinical picture of CeD is highly heterogeneous. The age of onset varies from early childhood to older age and patients may suffer from multitude of gastrointestinal or extraintestinal symptoms. Furthermore, there are many associated conditions, including Type 1 diabetes (T1D). We assessed whether the 39 non-HLA loci previously associated with CeD susceptibility are implicated in specific CeD phenotypes. **Methods:** The studied population comprised of 625 non-related Finnish CeD patients from whom detailed clinical data had been collected. The FINRISK population (n=1817) was included as a control group. The genotypes of 39 celiac-associated non-HLA SNPs (PMID:20190752) were available for all individuals. Case-control and case-only analysis were performed to investigate their MAF differences across dichotomous demographic, clinical, serological and histological celiac outcomes at diagnosis. After corrections for multiple tests, associations were significant at a  $10^4$  permutation threshold ( $P_{\text{EMP2}} < 0.05$ ). **Results:** *SH2B3/ATXN2* locus increased the risk of concomitant T1D in the case-control analysis (OR=4.39,  $P_{\text{EMP2}}=0.01$ ), remaining marginally significant in cases (OR~3.6,  $P_{\text{EMP2}}=0.09$ ). In the case-control analysis, *OLIG3/TNFAIP3* locus increased the risk of anemia (OR~1.70,  $P_{\text{EMP2}} < 0.006$ ) and malabsorption ( $P_{\text{EMP2}}=0.02$ ), and *ITGA4/UBE2E3* and *IL2/IL21* loci were protective (OR=0.57 and OR=0.71, respectively) to the risk of a more severe small bowel mucosal damage. Risk conferred by *CCR1/CCR3* locus ( $P_{\text{EMP2}} < 0.04$ ) was specific to milder small bowel mucosal damage (OR~1.6), negative serum CeD-autoantibodies (OR~3.1) and CeD-related symptoms in childhood (OR~1.6). *OLIG3/TNFAIP3*, *ITGA4/UBE2E3* and *CCR1/CCR3* loci reached nominal significance ( $P < 0.05$ ) also in the case-only analysis. The Xp22 *TLR7/TLR8* loci was associated (OR~0.30,  $P_{\text{EMP2}} < 0.04$ ) with CeD onset before  $\leq 7$  years of age, strongly reinforced in cases and with sex-dependent effects in the female strata (Breslow-Day test,  $P < 0.001$ ). **Conclusions:** This study provides novel evidence that distinct genome-wide non-HLA variants modulate specific CeD phenotypes. Given the established roles of *SH2B3* and *TLR7/TLR8* genes in bacterial/virus infections, it is plausible that environmental factors, including infections, also modulate CeD phenotype.

**Meta-analysis of genome-wide association studies for inflammatory bowel diseases in Korean population.** B.M. Kim<sup>1</sup>, B.D. Ye<sup>2</sup>, S. Jung<sup>1</sup>, J.W. Moon<sup>1</sup>, J.W. Baek<sup>1</sup>, M. Hong<sup>1</sup>, H.S. Lee<sup>1</sup>, S.H. Park<sup>2</sup>, S.K. Yang<sup>2</sup>, K. Song<sup>1</sup>. 1) Department of Biochemistry and Molecular Biology, Ulsan University, Seoul, Korea, Republic of; 2) Department of Gastroenterology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea.

Although genome-wide association studies (GWAS) have identified over 200 loci associated with IBD, studies in non-European populations are limited. To identify novel IBD susceptibility loci in Korean population, we performed meta-analysis comprising 3,481 IBD cases (1,967 Crohn's disease [CD], 1,514 Ulcerative colitis [UC]) and 5,166 controls. The three IBD datasets used include previously reported Korean Immunochip v1.0 data (672 IBD [330 CD, 342 UC] and 898 controls), Korean GWAS results (1,467 IBD [896 CD, 571 UC] and 3,783 controls), unpublished Korean Immunochip v2.0 data (1,342 IBD [741 CD, 601 UC] and 485 controls). Meta-analysis of the three datasets (888,449 common SNPs) did not reveal any novel IBD susceptibility loci at genome-wide significance. Of the previously reported 276 Caucasian IBD susceptibility SNPs, we replicated associations of 12 IBD loci, 14 CD loci, and 7 UC loci at genome-wide significance. rs59789950 in *CD28* at 2q33 (odds ratio = 1.21, 95% confidence interval = 1.14-1.30,  $P_{\text{meta}} = 1.14 \times 10^{-9}$ ) showed association with IBD at genome-wide significance for the first time in an Asian population. Additional 12 IBD loci, 10 CD loci, and 8 UC loci were replicated in Koreans beyond Bonferroni-adjusted significance threshold of  $P = 1.81 \times 10^{-4}$  (0.05/276). A further 52 known IBD loci, 40 CD loci, and 39 UC loci showed associations at  $P < 0.05$ . Although our study does not identify any novel IBD susceptible loci, successful replication of previously reported loci supports the shared genetic characteristics of IBD across populations.

**Genetic analysis of inflammatory markers reveals novel genetic associations and highlights the power of multivariate GWAS.** *J. Partanen<sup>1</sup>, S. Ruotsalainen<sup>1</sup>, P. Häppölä<sup>1</sup>, J. Nunez-Fontarnau<sup>1</sup>, V. Salomaa<sup>2</sup>, M. Salmi<sup>3,4</sup>, S. Jalkanen<sup>3,4</sup>, P. Paltia<sup>1</sup>, M. Pirinen<sup>1,5,6</sup>, J. Koskela<sup>1</sup>, S. Ripatti<sup>1,5,7</sup>.* 1) Institute for Molecular Medicine Finland, University of Helsinki, Helsinki, Finland; 2) National Institute for Health and Welfare, Helsinki, Finland; 3) MediCity Research Laboratory, University of Turku, Turku, Finland; 4) Institute of Biomedicine, University of Turku, Turku, Finland; 5) Department of Public Health, Clinicum, Faculty of Medicine, University of Helsinki, Helsinki, Finland; 6) Department of Mathematics and Statistics, University of Helsinki, Helsinki, Finland; 7) Broad Institute of MIT and Harvard, Cambridge, Massachusetts, USA.

**Introduction:** Genetic association studies are predominantly performed by univariate tests between genotype-phenotype pairs. However, multivariate methods combining multiple response variables can reveal associations missed in univariate tests, especially related to more complex biological processes. We illustrate the increased power of multivariate association testing using metaCCA software which implements canonical correlation analysis for multiple sets of univariate GWAS summary statistics. **Materials and Methods:** We studied genetic associations of 60 quantitative measurements of cardiovascular or immunologic relevance (Lim et al. 2014 PLoS Genetics). We first performed separate genome-wide associations studies (GWAS) for 24725 Finnish samples imputed with a population-specific reference panel of 2690 individuals, resulting in 11.7 million variants. Thereafter we performed metaCCA analysis on the summary statistics from the GWASes for phenotypically correlated clusters. **Results:** Within the 60 measures, we identified 5 phenotypically correlated clusters. Here we focus on one cluster comprising mainly inflammatory markers: 12 cytokines and growth factors (5 interleukins [IL-4, IL-6, IL-10, IL-12\_P70, IL-17], 1 interferon [IFN G], 1 chemokine [SDF 1A], 1 colony stimulating factor [GCSF], 1 tumor necrosis factor [TNF B] and 3 growth factors [FGF, PDGF BB, VEGF]). 6404 samples had complete data on the cluster measures. Within the cluster we identified 50 genome-wide significant loci by metaCCA ( $p < 5 \times 10^{-8}$ ,  $p$ -values are adjusted for the number of traits). We replicated 15 previously reported associations found in GWAS Catalog ( $p < 1 \times 10^{-5}$ ) within a 500kB distance from our top hits. Additionally, we identified 35 novel associations of which 12 have been previously associated with other cytokines or growth factors and an additional 14 with other immunological traits such as autoimmune diseases. The 12 univariate GWASes on the cluster traits revealed only 9 independent genome-wide significant loci, all of which were detected by metaCCA. The results are available at: [http://35.195.196.173/pheno/NORM\\_CLUSTER](http://35.195.196.173/pheno/NORM_CLUSTER). We are currently analyzing the four remaining clusters. **Conclusions:** By analyzing phenotypically correlated traits together we dramatically increase the number of genome-wide significant loci. When analyzed together with disease endpoints, these results can aid in the discovery of disease-related associations by drawing evidence from biologically relevant traits.

**Molecular prediction in inflammatory bowel disease.** *R. Liu<sup>1,2</sup>, H. Huang<sup>1,2</sup>, D. McGovern<sup>3</sup>, M. Daly<sup>1,2</sup>.* 1) The Broad Institute, Cambridge, MA; 2) Analytic and Translational Genetics Unit, Massachusetts General Hospital, Boston MA; 3) F. Widjaja Family Foundation Inflammatory Bowel and Immunobiology Research Institute, Cedars-Sinai Medical Center, Los Angeles, CA.

The inflammatory bowel diseases (IBD) are polygenic autoimmune disorders. Two major types of IBD are Ulcerative colitis (UC) and Crohn's disease (CD). Due to the heterogeneous presentation of IBD, diagnosis can be challenging in up to 20% of patients using the conventional classification. Diagnostic uncertainty and subsequent misclassification in IBD are associated with higher rates of complicated disease and relapse. Here we propose a molecular-based risk model as a novel clinical tool to discriminate CD from UC by aggregating genetics, serology and tobacco smoking information. We performed GWAS on the International IBD Genetics Consortium (IIBDGC) Immunochip cohort using phenotypes coded as CD (20,124) v.s. UC (15,160). After LD-clumping using the study cohort as reference, 7,816 SNPs remained and were used to build the genetic component of the model. We tested this model using a) 5-fold cross-validation on the IIBDGC data, and b) model trained on IIBDGC but tested on the CEDAR cohort (an independent cohort with 2,044 CD and 3,462 UC patients). We achieved an area under the curve (AUC) of 0.80 and 0.78 for discriminating CD from UC respectively. We next assessed the ability of serologies (ASCA (IgA/IgG), ANCA, anti-Cbir1, anti-OMPC and anti-I2) and smoking status (never, ex-smoker and current) to discriminate IBD subtype in the CEDAR cohort. The serology-only model and smoking-only model had AUC=0.82 and 0.53 respectively. Serology alone showed the best AUC but is uninformative in more than 10% of patients. Importantly genetics performs well when serology is uninformative (AUC=0.72), establishing that genetics and serology provide independent information. Furthermore, combining with genetic, serologic, and smoking status, we developed overall risk models designed to discriminate CD from UC with AUC=0.88. In conclusion, our analysis clearly suggests that molecular-based model combining genetics, serology and smoking information could complement current diagnostic strategies and help classify patients based on biologic state rather than imperfect clinical parameters.

**Phenome-wide association study (PheWAS) for sex biases in Human Leukocyte Antigen (HLA) associations.** J.H. Karnes<sup>1</sup>, L. Bastarache<sup>2</sup>, C.M. Shaffer<sup>2</sup>, J.D. Mosley<sup>2</sup>, S. Mallal<sup>2</sup>, D.M. Roden<sup>2</sup>, E.J. Phillips<sup>2,3</sup>, J.C. Denny<sup>2</sup>. 1) University of Arizona, Tucson, AZ; 2) Vanderbilt University Medical Center, Nashville, TN; 3) Institute of Immunology & Infectious Diseases, Murdoch University, Murdoch, Western Australia, Australia.

Human leukocyte antigen (HLA) genes have more phenotypic associations than any other locus in the human genome. However, recent evidence suggest sex bias in major histocompatibility complex (MHC)-associated shaping of the adaptive immune system, suggesting that reanalysis of HLA association studies by sex is required. We set out to investigate the interaction of sex with HLA associations across a comprehensive set of phenotypes. We performed phenome-wide association studies (PheWAS) for HLA genomic variation by sex and tested HLA\*sex interactions using BioVU, a de-identified electronic health records coupled to a DNA biorepository. Using SNP2HLA, we imputed two and four digit HLA alleles from a population of 29,712 European ancestry individuals genotyped on the Illumina HumanExome BeadChip. We tested association of HLA alleles by sex with 1,545 phenotypes derived from EHRs. Significance was achieved if an HLA allele was associated in either males or females at  $p < 1 \times 10^{-6}$  and a significant HLA\*sex interaction was observed at  $p < 0.05$ . A total of 84 HLA allele-phenotype associations showed significant HLA\*sex interactions. The strongest interaction observed was between *HLA-B\*27:05* and 'Other inflammatory spondylopathies' (interaction  $p = 3.3 \times 10^{-6}$ ), which was significant in men (odds ratio 7.97,  $p = 4.8 \times 10^{-21}$ ) but not women (odds ratio 1.58,  $p = 0.09$ ). Phenotypes associated with HLA alleles in men but not women included senile dementia (*DPB1\*03:01*), vitamin D deficiency (*B\*07*), noninfectious gastroenteritis (*DRB1\*04:01*), diabetic retinopathy (*DQB1\*02*), viral infection (*B\*27*), Graves' disease (*DPB1\*17:01*), emphysema (*DRB1\*13:02*), and allergic rhinitis (*A\*26:01*). Phenotypes associated with HLA alleles in women but not men included psoriasis (*C\*06:02*), cardiac arrest (*A\*11:01*), chronic liver disease and cirrhosis (*B\*14:01*), reticulosarcoma (*DPB1\*11:01*), inflammatory bowel disease (*DRB1\*01:03*), and ulcerative colitis (*DRB1\*01:03*). Several autoimmune phenotypes showed evidence of strong association in both sexes with markedly different odds ratios in males and females, including rheumatoid arthritis (*DQB1\*06*), lupus (*DRB1\*03:01*), and type 1 diabetes (*DQB1\*06:02*). We provide further evidence of a sex bias in MHC-associated influences on the adaptive immune system and further emphasize the need to interrogate sex differences in HLA association studies.

**Co-evolution between *Mycobacterium* and humans influences tuberculosis severity.** C.M. Stein<sup>1,2,3</sup>, M.L. McHenry<sup>1</sup>, J. Bartlett<sup>4</sup>, K. Fluegge<sup>1</sup>, R.P. Igo, Jr.<sup>1</sup>, N.B. Hall<sup>1</sup>, H. Mayanja-Kizza<sup>3,4</sup>, C. Wejse<sup>5</sup>, G. Sirugo<sup>6</sup>, W.H. Boom<sup>2,3</sup>, S.M. Williams<sup>1</sup>. 1) Population & Quantitative Health Sciences, Case Western Reserve University, Cleveland, OH, USA; 2) Medicine, Case Western Reserve University, Cleveland, OH, USA; 3) Uganda-CWRU Research Collaboration; 4) School of Medicine, Makerere Univ., Kampala, Uganda; 5) Department of Infectious Diseases/Center for Global Health, Aarhus Univ., Aarhus, Denmark; 6) Department of Systems Pharmacology and Translational Therapeutics, University of Pennsylvania, Philadelphia, PA, USA.

Susceptibility to tuberculosis (TB) is affected by both host (human) and pathogen (*Mycobacterium tuberculosis*, MTB) genetic variation. For those who develop active TB, there are also likely genetic factors that affect disease severity. Although genetic factors in each of the two species may independently affect TB severity, we have examined the possibility that genetic variants in the human and pathogen have co-evolved such that interactions between MTB lineage and human genetic variation reduce disease severity. We tested this hypothesis using TB cases ascertained through our household contact study in Kampala, Uganda in which we have identified three major MTB lineages, determined using previously characterized MTB markers. Assessing the role of MTB lineage in the context of human genotypes offered a unique opportunity to examine potential host-pathogen interactions in disease severity. First, we tested the association between single nucleotide polymorphisms (SNPs) in 29 candidate genes in the TNF, TLR/NLR, and IFNG/IL12 pathways and disease severity, using the TBscore developed by Wejse. Next, we modeled TB severity as a function of MTB lineage, and interactions between lineage and host genotype. In this case-only study, we analyzed 2 independent cohorts of TB cases with paired human and MTB DNA samples. In the human-only analyses, we observed association between multiple SNPs in *IL12B* and TBscore that replicated in both datasets (most significant SNP rs3212227,  $p = 0.007$  and  $p = 0.03$ , combined  $p = 0.0005$ ), supporting our previous association with TB in a genome-wide association study. With respect to interaction between the human genotypes and MTB lineage, we observed a significant interaction between SNPs in *SLC11A1* and Uganda lineage in both cohorts (rs17235409,  $p = 0.003$  and  $p = 0.04$ , combined  $p = 0.0002$ ). We observed a similar interaction between *STAT1* and Uganda lineage in both cohorts (rs11305,  $p = 0.036$  and  $p = 0.024$  respectively, combined  $p = 0.002$ ). Importantly, there was no association between TBscore and these genes in the absence of the interaction term. These findings demonstrate that *IL12B* is associated with severity of TB and that the severity of TB disease is modified by MTB lineage and its interaction with at least two genes, providing evidence that host-pathogen co-evolution exists in TB.

**2257T**

**Using *in vivo* eQTL interactions to identify the genetic drivers of variation in the transcriptomic response to sepsis.** E.E. Davenport<sup>1,2</sup>, K.L. Burnham<sup>3</sup>, C. Goh<sup>3</sup>, J. Radhakrishnan<sup>3</sup>, P. Hutton<sup>4</sup>, T.C. Mills<sup>3</sup>, A. Rautanen<sup>3</sup>, A.C. Gordon<sup>5</sup>, N. Soranzo<sup>6</sup>, A.S.V. Hill<sup>6</sup>, C.J. Hinds<sup>7</sup>, S. Raychaudhuri<sup>1,2,8</sup>, J.C. Knight<sup>8</sup>. 1) Division of Genetics and Rheumatology, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA; 2) Program in Medical and Population Genetics, Broad Institute of Harvard and MIT, Cambridge, MA, USA; 3) Wellcome Centre for Human Genetics, University of Oxford, Oxford, UK; 4) Adult Intensive Care Unit, John Radcliffe Hospital, Oxford, UK; 5) Section of Anaesthetics, Pain Medicine and Intensive Care, Imperial College, London, UK; 6) Wellcome Trust Sanger Institute, Cambridge, UK; 7) William Harvey Research Institute, Barts and The London School of Medicine, Queen Mary University, London, UK; 8) Faculty of Medical and Human Sciences, University of Manchester, Manchester, UK.

Sepsis is defined as organ dysfunction caused by a dysregulated immune response to infection. The clinical diagnosis identifies a heterogeneous population of patients with substantial individual variation in their response, making this a challenging disease to diagnose and treat. We have previously shown that Sepsis Response Signature (SRS) groups are the major predictor of transcriptomic variation in sepsis (Davenport et al., *Lancet Respir Med* 2016) even accounting for different infection sources (Burnham et al., *Am J Respir Crit Care Med* 2017). Specifically the SRS1 group identifies individuals with an immunosuppressed phenotype and a poorer outcome. The contribution of genetic variation to heterogeneity in gene expression can be determined through expression quantitative trait locus (eQTL) mapping. We hypothesized that some eQTL effects are modulated by SRS group resulting in eQTL interactions. Such interactions would indicate specific regulatory variants that are functionally dependent on SRS group, and could point to regulatory drivers of SRS group. There is now increasing interest in eQTL interactions to understand a wide range of complex medical phenotypes. We recruited 468 adult patients with sepsis due to community acquired pneumonia or fecal peritonitis. We profiled gene expression (microarray, Illumina HT12-v4) from 592 peripheral blood leukocyte samples collected within five days of ICU admission and generated genotyping data (Illumina Omni-Express and Core-exome). We first mapped *cis* eQTLs genome-wide using a linear mixed model and identified 2,152 probes with a Bonferroni corrected eQTL  $p < 5.2 \times 10^{-9}$ . We used the most significant SNP for each of these probes to identify *in vivo* eQTL interactions with SRS group. We observed that 279 eQTLs (>10% of all eQTLs) interact with SRS status (FDR < 0.05). SRS-eQTL interactions include transcription factors such as *IRF5* (FDR =  $1.3 \times 10^{-6}$ ) and *EPAS1* (FDR =  $7.1 \times 10^{-4}$ ). *IRF5* has a key role in antiviral and inflammatory responses and has an eQTL effect that is dampened in the SRS1 group. *EPAS1* is a hypoxia inducible transcription factor. From network analysis of differential expression between SRS groups, this is a key nodal gene that is both upregulated and has a magnified eQTL effect in the SRS1 group. These eQTL interactions with SRS group provide additional insight into regulatory mechanisms underlying disease and improve our understanding of how genetic variants are driving the individual response to sepsis.

**Genome-wide meta-analysis and functional analysis identified *POGLUT1* as the effector gene driven by rs2293370 in primary biliary cholangitis (PBC) susceptibility locus chromosome 3q13.33 in the Japanese population.** Y. Hitomi<sup>1,9</sup>, K. Ueno<sup>1,9</sup>, Y. Kawai<sup>1</sup>, N. Nishida<sup>2</sup>, K. Kojima<sup>3,4</sup>, M. Kawashima<sup>5</sup>, Y. Aiba<sup>6</sup>, M. Nagasaki<sup>3,4,7</sup>, K. Tokunaga<sup>1</sup>, M. Nakamura<sup>8</sup>. 1) Department of Human Genetics, Graduate School of Medicine, the University of Tokyo, Tokyo, Japan; 2) The Research Center for Hepatitis and Immunology, National Center for Global Health and Medicine, Ichikawa, Japan; 3) Department of Integrative Genomics, Tohoku Medical Megabank Organization, Tohoku University, Sendai, Japan; 4) Graduate School of Medicine, Tohoku University, Sendai, Japan; 5) Japan Science and Technology Agency (JST), Tokyo, Japan; 6) Clinical Research Center, National Hospital Organization (NHO) Nagasaki Medical Center, Omura, Japan; 7) Graduate School of Information Sciences, Tohoku University, Sendai, Japan; 8) Headquarters of PBC-GWAS study group in Japan, Clinical Research Center, NHO Nagasaki Medical Center, Omura, Japan; 9) These authors contributed equally.

Primary biliary cholangitis (PBC) is a chronic and cholestatic autoimmune liver disease caused by the destruction of intrahepatic small bile ducts. The higher monozygotic/dizygotic (MZ/DZ) ratio and the higher estimated relative sibling risk ( $\lambda_s$ ) in PBC patients as compared to unaffected individuals indicates the involvement of strong genetic factors in the development of PBC. Our previous genome-wide association study (GWAS) identified *HLA*, *TNFSF15*, and four other loci as susceptibility loci for PBC in the Japanese population. Here, in order to further elucidate the genetic architecture of PBC in the Japanese population, a GWAS was performed on an additional independent sample set, then a genome-wide meta-analysis with our previous GWAS was performed based on a whole-genome single nucleotide polymorphism (SNP) imputation analysis of a total of 4,045 Japanese individuals (2,060 PBC cases and 1,985 healthy controls). A susceptibility locus on chromosome 3q13.33 (including *ARHGAP31*, *TMEM39A*, *POGLUT1*, *TIMMDC1*, and *CD80*) was previously identified both in the European and Chinese populations and was replicated in the Japanese population (rs57271503: odds ratio [OR] = 0.7241,  $P = 3.5 \times 10^{-9}$ ). Subsequent *in silico* and *in vitro* functional analyses identified rs2293370, previously reported as the top-hit SNP in this locus in the European population, as the primary functional SNP. Moreover, e-QTL analysis in various organs, including pancreas, thyroid and whole blood, indicated that the effector gene of rs2293370 was *Protein O-Glucosyltransferase 1 (POGLUT1)* ( $P < 0.0005$  after Bonferroni multiple comparison correction). This is the first study to demonstrate that *POGLUT1*, and not *CD80* which encodes a well-known co-stimulatory signaling molecule necessary for antigen presentation from HLA class II to T cell receptor (TCR), is the effector gene regulated by the primary functional SNP rs2293370, and that increased expression of *POGLUT1* might be involved in the pathogenesis of PBC.

**The eQTL analysis on blood tissues of a cohort of Korean Crohn's disease patients.** B.D. Ye<sup>1</sup>, W. Liu<sup>2</sup>, S. Jung<sup>3</sup>, J. Baek<sup>3</sup>, J. Moon<sup>3</sup>, M. Hong<sup>3</sup>, H.S. Lee<sup>3</sup>, S.K. Yang<sup>1</sup>, J.J. Liu<sup>2</sup>, K. Song<sup>3</sup>. 1) Department of Gastroenterology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea; 2) Human Genetics, Genome Institute of Singapore, Singapore; 3) Department of Biochemistry and Molecular Biology, University of Ulsan College of Medicine, Seoul, Korea.

Recently, eQTLs has transformed the field of human genetics by providing a comprehensive, easily accessible and interpretable molecular link between genetic variation and organismal phenotypes. Gene expression levels vary among populations presumably due to differences in genotype frequencies, suggesting that population-specific eQTL effects exist. However, non-European ancestries are under-represented in eQTL database. We performed eQTL analysis using RNA-seq of whole blood in a cohort of 101 Korean Crohn's disease (CD) patients. After alignment by STAR, we used RSEM to estimate the transcript abundance, the expected read counts, and fragments per kilobase per million reads (FPKM) for each gene. After removing the low-expressed genes with at least 25% samples not expressed, 10,928 high-expressed genes are obtained. Using 6,633,636 SNPs in genome-wide association study (GWAS) data of 101 samples, eQTL analysis is implemented by matrixQTL, which is computationally efficient for both cis- and trans-eQTLs. The linear model is adopted, covariates including gender, age, age of diagnosis, family history, smoking status, disease phenotype based on Montreal classification. We found 87,086 cis-eQTLs with 74,383 eSNPs on 1,439 high-expressed genes with FDR less than 0.05. The significantly enriched pathways of these 1,439 eGenes include adaptive immune system, interferon signaling, endocytosis, cytokine signaling in immune system, etc. Following the eQTL mapping of 4,727 genome-wide significant SNPs from an independent IBD GWAS cohort, 1,017 SNPs has 1,507 cis-eQTLs on 10 eGenes including *HLA-DQB1*, *HLA-DQA1*, *HLA-DRB1*, *HLA-DRB5*, *HLA-DPB1*, *HLA-C*, *HLA-H*, *MAPK9*, *TUBB2A*, *PLCL1*. We also found some overlap between our eQTLs and the blood eQTL database on a very large cohort. Korean CD eQTL datasets will provide a valuable resource for link between genetic variation and gene expression and regulation in Asians.

**Host genetic variation for susceptibility of ascending *chlamydia* genital tract infection.** W. Zhong<sup>1</sup>, C. O'Connell<sup>2</sup>, H. Wiesenfeld<sup>3,6</sup>, S. Hillier<sup>4,6</sup>, H. Lee<sup>5,6</sup>, W. Geisler<sup>7</sup>, G. Anyalechi<sup>8</sup>, R. Kirkcaldy<sup>9</sup>, Y. Li<sup>1,3</sup>, T. Darville<sup>2</sup>, X. Zheng<sup>2</sup>. 1) Department of Biostatistics, University of North Carolina at Chapel Hill, Chapel Hill, NC; 2) Department of Pediatrics, University of North Carolina at Chapel Hill, Chapel Hill, NC; 3) Department of Genetics, University of North Carolina at Chapel Hill, Chapel Hill, NC; 4) Department of Obstetrics, Gynecology, and Reproductive Sciences, University of Pittsburgh, Pittsburgh, PA; 5) Department of Epidemiology, University of Pittsburgh, Pittsburgh, PA; 6) Magee-Womens Research Institute, Pittsburgh, PA; 7) Departments of Medicine and Epidemiology, University of Alabama at Birmingham, Birmingham, AL; 8) US Centers for Disease Control and Prevention, International Research and Programs Branch, Atlanta, GA.

**Background and objectives** *Chlamydia trachomatis* is the most commonly reported infectious disease in the US. Untreated infection can ascend to the uterus and fallopian tubes resulting in pelvic inflammatory disease (PID), which can lead to infertility. However, the diagnosis of upper genital tract infection is challenging, due to lack of symptoms in most women. The objective of this study is to determine DNA determinants and/or markers for women with ascending *chlamydia* genital tract infection as a target population for vaccine by integrated DNA and mRNA analysis. **Methods** We profiled blood mRNA transcriptome of 212 genotyped women (uninfected n=51, cervical only infected n=82, endometrial infected n=79) from two cohorts, ACE and TRAC, using expression microarray. We mapped expression quantitative trait loci (eQTLs) across the whole cohort, and response eQTLs (reQTLs) with variation of gene expressions in responses to *chlamydia* infection respectively. We tested eQTL effects in ascending infection and infertility in two independent cohorts, a PID Evaluation and Clinical Health (PEACH) longitudinal study, and a *chlamydia* associated tubal factor infertility Case-Control Study by Centers for Disease Control and Prevention (CDC). **Results** We identified 89,368 cis-eQTLs (<1 Mb) in 3,660 expressed genes (eGenes) at a 5% FDR ( $P < 7.89 \times 10^{-3}$ ). Totally 256 cis-eQTLs in 104 genes and 271 cis-reQTLs in 102 genes were nominally associated with infertility in both the PEACH and TIF cohorts ( $P < 0.05$ ). Association of these loci with ascension infection and infertility, suggest plausible roles of these genes in mediating variant effects on *chlamydia* induced ascension and long term sequelae, infertility. Among 256 cis-eQTLs and 271 cis-reQTLs, 71 loci in 18 genes were overlapped. The effects of these 71 loci in uninfected and infected were in the same direction, but of significantly different magnitudes. We also found 6,740 trans-ceQTLs (>1 Mb) in 445 eGenes and 5,618 trans-reQTLs in 233 eGenes. **Conclusions** We discovered candidate eQTLs as markers for susceptibility of *chlamydia* ascending infection.

**The genetic architecture of familial vitiligo.** *G.H.L. Roberts<sup>1</sup>, Y. Jin<sup>1,2</sup>, S. Santorico<sup>1,2</sup>, R. Spritz<sup>1,2</sup>.* 1) Human Medical Genetics and Genomics, University of Colorado, Anschutz Medical Campus, Aurora, CO; 2) Department of Pediatrics, University of Colorado, Anschutz Medical Campus, Aurora, CO; 3) Mathematical and Statistical Sciences, University of Colorado, Denver, CO.

Vitiligo is a common autoimmune disease in which patches of depigmented skin and hair result from destruction of skin melanocytes. Vitiligo is complex, involving multiple genes and environmental triggers. In three GWAS of vitiligo in European-derived Caucasians (EUR), we have identified 50 vitiligo susceptibility loci. Analyzing vitiligo age-of-onset as a secondary phenotype, we found that vitiligo is comprised of two age-of-onset subtypes, early-onset (mean 10.9 years) and late-onset (mean 34.0 years), with distinct underlying genetic architectures. ~20% of vitiligo patients report one or more affected first-degree relatives. We considered that such cases, belonging to 'multiplex families', may likewise constitute a latent vitiligo subtype with different genetic architecture from sporadic cases. We considered three hypothetical genetic architectures in multiplex families: (1) a polygenic architecture, in which common risk variants from the general population drifted to high frequency in the family, conferring higher-than-average risk to close relatives; (2) a mono- or oligogenic architecture, involving segregation of a highly-penetrant variant that is rare in the general population; or (3) a combination of 1 and 2. To address hypothesis 1, we constructed a genetic risk score based on the most-associated variant at each of the 50 GWAS loci, with ORs ranging from 1.15 to 2 and MAFs from 3% to 50%, plus one major histocompatibility complex (MHC) class II high-effect haplotype with OR 7.8 and MAF 3%. The risk score yields a mean difference ( $\Delta$ ) of 1.02 standard deviations comparing all vitiligo cases to controls (AUC=0.77). We compared risk score in one proband from 373 EUR multiplex vitiligo families to 4,069 unrelated sporadic EUR vitiligo cases. Mean risk score is significantly higher in multiplex probands than in singleton cases ( $\Delta=0.16$  standard deviations;  $P=0.004$ ). The difference remains significant after removing the high-effect MHC haplotype from the risk score. Among multiplex probands, higher risk score is associated with increasing number of affected close relatives ( $P=0.003$ ). Again, the association remains significant after removing MHC class II. This suggests that a high number of affected relatives within families reflects high polygenic risk rather than presence of a major locus. Thus, higher risk among affected probands of vitiligo multiplex families is due, at least in part, to polygenic inheritance of common low-to-moderate effect variants.

**Trans-ethnic analysis of the human leukocyte antigen region for ulcerative colitis reveals common disease signatures.** *F. Degenhardt, M. Wendorf, A. Franke, TE HLA working group.* Institute for Clinical Molecular Biology, Kiel, Germany.

Genome-wide association analyses have identified the major histocompatibility complex (MHC), also termed human leukocyte antigen (HLA), as one of the most disease-associated regions in autoimmune and chronic inflammatory diseases, e.g. inflammatory bowel disease (IBD). For IBD, stronger associations of HLA alleles have been observed for ulcerative colitis (UC) than Crohn's disease, the two main subtypes of IBD. Most HLA association analyses have targeted Caucasian populations in the past and systematic trans-ethnic fine mapping studies are lacking because of the lack of cohorts, high costs for wet-lab (e.g. next generation sequencing) based HLA allele typing and the lack of appropriate reference panels for the (cost-effective) imputation of HLA alleles that account for the polymorphism of the HLA in non-Caucasian ethnicities. Using our high-quality, multi-ethnic reference panel, including 1,360 samples of 8 different ethnicities, we imputed HLA alleles into 9 different ulcerative colitis case-control populations, including African American, Iranian, Indian, Chinese, Japanese, Korean, Caucasian, Maltese and Puerto Rican samples with a total of 3,856 cases and 6,875 controls. We further included our previously reported Caucasian data set (19,014 cases 21,677 controls) for comparison purposes in the analyses. We performed allele- and haplotype-based association analyses on alleles with a frequency of > 1% and identified alleles with consistent effect directions across all populations. Overall, classical HLA alleles and haplotypes contributed most to the statistical disease association than single SNPs. Effect sizes were as high as OR=2.8 [95% CI: 2.4-3.3] were observed for HLA-DQB1\*06-DRB1\*15 haplotypes in African American, East Asian and Caucasian samples while Iranian, Indian and Puerto Rican samples showed distinct disease haplotypes. The previously reported HLA-B\*52:01-C\*12:02 haplotype was highly associated with UC in the Korean (OR=3.9 [2.5-6.5]), Japanese (OR=2.9 [2.5-3.6]) and Indian (OR=2.1 [1.6-2.9]) samples and are in strong linkage-disequilibrium with the HLA Class II loci, leading to distinct association signatures than in the other ethnicities (roof-top like shape regional association plots). In conclusion, we identify population-specific and cross-population disease associated HLA alleles and is able to assign these signals to specific common haplotypes, showcasing also our previously established multi-ethnic imputation reference panel.

**Whole genome sequencing to identify gene-by-air pollution interactions that influence lung function in minority children.** A.C.Y. Mak<sup>1</sup>, M.J. White<sup>1</sup>, E. Lee<sup>1</sup>, M. Pino-Yanes<sup>2</sup>, K.L. Keys<sup>1</sup>, J. Liberto<sup>1</sup>, S. Huntsman<sup>1</sup>, D. Hu<sup>1</sup>, C. Eng<sup>1</sup>, S.S. Oh<sup>1</sup>, M.A. Seibold<sup>3</sup>, E.G. Burchard<sup>1</sup>, NHLBI TOPMed and NHGRI CCDG Genome Sequencing Project. 1) University of California San Francisco, San Francisco, CA, United States; 2) Research Unit, Hospital Universitario N.S. de Candelaria, Santa Cruz de Tenerife, Spain; 3) National Jewish Health, Denver, Colorado, United States.

Baseline lung function, quantified as forced expiratory volume in the first second of exhalation (FEV<sub>1</sub>), is one of the standard diagnostic criterion used by pulmonary clinicians to identify and classify lung diseases. FEV<sub>1</sub> is strongly influenced by genetics, with heritability estimates as high as 55%. Specifically, numerous genetic loci associated with FEV<sub>1</sub> have been identified, and there is also evidence that genetic ancestry plays a role in FEV<sub>1</sub> variation. Several epidemiological studies have identified early-life exposure to air pollution as a significant predictor of baseline lung function. Although there have been numerous genetic and epidemiological studies aimed at identifying the genetic and environmental factors responsible for variation in FEV<sub>1</sub>, the majority of the heritability remains undefined. FEV<sub>1</sub> is a complex phenotype that has been shown to be heavily influenced by both environmental and genetic factors. We hypothesize that a portion of the "hidden heritability" for FEV<sub>1</sub> may be explained by gene-by-environment (GxE) interactions. **Methods** We performed whole genome sequencing on 1,133 Puerto Rican children with asthma and available early-life exposure to air pollution data. We then constructed multiplicative interaction models (single nucleotide polymorphism [SNP] x air pollution). We then performed a GWIS (genome-wide interaction study) to test the effect of each interaction model on variation in FEV<sub>1</sub>. All regression models were adjusted for age, sex, global ancestry, and the main effects of the specified SNP and air pollution. **Results and Conclusions** We identified several GxE interactions associated with FEV<sub>1</sub> in Puerto Rican children with asthma. Our preliminary results indicate that GxE interactions may play an important role in FEV<sub>1</sub> variation in this population.

The human leukocyte antigen (HLA) region harbors genes that are crucial to many human diseases. However, it remains a challenge to pinpoint the causal variants for these associations due to the extreme complexity of the region. We constructed the largest multi-ethnic HLA haplotype panel to date to better understand immune related adaptive evolution, and to facilitate fine-mapping studies from genome-wide association studies (GWAS). First, we inferred HLA types at G-group resolution using whole-genome sequences (WGS) from 20,209 individuals of different ancestries (10,699 Europeans, 7,644 African Americans (AA), 1,016 Hispanics and 850 East Asians) using population reference graphs (Dilthey et al. 2016). We evaluated inferred HLA types against sequencing based typing (SBT) among 295 Japanese samples sequenced at 15x coverage. The accuracies for HLA-A, B, C, DQA1, DQB1 and DRB1 were 95.4%, 97.9%, 98.5%, 99.3%, 98.2% and 97.2% respectively. We observed high levels of differentiation in population allele frequencies among inferred HLA types ( $P = 8.7e-267$ ). In many cases these differences are likely to be related to adaptive selection such as enrichment for the B\*53:01:01G and C\*04:01:01G alleles in AA samples that have been previously associated with malaria protection. We next built a multi-ethnic HLA reference panel based on inferred HLA types and genetic variation in 5,376 multi-ethnic samples. To evaluate the imputation accuracy of the multi-ethnic panel, we compared imputed HLA haplotypes against SBT among 1,067 AA subjects. The average accuracy among the six classical HLA genes was 96.3%, compared to 77.4% when using a European panel of 5,225 samples alone. To illustrate fine-mapping advantages due to increasing ancestral diversity in the reference panel, we meta-analyzed published HIV-1 virus load GWAS in a total of 6,315 European and 2,924 AA subjects. The most significantly associated allele was an amino acid at HLA-B position 97 in both populations. However, conditional analysis identified different secondary associations at an amino acid at HLA-B position 67 and B\*08:01:01G for the European and AA respectively. These results highlight the benefits of a multi-ethnic reference panel for the discovery and characterization of HLA-disease associations. In the next phase, we will build an HLA panel using >20,000 WGS. This resource will open an exciting opportunity to understand immune-related genetic architecture across populations of diverse ancestries.

**Validated South Asian HLA imputation and association analysis uncovers a HLA-DPB1 specific effect on hepatitis B vaccine response in infants from Bangladesh.** K. Auckland<sup>1</sup>, A.J. Mentzer<sup>1</sup>, R. Haque<sup>2</sup>, G. Smits<sup>3</sup>, C. Pomilla<sup>4</sup>, J.A. Noble<sup>5</sup>, K. Jeffery<sup>6</sup>, F. van der Klis<sup>7</sup>, A.V.S. Hill<sup>1</sup>, M.S. Sandhu<sup>1</sup>, W.A. Petri Jr.<sup>1</sup> 1) Wellcome Centre for Human Genetics, University of Oxford, Oxford, Oxfordshire, United Kingdom; 2) International Centre for Diarrhoeal Disease Research, Dhaka, Bangladesh; 3) National Institute for Public Health and Environment, Bilthoven, The Netherlands; 4) The Sanger Institute, University of Cambridge, Hinxton, Cambridge, United Kingdom; 5) Children's Hospital Oakland Research Institute, Oakland, California, United States of America; 6) Microbiology Department, The John Radcliffe, Oxford, Oxfordshire, United Kingdom; 7) University of Virginia School of Medicine, Charlottesville, Virginia, United States of America.

**Background:** Vaccine responses are highly variable as a result of host genetic and environmental factors and in some individuals such responses may be absent increasing the risk of vaccine failure. Despite our increasing understanding of the genetic contribution to vaccine response heterogeneity, large-scale GWAS studies of multiple vaccine responses in South Asian populations with high burden of preventable disease are lacking. **Methods:** We have undertaken a pilot-phase genome-wide association study seeking to identify the genetic variants associated with multiple vaccine responses using ~1.7 million variants genotyped in 541 children from Bangladesh enrolled in PROVIDE (Performance of Rotavirus and Oral Polio Vaccines in Developing Countries). Vaccine responses were defined as quantitative antibody levels measured against eight antigens targeting six separate pathogens. Classical HLA types were generated for all individuals with exon-based NGS genotyping to both validate and undertake HLA imputation and association testing. **Results:** Significant associations were observed between allelic, residue and SNP variants in the class II MHC with response to hepatitis B surface antigen ( $P=1.3 \times 10^{-20}$ ), localising only to *HLA-DPB1*, with no *HLA-DRB1* signal observed; and pertussis pertactin ( $P=1.2 \times 10^{-8}$ ), localising to *HLA-DQB1*. Subthreshold associations were observed with response to diphtheria toxin; pertussis filamentous haemagglutinin adhesin and toxin. Little overlap was observed for associated variants between each vaccine response measured. No associations of genome-wide significance were observed with response to tetanus toxin, attenuated measles or the conjugated *Haemophilus influenzae* vaccines. Concordance between classically typed and imputed HLA alleles using SNP2HLA with a customised reference panel demonstrated 4 digit (2-field) concordance estimates across the class II of over 93%. **Discussion:** By undertaking and validating the first HLA-focussed GWAS of multiple vaccine responses in South Asian children, we have identified genetic variants determining vaccine response heterogeneity and have discovered features of HLA associations distinguishing this cohort from other published populations. We are undertaking the replication analysis in a further ~700 children from Bangladesh. Characterising the genetic determinants of vaccine response heterogeneity could offer a cost-effective and feasible method to significantly reduce the incidence of vaccine failure.

Red blood cell (RBC) measurements are polygenic traits, and GWAS, exome chip and sequencing analyses have identified hundreds of associated genetic variants in European, Asian, African and Hispanic ancestry populations. However, additional loci remain undiscovered and causal variant(s) at each locus have not been well characterized. We performed WGS-based association analyses for hemoglobin (HGB), hematocrit (HCT), mean corpuscular hemoglobin (MCH), mean corpuscular hemoglobin concentration (MCHC), mean corpuscular volume (MCV), RBC count and red cell distribution width (RDW) in multi-ethnic populations from the NHLBI TOPMed Project, consisting of 25,080 European, African, Hispanic and Asian ancestry individuals from nine studies. More than 42,400,000 SNPs ( $MAC \geq 10$ ) were tested for association using inverse-normal transformed residuals in a multi-ethnic mega-analysis, adjusting for age, sex, study, relatedness, population structure and residual heteroscedasticity. We identified six novel loci reaching genome-wide significance ( $P < 5E-8$ ) that remained significant after accounting for all previously reported RBC-associated variants ( $P_{conditional} < 2E-6$ ). The six novel loci include *MSRA*-rs1484641 ( $MAF=0.35$ ) for HCT, *CREBBP*-rs129965 ( $MAF=0.16$ ) for MCHC, *FOXO6*-rs557606786 ( $MAF=0.001$ ) and *ANKS1A*-rs13207848 for MCV ( $MAF=0.14$ ), and *4q28*-rs192665038 ( $MAF=0.003$ ) and *18q23*-rs558218738 ( $MAF=0.001$ ) for RDW. All novel variants, except for *ANKS1A*-rs13207848, showed disparate allele frequencies across ancestral populations. We sought replication for these novel variants in UK Biobank, Kaiser and WHI-SHARE imputed GWAS datasets, but none of them was replicated ( $P > 0.05$ ). A total of 26 previously reported RBC trait loci were confirmed to be associated with one or more RBC traits at genome-wide significance in our TOPMed analysis, and six of them (*HBA*, *HBB*, *HFE*, *SP1*, *ABCA7* and *RP11-321F6.1*) harbored residual secondary signals after conditional analysis ( $P_{conditional} < 5E-8$ ). Finally, in the SKAT and burden tests which aggregated rare variants (alternative allele frequency  $< 0.01$ ) using 5 or 50kb sliding windows, five previously reported GWAS loci were genome-wide significant ( $P < 4E-8$  for 5kb window, and  $P < 4E-7$  for 50kb window), including the well-established *HBA* and *HBB* loci, *APCDD1L*, *MXD3* and *MOXD1*. In summary, our results suggest that WGS in larger sample sizes are needed for capturing variants or indels with moderate to larger effects on RBC traits that were missed by GWAS.

**Large-scale genome-wide association study identified candidate genes for childhood nephrotic syndrome in Japanese.** X. Jia<sup>1</sup>, T. Horinouchi<sup>2</sup>, Y. Hitomi<sup>1</sup>, Y. Kawai<sup>1,3,4</sup>, K. Nozu<sup>2</sup>, C. Nagano<sup>2</sup>, T. Yamamura<sup>2</sup>, K. Kojima<sup>3,4,5</sup>, M. Nagasaki<sup>3,4,5</sup>, K. Iijima<sup>2</sup>, K. Tokunaga<sup>1</sup>. 1) Department of Human Genetics, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan; 2) Department of Pediatrics, Graduate School of Medicine, Kobe University, Kobe, Japan; 3) Department of Integrative Genomics, Tohoku Medical Megabank Organization, Tohoku University, Sendai, Japan; 4) Graduate School of Medicine, Tohoku University, Sendai, Japan; 5) Graduate School of Information Sciences, Tohoku University, Sendai, Japan.

Idiopathic nephrotic syndrome (INS) is the most common cause of kidney disease in children, but the underlying genetic etiology is not well understood. Our group has conducted the first genome-wide association study (GWAS) for childhood INS in the Japanese population, genome-wide significant association was identified in *HLA-DR/DQ* region and disease-associated *HLA* alleles were further clarified ("Strong Association of *HLA-DR/DQ* Locus with Childhood Steroid-Sensitive Nephrotic Syndrome in the Japanese Population". *Journal of the American Society of Nephrology*). To identify the other candidate loci contributing to the susceptibility of childhood INS, especially the disease-related genes in non-*HLA* regions, we performed an extended GWAS in the Japanese population with large samples. A total of 1,152 patients with childhood-onset INS and 2,807 adult healthy controls were genotyped using Affymetrix 'Japonica Array' in the discovery stage. Whole-genome imputation was conducted using a phased reference panel of 2,049 healthy Japanese individuals (2KJPN panel). Quality control was performed to exclude the individuals with low calling rate (<97%) and the variants with low genotyping rate (<97%), minor allele frequency (MAF) <1% and Hardy-Weinberg equilibrium (HWE) test p-value <1×10<sup>-6</sup>. Association analysis was conducted using logistic regression with adjustment of gender and principal components (PCs). In GWAS, the most significant association was detected in *HLA-DR/DQ* region as we reported before (rs754421875, P=5.42×10<sup>-47</sup>, odds ratio (OR)=0.32). Another signal on chromosome 19 achieved genome-wide significance (P=9.69×10<sup>-18</sup>, OR=1.83). The validation and replication of candidate variants will be done to confirm the associations and further elucidate the disease-associated variants. With this large sample size, the power of the current GWAS exceeded 80% to detect common variants (MAF>=5%) with genotypic relative risk above 1.95, making it's possible to detect disease-associated genetic factors with modest associations as well as the associated variants with low allele frequencies. This study will improve our knowledge of the genetic background of childhood INS, providing a better understanding of the pathogenic mechanism.

**Novel transcriptomic analysis of total immunoglobulin E (IgE) in Puerto Rican children.** Y. Jiang<sup>1,2</sup>, T. Wang<sup>1</sup>, E. Forno<sup>1</sup>, G. Canino<sup>3</sup>, E. Acosta-Pérez<sup>3</sup>, W. Chen<sup>1</sup>, J.C. Celedón<sup>1</sup>. 1) Division of Pulmonary Medicine, Department of Pediatrics, Children's Hospital of Pittsburgh of UPMC, University of Pittsburgh, Pittsburgh, PA; 2) School of Medicine, Tsinghua University, Beijing, China; 3) Behavioral Sciences Research Institute, University of Puerto Rico, San Juan, PR.

Early sensitization with immunoglobulin E (IgE)-mediated allergic inflammation can result in the development of asthma and/or allergic diseases later in life. Although genetic and epigenetic determinants have been associated with serum total IgE and asthma, the underlying mechanisms are still largely unknown. In this study, we performed a novel transcriptomic study of total serum IgE in a cohort of Puerto Rican children, which have the highest prevalence of asthma among all ethnic groups. Whole transcriptome sequencing was performed on white blood cells from 238 children with asthma and 234 controls. A regression framework was applied to identify genes associated with total IgE. Genes that were significantly associated with total IgE were combined to build a statistical prediction model. A total of 83 genes were significantly associated with total IgE (false discovery rate P < 0.1), of which genes *IL5RA* and *IL17RB* are known to affect allergic inflammation. Most of our findings were validated in microarray data of whole blood samples from another Puerto Rican cohort (n=84). Integrated with DNA genotyping data, the expression quantitative trait locus (eQTL) studies identified significant genotype-expression pairs, including several that have been reported, such as *rs11136344/PARP10*, *rs745307/CD40*. Furthermore, pathway analysis revealed 9 significantly enriched pathways (P < 0.01), including Th1 and Th2 activation pathways. A prediction model achieved satisfactory performance (AUC=0.80). Our findings advance the knowledge of allergy pathogenesis and offer a potential diagnostic tool for allergic diseases in a clinical setting.

**Large-scale PheWAS of the MHC region in ~170,000 Japanese using NGS-based classical and non-classical HLA imputation.** Y. Okada<sup>1,2</sup>, J. Hirata<sup>1</sup>, K. Hosomichi<sup>2</sup>, S. Sakaue<sup>1</sup>, M. Kanai<sup>1</sup>, H. Nakaoka<sup>4</sup>, K. Ishigaki<sup>2</sup>, K. Suzuki<sup>1</sup>, M. Akiyama<sup>2</sup>, T. Kishikawa<sup>1</sup>, K. Ogawa<sup>1</sup>, T. Masuda<sup>1</sup>, K. Yamamoto<sup>1</sup>, M. Hirata<sup>5</sup>, K. Matsuda<sup>5</sup>, I. Inoue<sup>4</sup>, M. Kubo<sup>2</sup>, Y. Kamatani<sup>2</sup>. 1) Osaka University Graduate School of Medicine, Osaka, Japan; 2) RIKEN Center for Integrative Medical Sciences, Yokohama, Japan; 3) Kanazawa University, Kanazawa, Japan; 4) National Institute of Genetics, Shizuoka, Japan; 5) The University of Tokyo, Tokyo, Japan.

The major histocompatibility complex (MHC) region confers genetic risk on a variety of human phenotypes, while detailed fine-mapping has yet to be elucidated. Here, we conducted NGS-based typing of the 33 human leukocyte antigen (HLA) genes of the Japanese population ( $n = 1,120$ ), providing high resolution allele catalogue up to 6-digit HLA alleles and linkage disequilibrium (LD) structure of both classical and non-classical HLA genes. Together with population-specific deep whole-genome sequencing (WGS) data of Japanese (on average 25 $\times$ ,  $n = 1,276$ ), we conducted NGS-based HLA, SNV, and Indel imputation of the large-scale genome-wide association (GWAS) genotype data of Japanese from BioBank Japan Project, a nation-wide hospital-based cohort of Japan ( $n = 166,190$ ). A phenome-wide association study (PheWAS) assessing 106 clinical phenotypes including human complex diseases, as well as anthropometric, biochemical, and hematological quantitative traits, identified abundant significant genotype-phenotype associations across 52 phenotypes. Fine-mapping within the MHC region revealed multiple association patterns conferring independent risks from the classical HLA genes including those represented as non-classical HLA gene variants, non-HLA variants within MHC, and long-range haplotype spanning the entire MHC region. We also identified novel MHC associations of the traits (pollinosis, hyperlipidemia, myocardial infarction, stable angina, type 2 diabetes, liver cancer, liver cirrhosis, and nephrotic syndrome). MHC region-wide heritability estimates and genetic correlation network analysis elucidated polygenic architecture shared across the phenotypes, which was distinct between classical HLA variants and other variants in MHC. This study should contribute to our understanding of genetic and phenotypic landscape of MHC.

**Specific interaction between host immune-related genetic factors and lineage in *Mycobacterium tuberculosis* identified from pathogen lineage based genome-wide association study in tuberculosis.** Y. Omae<sup>1</sup>, L. Toyo-oka<sup>1</sup>, S. Mahasirimongkol<sup>2</sup>, H. Yanai<sup>1</sup>, N. Smittipat<sup>3</sup>, P. Palittapongarnpim<sup>3</sup>, S. Nedsuwan<sup>2</sup>, S. Wattanapokayakit<sup>2</sup>, N. Satproedprai<sup>2</sup>, P. Sawanpanyalert<sup>2</sup>, W. Inunchot<sup>2</sup>, E. Pasomsub<sup>2</sup>, N. Wichukchinda<sup>2</sup>, T. Mushiroda<sup>4</sup>, M. Kubo<sup>4</sup>, K. Tokunaga<sup>1</sup>. 1) The University of Tokyo, Bunkyo-ku, Tokyo, Japan; 2) Ministry of Public Health, Nonthaburi, Thailand; 3) National Center for Genetic Engineering and Biotechnology, Pathum Thani, Thailand; 4) RIKEN Center for Integrative Medical Sciences, Yokohama, Japan.

Tuberculosis (TB) is one of the three major global infectious diseases caused by pathogenic bacterium, *Mycobacterium tuberculosis* (MTB). Although twin studies suggested the contribution of host genetic factors to TB onset, previous genome-wide association studies (GWASs) for TB have faced difficulty in identifying the genetic factors concordant among independent GWASs. MTB is known to have the heterogeneity in its genome structure and seven major global lineages have been reported worldwide. We recently conducted a stratified GWAS for TB in Thailand based on the lineage information of MTB from 686 TB patients and assessed possible interaction between pathogen genomic heterogeneity and host genetic factors. The pathogen-lineage based GWAS revealed a genome-wide significant association of one SNP on chromosome 1p13, which was specifically associated with non-Beijing lineage infected cases with age at onset older than 45 years of age ( $p=2.54E-08$ , odds ratio (OR)=1.74 [95%CI=1.43-2.12]). The SNP was located near the *CD53* gene, which encodes a leukocyte surface glycoprotein and known as a modulator of cytokine production (Y. Omae, et al., *Journal of Human Genetics* 2017). In this study, we further applied whole genome SNP imputation for our dataset and revealed that SNPs on chromosome 6p21 showed the strongest association with Beijing lineage infected cases ( $p=2.14E-07$ , OR=2.00 [95%CI=1.53-2.61]). The 6p21 locus included class II human leukocyte antigen (*HLA*) genes, whose associations with TB have been reported from the previous GWASs in European and Han Chinese. HLA allele imputation based on the surrounding SNP genotypes revealed the strongest association of *HLA-DRB1\*09:01* allele with Beijing lineage infected cases ( $p=5.47E-06$ , OR=1.81 [95%CI=1.40-2.35]). Beijing lineage isolates were reported to induce lower levels of the inflammatory cytokines in monocyte-derived macrophages and dendritic cells than non-Beijing lineage isolates *in vitro*, thus the phenotypic differences in MTB can affect the risk of host genetic factors and acquired immunity via class II *HLA* might be an important step to fight against specific lineage of this pathogen. Our findings demonstrate the importance of analyzing the interaction between host and pathogen genomes in TB.

**Published and novel human associations of blood cell traits in the Healthy Nevada Project cohort.** K. Schlauch, R. Read, J. Metcalf, S. Rybariski, S. Sweet, J. Grzymalski. Desert Research Institute, Reno, NV.

**Background:** In 2017, Renown Health and DRI began the Healthy Nevada Project, consisting of an extensive Electronic Medical Record database and genotypic data of more than 10,000 individuals in Northern Nevada based on the Illumina Human OmniExpress-24 BeadChip. **Methods:** In this study, a genome-wide association study (GWAS) was performed on 4,610 Healthy Nevada Project participants to assess the genotypic association of Mean Platelet Volume (MPV), Mean Corpuscular Volume (MCV), and Platelet Counts (PC) against 602,000 genotypes from the Illumina Human OmniExpress-24 BeadChip. After performing standard quality control measures (verifying 95% SNP call rates, 95% individual call rates, Hardy-Weinberg Equilibrium with  $p < 1 \times 10^{-6}$ ), 498,709 quality-controlled genotypes with minor allele frequency  $> 1\%$  and 4,532 patients were tested for association using PLINK v. 1.9. Linear regression was performed on each SNP to measure the genetic association between genotype and quantitative MPV, MCV and PC measures, using age and gender as covariates, and the standard log-additive genetic model, following previous similar studies. **Results:** This study identified 215 statistically significant SNPs putatively associated ( $p < 5 \times 10^{-8}$ ) with at least one of the blood cell traits. SNPs associated with MPV lie in eight genomic regions; five of these regions were reported previously in at least one other MPV study. Specifically, SNPs rs342293, rs342296 and rs342275 in region 7q22.3 represent our highest association with MPV ( $p < 2 \times 10^{-13}$ ) and were linked to MPV, PC, and platelet formation in five previous GWAS. All three SNPs had positive effect sizes. Additionally, we found rs385893 in region 9p24.1 to be statistically significantly associated to PC in our cohort ( $p=2.67 \times 10^{-10}$ , and beta coefficient=-.09); this SNP was linked to PC and MPV in at least three earlier GWAS. We also identified ten SNPs in a region within the *MYB* gene in 6q23.3 with MCV  $p$ -values  $< 1 \times 10^{-10}$  and positive effect sizes; these SNPs were previously identified as associated to MCV in at least three other GWAS. Five SNPs in the 22q12.3 region were also identified here to be associated with MCV, as in several previous GWAS. Our study also links several yet unidentified regions with high statistical significance with one or more blood cell traits awaiting further investigation. **Conclusion:** This study shows previously identified and putative novel associations in blood cell traits in the Healthy Nevada Project cohort.

**Genome-wide association study of HIV-1 subtype C in Botswana population.** A.K. Shevchenko<sup>1</sup>, S.V. Malov<sup>1</sup>, D.V. Zhernakova<sup>1,2</sup>, N. Cherkasov<sup>1</sup>, A. Svitin<sup>1</sup>, W. Xie<sup>3,4</sup>, V. Novitsky<sup>3,4</sup>, M. Essex<sup>3,4</sup>, S.J. O'Brien<sup>1</sup>. 1) Dobzhansky Center for Genome Bioinformatics, SPSU, St. Petersburg, St. Petersburg, Russian Federation; 2) University of Groningen, University Medical Center Groningen, Department of Genetics, Groningen, the Netherlands; 3) Harvard T.H. Chan School of Public Health AIDS Initiative, Department of Immunology and Infectious Diseases, Harvard T.H. Chan School of Public Health, Boston, Massachusetts, USA; 4) Botswana Harvard AIDS Institute, Gaborone, Botswana.

HIV-infection is a deadly chronic disease spreading across all continents. More than 36 000 000 people currently live with HIV and more than 1 000 000 die due to AIDS (UNAIDS, 2015). Despite efforts and resources directed to the fight against the HIV epidemics for more than three decades, still currently there exists no effective vaccine or cure. According to UNAIDS, Botswana falls into top 3 countries with the highest HIV prevalence in the world with adult aged 15 to 49 HIV prevalence rate of 22.2% (UNAIDS, 2015). Moreover, HIV-1 subtype C (widespread in Botswana), which accounts for over half of HIV-1 infections worldwide, is understudied, because most studies focus on other subtypes. Genome-wide association studies (GWAS) allow to identify common variants associated with the trait in question. In order to efficiently search for the genetic associations we have previously developed GWATCH web platform (Svitin et al, 2014). The broad goal of the Botswana GWAS project is to identify genetic determinants of susceptibility and resistance to infection by HIV-1 subtype C among people severely affected by HIV/AIDS in Botswana. By conducting GWAS analysis on HIV-1C case/control dataset consisting of 762 Tswana people (combined from two partly overlapping datasets of 809 microarray and 362 WGS samples), we found several gene regions slightly below significance level. One of these loci was successfully replicated in the longitudinal study on CD4 and viral load (VL) trajectories in a total of 556 treatment-naive HIV-1C infected individuals in Botswana, which was the first GWAS for HIV-1C acquisition and control of viral replication and the first GWAS in this population (Xie et al, 2016). Despite different types of clinical data in the compared cohorts (HIV infection & AIDS progression), this is an interesting and noteworthy replication. Currently we are working on the replication of our findings in other available datasets. 1. Svitin A. et al. (2014). GWATCH: a web platform for automated gene association discovery analysis. **2273F****Genetic basis of hypoxia-induced excessive erythrocytosis: Role of *SENP1* gene regulation.**

*P. Azad<sup>1</sup>, A. Akbari<sup>2</sup>, G. Chen<sup>3</sup>, D. Zhou<sup>1</sup>, O. Poulsen<sup>1</sup>, Y. Hsiao<sup>1</sup>, E. Bouhassira<sup>4</sup>, V. Bafna<sup>5</sup>, P. Mali<sup>6</sup>, G. Haddad<sup>1,5,6</sup>.* 1) Department of Pediatrics, University of California San Diego, La Jolla, CA; 2) Department of Computer Science and Engineering, University of California San Diego, La Jolla, CA; 3) Department of Bioengineering, University of California San Diego, La Jolla, CA; 4) Department of Medicine, Albert Einstein College of Medicine, Bronx, NY; 5) Department of Neurosciences, University of California, San Diego, La Jolla, CA; 6) Rady Children's Hospital, San Diego, CA.

Since polycythemia is a predominant trait in some high altitude dwellers (Chronic Mountain Sickness, CMS, or Monge's disease) but not others living at the same altitude in the Andes, we took advantage of this human "experiment in nature" and studied both populations (with CMS and without, non-CMS). In order to understand the molecular basis for polycythemia of high altitude, we generated a disease in-the dish-model by re-programming fibroblasts from CMS and non-CMS subjects. In addition, we have done whole genome sequencing of subjects from this region (CMS and non-CMS) to study whether there was a genetic adaptation to high altitude. Using both iPS cells and genomic data, we demonstrated that *SENP1* (a candidate gene) plays an important role in the polycythemia response to hypoxia in CMS. By altering *SENP1*, we converted the non-CMS into CMS cells and vice versa in our in-vitro studies. In this current study, using bioinformatics tools (PreCIOS), we prioritized the potential causal SNP(s) (out of the 95 differential SNPs) for up-regulating *SENP1* in CMS or preventing this up-regulation in non-CMS cells under hypoxia. We found 7 SNPs that could be critically linked to the upstream regulation in *SENP1* expression. In addition, we identified the transcriptional regulators that bind to the genomic region containing the candidate SNPs in the *SENP1* gene region. Indeed, when we compared the transcriptional response of CMS to that of non-CMS cells in hypoxia, we found that CMS cells up-regulated *SENP1*, suggesting that this up-regulation could underlie the excessive erythrocytosis present in the CMS population. Additionally, we are starting to evaluate the contribution of each candidate SNP (or their combination) in the hypoxia-induced up-regulation of *SENP1*, such as switching (A to G) the allele in CMS subjects for one shortlisted SNPs (rs11613781) in non-CMS, as we have done recently using CRISPR/Cas9. We conclude that the increased erythropoietic hypersensitivity to hypoxia in CMS subjects is genetic in nature and depends on an increase in *SENP1* expression under hypoxia. By combining the iPS technology with this unique Andean population that has adapted (or mal-adapted) to chronic hypoxia over thousands of years, we have built an in-vitro model to probe at the exact genetic mechanisms underlying this adaptation to high altitude.

**2274W****Identification of three novel loci associated with systemic lupus erythematosus (SLE) and evaluation of SLE genetics in drug repositioning.**

Yang<sup>1</sup>.* 1) The University of Hong Kong, Hong Kong, China; 2) Guangzhou Women and Children's Medical Center, Guangzhou, China; 3) Institute/department of Dermatology, no.1 Hospital, Anhui Medical University, Hefei, China; 4) Division of Genetics and Molecular Medicine, King's College London, London, UK; 5) Department of Epidemiology and Biostatistics, School of public Health, Anhui Medical University, Hefei, China; 6) Department of Dermatology, China-Japan Friendship Hospital, Beijing, China.

Systemic lupus erythematosus (SLE) is prototype autoimmune disease with a diverse spectrum of clinical symptoms, ranging from skin rash to end-organ damage. Through trans-ethnic genome-wide association studies (GWAS), we recently identified ten novel loci associated with SLE. In this study, we aimed to replicate loci with suggestive association signals in an additional 6,728 SLE cases and 8,631 healthy controls of Chinese ancestry. We identified three novel loci that passed the genome-wide significance, including *ST3AGL4* (rs13238909,  $P_{meta} = 4.40E-08$ ), *MFHAS1* (rs2428,  $P_{meta} = 1.17E-08$ ), *CSNK2A2* (rs2731783,  $P_{meta} = 1.08E-09$ ), and confirmed the association of *CD226* locus with SLE (rs763361,  $P_{meta} = 2.45E-08$ ). We further performed fine mapping analyses at the newly identified loci and found two putative causal variants in *CSNK2A2* locus. The putative causal variants reside in an enhancer and are associated with expression of *CSNK2A2* in B-lymphocytes, suggesting a potential mechanism of the association. To explore biological insight underlying the SLE susceptibility loci, we prioritized putative risk genes by integrating the GWAS findings with functional annotations. We identified 78 putative SLE risk genes and demonstrated that they are more likely to encode proteins interacting with molecular targets of approved SLE drugs. Our study also suggested that several drugs approved for other diseases might have effects on SLE patients. In summary, this study identified three novel loci associated with SLE and demonstrated the role of SLE GWAS findings in drug repositioning.

**Endometrial microRNA networks associated with pelvic inflammatory disease progression.** L. Dong<sup>1</sup>, C. O'Connell<sup>2</sup>, J. Xu<sup>3</sup>, H. Wiesenfeld<sup>4,5</sup>, S. Hillier<sup>4,5</sup>, T. Darville<sup>2</sup>, X. Zheng<sup>2</sup>. 1) Department of Biostatistics, University of North Carolina at Chapel Hill, Chapel Hill, NC; 2) Department of Pediatrics, University of North Carolina at Chapel Hill, Chapel Hill, NC; 3) College of Bioinformatics Science and Technology, Harbin Medical University, Harbin, China; 4) Department of Obstetrics, Gynecology, and Reproductive Sciences, University of Pittsburgh, Pittsburgh, PA; 5) Magee-Womens Research Institute, Pittsburgh, PA.

**Background and objectives:** *Chlamydia* (CT) and *gonorrhea* (GC) are the most common sex transmitted infection. Untreated infection can ascend from cervix to uterus and fallopian tubes resulting in pelvic inflammatory disease (PID). Our previous study revealed distinct blood mRNA transcriptome profiles associated with PID. MicroRNAs (miRNAs) modulate processing of up to 60% of human mRNA transcripts. The objective of this study is to determine human endometrial tissue miRNA networks associated with PID progression, key drivers of these networks and their target mRNAs. **Methods and results:** Endometrial miRNA from 57 women from two cohorts was profiled by seq based whole transcriptome assay. We compared profiles of women with clinical PID and endometrial GC and/or CT infection and inflammation (n=10), defined as cases, to those of asymptomatic women with cervical only infection and no inflammation (n=12), defined as controls, to determine disease-associated immune responses. We also compared the responses of these 10 cases to responses of 19 women who had pelvic pain, but no infection. Cases possessed a profile that distinguished them from controls, as well as women with pelvic pain without infection. The responses of asymptomatic women without inflammation but with cervical only infection were indistinguishable from asymptomatic, uninfected women. Weighted gene co-expression network analysis identified 4 miRNA modules (clusters of highly correlated miRNAs) associated with PID. Three out of four disease associated modules were validated in 5 women with subclinical PID who had asymptomatic endometrial infection and inflammation. The disease modules abated one month after curation of infection. These findings indicate the disease associated modules were driven by endometrial infection induced inflammation instead of abdomen pain. Experimentally validated and high-confidence predicted mRNA targets of disease modules were identified by Ingenuity Pathways Analysis, and validated by endometrial mRNA seq using 7 cases and 6 uninfected controls. The target mRNAs were enriched in T cell signaling, myeloid cell genes and cell growth and death pathways. The key miRNAs regulating these pathways were further revealed by miRNA-miRNA functional synergistic network analysis. **Conclusions:** Endometrial miRNA profiles reveal miRNA networks associated with PID progression that are driven by endometrial infection induced inflammation.

**In-depth analysis of differential DNA methylation reveals novel disease genes and pathways in SLE.** W. Yang, M. Guo, T.Y. Wang, Y.F. Wang, J.J. Shen, Y.L. Lau. University of Hong Kong, Hong Kong, China.

Systemic lupus erythematosus (SLE) is a prototype autoimmune disease with unclear pathogenesis. DNA methylation is an important regulatory mechanism on gene expression, which provides a key angle to understand disease mechanisms. Using public available methylation data for SLE, we performed integrative analyses of differentially methylated regions (DMR) and methylation sites with differential variability (DVS). We identified the most DMRs in T cells, while majority of DVSs were found in B cells, featuring hyper variability in enhancers. We observed a prominent T cell receptor (TCR) signaling cluster with consistent hypermethylation and a B cell receptor (BCR) cluster with high variability in SLE samples. Genes involved in innate immunity were often found hypomethylated, while adaptive immunity genes were featured with hypermethylation. Significant co-localization of DMRs and DVSs with SLE susceptibility loci was also observed. Using LASSO, a machine learning method, we selected a panel of CpGs that accurately distinguished SLE patients from healthy individuals, and correlated with disease activities. These differentially methylated genes may further help us understand the pathways involved in the disease, and to develop biomarkers for its diagnosis and treatment.

**RATIONALE:** CD4+ T helper cells are known to play a role in pathogenesis of asthma and are therefore good target tissues for elucidating disease mechanisms. In this study, we aimed to characterize differential gene and transcript level expression of CD4+ T cells in asthmatics and non-asthmatics from the Barbados asthma genetics study (BAGS). **METHODS:** Paired-end RNA-Seq on RNA from CD4+ T-cells isolated from 84 samples was performed on the Illumina HiSeq4000, using the TruSeq Total RNA Ribozero kit for library preparation. 10 samples were excluded from further analysis due to high percentages of ribosomal bases (greater than 20%). Low quality RNA-Seq read removal and adapter trimming were performed using BBDUK. The trimmed reads for all samples were mapped and assembled using the HISAT2 graph aligner and STRINGTIEv1.3.0 with the UCSC hg38 reference genome. Assembled transcripts from all samples were merged using STRINGTIEv1.3.0 to create a uniform set of transcripts and to re-estimate the transcript abundance. Gene/transcript expression tables were created with the Ballgown R package. Transcripts whose FPKM (fragments per kilobase of transcript per million mapped reads) measures had a cross-sample variance less than 1 were removed to filter out low abundance genes. Ballgown's "stattest" function was used to perform differential gene and transcript expression using FPKM measurements, between 43 atopic asthmatic cases and 19 non-atopic non-asthmatic controls. **RESULTS:** Among the 43 atopic asthmatics and 19 non-asthmatic controls included in the analysis, there were 8,416 genes and 24,060 transcripts that had transcripts with variance greater than 1 across all samples. Differential expression analysis identified 17 genes with a P-value less than 0.001. *ANAPC15* and *EPC1* were the most significant genes with a P-value of  $6.3 \times 10^{-2}$  and  $1.1 \times 10^{-4}$ , respectively. **CONCLUSIONS:** Differentially expressed genes like *ANAPC15* and *EPC1* might play a role in asthma pathogenesis. Future work will include incorporating additional subjects and using gene set enrichment analysis to identify gene regulatory networks associated with dysregulation of CD4+ T cells in asthma. Future analyses will also include identifying expression quantitative trait loci (eQTL) specific to cases and identify any novel eQTLs in cases compared to non-atopic controls.

**2278T**

**Leukocyte gene expression signatures of asthma severity.** J.A. Resztrak<sup>1</sup>, A.K. Farrell<sup>2</sup>, J.E. Mair-Meijers<sup>1</sup>, A. Alazizi<sup>1</sup>, S. Zilioli<sup>2</sup>, R. Pique-Regi<sup>1</sup>, R.B. Slatcher<sup>2</sup>, F. Luca<sup>1</sup>. 1) Center for Molecular Medicine and Genetics, Wayne State University, Detroit, MI; 2) Department of Psychology, Wayne State University, Detroit, MI.

Allergic asthma is the most common chronic disease in children in the industrialized world, and it remains the most common reason for hospitalization other than infections. There are striking disparities in asthma prevalence in the US population: African American children are 1.6 times overrepresented within asthmatics and three times more likely to be hospitalized and die as a consequence of asthma compared to European American children. GWA studies found several hundred SNPs associated with asthma (most of them located outside the coding regions), but the factors influencing asthma severity and response to therapy remain largely unknown. We followed a cohort of almost two hundred predominantly African American asthmatic children living in Detroit Metropolitan Area annually for a period of two years. We collected genotypic and extensive phenotypic information on over one hundred asthma-related variables, including asthma symptoms, medication use, pulmonary function, and others. Here we present the analyses of leukocyte RNA-seq in 165 subjects. Expectedly, blood cell composition has a major effect on gene expression, after correcting for technical and biological confounders. For example, we find 15808 genes (DEGs; FDR = 10%) whose expression is associated with lymphocyte proportion. Additionally, we performed eQTL mapping and identified 4325 eGenes (FDR = 10%), over a thousand of which have not previously been detected in GTEx blood data. Our eGenes are enriched for genes associated with GWAS catalog traits ( $OR \approx 1.14$ ,  $p_{val} \approx 0.0004$ ), and include 30 genes previously associated with asthma. This dataset will be useful to identify the genetic and environmental exposures that modify the molecular pathways and contribute to disease severity.

## 2279F

**Single-cell RNA-sequencing of bulk peripheral blood mononuclear cells from idiopathic multicentric Castleman disease (iMCD) reveals leukocyte heterogeneity underlying disease pathology.** M. Gonzalez<sup>1</sup>, D. Shilling<sup>2</sup>, F. Mafra<sup>1</sup>, J. Smiler<sup>1</sup>, C. Kao<sup>1</sup>, J. Garifallou<sup>1</sup>, R. Pellegrino<sup>1</sup>, D. Fajgenbaum<sup>2</sup>, H. Hakonarson<sup>1,3</sup>. 1) Center for Applied Genomics, The Children's Hospital of Philadelphia, Philadelphia, PA; 2) Division of Translational Medicine and Human Genetics, Hospital of the University of Pennsylvania, Philadelphia, PA; 3) Department of Pediatrics, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA.

Castleman disease (CD) describes a group of heterogeneous lymphoproliferative disorders that share a distinct spectrum of lymph node histopathological features, including atrophic or hyperplastic germinal centers, hypervascularization, polyclonal lymphoproliferation, and/or polytypic plasmacytosis. Hallmarks of idiopathic multicentric CD (iMCD) include multiple regions of enlarged lymph nodes, cytokine-driven multiple organ system impairment, and systemic inflammatory symptoms, which ultimately lead to a ~35% 5-year mortality rate. Despite approximately 1,500 cases of iMCD diagnosed per year in the US, very little is known about the cell types, signaling pathways and molecules that drive the disease. Therefore, we performed single-cell RNA-sequencing (scRNA-seq) to characterize 39,457 bulk peripheral blood mononuclear cells (PBMCs) isolated from an iMCD patient at distinct time points during his disease course; PBMCs were collected while the patient was in remission (no abnormal laboratory values or clinical features) and three days prior to admission to the intensive care unit for an acute flare episode, characterized by constitutional symptoms, ascites, thrombocytopenia, hypoalbuminemia, and kidney failure. The cellranger pipeline (10x Genomics, v.2.1.0) was used for initial analysis and aggregation of samples. 19,322 cells (17,327 mean reads/cell, 823 median genes/cell) were recovered from bulk PBMCs in flare and automated clustering identified 18 distinct cellular populations. 20,135 cells (16,283 mean reads/cell, 799 median genes/cell) were recovered from bulk PBMCs collected during remission identifying 21 distinct cellular populations. Further, single-cell transcriptomes from both time points were aggregated and normalized to allow comparison between immune cell populations in flare and remission. These comparisons indicate multiple population specific alterations and changes in gene expression during flares that may explain disease specific pathology. This collection of single-cell transcriptomes and distinct classification of cellular subsets provide a novel resource for understanding gene expression and cell population changes in iMCD flare.

Fava and Schurr contributed equally to this project.

**Background** Type-1 reactions (T1Rs) are pathological inflammatory episodes and main contributors to nerve damage in leprosy. Previous studies revealed a significant overlap in the genetic control of T1R with Crohn's disease. Here, we searched for rare coding variants as risk factors for T1R and evaluated to what extent such rare amino acid changes were shared with Parkinson's disease (PD), a neurodegenerative disease where inflammation is a key component. **Methods** Seven known T1R associated genes were targeted for deep resequencing in 474 leprosy-patients from Vietnam. Of these, 237 were T1R-affected cases that were compared to 237 T1R-free matched controls. The gene-wise enrichment of nonsynonymous variants was tested with both kernel based (SKAT) and burden methods. The impact of amino acid changes on protein structure was assessed with PyMol. Wild-type RAW cells and RAW cells edited with CRISPR/Cas9 to introduce T1R and PD associated mutations were challenged with BCG or *Mycobacterium leprae* for up to 6 hours. Upon infection, we estimate the impact of selected mutations in the ROS production and in apoptosis. **Results** Of the seven genes tested two showed statistical evidence of association with T1R. For the Parkin coding gene *PRKN* (formerly *PARK2*) seven rare variants were enriched in T1R-affected cases ( $p_{\text{SKAT-O}} = 7.4 \times 10^{-6}$ ). T1R-risk amino acids substitutions in Parkin were enriched in Parkin residuals observed mutated in patients suffering from PD ( $p = 1.1 \times 10^{-3}$ ). The second gene-wise association with T1R was found for the *LRRK2* were nonsynonymous variants were enriched in T1R-free controls ( $p_{\text{SKAT-O}} = 1.6 \times 10^{-4}$ ). This gene-wise association was driven almost entirely by the gain of function variant R1628P ( $p = 0.004$ ; OR = 0.29) that is a known PD risk factor in Asian populations. We observed that genome-edited RAW 1628 P/P mutants challenged with BCG and *M. leprae* had increased ROS production compared to wildtype cells. RAW 1628 P/P also strongly reduced apoptosis and necrosis increasing cell survival upon BCG challenge ( $p < 0.001$ ). **Conclusion** Amino acid mutations in *LRRK2* and *PRKN* are critically involved in the pathogenesis of T1R. The mutations displayed a strong pleiotropic effect with Parkinson's disease. Hence, neuroinflammation in PD and peripheral nerve damage in T1R share overlapping mechanisms of pathogenicity.

**Chromatin accessibility landscapes of large and small airway cells annotate multiple COPD susceptibility GWAS regions.** C.J. Benway, F. Du, M.H. Cho, E.K. Silverman, X. Zhou. Channing Division of Network Medicine, Brigham and Women's Hospital, Boston, MA.

Genome-wide association studies (GWAS) have identified hundreds of genome-wide significant loci for respiratory disease, including Chronic Obstructive Pulmonary (COPD), asthma, pulmonary fibrosis, lung function and COPD-related phenotypes. However, identification of causal variants and functional annotation in the appropriate cell type at these loci remain a major challenge. To gain a better understanding of COPD and other respiratory diseases, we sought to functionally annotate GWAS loci using chromatin accessibility profiling of small airway and bronchial epithelial cells from healthy human lungs. We performed Omni-ATAC-seq in small airway epithelial cells (SAEC) from two biological replicates and bronchial epithelial cells (NHBE) in one biological replicate as well as the 16HBE human bronchial epithelial cell line. We confirmed that Omni-ATAC-seq outperforms Fast-ATAC-seq in 16HBE cells with regard to mtDNA contamination, signal-to-noise, library complexity, and enrichment in annotated genomic regions such as transcription start sites and CTCF sites. We tested for enrichment of 22 COPD susceptibility GWAS loci in the lung epithelial ATAC-seq peaks. Sets of SNPs within GWAS loci were generated either by a heuristic or Bayesian fine-mapping approach. For the heuristic approach, LD proxy SNPs ( $LD r^2 > 0.8$ ) were determined for each lead SNP based on 1000 Genomes data. For the bayesian fine-mapping approach, candidate causal variants for each locus were determined using the Probabilistic Identification of Causal SNPs (PICS) algorithm. To aid in the functional annotation of COPD GWAS loci, we compared chromatin accessibility peaks and signals of these different cell types. Both primary lung subtypes were highly correlated with one another, but the 16HBE bronchial epithelial cell line was only moderately correlated with its primary counterpart. We identified 9,112 differentially accessible peaks ( $FDR < 0.05$ ) between large and small airway epithelial cells. Further, we profiled genome-wide footprinting of 533 transcription factors using the Protein Interaction Quantification (PIQ) computational method. Our work confirms the performance of Omni-ATAC-seq, and suggests cell lines substantially differ from primary cells in chromatin accessibility. These factors should be considered when mapping respiratory disease loci. Further work identifying peak enrichment in fine-mapping regions is ongoing.

**Phenotypic clustering reveals distinct subtypes of polycystic ovary syndrome with novel genetic associations.** M. Dapas<sup>1</sup>, F.T.J. Lin<sup>1</sup>, R. Sisk<sup>1</sup>, R.S. Legro<sup>2</sup>, M. Urbanek<sup>1,3,4</sup>, M.G. Hayes<sup>1,4,5</sup>, A. Dunai<sup>6</sup>. 1) Department of Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL; 2) Department of Obstetrics and Gynecology, Penn State College of Medicine, Hershey, PA; 3) Center for Genetic Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL; 4) Center for Reproductive Science, Northwestern University Feinberg School of Medicine, Chicago, IL; 5) Department of Anthropology, Northwestern University, Evanston, IL; 6) Division of Endocrinology, Diabetes & Bone Disease, Icahn School of Medicine at Mount Sinai, New York, NY.

Understanding the genetic architecture of complex diseases is a central challenge in human genetics. Often defined according to arbitrary diagnostic criteria, complex diseases can represent the phenotypic convergence of numerous genetic etiologies. Identifying and addressing genetic heterogeneity in complex diseases could increase power to detect causal variants and improve treatment efficacy. Polycystic ovary syndrome (PCOS) is a complex disease diagnosed by the presence of at least two of its three cardinal reproductive features: hyperandrogenism, chronic anovulation, and polycystic ovarian morphology. Accordingly, there are four different affected phenotypes with a net prevalence of 15% in women of reproductive age. PCOS is also frequently associated with insulin resistance, obesity, and dysglycemia. This phenotypic variation may reflect an underlying genetic heterogeneity, which would limit findings from genome-wide association studies (GWAS). We performed this study to test the hypothesis that there are subtypes of PCOS with distinct genetic architectures. Using data from 932 cases from our previously published GWAS (Hayes et al., 2015), we performed unsupervised hierarchical clustering on eight adjusted quantitative traits: testosterone, dehydroepiandrosterone sulfate (DHEAS), insulin, glucose, BMI, sex hormone binding globulin (SHBG), luteinizing hormone (LH), and follicle-stimulating hormone (FSH). The clustering revealed two distinct phenotypic subtypes: 1) a "reproductive" group (23.4%) characterized by higher LH and SHBG levels with relatively low BMI and insulin levels and 2) a "metabolic" group (37.4%) characterized by higher BMI and glucose and insulin levels with relatively low SHBG and LH levels. We then repeated the GWAS limiting the cases to either the reproductive or metabolic subtype. We identified alleles in five novel loci that were associated with the reproductive PCOS subtype at genome-wide significance (*PRDM2/KAZN1*,  $P=3.3 \times 10^{-10}$ ; *IQCA1/ACKR3*,  $P=1.4 \times 10^{-9}$ ; *BMPR1B/UNC5C*,  $P=4.6 \times 10^{-9}$ ; *CDH10*,  $P=1.2 \times 10^{-8}$ ; *ANXA6*,  $P=1.2 \times 10^{-8}$ ) and one locus that was significantly associated with the metabolic subtype (*KCNH7/FIGN*,  $P=1.0 \times 10^{-8}$ ). These findings support the hypothesis that there are reproductive and metabolic subtypes of PCOS with distinct genetic architectures and demonstrate how precise phenotypic delineation can be more powerful than increases in sample size for genetic association studies.

## 2283W

**Characterization of the genomic and gene expression of *SEMA3D* in multifactorial Hirschsprung disease.** . Gunadi<sup>1</sup>, NYP. Budi<sup>1</sup>, K. Iskandar<sup>1,2</sup>, A. Makhmud<sup>1</sup>. 1) Faculty of Medicine, Public Health and Nursing, Universitas Gadjah Mada, Yogyakarta, Indonesia; 2) UGM Academic Hospital.

**Background:** Recently, the *semaphorin 3D (SEMA3D)* gene has been implicated in intestinal aganglionosis. We aimed to characterize the genomic and gene expression of *SEMA3D* in the development of Hirschsprung disease (HSCR) in Indonesia. **Methods:** We performed Sanger sequencing on 54 HSCR patients to find pathogenic variants in *SEMA3D*. Next, we determined *SEMA3D* expression in the colon of 18 HSCR patients and 13 non-HSCR controls by quantitative real-time polymerase chain reaction (RT-PCR). **Results:** Sanger sequencing showed no rare variants in the *SEMA3D*, but one common variant in exon 17 (rs7800072). The risk allele frequency (C) at rs7800072 among HSCR patients was 22.5%. Quantitative RT-PCR showed that the *SEMA3D* expression was strongly up-regulated (5.5-fold) in the ganglionic colon of HSCR patients compared to control colon ( $10.8 \pm 2.1$  vs.  $13.3 \pm 3.9$ ;  $p=0.034$ ). **Conclusion:** *SEMA3D* gene expression, but not *SEMA3D* rare variant, might contribute to the development of HSCR in Indonesia. In addition, this study is the first report of *SEMA3D* investigation in Asian ancestry.

Cho<sup>4</sup>, TOPMed PFT, COPD and Lung Working Groups. 1) Center for Public Health Genomics, University of Virginia, Charlottesville, VA; 2) Department of Biostatistics, University of Michigan; 3) Department of Medicine, Brigham and Women's Hospital; 4) Channing Division of Network Medicine, Brigham and Women's Hospital and Harvard Medical School; 5) Department of Medicine, Columbia University; 6) Department of Epidemiology, Human Genetics & Environmental Sciences, UTHealth School of Public Health; 7) Division of Biomedical Informatics and Personalized Medicine, Department of Medicine, University of Colorado School of Medicine Anschutz Medical Campus; 8) Epidemiology Branch, National Institute of Environmental Health Sciences; 9) Department of Biostatistics, Boston University School of Public Health; 10) Department of Medicine, Boston University School of Medicine; 11) Department of Medicine, University of Maryland; 12) Division of Sleep and Circadian Disorders, Department of Medicine, Brigham and Women's Hospital; 13) Division of Pulmonary, Critical Care and Sleep Medicine, University of Washington; 14) Departments of Epidemiology and Medicine, University of Washington.

Chronic obstructive pulmonary disease (COPD), the third leading cause of death in the United States, is diagnosed by a decrease in lung function, namely forced expiratory volume in one second (FEV1) and its ratio to forced vital capacity (FEV1/FVC). Genome-wide association studies (GWAS) of lung function and COPD have already identified over 100 loci associated with one or more of these measures and conditions. We performed whole genome sequence (WGS) analysis of lung function traits (FEV1, FEV1/FVC and FVC) and COPD in the NHLBI Trans-Omics for Precision Medicine (TOPMed) Program to examine evidence for rare and/or common trait-associated variants that were not identified in previous GWAS. WGS had deep (~30X) coverage with joint-sample variant calling and comprehensive variant level quality control in >50,000 TOPMed samples (freeze 5b). Lung function measures and COPD were analyzed in a subset of 8,332 subjects from four population-based and two family-based studies, as well as 8,471 individuals from the COPD-ascertained COPDGene study. These samples included 4,232 moderate-to-severe COPD cases out of which 1,644 had severe COPD. We conducted pooled analyses combining White (n=11,667), African Americans (n=3,912), Hispanic (n=711) and Asian (n=515), in addition to race/ethnic stratified analyses, with covariate adjustment for age, sex, height, weight, current and former smoking, pack-years of smoking, PCs of ancestry and sequencing center. After removing variants with Heterozygosity Count < 30, single variant quantitative trait analysis of population- and family-based samples identified novel associations with FVC in Whites near *GALR1* (minor allele frequency [MAF]=0.39;  $P=3 \times 10^{-8}$ ) and with FEV1 in African Americans near *LGALS8* (MAF=0.04;  $P=1.5 \times 10^{-8}$ ). In combined analysis across population-based and COPD-ascertained samples, we identified novel loci for FEV1/FVC near *ZNF462* (MAF=0.39;  $P=3.2 \times 10^{-8}$ ) in pooled analysis of all race/ethnic groups, and for FEV1 near *GALNT18* (MAF=0.30;  $P=4.3 \times 10^{-8}$ ) and FVC near *CMIP* (MAF=0.13;  $P=1.3 \times 10^{-8}$ ) in stratified analysis of African Americans. We further identified a novel association for moderate-to-severe COPD in pooled analysis of all race/ethnic groups near *GRK7* (MAF=0.006;  $P=3.4 \times 10^{-8}$ ). Replication of these findings will be needed. Our study thus identified multiple novel signals for lung function in African Americans and multi-ethnic samples, demonstrating the benefits of dense coverage across the genome by WGS. .

**Clonal expansion and diversification of cancer-associated mutations in endometriosis and normal endometrium.** H. Nakaoka<sup>1</sup>, K. Suda<sup>2</sup>, K. Yoshihara<sup>2</sup>, T. Enomoto<sup>2</sup>, I. Inoue<sup>1</sup>. 1) National Institute of Genetics, Mishima, Japan; 2) Department of Obstetrics and Gynecology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.

Endometriosis is characterized by ectopic endometrial-like epithelium and stroma. A more complete molecular characterization of the pathogenesis of endometriosis is to develop better treatments. Whole-exome and target-gene sequencing were performed for 107 ovarian endometriotic epithelium and 82 normal uterine endometrial epithelium samples isolated from frozen sections by laser-microdissection. In both normal and endometriotic epithelium samples, numerous somatic mutations were identified within genes frequently mutated in endometriosis-associated cancers. Analysis of mutant allele frequency (MAF) in endometriotic epithelium revealed a unique mutational landscape, wherein *KRAS* was frequently mutated, with a higher MAF accompanied by arm-level copy number alterations, leading to clonal expansion of cells carrying these changes. MAF distributions in normal endometrium were lower than in endometriotic epithelium. To show that each endometrial gland was clonal in origin, we prepared and sequenced single endometrial glands and found that each gland carried a clonal state of distinct mutations, proving how heterogeneous and mosaic-like the cellular and genomic architecture of endometrial epithelium is. The identified somatic mutations can be the pathogenic footprints showing a lineage from normal uterine epithelium to endometriosis to subtypes of ovarian cancers, corroborating with previous epidemiological evidence. Remarkable increases in MAF of *KRAS* mutations in endometriotic epithelium suggests that retrograde flow of endometrial cells already harboring *KRAS* mutations have selective advantages at ectopic sites, leading to the development of endometriosis. Our genomic study supports Sampson's century-old retrograde hypothesis of the origin of endometriosis.

**Primary sclerosing cholangitis, a common co-morbidity in inflammatory bowel disease.** J. Koskela<sup>1,2,3</sup>, M.D. Voskuil<sup>4</sup>, M. Rivas<sup>5</sup>, B. Avila<sup>2,6</sup>, C. Stevens<sup>2,6</sup>, S. Ripatti<sup>7</sup>, A.N. Ananthakrishnan<sup>7</sup>, R. Xavier<sup>8</sup>, H. Soko<sup>6</sup>, R.K. Weersma<sup>4</sup>, M. Färkkilä<sup>3</sup>, M.J. Daly<sup>2,6</sup>. 1) Institute for Molecular Medicine Finland (FIMM), University of Helsinki, Finland, Helsinki, Uusimaa, Finland; 2) Broad Institute of MIT and Harvard, Cambridge, MA, USA; 3) Helsinki University and Helsinki University Hospital, Clinic of Gastroenterology Helsinki, Finland; 4) Department of Gastroenterology and Hepatology, University of Groningen, University Medical Center Groningen, Groningen, the Netherlands; 5) Department of Biomedical Data Science, Stanford University; 6) Analytic and Translational Genetics Unit, Massachusetts General Hospital, Boston, MA, USA; 7) Massachusetts General Hospital and Harvard medical school, Boston, MA, USA; 8) Department of Gastroenterology, Saint Antoine Hospital, APHP, Paris, France.

Primary sclerosing cholangitis (PSC) is a rare and progressive inflammatory disease of the bile ducts with no effective therapy currently available. While the prevalence of PSC has been reported only at 15.3-32/100,000, PSC is the most common cause of liver transplantations in Nordic countries. Additionally, PSC patients are at high risk of cholangiocarcinoma (up to 1000x) compared to population control and substantial risk of colorectal cancer. PSC is commonly associated with inflammatory bowel disease (IBD) as ~70% of PSC-patients present with PSC-IBD. When co-occurring with IBD, PSC is most often (80% of cases) associated with ulcerative colitis. So far it is unclear whether PSC-IBD is an independent entity or whether it only manifests as an IBD subtype, however up to 8% of patients with IBD have diagnostic findings in MRI. A recent (and largest) genome wide association study using imputed array data of 4,796 PSC cases estimated the genetic correlation of IBD and PSC to 29%, while confirming most previously reported variants and identifying 4 new loci, as up to 19 loci have now been associated with PSC. We are currently analyzing the largest whole exome sequencing (WES) study on PSC, aiming at meta-analyzing > 1000 patients of European and Finnish ancestry. So far, we have finished the analysis of 511 Finnish samples and 8913 population controls. These PSC patients already represent more than 10% of total estimated Finnish PSC population. In addition to DNA, deep phenotyping and health status information, sequential endoscopic retrograde cholangiographic examinations (ERC), biliary cytology, bile samples have been collected from the Finnish patients. Out of the 19 loci described so far, we identified nominally significant ( $p < 0.05$ ) associations in 8 genes reported earlier and in 12 loci within a 500kb window of the previously implicated gene ( $p < 0.01$ ). After excluding significant associations from a large WES study on IBD (unpublished), we confirm a strong MHC component and two suggestive loci specific to PSC in *3p21.31* with protective intronic variant on *RNF123* (OR=0.7, case MAF 20%,  $p=3.22e-5$ ) and a risk-carrying missense variant on *QRICH1* (OR=1.6, case MAF 12%,  $p=9.19e-6$ ), both regions being described associated with IBD previously. Interestingly, *RNF123* (probability of LoF intolerance = 0.97) is a neighbor gene to *MST1*, a previously described PSC risk locus. The Finnish results are available at: <http://35.233.15.189/pheno/PSC.txt>.

## 2287T

**Multi-omic analysis of discordant and concordant sib-pairs with inflammatory bowel disease.** A.B. Stiemke<sup>1</sup>, S.R. Brant<sup>2,3</sup>, C.L. Simpson<sup>1</sup>. 1) Department of Genetics, Genomics, and Informatics, University of Tennessee Health and Science Center, Memphis, TN; 2) Department of Medicine, Department of Genetics and the Human Genetics Institute of New Jersey, Rutgers, The State University of New Jersey, New Brunswick and Piscataway, NJ; 3) Meyerhoff Inflammatory Bowel Disease Center, Department of Medicine, School of Medicine and Department of Epidemiology, School of Public Health, Johns Hopkins University, Baltimore, MD.

**Background:** Inflammatory bowel disease (IBD) is an immune-mediated chronic intestinal disorder that is typically divided into two distinct types; ulcerative colitis (UC) and Crohn's disease (CD). Over 240 IBD susceptibility loci have been identified however, much of the etiology remains unexplained and even within families the disease can have a heterogeneous clinical presentation. Here we present a study attempting to discern the cause of that heterogeneity in discordant and concordant sib-pairs by comparing whole exome sequencing, epigenetic differences using DNA methylation analysis and gene expression using RNAseq. **Methods:** A total of 96 discordant and concordant sib-pairs were included in the study. Genomic DNA and RNA were extracted from peripheral blood mononuclear cells that were isolated using cell sorting from whole blood. DNA methylation values were measured using the Illumina EPIC array. Whole exome sequencing was performed using the Illumina TruSeq Exome kit, and RNAseq was performed using the Illumina RNA Kit v2. **Results:** Current results have identified over 5000 variants that are being filtered and prioritized for further analysis and cross comparison to additional datasets, as well as employing integrative approaches. Additional results will be presented. **Conclusion:** Combining data from multiple technologies is an important next step for interpreting the results of genome-wide association studies (GWAS) and there is currently no agreement on the best approach for integrating these data. Given the known genetic and clinical heterogeneity in IBD, using discordant and concordant sib-pairs attempts to leverage the expected sharing between the sibs as supporting information to inform future studies.

## 2288F

**Genetic association between human leukocyte antigen (HLA)-DR, -DQ, -DP and gallstone disease in Han Chinese.** H. Yang<sup>1</sup>, P. Yang<sup>2,3,4,5</sup>, C. Tsa<sup>2,4</sup>, C. Tsa<sup>2,4</sup>, T. Liu<sup>2,4</sup>, K. Ho<sup>2,4</sup>, J. Lee<sup>2,3,4</sup>, M. Li<sup>2,4</sup>, D. Chu<sup>2,4</sup>, F. Lee<sup>2,4</sup>, H. La<sup>2,4</sup>, S. Shyr<sup>6</sup>, S. Lee<sup>6</sup>, C. Chung<sup>6</sup>, Y. Wu<sup>6</sup>, P. Lin<sup>1</sup>, Y. Lien<sup>1</sup>, C. Lin<sup>1</sup>, M. Lin<sup>1</sup>, S. Shih<sup>3,4,7</sup>, Y. Lee<sup>1,8,9,10</sup>. 1) Department of Medical Research, MacKay Memorial Hospital, New Taipei City, Taiwan; 2) Department of General Surgery, MacKay Memorial Hospital, Taipei, Taiwan; 3) Department of Medicine, MacKay Medical College, New Taipei City, Taiwan; 4) Department of Nursing, MacKay Junior College of Medicine, Nursing, and Management, Taipei, Taiwan; 5) Department of Pharmacology and Graduate Institute of Medical Sciences, Taipei Medical University, Taipei, Taiwan; 6) Department of Nursing, MacKay Memorial Hospital, Taipei, Taiwan; 7) Division of Gastroenterology, Department of Internal Medicine, MacKay Memorial Hospital, Taipei, Taiwan; 8) Department of Pediatric Endocrinology, MacKay Children's Hospital, Taipei, Taiwan; 9) Institute of Biomedical Sciences, MacKay Medical College, New Taipei City, Taiwan; 10) Department of Pediatrics, School of Medicine, College of Medicine, Taipei Medical University, Taipei, Taiwan.

**Background and Goal:** Biliary calculi in gallbladder induce latent and persist inflammatory responses and related multiple symptoms called gallstone disease (GSD). We know the pathological and environmental risk factors of GSD. However, the immune-regulation in GSD are still elusive. Human leukocyte antigens (*HLA*) are correlated with many gastrointestinal disorders and expressed in gallbladder epithelial cells. In this study, we investigated whether the *HLA* will link to GSD susceptibility. **Methods:** Genomic DNA was isolated from 577 GSD patients and 371 gallstone-free controls. *HLA-DRB1*, *-DQB1*, *-DPB1* sequence variants were typed using Sequence-Based Typing and identified by IMGT database alignment. Differences in the frequencies of these alleles between GSD patients and control subjects were evaluated using the chi-squared test with Yates' correction and Fisher's exact test where appropriate. The odds ratio (OR) and 95% confidence interval (95% CI) for each allele were calculated. Haplotype and Hardy-Weinberg Equilibrium test were evaluated by Pypop 0.7.0. **Results:** We found the associations between GSD and *HLA* compared to controls. *HLA-DRB1\*12:02* (OR=1.36, *P*=0.04), *-DRB1\*12:01* (OR=1.68, *P*=0.02), *-DRB1\*16:02* (OR=0.60, *P*=0.01). Serotype of *DRB1\*02* (OR=1.49, *P*=0.002); *DRB1\*16* (OR=0.59, *P*=0.009). *HLA-DQB1\*03:01* (OR=1.30, *P*=0.01). Haplotype *HLA-DRB1\*12:01-DQB1\*03:01* (OR=1.70, *P*=0.02). *DRB1\*16:02-DQB1\*05:02* (OR=0.61, *P*=0.01). *DRB1\*12:01-DPB1\*05:01* (OR=2.29, *P*=0.01). *DRB1\*16:02-DPB1\*05:01* (OR=0.51, *P*=0.006). *DRB1\*12:01-DQB1\*03:01-DPB1\*05:01* (OR=2.22, *P*=0.02). *DRB1\*16:02-DQB1\*05:02-DPB1\*05:01* (OR=0.57, *P*=0.02). **Conclusions:** Our finding is the first report in specific *HLA* correlate to GSD. Our data facilitated an evaluation of the effects of individual *HLA* alleles consisting of disease-prone/disease-resistant.

**2289W**

**Association between the *SLCO1B* locus and alcohol-associated chronic pancreatitis.** T. Nagpal<sup>1</sup>, P. Greer<sup>1</sup>, C. Shelton<sup>1,2</sup>, D. Yadav<sup>1</sup>, D.C. Whitcomb<sup>1,2</sup>, NAPS2 Consortium. 1) Gastroenterology, Hepatology and Nutrition, University of Pittsburgh, Pittsburgh, PA; 2) Department of Human Genetics, University of Pittsburgh, Pittsburgh, PA.

**Background:** Chronic pancreatitis (CP) is an acquired, complex, progressive, fibro-inflammatory disorder of the pancreas characterized by variable atrophy, fibrosis, pain, pancreatic exocrine and endocrine insufficiency and dysplasia. Multiple pathogenic genetic variants were originally identified by linkage (*CFTR*, *PRSS1*) and candidate gene studies (*SPINK1*, *CTRC*, *CPA1*, *CASR*). We conducted the first 2-stage GWAS using the North American Pancreatitis Study 2 (NAPS2) consortium cohort (Whitcomb, *Nature Genetics*. 2012) with 676 cases and 4,507 controls, followed by 910 cases and 4,170 controls to identify a protective *PRSS1-PRSS2* locus and *CLDN2* risk locus. Additional loci with suggestive association were identified, including loci at 12p12.1–12p12.2 ( $P < 10^{-5}$ ). **Aim:** To expand the NAPS2 cohort of pancreatitis patients and identify potential pancreatitis risk alleles on chromosome 12. **Methods:** Well-phenotyped patients with recurrent acute pancreatitis (RAP) and CP were recruited into the NAPS2 cohort. 25 common SNPs that spanned the region of interest across 12p12.1–12p12.2 were genotyped. The allele frequencies in alcohol-CP/RAP ( $n = 433$ ) vs non-alcohol-CP/RAP ( $n = 762$ ) cases were compared using Fisher's exact test. Pancreatic tissue samples that underwent RNA-Seq were examined for expression of candidate genes. **Results:** 8 out of the 25 variants are in linkage disequilibrium ( $LD > 0.8$ ) and form a haplotype block with lead SNPs rs11045681 and rs11045699 ( $LD = 1$ ). Both SNPs are deleterious missense mutations in *SLCO1B7* (SIFT scores of 0 and 0.01) and negatively associated with alcohol-related pancreatitis ( $P = 6.3 \times 10^{-6}$  and  $OR = 0.61$  for rs11045681;  $P = 3.1 \times 10^{-6}$  and  $OR = 0.60$  for rs11045699). These genes produce organic anion transporter proteins and are mainly expressed in the human liver. Specifically, *SLCO1B1* and *SLCO1B3* uptake complex bile acids, hormones, etc. from the blood into the liver. RNA-Seq identified expression of *SLCO1B3* transcript in pancreatic tissue from patient with RAP. **Conclusion:** The *SLCO1B3-SLCO1B1-SLCO1B7* haplotype was underrepresented in alcoholic pancreatitis patients and may be protective against alcohol-related pancreatitis. We hypothesize that expression of these transporters in the regenerating pancreas after an acute pancreatitis attack may increase toxicity in pancreatic cells. Lack of ectopic expression, as expected from this haplotype, results in protection from the exposure to alcohol and tobacco in alcoholic CP.

**Discovery of novel genetic loci for kidney traits using whole genome sequencing: The trans-omics for precision medicine (TOPMed) project.** B.M. Lin<sup>1</sup>, L. Raffield<sup>2</sup>, J. Brody<sup>3</sup>, J.A. Perry<sup>4</sup>, D.Y. Lin<sup>1</sup>, N. Franceschini<sup>5</sup>, TOPMed Kidney Working Group. 1) Department of Biostatistics, University of North Carolina at Chapel Hill, Chapel Hill, NC; 2) Department of Genetics, University of North Carolina at Chapel Hill, Chapel Hill, NC; 3) Department of Epidemiology, University of North Carolina at Chapel Hill, Chapel Hill, NC; 4) Cardiovascular Health Research Unit, University of Washington, Seattle, WA; 5) Department of Medicine, University of Maryland, Baltimore, MD.

Chronic kidney disease (CKD) is a common but frequently unrecognized medical condition that is associated with high morbidity and mortality. Presence of CKD is defined by low estimated glomerular filtration rate (eGFR), a heritable measure of kidney function. To identify genetic loci for eGFR, we conducted whole genome sequencing analysis of 23,732 participants of 10 multi-ethnic (European, African, East Asian, and Hispanic) cohort studies within the NHLBI TOPMed Project. An extensive, centralized quality control was performed in the sequencing data. Calibrated serum creatinine was used to estimate eGFR, which was inverse normalized within study and ethnic groups and rescaled to recover original trait variances. We applied linear mixed models adjusted for age, sex, study, and ethnicity; the variance components were modeled by the genetic relationship matrix estimated from the whole genome sequencing data. In single-variant tests with minor allele counts  $> 10$ , there was no evidence of inflation ( $\lambda = 1.009$ ). Four loci were significantly associated with eGFR at the genome-wide significance threshold of  $P = 5.0 \times 10^{-8}$ , including three novel loci (*NBPF7*, rs184708696, MAF 0.04%,  $P = 2.95 \times 10^{-8}$ ; *BOLL*, rs375059924, MAF 0.07%,  $P = 4.57 \times 10^{-10}$ ; and *FAM46A*, rs143018620, MAF 0.09%,  $P = 2.13 \times 10^{-9}$ ). At the *FAM46A* locus, the signal extended for 94.2 kb upstream of the gene and was comprised of several highly correlated low frequency variants present in individuals of East Asian ancestry ( $n = 2,208$ ). Compared to individuals with the rs143018620 reference allele, each additional copy of the minor allele increased eGFR by 8.9 ml/min/1.73m<sup>2</sup> (standard error = 1.5 ml/min/1.73m<sup>2</sup>). Several signals that almost reached genome-wide significance were located in known eGFR loci, including *GATM*, *GCKR*, *BCAS3*, and *PDILT/UMOD*. Gene-based burden tests of loss of function variants with  $MAF < 1\%$  did not reach genome-wide significance. In conclusion, analyses of deep sequenced TOPMed whole genome sequencing in multi-ethnic studies have identified three novel genome-wide significant loci for eGFR, including a rare, long-range haplotype specific to East Asians that confers a protective effect for kidney function.

**2291F**

**Genetic analysis of 400 patients with aHUS refines understanding and implicates a new gene in this disease.** *F. Bu<sup>1,2</sup>, Y. Zhang<sup>1</sup>, K. Wang<sup>3</sup>, N. Ghiringhelli Borsa<sup>1</sup>, M. Jones<sup>1</sup>, A. Taylor<sup>1</sup>, E. Takanami<sup>1</sup>, N. Meyer<sup>1</sup>, K. Frees<sup>1</sup>, C. Thomas<sup>1</sup>, C. Nester<sup>1,4</sup>, R. Smith<sup>1,4</sup>.* 1) Molecular Otolaryngology and Renal Research Laboratories, University of Iowa, Iowa City, IA, USA; 2) Medical Genetics Center, Southwest Hospital, Chongqing, China; 3) College of Public Health, University of Iowa, Iowa City, IA, USA; 4) Divisions of Nephrology, Department of Internal Medicine and Pediatrics, Carver College of Medicine, University of Iowa, Iowa City, IA, USA.

Atypical hemolytic uremic syndrome (aHUS) is a life-threatening thrombotic microangiopathy (TMA) that primarily affects the kidney although other organ involvement can be seen. Dysregulation of the alternative pathway of complement at the endothelial cell surface triggered by a variety of events has been implicated in disease pathogenesis. Genetic variation in complement genes and autoantibody against complement proteins are known to be predisposing factors, however the interpretation of variant effect in known aHUS genes can be ambiguous. In addition, in half of patients genetic/autoimmune causality is unclear. In this study, we sequenced and analyzed 93 TMA-related genes in 516 aHUS patients. 400 patients passed controls for sequencing quality, population stratification and relatedness. 63,345 non-Finnish European subjects from the Genome Aggregation Database and 600 in-house healthy subjects were used as two control groups. We applied the Fisher's exact, modified Poisson exact and SKAT-O tests to show that aHUS patients are enriched for novel/ultra-rare variants in the *CFH*, *C3*, *CD46*, *CFI* and *DGKE* genes. We show that variants accumulate in featured domains of *CFH*, *CD46* and *C3*, and using a sliding-window analysis, propose a minor allele frequency of 0.1% as the threshold above which a variant in known aHUS genes should not be considered pathogenic unless significant association is reported. Based on this threshold and a literature review, we reclassify 20 variants previously implicated in aHUS as non-pathogenic. In addition, we show that aHUS patients are not enriched for multiple causal variants. Finally, we implicate *VTN*, which encodes an inhibitor of the terminal complement pathway, as an aHUS-associated gene.

Stefansson<sup>1,2</sup>.* 1) deCODE genetics/Amgen, Inc., Reykjavik, Iceland; 2) Faculty of Medicine, University of Iceland, Reykjavik, Iceland; 3) Department of Immunology, Landspítali University Hospital, Reykjavik, Iceland; 4) Department of Internal Medicine, Landspítali University Hospital, Reykjavik, Iceland; 5) Department of Obstetrics and Gynecology, Landspítali University Hospital, Reykjavik, Iceland; 6) School of Engineering and Natural Sciences, University of Iceland, Reykjavik, Iceland.

Gallstones are responsible for one of the common diseases in the Western world. Due to the threat of complications, such as acute pancreatitis, it is commonly treated with cholecystectomy. We performed a meta-analysis of two genome-wide association studies of gallstone disease from Iceland and the UK, totaling 27,174 cases and 736,838 controls, uncovering 21 novel variants at 20 loci that associate with the disease. Two distinct low frequency missense variants in a gene involved in bile acid transport associate with an increased risk of gallstone disease. Based on these associations and reported functional studies, we conclude that lower bile acid transport is accompanied by greater risk of gallstone disease. Two other low frequency missense variants in other genes also associate with an increased gallstone disease risk. Additionally, we describe 17 novel common variants that associate with gallstone disease. Taken together with replication of previously reported variants, this highlights the role of cholesterol metabolism and the enterohepatic circulation of bile acids in gallstone disease.

Hayes<sup>1</sup>. 1) Northwestern University Feinberg School of Medicine, Chicago, IL; 2) Vanderbilt University Medical Center, Nashville, TN; 3) Cincinnati Children's Hospital Medical Center, Cincinnati, Ohio; 4) Children's Hospital of Philadelphia, Philadelphia, PA; 5) Geisinger, Danville, PA; 6) Pennsylvania State University, State College, PA; 7) University of Pennsylvania, Philadelphia, PA; 8) Marshfield Clinic Research Institute, Marshfield, WI; 9) University of Washington Medical Center, Seattle, WA; 10) Icahn School of Medicine at Mount Sinai, New York, NY.

Polycystic ovary syndrome (PCOS) is the most common endocrine disorder affecting 5-15% of reproductive age women worldwide. It is a leading risk factor for infertility and type 2 diabetes in females, but its genetic etiology is highly complex hindering diagnosis and treatment in clinical practice. To date, Genome-Wide Association Studies (GWAS) of PCOS have identified 30 genome-wide significant variants spanning 20 unique loci, although these account for a limited proportion of the estimated heritability. Leveraging integrated phenotype and genotype data of 83,717 multi-ethnic individuals from the eMERGE (electronic MEDical Records and GENomics) network, we constructed a polygenic risk score (PRS) for PCOS by summing the allele dosage of the susceptibility variants in each individual weighted by the reported effect size. The same phenome-wide association study (PheWAS) was performed in an independent biobank sample (BioVU, n=18,370) to replicate our finding. We also performed comparative PheWAS using individual risk variants as well as the PRS to identify unique risk factors with high pleiotropy and/or comorbidity with PCOS. We identified several clinical phenotypes associated with the PRS for PCOS approaching phenome-wide significance ( $P < 2.5 \times 10^{-5}$ ) that may be either symptomatic or cryptogenic, including neoplasms and reproductive diseases such as 'Malignant neoplasm of renal pelvis' ( $P = 1.44 \times 10^{-4}$ , OR=0.88), 'Polycystic ovaries' ( $2.04 \times 10^{-4}$ , OR=1.08), 'Viral hepatitis C' ( $5.48 \times 10^{-4}$ , OR=0.96), and 'Ovarian dysfunction' ( $1.01 \times 10^{-3}$ , OR=1.06). The phenotype-PRS association of 'Polycystic ovaries' ( $P = 0.047$ , OR=1.21) was confirmed and remained significant in our replication sample. In the single variant PheWAS, two phenotypes reached phenome-wide significance: 'Neuralgia, neuritis, and radiculitis NOS' (rs2272046, *HMG2*,  $P = 9.75 \times 10^{-5}$ , OR=1.36) and 'Type 1 diabetes with renal manifestations' (rs705702, *SUOX*,  $P = 2.30 \times 10^{-5}$ , OR=1.27). Several of these associations were previously unknown, thereby providing new insight into the etiology of PCOS. Our findings demonstrate that individual genome-phenome data available from electronic health records can provide opportunities to stratify patients' genetic risk of PCOS and discover the potential shared biology between PCOS and other diseases.

**2294F****Genetic variation in the *SIM1* locus is associated with erectile dysfunction.**

Van Den Eeden<sup>1</sup>. 1) DOR, Kaiser Permanente, Oakland, CA; 2) Department of Bioengineering and Therapeutic Sciences, University of California San Francisco, San Francisco, California, 94158, USA; 3) Institute for Human Genetics, University of California San Francisco, San Francisco, California, 94158, USA; 4) Division of Medical Genetics, University of Washington School of Medicine, Seattle, Washington, 98195, USA; 5) Department of Epidemiology and Biostatistics, University of California San Francisco, San Francisco, California, 94158, USA; 6) Department of Surgery (Urology), University of Utah School of Medicine, Salt Lake City, Utah, 84132, USA; 7) Department of Urology, University of Washington School of Medicine, Seattle, Washington, 98195, USA.

Erectile dysfunction affects millions of men worldwide. Twin studies support the role of genetic risk factors underlying erectile dysfunction, but no specific genetic variants have been identified for erectile dysfunction. We conducted the first large-scale genome-wide association study (GWAS) of erectile dysfunction in 36,649 men in the multiethnic Kaiser Permanente Northern California GERA cohort. We also undertook replication analyses in 222,358 men from the U.K. Biobank. In the discovery cohort, we identified a single locus on chromosome 6 near the single-minded family bHLH transcription factor 1 (*SIM1*) gene that was significantly associated with the risk of erectile dysfunction (rs17185536-T, Odds Ratio = 1.26,  $p = 3.4 \times 10^{-26}$ ). The association replicated in the U.K. Biobank sample (Odds Ratio = 1.25,  $p = 6.8 \times 10^{-14}$ ), and the effect is independent of known erectile dysfunction risk factors, including body mass index (BMI). The risk locus resides on the same topologically associating domain as *SIM1*, interacts with the *SIM1* promoter, and the rs17185536-T risk allele and two other associated alleles in the locus showed differential enhancer activity in luciferase assays. *SIM1* is part of the leptin-melanocortin system, which has an established role in body weight homeostasis and sexual function. Because the variants associated with erectile dysfunction are not associated with differences in BMI, our findings suggest a mechanism that is specific to sexual function.

**2295W**

**Genome-wide association study of lipedema phenotype in the UK Biobank.** Y.C. Klimentidis, K.L. Herbst, Z. Chen. University of Arizona, Tucson, AZ.

Lipedema is a common disorder characterized by excessive deposition of subcutaneous adipose tissue (SAT) in the legs and hips, occurring mainly in women after puberty. It often results in pain and impaired mobility. Although it may be relatively common, the etiology of lipedema is poorly understood, and no specific genes have yet been linked to it. We used data on approximately 250,000 women from the UK Biobank to identify those with and without a lipedema phenotype. Measures of segmental body composition from bioelectric impedance analysis, hip and waist circumferences, along with information on pain in legs were used to define cases and controls. Genome-wide association analyses were performed to identify genetic risk factors for lipedema, exploring a range of different case/control definitions and prevalence estimates. We identified several loci, including *CCDC92*, *COBLL1*, and *LYPLAL1* as being consistently associated with the lipedema phenotype. Using a gene-based analysis, we also identified the *HMGCS1* gene. Follow-up analyses suggest an enrichment of genes expressed in SAT. Our findings point to specific genetic risk factors for lipedema, some of which have previously been identified as sex-differentiated loci for waist-to-hip ratio, and provide a starting point for better understanding the pathophysiology of lipedema.

**Identification of genetic loci related to circulating reproductive hormone levels by GWAS in Japanese men.** Y. Sato<sup>1</sup>, A. Tajima<sup>2</sup>, S. Kogusuri<sup>1</sup>, A. Fujii<sup>1</sup>, T. Sato<sup>2</sup>, I. Imoto<sup>3</sup>, T. Iwamoto<sup>4</sup>. 1) Graduate School of Biomedical Sciences, Tokushima University, Tokushima, Japan; 2) Graduate School of Advanced Preventive Medical Sciences, Kanazawa University; 3) Aichi Cancer Center Research Institute; 4) Reproduction Center, Sanno Hospital.

**BACKGROUND:** Genetic contributions to population-level variations in circulating reproductive hormone levels are expected; however, the genetic determinants of reproductive hormone levels remain poorly understood. In this study, to identify loci related to plasma inhibin B, luteinizing hormone (LH), follicle-stimulating hormone (FSH), testosterone, and sex hormone-binding globulin (SHBG) levels, we conducted two-stage genome-wide association study (GWAS) in Japanese men. Although previous genome-wide association studies (GWASs) of several reproductive hormones such as testosterone, dihydrotestosterone, SHBG, LH and FSH have been conducted in several populations, this is the first GWAS in individuals of Japanese nationality. **METHODS:** In the discovery stage, 811 men were genotyped using the Illumina Human Core V.1.0 DNA Analysis kit (Illumina, San Diego, CA, USA) and then imputation was performed using BEAGLE V.4.1. Association analysis between each single-nucleotide polymorphism (SNP) and hormone levels was performed using multiple linear regression analysis with age and body mass index as covariates. Subsequently, we performed a replication study using an additional 722 Japanese men. The results of the discovery and replication stages were combined in a meta-analysis. **RESULTS:** For all hormones, GWAS failed to reveal any SNPs showing genome-wide significance ( $P < 5 \times 10^{-8}$ ) in the discovery stage. On setting a suggestive significance threshold ( $P$  of  $< 5 \times 10^{-6}$ ) in the discovery stage, a total of 12 loci were found to be associated with inhibin B (five loci), LH (two loci), testosterone (four loci), and SHBG (one locus). We selected only the most significant SNP in each locus for replication genotyping. Only one SNP on chromosome 12 showed a significant association with inhibin B levels (Bonferroni-corrected  $P < 0.05$ ) in the replication stage. When we combined the discovery and replication results in a meta-analysis, this SNP was nominally associated with plasma inhibin B levels ( $P = 1.2 \times 10^{-7}$ ). **CONCLUSION:** In this GWAS, we identified one SNP on chromosome 12 that was nominally associated with plasma inhibin B levels in Japanese men, though we detected no loci related to the other four reproductive hormones.

**Large scale GWAS meta-analyses unravel loci associated with albuminuria.** A. Teumer<sup>1,2</sup> on behalf of the CKDGen Consortium. 1) Institute for Community Medicine, University Medicine Greifswald, Greifswald, Germany; 2) DZHK (German Center for Cardiovascular Research), partner site Greifswald, Greifswald, Germany.

Elevated concentrations of albumin in the urine (albuminuria) are associated with increased risk of kidney disease progression, end-stage renal disease, and cardiovascular morbidity and mortality. Albuminuria is a hallmark of diabetic kidney disease (DKD), the leading cause of end-stage renal disease for which effective treatment is limited. Previous genome-wide association studies (GWAS) have identified very few loci at level of genome-wide significance ( $p$ -value  $<5E-8$ ). To gain additional insights into the pathophysiological mechanisms underlying albuminuria, we conducted a meta-analysis of 54 GWAS of the urinary albumin-to-creatinine ratio (UACR), after inverse normal transformation of the age- and sex-adjusted residuals of log-transformed UACR, in 564,257 individuals of different ancestries, overall and stratified by diabetes. High-quality 1000 Genomes or HRC-imputed genotypes were available at up to 8 million genetic variants. In the overall sample, we identified 58 genomic 1-Mb regions containing at least one SNP associated with UACR at level of genome-wide significance, explaining 0.7% of the trait variance. Restricting the analysis to the 547,361 European ancestry (EA) individuals resulted in 61 genome-wide significant loci, whereas 56 overlapped with the trans-ethnic meta-analysis. Among the 47,816 EA individuals with diabetes, four loci were genome-wide significant, whereas two of them were specific for the diabetes sample. Fine-mapping of the EA associations revealed 63 independently associated SNPs. In the EA analysis, 18 regions contained credible sets of  $\leq 10$  SNPs with a cumulated 99% probability for including the causal variant underlying the GWAS signal (median region size 14 kb, IQR 5-43 kb). For several loci, colocalization of GWAS signals with gene expression in different tissues from the GTEx Project and from additional kidney resources highlighted potentially causal genes. This GWAS meta-analysis using a substantially increased sample size and state-of-the-art imputation panels revealed more than 60 loci associated with albuminuria, most of them novel. These results highlight novel pathways influencing albuminuria, and provide a list of candidate targets to improve treatment of kidney disease.

**Whole exome sequencing analysis in biliary atresia: A follow-up study.** W.Y. Lam<sup>1</sup>, J.S. Hsu<sup>2</sup>, C.S. Tang<sup>1</sup>, M.T. So<sup>1</sup>, P.H.Y. Chung<sup>1</sup>, P.K.H. Tam<sup>1</sup>, M.M. Garcia-Barcelo<sup>1</sup>. 1) Department of Surgery, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong; 2) Department of Psychiatry, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong.

Biliary Atresia (BA) is a severe and complex neonatal disorder characterized by aggressive fibrosclerosis and inflammatory obliteration of the extrahepatic biliary tract. The Southeast Asian population has the highest prevalence (1/5000 live births). The Kasai portoenterostomy is often performed to improve bile drainage, but the majority of the BA patients ultimately require liver transplant, making the disease the most common cause of pediatric liver transplant. Most BA cases are sporadic, and the etiology of BA remains unclear. In cholangiocytes, vascular endothelial growth factor A (VEGF-A) regulates cell proliferation during development, and mutations in VEGF were suggested to be associated with BA. Previously, we identified *ADD3* as a susceptibility factor for BA through genome-wide association analysis and showed that reduced *ADD3* expression levels correlated with the risk *ADD3* allele. In this follow-up study, we performed whole exome sequencing on 92 BA trios from the Southeast Asian population to identify potential variants, genes and biological pathways associated with BA. Our preliminary analysis found a de novo frameshift insertion in the *FLT1* gene, which encodes VEGF receptor 1 to regulate VEGFA signaling. *FLT1* is highly intolerant to loss-of-function mutation ( $pLI=1.0$ ), and the insertion is extremely rare, not found in the ExAC or gnomAD databases. Further analysis results will be presented for additional insights on the pathogenesis of BA, which will guide our functional studies using in-house human organoid system. This project is supported by Li Ka Shing donation account - enhanced new staff start-up packages to Patrick H.Y. Chung.

**2299T**

**Large scale Mendelian randomization scan reveal novel pathway linking education attainment and central adiposity to gastroesophageal reflux disease.** *JS. Ong, J. An, M. Law, D. Whiteman, P. Gharahkhani, S. MacGregor.* QIMR Berghofer Medical Research Institute, 300 Herston Road, Brisbane, Australia.

Gastroesophageal reflux disease (GERD) is a common chronic disorder where affected individuals experience frequent acid reflux from the stomach into the esophagus. Previous work has shown GERD is related to complications in the upper digestive system and is strongly associated to risk of Barrett's esophagus and the rapidly fatal cancer esophageal adenocarcinoma. Apart from obesity, little is known about what actually causes GERD. We recently identified new loci implicated in this disease through a GWAS (72,334 cases and 263,352 controls) using data from both the UK Biobank and the Australian QSkin cohort. To determine which modifiable risk factors alter GERD risk, we performed a large scale Mendelian randomization (MR) analysis. MR is an instrumental variable technique based on using genetic variants as confounding-free instruments for exposures of interest. We evaluated the evidence for causality for a comprehensive set of possible risk factors for GERD. Odds ratios on GERD were estimated based on per SD change in the risk factor evaluated. We tested a series of anthropometric traits, fasting glucose, cholesterol levels, systolic blood pressure, vitamin D, coffee intake, alcohol consumption and education attainment; all were not associated with GERD except for traits related to obesity, height and education. We showed that BMI is causally associated with GERD, and for the first time show that education may be causally associated (1 SD lower years of schooling confers OR=1.09 for GERD,  $p=2e-4$ ). We also found a suggestive association between white blood cell count (OR=1.006,  $p=0.003$ ) and GERD, although this was not significant following multiple testing correction. Using instruments for anthropometric traits that are not associated with BMI, we also showed that decreased height (OR=1.02,  $p=8e-15$ ) and more interestingly, higher BMI-adjusted waist-hip ratio (OR=1.08,  $p=1e-10$ ) were associated with higher susceptibility to GERD. Our findings identify a novel causal link between adiposity (and specifically central adiposity) and GERD development. It is unclear whether the observed association between education attainment and GERD is mediated through BMI. At the meeting we will further present our sex-stratified findings and a phenotype-based stratification MR technique to dissect other potential mechanisms (stratified by obesity pathway) linking BMI and GERD.

**Gut microbiome and irritable bowel syndrome with or without anxiety and depression symptoms.** *K.H Bahk<sup>1</sup>, H.A Park<sup>1,2</sup>, J.H Sung<sup>1</sup>.* 1) Genome Epidemiology, Department of Epidemiology, Graduate School of Public Health, Seoul National University, Seoul, Korea; 2) Department of Emergency Medicine, Hallym University Dongtan Sacred Heart Hospital, Gyeonggi, Korea.

**BACKGROUND:** Irritable bowel syndrome (IBS) is a common functional gastrointestinal disorder, but the risk factors of IBS are largely elusive. Recent evidence has suggested that in the development of IBS, similar to inflammatory bowel diseases, "gut-brain" axis and microbial dysbiosis might matter. We attempted to identify microbial characteristics for those having IBS according to comorbid psychological symptoms. **METHODS:** We asked IBS symptoms (Rome III), state-trait anxiety inventory, depressive symptoms (CES-D), and also analyzed stool microbial samples (16S rRNA gene analysis) for 672 individual from the Korean Healthy Twin Study. Using the Illumina's MiSeq platform, we obtained pyrosequencing data and filtered it through Chimera removal (QIIME) and sequence quality check. We measured operational taxa units (OTUs) using QIIME based on Uclust open reference, and aligned sequence using 13\_8 revision of the Greengenes database. We estimated the  $\alpha$ -diversity using four indices (Observed, Chao1, Shannon, and InvSimpson) and  $\beta$ -diversity using UniFrac distances and Bray-Curtis dissimilarity. The multivariate analysis, MaAsLin (Multivariate Association with Linear Models), was used to association test between microbial taxa and "gut-brain" axis phenotype. **RESULTS AND INTERPRETATIONS:** We compared  $\alpha$ -diversity between IBS with psychological symptoms ( $n=56$ ), IBS only ( $n=25$ ), psychological symptoms only ( $n=420$ ), and control group ( $n=171$ ). The  $\alpha$ -diversity of all IBS patients was slightly lower than those IBS-free subjects without psychological symptoms. IBS with anxiety and the IBS with depressive symptoms showed significantly lower  $\alpha$ -diversity than IBS without psychological symptoms. The distance matrices, created by  $\beta$ -diversity (Unweighted/weighted UniFrac distances, Bray-Curtis dissimilarity) to compare MZ twin pairs, DZ twins and non-twin siblings, family and unrelated group, indicated that there is no significant difference between the MZ and DZSib, but between the other groups. When we compared OTU levels, the Firmicutes phylum, including the *Catenibacterium* genus, *Clostridium* genus, and *Ruminococcaceae* family was significantly less populated for IBS group. Our study supports that microbial profile is associated with gut-brain axis which might have consequences on the development of IBS.

## 2301W

**Mitochondrial genetic variation is not associated with increased risk of developing uterine fibroids in African American or European American women.** B.S. Mautz<sup>1,2,3</sup>, J.N. Hellwege<sup>1,2,3</sup>, T.L. Edwards<sup>1,2,3,4</sup>, D.R. Velez Edwards<sup>2,3,4,5</sup>. 1) Department of Medicine, Vanderbilt University Medical Center, Nashville, TN; 2) Institute for Medicine and Public Health, Vanderbilt University Medical Center, Nashville, TN, United States; 3) Vanderbilt Genetics Institute, Vanderbilt University Medical Center, Nashville, TN, United States; 4) Vanderbilt Epidemiology Center, Vanderbilt University Medical Center, Nashville, TN, United States; 5) Department of Obstetrics and Gynecology, Vanderbilt University, Nashville, TN, United States.

Uterine fibroids affect up to 70% of women by menopause and lead to large healthcare and lost work costs. African American (AA) women have up to a threefold increased risk of developing fibroids, as well as larger and multiple fibroids relative to European American (EA) women. Several autosomal SNP associations have been reported. However, no study has investigated the impact of mitochondrial genetic variation on fibroids despite differences in haplogroups in those with European and African ancestry which might contribute to the racial disparities. We used data from Vanderbilt University's BioVU, a biorepository of de-identified electronic medical records (EMR) linked to DNA, to investigate potential mitochondrial SNP and haplogroups associated with the risk of fibroids. Mitochondrial SNPs were extracted from Affymetrix Axiom Biobank arrays in EAs (N = 2273) and AAs (N = 1383). Fibroid status was assessed in the EMR through validated algorithms, including pelvic imaging and an intact uterus to define controls. Mitochondrial haplogroup assignment was performed using Haplogrep2 software. Fibroid characteristics (number, volume, and largest dimension) were extracted from imaging reports for a subset of AA cases. Single SNP association identified 4 suggestive variants in AAs (rs2854122, OR = 0.69 [95% CI: 0.508, 0.938], p = 0.018; rs2854128 OR = 0.439 [0.206, 0.936], p = 0.033; rs41337244 OR = 0.51 [0.271, 0.959], p = 0.037; rs2853496, OR = 0.868 [0.766, 0.983], p = 0.026). One SNP (rs2854122) is in a non-coding region, while the other 3 define Haplogroup H, or are in *CYTOCHROME B* and *ND4* genes, respectively. The three top SNPs in the EAs (Affx-52321495, OR = 1.36 [1.01, 1.84], p = 0.04; Affx-52321475, OR = 1.61 [1.01, 2.59], p = 0.047; Affx-52321472, OR = 1.95 [1.01, 3.76], p = 0.048) are all in the *ND5* gene and unnamed. However, all SNPs are not statistically significant after accounting for multiple tests. The majority (77.4%) of EAs were assigned to haplogroup H or U, and 5 and 8 different haplogroups were represented among EA and AA participants, respectively. We found no relationship of haplogroup with risk of developing fibroids in either cohort, and mitochondrial haplogroup was unrelated to fibroid number or size in AA women. Our study did not show evidence for mitochondrial variants being associated with fibroid risk or specific fibroid characteristics.

**Rationale:** Individuals with interstitial lung abnormalities (ILA) share a clinical syndrome similar to that observed in idiopathic pulmonary fibrosis (IPF) including physiologic decrements, radiologic progression, accelerated lung function decline, and an increased risk of death. ILA are associated with the most common and highest genetic risk locus in IPF, the *MUC5B* promoter polymorphism rs35705950. However, additional variants associated with ILA and the extent of overlap of the genetic risk between ILA and IPF are not recognized. **Methods:** ILA and the subpleural-predominant ILA subtype were visually assessed on chest computed tomography (CT) scans in European- and African-ancestry participants from the AGES, COPDGene, Framingham Heart, ECLIPSE, MESA, and SPIROMICS studies. Genome-wide variants were imputed utilizing the Haplotype Resource Consortium panel. We performed a genome-wide association study (GWAS) of ILA in each cohort using logistic regression adjusting for age, sex, pack-years smoking, and principal components of genetic ancestry. Cohort-level results were combined using a fixed-effects meta-analysis. Sixteen distinct ( $R^2 < 0.8$ ) IPF GWAS SNPs from the NHGRI-EBI GWAS catalog were assessed for association with ILA and subpleural ILA. **Results:** Genome-wide SNP genotyping data were available in 1,868 ILA cases and 12,871 controls. The *MUC5B* promoter variant rs35705950 was significantly associated with both ILA ( $p=2.1 \times 10^{-11}$ ) and subpleural ILA ( $p=1.1 \times 10^{-10}$ ). We discovered a novel genome-wide significant association with ILA near *IPO11* (rs6886640,  $p = 5.8 \times 10^{-9}$ ) and with subpleural ILA near *HTR1E* (rs7744971,  $p=2.7 \times 10^{-8}$ ). In an assessment of ILA association with prior 16 IPF GWAS SNPs, we identified 13 of 16 directionally consistent associations. Of these 13 SNPs, 5 SNPs (near *MUC5B*, *DSP*, *DPP9*, *TOLLIP*, and *FAM13A*) were significantly associated ( $p < 0.05/16$ ) with ILA and 4 SNPs were nominally significant ( $p < 0.05$ ). **Conclusions:** In a GWAS of ILA and subpleural ILA in six studies, we confirmed the previously described association with a *MUC5B* promoter variant and discovered additional significant associations near *IPO11* and *HTR1E*. Additional investigation is needed to replicate novel findings; however, our study demonstrates that IPF GWAS SNPs are enriched for ILA associations, suggesting a common genetic pathway between ILA and IPF, and advances the possibility of ILA as a precursor lesion for IPF.

**Evaluation of polygenic risk scores for chronic obstructive pulmonary disease in a biobank linked to electronic health records.** V.L. Martucci<sup>1,2</sup>, B. Richmond<sup>3</sup>, T. Blackwell<sup>4</sup>, L.K. Davis<sup>1,4,5</sup>, M.C. Aldrich<sup>1,2,6,7</sup>. 1) Vanderbilt Genetics Institute, Vanderbilt University, Nashville, TN; 2) Department of Thoracic Surgery, Vanderbilt University Medical Center, Nashville, TN; 3) Division of Allergy, Pulmonary, and Critical Care Medicine, Vanderbilt University Medical Center, Nashville, TN; 4) Division of Genetic Medicine, Department of Medicine, Vanderbilt University Medical Center, Nashville, TN; 5) Department of Psychiatry and Behavioral Sciences, Vanderbilt University Medical Center, Nashville, TN; 6) Division of Epidemiology, Vanderbilt University Medical Center, Nashville, TN; 7) Department of Biomedical Informatics, Vanderbilt University Medical Center, Nashville, TN.

Chronic obstructive pulmonary disease (COPD) is the third leading cause of mortality in the U.S. and worldwide. COPD is characterized by persistent respiratory symptoms and reduced lung function, causing significant morbidity. Pulmonary function testing (PFT) is used to determine disease status, with the ratio of forced expiratory volume in one second (FEV<sub>1</sub>) to forced vital capacity (FVC) less than 0.7 considered diagnostic for COPD. Electronic health records (EHR) provide large-scale, routine healthcare data for COPD research, and linking EHR with genetic information provides unique opportunities for discovery of genetic risk factors. We investigated genetic predictors of COPD and lung function within a spirometry-defined clinical cohort at Vanderbilt University Medical Center. We identified individuals over 45 years of age who received PFTs between August 2014-September 2017 (N = 14,058). We selected participants from BioVU, the Vanderbilt de-identified biobank linked to EHR. Individuals were previously genotyped on the Illumina MEGA-Ex, Omni and Quad arrays. Over 6 million SNPs and 1,065 individuals remained after standard QC and imputation to 1000 Genomes. We defined COPD cases as individuals with a pre- or post-bronchodilator FEV<sub>1</sub>/FVC < 0.7 (N = 343 cases, 722 controls). SNPs associated with COPD or lung function were identified from the NHGRI-EBI GWAS catalog to construct weighted polygenic risk scores (PRS) using PRSice software. Logistic or linear regression models examined associations between PRS and COPD or lung function, respectively, adjusting for sex and age at last clinic visit. The odds ratio for a 1 standard deviation change in a PRS with 91 SNPs was 2.60 [95% confidence interval (CI): 0.83 to 8.21]. A PRS with 64 SNPs was inversely associated with FEV<sub>1</sub>/FVC ( $\beta$  = -0.46, 95% CI: -1.24 to 0.33), although not statistically significant. Inverse associations were observed with FEV<sub>1</sub> ( $\beta$  = -0.04, 95% CI: -0.09 to -0.01) and FVC ( $\beta$  = -0.05, 95% CI: -0.10 to 0.001), although only the association with FEV<sub>1</sub> was statistically significant ( $p \leq 0.05$ ). These preliminary results demonstrate the potential for PRS to elucidate polygenic contributions to COPD. We will present extended analyses using PRS applied to 200,000 adults in BioVU using a natural language processing algorithm to identify COPD patients.

**Genome-wide polygenic risk scores for chronic kidney disease in the UK biobank.** *H.T. Vy<sup>1</sup>, L. Chan<sup>2</sup>, K. Chaudhary<sup>1</sup>, S. Coca<sup>2</sup>, R. Do<sup>1,2</sup>, G.N Nadkarni<sup>2</sup>.* 1) Charles Bronfman Institute for Personalized Medicine, Icahn School of Medicine, New York, NY; 2) Division of Nephrology, Department of Medicine, Icahn School of Medicine, New York, NY; 3) Department of Genetics and Genomic Sciences, Icahn School of Medicine, New York, NY.

Early detection and treatment of chronic kidney disease (CKD) can potentially prevent disease onset and delay disease progression. In addition to traditional methods of detection which are based on measurements of laboratory values indicative of kidney function, genetic testing has emerged as a potential tool for the identification of high-risk individuals. Recent genome-wide association (GWA) studies have tested for associations between millions of single nucleotide variants (SNVs) and CKD, and have successfully identified a number of genetic loci for CKD. However, the predictive ability of the aggregate effect of these SNVs on CKD risk at a genome-wide level has not yet been explored. In this study, we generated per-individual genome-wide additive polygenic risk scores using publicly available CKD GWA association statistics and tested these scores for association with CKD in 8,432 cases and 400,529 controls of self-identified white British ancestry in the UK Biobank (UKBB) data set. We calculated different polygenic scores from four different sets of SNVs: 1) 33 loci significantly associated with estimated glomerular filtration rate (eGFR-crea); 2) 53 loci significantly associated with CKD risk; 3) >38,000 independent SNVs using a linkage disequilibrium (LD) pruning approach of  $r^2 < 0.80$  and  $P < 0.05$ ; and 1,797,807 SNVs with re-assigned coefficients adjusted for the effects of LD by LDpred. Among the four polygenic scores, the LDpred-adjusted polygenic score demonstrated the most robust association with CKD risk with an area-under-curve of 0.703. Using this score, individuals at the top 5% of the distribution had a more than 2-fold risk for CKD compared to those at the bottom 20%. Similar associations were also observed for other ancestries (African, East Asian) within UKBB. In conclusion, we demonstrate the utility of polygenic predictors for CKD risk through the identification of polygenic high-risk individuals for CKD across different ancestral populations.

**RNA-seq from human pancreatic tissue with chronic pancreatitis provides insight into etiopathogenesis and classification.** *C.A. Shelton<sup>1,2</sup>, D.C. Whitcomb<sup>1,2</sup>.* 1) Division of Gastroenterology, University of Pittsburgh, Pittsburgh, PA; 2) Department of Human Genetics, University of Pittsburgh, Pittsburgh, PA.

Pancreatitis is a complex, genetically heterogeneous acute and chronic inflammatory disorder of the pancreas. There is wide variability in disease progression, pain and loss of function, even among patients with apparently identical susceptibility factors. Human tissue has been largely unavailable for study, and the majority of knowledge regarding molecular pathways of disease progression is from mouse models. However, few therapies proven to be effective in mouse models have had a positive impact on human disease, and there is no effective treatment for chronic pancreatitis (CP). Leftover tissue from *total pancreatectomy with islet autotransplantation* (TPIAT)—a surgical option for some patients with CP—represents an untapped resource to study biological drivers of CP in humans. This tissue is collected at the optimal time to evaluate underlying pathogenesis — *after* a pathogenic, progressive natural history is predicted, but *before* insulin-producing islets are lost. RNA was extracted from TPIAT RNALater samples (1 *PRSS1* CP; 2 idiopathic CP; 1 alcoholic recurrent acute pancreatitis (RAP)) and histologically normal tissue from pancreatic cancer cases, matched for age, sex and race. RNA integrity was consistent among samples, and paired-end total RNA-sequencing was used for optimal coverage. On principal component analysis, controls clustered and clear separation was seen between TPIAT tissue by stage (recurrent acute vs. chronic) and etiology. With a false discovery rate  $< 0.05$ , nearly 500 genes were found to be differentially expressed by at least 2-fold. The most significantly upregulated genes were immunoglobulins, indicating a humoral immune response. Additionally, stellate cell activation was found to be the most significantly upregulated pathway in cases — an expected response to pancreatic injury. Differences between cases by stage and etiology also revealed new and expected pathways indicative of etiopathogenesis. For example, the most significant pathways upregulated in the alcoholic RAP tissue compared to idiopathic and genetic chronic pancreatitis were oxidative phosphorylation and mitochondrial dysfunction—established pathologic responses to alcohol. Although this is a small sample size, these results replicate findings from mouse models, lending biological plausibility. Our findings suggest that RNA-Seq may be useful for further classification of pancreatitis subtypes and reveal targets for early diagnosis and targeted treatment.

**Genetic studies of body proportion (sitting height ratio) shed light on the recent evolution of human skeletal growth.** *E.R. Bartell<sup>1,2,3</sup>, K.M. Tsuo<sup>1,2,3</sup>, K. Lin<sup>4</sup>, J.B. Cole<sup>1,2,3</sup>, S. Vedantam<sup>1,2,3</sup>, R.S. Fine<sup>1,2,3</sup>, R.M. Salem<sup>1,2,3</sup>, Y. Chan<sup>1,2,3</sup>, R. Walters<sup>1</sup>, J.N. Hirschhorn<sup>1,2,3</sup>.* 1) Department of Genetics, Harvard Medical School, Boston, MA; 2) Division of Endocrinology and Center for Basic and Translational Obesity Research, Boston Children's Hospital, Boston, MA; 3) Broad Institute of the MIT and Harvard, Cambridge, MA; 4) Nuffield Department of Population Health, Oxford, UK.

Genome-wide association studies (GWAS) have identified hundreds of common genetic variants associated with human height; however, less is known about the genetics of body proportion. A greater understanding of the genetics of Sitting Height Ratio (SHR, sitting height divided by standing height), a commonly-used measure of skeletal proportion, would expand our understanding of skeletal growth. Taken together with the genetics of human height, genetic variants can be classified into those affecting predominantly long bones (legs), spine/head, or overall height. Objective: To expand our understanding of skeletal growth using genetic studies of SHR. We use data from the UK Biobank to expand our genome-wide association study of SHR (Chan et al. 2015) from ~25,000 to >400,000 individuals. In this abstract, we use association results from BOLT-LMM, in ~500,000 individuals. Height-increasing alleles that decrease SHR were deemed to act primarily on the legs/long bones, and height-increasing alleles that increase SHR were deemed to act primarily on the head/spine. For analyses of selection, we used methods from our earlier work (Turchin et al., 2012), and expanded study populations to include those genotyped in the China Kadoorie Biobank (CKB), constituting ~100,000 further individuals. We identified >600 genome-wide significant SHR-, Height-, or both-associated variants ( $p < 5 \times 10^{-8}$ ). We used the SHR association data to classify height variants according to their upper or lower body effect. We next re-examined a signal of selection we had previously demonstrated for height-associated variants (the difference in height between northern and southern Europeans is partly explained by differential selection on height-associated variants). In preliminary analyses, the signal of selection appears stronger in height-associated variants that act on long bones than in variants that act on spine/head length; if confirmed in the larger sample, this would indicate that recent evolutionary pressures differentially altered limb length within Europe. Results also show more differentiation in allele frequencies at loci that affect torso length in CKB populations as compared to leg length; this may argue for different selection pressures acting on the two different study populations. We have identified many novel loci associated with SHR that offer new insights into the genetic, biological and evolutionary basis of body proportion and skeletal growth.

**Translating osteoarthritis GWAS signals into therapeutic targets.** *L.C. McCarthy<sup>1</sup>, I. Tachmazidou<sup>1</sup>, K. Hatzikotoulas<sup>2</sup>, L. Southam<sup>2,3</sup>, J. Esparza-Gordillo<sup>4</sup>, J. Hoffman<sup>1</sup>, J. Larkin<sup>4</sup>, P. Fisher<sup>1</sup>, T. Johnson<sup>1</sup>, M. Koprulu<sup>2,5</sup>, E. Zengin<sup>6,7</sup>, J. Steinberg<sup>2,8</sup>, J.M. Wilkinson<sup>9</sup>, S. Bhatnagar<sup>9</sup>, M.N. Nelson<sup>4</sup>, R.A. Scott<sup>1</sup>, E. Zeggini<sup>2</sup>, arcOGEN Consortium.* 1) GlaxoSmithKline, Stevenage, United Kingdom; 2) Wellcome Trust Sanger Institute, Wellcome Genome Campus, UK; 3) Wellcome Centre for Human Genetics, University of Oxford, UK; 4) GlaxoSmithKline, King of Prussia, US; 5) University of Cambridge, UK; 6) University of Sheffield, UK; 7) Dromokaiteio Psychiatric Hospital, Greece; 8) Cancer Council NSW, Australia; 9) McGill University, Canada.

Osteoarthritis (OA) is the leading cause of disability globally. Pain management and joint replacement are the therapeutic options currently available to OA patients, and there remains an enormous unmet medical need for effective disease modifying drugs. We conducted the largest genome-wide association study for OA to date (70,588 cases and 263,702 controls) using UK Biobank data, and meta-analysed the data with arcOGEN consortium OA data, to reveal 43 genome-wide signals, 32 of which are novel. Our focus is the translation of these genetic signals into the identification of targets for new drugs which impede OA joint degeneration and may promote OA joint healing. The following evidence elements contributed to refining the list of genes likely to drive OA association signals: fine mapping, variant effect prediction (VEP), colocalization with eQTL signals, gene mutations driving rare human skeletal/joint phenotypes including early onset OA, differential protein and/or RNA expression and/or methylation in OA vs. normal joint tissue, gene mutations driving relevant skeletal/joint phenotypes in animal models. Following integration of these evidence strands, 15 loci had only 1 gene with supportive evidence for driving the OA signal. There were 21 loci containing  $\geq 2$  genes with OA related evidence. 7 loci had no genes with plausible evidence for driving the OA signal. Five (*TGFB1*, *IL11*, *MST1R*, *DPEP1*, *PTHLH*) of the potential effector genes, based on human genomics and animal model evidence, have therapeutics approved or in clinical trials for a range of indications, and mechanisms of action consistent with potential efficacy for OA. Of the 137 genes in OA loci with any evidence supporting their role in OA susceptibility, 100 are predicted to be potentially tractable to small molecule modulation, and 70 are predicted to be tractable to biological therapeutic intervention. Where molecular tools exist, or can be created, to modulate the products of these genes, we will test their activity in models of OA. We describe approaches to translating OA GWAS signals to potential new drug targets.

**2308T**

**Integration analysis of multi-omics data for osteoporosis biomarker discovery.** C. Qiu, F.T. Yu, K.J. Su, H.W. Deng, H. Shen. Tulane University School of Public Health and Tropical Medicine, New Orleans, LA.

Osteoporosis is an increasingly serious public health problem, which is characterized by low bone mineral density (BMD). To date, the functional roles of the most reported biomarker that are associated with BMD remain unclear. To increase the understanding of the biological mechanisms of BMD variation, it is necessary to leverage multiple high dimensional datasets to capture the complexity of biological networks. Recent advent of high throughput technologies has created an opportunity for integrating multi-omics data to build a comprehensive and dynamic model of the molecular changes in osteoporosis. In this study, we generated the multi-omics datasets with three data types (mRNA, methylation, and metabolomics) from 120 subjects with extremely high (n=61) and low (n=59) hip BMDs. By focusing on potential interesting biomarkers (differentially expressed genes, differential methylated CpG sites, and differential metabolites) generated from single layer analysis, we applied a data integration analysis for biomarker discovery using latent components (DIABLO) to identify the key omics biomarkers for BMD variation. We identified a multi-omics signature of 22 and 15 mRNA biomarkers, 36 and 11 metabolomics biomarkers, 11 and 5 methylation biomarkers on the first two components, respectively. The DIABLO model displayed a better discrimination of BMD variation with the methylation and metabolomics than with mRNA data. Correlation analysis showed a strong correlation between mRNA and metabolomics, and 17 mRNA biomarkers, 23 metabolomics biomarkers, and 6 methylation biomarkers in the first component were highly negatively correlated with the first component. A relevance network analysis highlighted two clusters, both including features from the three types of omics data. In addition, we performed Gene Ontology analysis on the largest cluster consisting of 32 omics biomarkers. Interestingly, several biomarkers (e.g., *ICA1L*, *PCAT1*) have been associated with BMD variation through previous genome-wide association studies. In conclusion, we reconstructed the biological network in multi-omics level and identified several novel biomarkers that may mediate variation in risk of osteoporosis. Our results highlighted the advantages of using integration analysis to add value to the traditional single layer analysis.

**Cellular crosstalk between retinoic acid and pesticides: A model for understanding osteoporosis through genomic and non-genomic pathways.** H.S. Sandhu<sup>1,2</sup>, G. Singh<sup>1,4</sup>, S. Puri<sup>2,3</sup>, A.J.S. Bhanwer<sup>1</sup>. 1) Department of Human Genetics, Guru Nanak Dev University, Amritsar, India; 2) Centre for Stem Cell and Tissue Engineering, Panjab University, Chandigarh, India; 3) Biotechnology Branch, UIET, Panjab University, Chandigarh, India; 4) Department of Anthropology, Panjab University, Chandigarh, India.

The altered bone quality and increased risk of fractures featuring the debilitating bone loss disease osteoporosis involves a crosstalk between various environmental, nutritional and genetic factors. Environmental intoxicants such as pesticides adversely affect the skeletal homeostasis by binding to receptors on bone marrow mesenchymal stem cells (MSCs) and exacerbating the adipogenic differentiation of these inherent stem cells. To understand this mechanism, a dual approach was employed comprising of (1) a murine cell-based test system for continuous, label-free monitoring of the effect of retinoic acid, a model compound for osteoporosis, and an organophosphate pesticide chlorpyrifos (CPF) on adipogenic differentiation, and (2) a human case-control sample set. The *in vitro* model of C3H10T1/2 MSCs generated by combined treatment with 2 $\mu$ M RA+ 50 $\mu$ M CPF showed vastly increased adipogenic differentiation as compared to vehicle control and independent treatments. These results were characterized by microscopic and biochemical studies. Expression analysis of major adipogenic genes by RT-PCR suggested an upregulation of *adipsin* (*ADN*) and *perilipin-1* (*PLIN1*). Screening for various pathway inhibitors revealed GSK3 $\beta$  to be the key player, with its inhibitor LiCl resulting in complete blockade of lipid accumulation and downregulation of these adipogenic markers. For validating the role of these genes, peripheral blood was collected from 102 male/female subjects from North India having direct exposure to pesticides and bone quantitative ultrasound t-score  $\leq -1$ , and compared with 167 age/gender matched healthy controls with t-score  $> -1$  and without any direct pesticide exposure. CPF residues were quantified in a representative sample set using HPLC and showed a higher mean concentration in cases (198.231 ng/ml) as compared to controls (114.45 ng/ml). Analysis of the genetic variants of *ADN* and *PLIN1* by PCR-based methods revealed that rs1683563 and rs2304796 respectively, conferred 1.7-2.3 fold risk towards the susceptibility of bone loss upon pesticide exposure. However, only redundant gene-gene interactions were prevalent among these variants. The present study highlights that *ADN* and *PLIN1* might be important susceptibility loci for an increased risk of osteoporosis upon pesticide exposure, however, ethnicity differences need to be considered. Hence, impairment in metabolic pathways resulting in obesity and related phenotypes also exerts its influence on bone health.

**A variant in *MEGF6* gene predisposes to osteoporosis.** C.C. Teerlink<sup>1</sup>, J. Stevens<sup>1</sup>, D.C. Hughes<sup>1,2</sup>, C.P. Brunker<sup>1,3</sup>, M.J. Juryne<sup>4</sup>, D. Grunwald<sup>5</sup>, L.A. Cannon-Albright<sup>1,6,7</sup>. 1) Genetic Epidemiology, Department of Internal Medicine, University of Utah School of Medicine, Salt Lake City, UT; 2) Rehabilitation Services, University of Utah, Salt Lake City, UT; 3) Geriatric Medicine, Intermountain Healthcare, Salt Lake City, UT; 4) Orthopedic Surgery, University of Utah, Salt Lake City, UT; 5) Human Genetics, University of Utah, Salt Lake City, UT; 6) George E. Wahlen Department of Veterans Affairs Medical Center, Salt Lake City, UT; 7) Huntsman Cancer Institute, Salt Lake City, UT.

Osteoporosis is a common skeletal disorder characterized by deterioration of bone tissue in later life. The set of genetic factors contributing to osteoporosis is not completely specified. We performed a relatively small exome-sequencing study on previously sampled osteoporosis pedigree members designed to identify rare, highly penetrant variants that segregate with disease following a dominant mode of inheritance. The osteoporosis pedigree resource consists of 1,871 individuals in 276 multi-generational pedigrees with 4–46 sampled individuals per pedigree. All study participants received bone mineral density (BMD) scans via Hologic QDR 4500A fan-beam dual X-ray absorptiometry bone densitometer of the hip and spine. BMD scores were converted to a normalized age- and sex-adjusted score (T-score). We performed exome sequencing on affected-relative-pairs, approximately cousins, from 10 high-risk osteoporosis pedigrees with an extreme phenotype defined as the lowest 5% of the distribution of T-scores across all subjects to identify rare coding variants that may contribute to osteoporosis in these families. Variants were filtered on population frequency (minor allele < 0.005) and concordance between sequenced relative pairs, resulting in 319 candidate variants. We further reduced the set of candidate variants by requiring that the gene of origin had at least one previously reported association to osteoporosis identified via PubMed search, resulting in 12 candidates. The 12 remaining candidates were tested for segregation via Taqman assay in the additional, previously sampled, affected relatives of the index carriers, which revealed a rare variant in the *MEGF6* gene (rs755467862 at chr1:3,440,693 (hg19)) with strong evidence for segregation (6 affected relatives carrying the variant, RVsharing probability = 1.2E<sup>-4</sup>). The *MEGF6* gene resides in the 1p36.3 cytogenetic band which has two previous reports of evidence for linkage to osteoporosis. We are currently generating loss-of-function alleles in the 2 zebrafish *MEGF6* orthologues, *megf6a* and *megf6b*, to determine the biological role for this gene and variant in osteoporosis predisposition.

**2311T**

**Genetic variants in ER stress signaling molecules *IRE1* and *XBP1* are associated with human bone and tooth phenotypes.** Y. Zhou<sup>1</sup>, H. Ouyang<sup>2,3</sup>, D. McNeil<sup>4</sup>, R. Weyant<sup>5</sup>, R. Crout<sup>6</sup>, R. Slayton<sup>6</sup>, T. Burns<sup>7</sup>, S. Levy<sup>8</sup>, M. Marazita<sup>1</sup>, J. Shaffer<sup>9</sup>. 1) Department of Oral Biology, University of Pittsburgh, Pittsburgh, PA, 15219; 2) Texas A&M University, Dallas, Texas 75246; 3) University of Texas Southwestern Medical Center; 4) West Virginia University, Morgantown, West Virginia; 5) School of Dental Medicine, University of Pittsburgh, Pittsburgh, PA; 6) School of Dentistry, University of Washington, Seattle, WA, USA; 7) College of Public Health, University of Iowa, Iowa City, IA; 8) University of Iowa College of Dentistry, Iowa City, IA; 9) Department of Human Genetics, University of Pittsburgh, Pittsburgh, PA, 15261.

**Introduction** Our work in mice suggests that the endoplasmic reticulum stress *IRE1/XBP1*s signaling axis is important for mineralized tissues, with roles in bone formation and tooth eruption. Specifically, mice with the *IRE1*-coding gene *ERN1* knocked out in *Osterix*-positive cells showed delayed tooth eruption, skeletal and dental morphological differences, and low bone mineral density (BMD). Whether genetic variants in these genes influence bone and dental phenotypes in humans remains unknown. Therefore, we employed an *in silico* candidate gene approach testing association of variants in *ERN1* and *XBP1* with BMD, tooth eruption, and dental caries. **Methods** Participants were white, non-Hispanic children from the Center for Oral Health Research in Appalachia (N=506; ages 0-6), Iowa Fluoride Study (N=410; ages 3-6) and Iowa Head Start Study (N=266; ages 0-6). These cohorts were genotyped together using an Illumina SNP chip. Common SNPs in the candidate genes plus 500kB up- and downstream were tested for genetic association with timing of primary tooth eruption, dental caries, and DXA-derived spine and hip BMD and BMC while adjusting for ancestry and pertinent covariates. A total of 1363 and 1395 SNPs were tested for *ERN1* and *XBP1*, respectively. The locus-wise threshold for significance given the effective number of independent tests was  $P < 2E-4$ . **Results** We observed significant associations for both *ERN1* and *XBP1* with bone phenotypes. For the *XBP1* region, we detected the association of rs75752758 with spine BMC ( $P=2E-6$ ). This SNP also showed suggestive evidence of association for all other bone phenotypes (hip BMD  $P=7E-4$ , hip BMC  $P=9E-4$ , spine BMD  $P=7E-4$ ). For the *ERN1* region, SNP rs71376922 ( $P=2.5E-5$ ) was associated with hip BMD. This SNP is in strong LD with a variant in known promoter and enhancer regions in osteoblasts. A different SNP in the 5' regulatory region of *ERN1*, rs75160892, was associated with dental caries ( $P=1E-4$ ); this SNP is in LD with several SNPs showing enhancer chromatin marks in multiple cell types and one SNP that is a known eQTL for *ERN1*. **Conclusion** Our findings suggest that common variants at the *ERN1* and *XBP1* loci are associated with both bone and dental phenotypes in humans. These data, along with the mouse model showing deregulated bone and tooth development, highlight a role of the *IRE1/XBP1*s axis in regulating these biological processes. **Funding** U01-DE018903, R03-DE024264, R01-DE014899, R01-DE009551, R01-DE12101, R01-CA182418.

**2312F**

**Comprehensive functional annotation of susceptibility SNPs associated with osteoporosis.** *Y. Guo, Y.J. Zhang, H.M. Niu, S.S. Dong, T.L. Yang.* Key Laboratory of Biomedical Information Engineering of Ministry of Education, School of Life Science and Technology, Xi'an Jiaotong University, Xi'an, China.

We aimed to provide a comprehensive functional annotation of osteoporosis-associated SNPs identified by previous genome-wide association studies (GWASs) and genetic association studies and offer guides for post-GWASs functional experiments. In this study, a total of 10,891 susceptibility SNPs (487 sentinel SNPs and 10,839 proxy SNPs in LD) were included. The target genes of all functional SNPs are enriched in osteoporosis-related pathways, including basal cell carcinoma, Wnt signaling pathway, and Hedgehog signaling pathway. Over 90% of the susceptibility SNPs are located in non-coding regions and it is difficult to understand their functional roles. Therefore, we annotated these SNPs via various functional databases. We identified 937 functional SNPs, including 1 nonsense SNPs, 17 missense SNPs with protein damaging effects, 47 UTR SNPs which might affect microRNA binding, 20 promoter and 851 enhancer SNPs which might affect transcription factor (TF) binding. The enhancer SNPs and promoter SNPs are enriched in 19 TFs, and 9 of these 19 TFs have been confirmed in mouse knockout models for association with osteoporosis. To integrate the GWAS and eQTL data, we used SMR approach and discovered a total of 111 instances of gene-trait-associated changes in expression at a false-discovery rate < 0.05. These genes were primarily identified in eQTL derived from pathophysiological relevant tissues, like whole blood and muscle skeletal. 19 of 111 (17.12%) trait-associated genes have been shown to be associated with osteoporosis-associated phenotypes in mouse knockout model. 21/111 trait-associated gene were differentially expressed during osteoblast differentiation. There are 5 trait-associated genes (*ARHGAP1*, *CBFB*, *CTNNB1*, *FGFRL1*, and *SOC22*) were annotated in both mouse knockout models and osteoblast differentiation. Our work is not only useful for understanding the etiology of osteoporosis and the biology of non-coding sequences in the genome, but also guides for post-GWAS functional experiments.

**miRNAs targeting the mechanotransduction pathway associated with osteon number in aging baboons.** *E.E. Quillen<sup>1,2</sup>, L.A. Cox<sup>1,2</sup>, D.P. Nicoletta<sup>3</sup>, T.L. Bredbenner<sup>4</sup>.* 1) Department of Internal Medicine - Molecular Medicine, Wake Forest School of Medicine, Winston-Salem, NC; 2) Center for Precision Medicine, Wake Forest School of Medicine, Winston-Salem, NC; 3) Materials Engineering Department, Southwest Research Institute, San Antonio, TX; 4) Department of Mechanical and Aerospace Engineering, University of Colorado Colorado Springs, Colorado Springs, CO.

The key cells regulating bone and cartilage remodeling – osteocytes, osteoblasts, osteoclasts and chondrocytes – are acutely responsive to external mechanical signals through a process known as mechanotransduction. The goal of this study is to determine if miRNAs targeting the mechanotransduction pathway are associated with increased bone fragility using a baboon model. No work was done on living animals and no animals were euthanized specifically for this study. RNA was extracted from white blood cells collected at necropsy and miRNA libraries were sequenced on the Illumina HiSeq2500. Predicted miRNAs were identified based on miRbase. miRNAs from 20 miRNA families predicted to target genes identified as part of the generalized mechanotransduction pathway were identified using TargetScan version 7.2. Skeletal fragility is a major risk factor for fracture but is incompletely indexed by the most common clinical indicator, bone mineral density. Histological analysis of the cortical midshaft and femoral neck of each baboon was used to characterize a panel of traits including osteon number and size as well as the area of Haversian canals. Linear models of the influence of miRNAs on these measures of bone structure were fit while controlling for age, sex, and body size of the baboons. Associations with 9 miRNAs passed Bonferroni correction, with the three largest effect sizes in isoforms of miR-9-5 on osteon number. This miRNA has previously been associated with reductions in skeletal cell proliferation, differentiation, and adhesion *in vitro*. Regulation of this miRNA is a possible mechanism of action for the osteoporosis drug strontium ranelate. This finding suggests This work was funded by NIH/NIAMS R01 AR064244 and R01 AR060341.

**A genome-wide SNP x smoking interaction study identifies novel genetic risk loci for aggressive periodontitis in smokers and gives evidence that *ST8SIA1* is regulated by tobacco smoke.** A.S. Schaefer<sup>1</sup>, S. Freitag-Wolf<sup>1</sup>, M. Munz<sup>1</sup>, R. Wiehe<sup>1</sup>, A. Franke<sup>2</sup>, W. Lieb<sup>3</sup>, H. Dommisch<sup>1</sup>, *European Periodontitis Consortium*. 1) Charité - University Medicine Berlin, Research Center ImmunoSciences, Dept. of Periodontology and Synoptic Dentistry, Berlin, Germany; 2) Institute of Medical Informatics and Statistics, University Clinic Schleswig-Holstein, Kiel, Germany; 3) Institute of Clinical Molecular Biology, Christian-Albrechts-University Kiel, Germany; 4) Institute of Epidemiology, Christian-Albrechts-University Kiel, Germany.

Periodontitis (PD) is an inflammatory disease of the oral cavity that leads to the resorption of the alveolar bone. The early-onset and severe phenotype aggressive periodontitis (AgP) has a heritability of 50%. Smoking is a well-established environmental risk factor for PD but there is considerable variation in age of disease onset and bone loss among smokers. Differences in smoking intensity are not solely responsible for this variation. It is also influenced by genotype differences between patients, which respond differently to exposure to the same environmental factor, indicating that to some extent, the sensitivity to smoking rather than AgP itself is inherited. Here, we investigated whether the relative risk of AgP in smokers is modified by genetic variants. For this purpose, we used imputed genotype data from a recently performed genome-wide association study. We regarded the early-onset phenotype AgP as particularly suited for this investigation, because the proposed gene x environment interaction (GxE) is revealed within years of exposure rather than within decades. We adopted a 2-tiered approach, including the verification in control individuals of the gene-smoking independence assumption implicit to the case-only design, followed by a case-only analysis to identify gene-smoking interactions that are relevant for the disease etiology of PD (stage I). Subsequently, we performed a case-control analysis, to identify variants that show additional gene-smoking interaction beyond the specific disease phenotype of PD (stage II). To proof the transcriptional response of identified SNP associations at protein coding genes to cigarette smoke, we stimulated primary gingival fibroblasts with cigarette smoke extract *in vitro*. Genome-wide analysis of GxE was performed with 896 AgP cases and 7,104 controls. In the case-only design, 13 loci corresponded to the pre-assigned significance cut-off for suggestive association with  $P < 5 \times 10^{-5}$ , supported by  $\geq 2$  flanking SNPs with  $P < 10^{-5}$ . In the case-control design, performed to assess GxE beyond the specific disease phenotype of AgP, we found 5 additional loci. In the smoke stimulated cells, *ST8SIA1* showed significant upregulation ( $p < 10^{-7}$ , five biological replicates). We conclude that *ST8SIA1* is a risk gene for AgP and the effects of the associated variants are exposed in conjunction with smoking in genetically predisposed individuals.

**CRISPR/Cas9 mediated edits in osteoblast cell lines to characterize a novel osteoporosis gene, *DAAM2*.** L. Laurent<sup>1</sup>, J.A. Morris<sup>1,2</sup>, A. Luco<sup>3</sup>, L. Nguyen-Yamamoto<sup>3</sup>, A. Pramatarova<sup>4</sup>, D. Goltzman<sup>5</sup>, J.B. Richards<sup>1,2,6,7</sup>. 1) Lady Davis Institute, Jewish General Hospital, McGill University, Montreal, Quebec, Canada; 2) Department of Human Genetics, McGill University, Montreal, Quebec, Canada; 3) Research Institute of the McGill University Health Centre, Montreal, Quebec, Canada; 4) McGill University and Genome Quebec Innovation Centre, Montreal, Quebec, Canada; 5) Division of Endocrinology, Department of Medicine, McGill University, Montreal, Quebec, Canada; 6) Departments of Medicine and Epidemiology, Biostatistics and Occupational Health, McGill University, Montreal, Quebec, Canada; 7) Department of Twin Research and Genetic Epidemiology, King's College London, London, UK.

**Introduction:** Osteoporosis is a common and complex disease for which novel therapeutic options are a health priority. Through large-scale GWAS followed by integrative analyses with statistical fine-mapping and functional genomics, we have identified a list of target genes with strong evidence for being novel osteoporosis genes. We are developing a genome editing validation pipeline to validate target genes and have selected one top candidate gene as a proof-of-principle study, *DAAM2*. Using CRISPR/Cas9 and the human osteoblast cell line, SaOS-2, we studied the effect of knocking down *DAAM2* in this osteoblast-like cell with the ability to mineralize. **Methods:** Three guide RNAs (gRNA) targeting exon 2 of *DAAM2* were designed and cloned in the PX458 plasmid expressing green fluorescent protein (pSpCas9(BB)-2A-GFP). SaOS-2 cells were transfected with the constructed plasmids or an intact control plasmid and GFP-sorted in a single-cell model. Clones edited successfully with double-stranded breaks in *DAAM2* were identified by immunofluorescence and Western blot as well as MiSeq sequencing. Bone phenotypes such as mineralization, alkaline phosphatase (ALP) activity and collagen type I (*COL1A1* and *COL1A2*) expression were assessed. **Results:** Successful edits were induced using two of three gRNAs, and decreases of 82.5% and 66.5% of *DAAM2* protein level was detected for the two edited clones compared to control cells. We observed a 9-fold increase of mineralization in control cells treated with osteogenic factors, whereas induced mineralization was not observed in clones with successful *DAAM2* edits. No difference of ALP activity was reported in the three strains. Finally, an increase of *COL1A2* mRNA levels was observed for only one of the edited clones compared to control cells. **Conclusions:** In summary, by successfully applying CRISPR/Cas9 editing to decrease *DAAM2* protein expression in a human osteoblast cell line, we have confirmed that *DAAM2* is crucial for bone biology. Further studies will improve our understanding of the *DAAM2* molecular pathway and are currently underway. Finally, this study is a proof of concept, which will validate our target gene approach to discover new therapeutic targets for osteoporosis.

Human adult height is a highly heritable, classic polygenic trait. Previous genome wide association study (GWAS) meta-analyses and exome chip studies by the GIANT consortium and others have identified >900 independent common variant association signals in >400 near-independent genetic loci that explain >25% of the heritability in height. To identify additional associations with height, we performed a GWAS on 456,426 European-ancestry participants from UKBiobank (UKB) using BOLT-LMM and combined these results with available GWAS summary statistics from GIANT (N~250,000; Wood et al. 2015). We identified 3,290 genome-wide significant associations in 712 loci, explaining >30% of heritability. In parallel, we are performing a meta-analysis of >250 studies from 6 different ancestries (not including UKB, total N = 906,589). All have genotype data imputed from the 1000Genomes Phase3 reference panel; many European-ancestry samples were also imputed to the Haplotype Reference Consortium or population-specific reference panels. Linear mixed effects models (implemented in Rvtest) and the first four principal components were used to adjust for relatedness and population structure. Association testing used inverse normally transformed age-adjusted residuals, stratified by sex and (if relevant) disease status. A preliminary meta-analysis using raremetal in 140 of these studies with European ancestry samples (total N = 618,362), imputed to 1000Genomes Phase3, identifies 1186 independent loci (defined as 1Mb apart from each other), including novel signals. Of the 1000 lead variants where UKB results were available, 918 strongly replicated in UKB ( $p < 5 \times 10^{-8}$ , which is  $p < 0.05$  corrected for 1000 tests). Encouragingly, despite the large sample size, little evidence of association was observed at a highly stratified variant known to be associated with lactase persistence (rs4988235,  $p$ -value = 0.002). We will be adding data from cohorts from multiple ancestries and from the UKBiobank, providing a multiethnic discovery meta-analysis sample size of >1.5 million; large additional replication cohorts will be available. Secondary analyses will include fine mapping, aggregate testing of low frequency variants, and pathway analyses to delineate likely causal genes and biological mechanisms. Through our collaborative efforts, we have assembled a unique, large resource for understanding the genetic architecture of height and, more generally, polygenic traits.

**Expression quantitative trait locus data from human osteoclasts suggests a role for the *C7orf73* and *DCSTAMP* genes in Paget's disease of bone.** S.G. Wilson<sup>1,2,3</sup>, B.H. Mullin<sup>1,2</sup>, K. Zhu<sup>1,2</sup>, S.J. Brown<sup>2</sup>, S. Mullin<sup>1,2</sup>, J. Tickner<sup>1</sup>, N.J. Pavlos<sup>1</sup>, F. Dudbridge<sup>4</sup>, J. Xu<sup>1</sup>, J.P. Walsh<sup>2,5</sup>. 1) School of Biomedical Sciences, The University of Western Australia, Crawley, WA, Australia; 2) Department of Endocrinology & Diabetes, Sir Charles Gairdner Hospital, Nedlands, WA, Australia; 3) Department of Twin Research & Genetic Epidemiology, King's College London, London, UK; 4) Department of Health Sciences, University of Leicester, Leicester, UK; 5) Medical School, University of Western Australia, Crawley, WA, Australia.

Paget's disease of bone (PDB) is a focal disorder of bone remodeling with clinical features of bone pain, deformity, neurological complications and risk of malignant transformation. The disease process is initiated by increases in osteoclast mediated bone resorption with a subsequent compensatory increase in new bone formation resulting in a mosaic of woven and lamellar bone at affected sites that disrupts bone architecture and structure. While the primary feature of PDB at the cellular level is increased bone resorption, the osteoclasts in affected bone are larger in size than normal osteoclasts, have more nuclei and display characteristic intra-nuclear inclusion bodies. Genetic factors have been shown to play an important role in the pathogenesis of PDB, and genome-wide association studies (GWAS) have identified 7 genetic loci as associated with PDB at the genome-wide level. Expression quantitative trait locus (eQTL) studies using disease-relevant cell types have increasingly been integrated with the results from GWAS to identify genes through which the observed GWAS associations are potentially mediated. We recently generated a unique osteoclast-specific eQTL resource using cells differentiated *in vitro* from 158 participants for study of the genetics of bone disease. Considering the major role osteoclasts have in PDB, we used this resource to investigate potential genetic regulatory effects for the 7 genome-wide significant loci for PDB. All expressed genes located within 500 kb of each GWAS variant were included in the analysis, which was performed using the FastQTL software. After correction for multiple testing, we observed statistically significant associations for rs4294134 with expression of the gene *C7orf73*, and rs2458413 with expression of the genes *DPYS* and *DCSTAMP*. The eQTL associations observed for rs4294134 with *C7orf73*, and rs2458413 with *DCSTAMP* were further supported by eQTL data from other tissue types. The product of the *C7orf73* gene has not been extensively studied, however the *DCSTAMP* gene has an established role in osteoclast differentiation and the associations seen between rs2458413 and PDB are likely mediated through regulatory effects on this gene. This study further highlights the value of eQTL data in determining which genes are relevant to GWAS loci.

**RNA sequencing of osteocalcin-positive blood cells from adolescent idiopathic scoliosis patients reveals abnormal expression of cytoskeletal genes.** E.A. Terhune<sup>1</sup>, C.I. Wethey<sup>1</sup>, R.M. Baschal<sup>1</sup>, M.T. Cuevas<sup>1</sup>, K.D. Robinson<sup>1</sup>, K.A. Payne<sup>1</sup>, K.L. Jones<sup>2</sup>, N.H. Miller<sup>1,3</sup>, E.E. Baschal<sup>1</sup>. 1) Department of Orthopedics, University of Colorado Anschutz Medical Campus, Aurora, CO; 2) Department of Pediatrics, University of Colorado Anschutz Medical Campus, Aurora, CO; 3) Musculoskeletal Research Center, Children's Hospital Colorado, Aurora, CO.

Background: Adolescent Idiopathic Scoliosis (AIS) is the most common pediatric spinal deformity, which affects ~3% of healthy children. The hereditary nature of this disorder is well accepted, but the overall genetic etiology of AIS is not well understood. Recent studies have identified osteocalcin-expressing blood cells originating from the bone marrow compartment, which represent a unique opportunity to study bone biology without requiring the collection of patient bone samples. Methods: In this study, we isolated osteocalcin-positive peripheral blood mononuclear cells (PBMCs) from the blood of four female AIS patients and four controls via fluorescence-activated cell sorting (FACS). We isolated RNA from these cells and completed RNA sequencing to identify the transcriptome profiles of osteocalcin-positive PBMCs in AIS and control individuals. Cufflinks software was used to calculate FPKM (normalized transcript levels) and p-values for AIS vs. control gene expression. Principal component analysis revealed that the samples were clustered based on both scoliosis status and cell sorting quality. We decided to analyze only the samples with high quality cell sorting, leaving us with two AIS and two control samples. We then used the Cytoscape plugin BiNGO to identify pathways and GO terms that are over-represented in the genes that have significantly different expression levels in AIS vs. control individuals. Results: We found that 34 transcripts were differentially expressed between AIS and control cells (either >2 or <-2 FPKM fold change and  $p < 0.05$ , or  $p < 0.01$ ). These transcripts included those from microtubule genes, which were mildly upregulated in AIS (*KIF2A*, 1.23 fold change,  $p = 0.0043$ ; *CALM1*, 1.2 fold change,  $p = 0.0085$ ) and actin genes, which were downregulated in AIS (*CAPG*, -2.03 fold change,  $p = 0.031$ ; *FGD3*, -2.13 fold change,  $p = 0.00047$ ; *VCL*, -2.19 fold change,  $p = 0.023$ ; and *RAB10*, -2.15 fold change,  $p = 0.0075$ ). BiNGO analysis revealed that these 34 transcripts were enriched in GO terms related to actin-based cell projections, other cytoskeletal proteins, and glycoproteins. Conclusions: This is the first study to analyze circulating osteocalcin-positive cells in AIS, and we suggest that abnormal expression of cytoskeletal genes in bone-forming precursor cells may contribute to AIS etiology.

**2319W**

**Investigating the GWAS-implicated loci for rheumatoid arthritis in Pakistani population.** M. Aslam<sup>1,2</sup>, P. John<sup>2</sup>, F. Kang-Hsien<sup>1</sup>, A. Bhatti<sup>2</sup>, E. Feingold<sup>1</sup>, F. Demirci<sup>1</sup>, M. I. Kamboh<sup>1</sup>. 1) University of Pittsburgh, Pittsburgh, PA; 2) National University of Sciences and Technology, Islamabad, Pakistan.

Rheumatoid arthritis (RA) is a complex, multifactorial, autoimmune disorder that is characterized by chronic inflammation of the joints. A complex interplay between genetic and environmental factors initiates the abnormal response of the immune system and leads to disease manifestation. The heritability estimate for RA is approximately 60%. RA affects ~1% of the general population worldwide while its prevalence is ~0.5% in Pakistan. Genome-wide association studies (GWAS) have identified more than 50 RA genetic loci in European populations. Given the anticipated overlap of RA-relevant genes and pathways across different ethnic groups, we sought to replicate 58 GWAS-implicated RA-related SNPs reported in Europeans in our Pakistani case-control sample. We genotyped 58 SNPs in 1959 unrelated Pakistani subjects comprising 1,222 RA cases and 737 controls. All cases met the ACR 1987 classification criteria for RA. Genotyping was performed using iPLEX or TaqMan methods. A total of 42 SNPs were included in the final association analysis after excluding those that failed assay design/run or post-run QC analysis. Ten SNPs (*PVT1*/rs1516971, *PADI4*/rs2240336, *CEP57*/rs4409785, *STAT4*/rs13426947, *HLA-B\*IMICA*/rs2596565, *C5orf13*/rs26232, *CCL21*/rs951005, *GATA3*/rs2275806, *CD5*/rs595158 and *HLA-DRB1*/rs660895) were replicated in our Pakistani sample at false discovery rate (FDR) <0.20 with *P* values ranging from 4.73E-06 to 4.02E-02. Our results indicate that several RA susceptibility loci are shared between Pakistani and European populations supporting the role of common genes/pathways.

**2320T****Associations between gene expression and clinical disease activity during and after pregnancy among women with rheumatoid arthritis: A pilot study.**

**A pilot study.** D. Jawaheer<sup>1,2,3</sup>, D. Goin<sup>1,4</sup>, M. Smed<sup>5</sup>, N. Jewell<sup>6</sup>, L. Pachter<sup>6</sup>, J.L. Nelson<sup>7,8</sup>, J. Olsen<sup>9</sup>, M. Hetland<sup>6,10</sup>, V. Zoffmann<sup>9</sup>, H. Kjærgaard<sup>6</sup>. 1) UCSF Benioff Children's Hospital Oakland Research Institute, Oakland, CA; 2) University of California San Francisco, San Francisco, CA; 3) Aarhus University, Aarhus, Denmark; 4) University of California Berkeley, Berkeley, CA; 5) Juliane Marie Center, Copenhagen, Denmark; 6) California Institute of Technology, Pasadena, CA; 7) Fred Hutchinson Cancer Research Center, Seattle, WA; 8) University of Washington, Seattle, WA; 9) DANBIO, Glostrup, Denmark; 10) University of Copenhagen, Copenhagen, Denmark.

**Objective:** To identify genes whose expression patterns during the pregnancy and post-partum periods are associated with clinical disease activity among women with rheumatoid arthritis (RA). **Methods:** We have established a prospective RA pregnancy cohort, with clinical data and blood samples collected before, during and after pregnancy. Women who improved during pregnancy were selected for analysis (n=8). RA disease activity (DAS28CRP4) was assessed at each time point. Global gene expression profiles were generated using RNA-sequencing (RNA-seq). Raw reads were pseudo-aligned and quantified using kallisto. Random effects regression models were used to test for association between gene expression and RA disease activity (a) during pregnancy (P1), and (b) in the post-partum period (P2). Significance was assessed using a FDR-adjusted threshold of  $q < 0.05$  and a fold-change (FC) of at least 2. **Results:** During pregnancy, 444 genes had expression patterns significantly associated with disease activity, of which 20 showed at least 2-fold change in expression. While these 20 genes were not significantly enriched in specific pathways, several had immune-related functions and included the GNL1, FKBP8, CTSE, IFIT3 and IGKV3-20 genes. GNL1 encodes a protein that is a component of cytotoxic granules in T cells; FKBP8 is involved in immune-regulation, lymphocyte signaling, and regulation of apoptosis; CTSE is involved in antigen processing; IFIT3 and IGKV3-20 are involved in immune-regulation. In the post-partum period, 2,030 genes had expression patterns significantly associated with disease activity, with 64 of these showing at least 2-fold change in expression from the third trimester. This set of 64 genes was significantly enriched in several immune-related pathways including inflammatory response, defense response, innate immune response and regulation of inflammatory response. Interestingly, there was no overlap between the 20 genes and the 64 genes with expression patterns associated with RA disease activity during and after pregnancy, respectively. **Conclusion:** In this pilot RA pregnancy cohort study with longitudinal RNA-seq data, several candidate genes were identified as significantly associated with disease activity during the pregnancy and post-partum periods. However, the findings also suggest that different mechanisms may be involved in the pregnancy-induced improvement and post-partum flare.

**2321F****GWAS suggests an association between lipid metabolism and avascular necrosis of the hip.**

M.M. Lee<sup>1</sup>, M. Shivakumar<sup>2</sup>, S.A. Lietman<sup>2</sup>, T.R. Bowen<sup>2</sup>, Y. Zhang<sup>1</sup>. 1) Genomic Medicine Institute, Geisinger, Danville, PA; 2) Orthopedic Department, Geisinger, Danville, PA; 3) Biomedical & Translational Informatics Institute, Geisinger, Danville, PA.

**Background:** Avascular Necrosis (AVN) is the death of bone tissue due to loss of blood to the bone. Trauma, alcoholism and steroids are risk factors for AVN. Familial and twin studies also suggested the existence of a genetic predisposition. In this study, we conducted a GWAS in patients with AVN of the hip from the Geisinger MyCode® Community Health Initiative to search for possible genetic causes of AVN of the femoral head. **Method:** The AVN cohort was identified from electronic health record (EHR) using ICD codes. Cases were patients with either ICD-9 code of 733.42 or ICD-10 code of M87.05. Controls did not have any of these codes. The controls were randomly selected and were matched for age and BMI. Genotype data was generated using Illumina OmniExpressExome. SNPs with marker call rate <99% or minor allele frequency <1% were removed. Samples with missing genotypes > 5% were removed from further analysis. One of the pairs of individuals with first- or second-degree relatedness were also removed from the analysis. A total of 197 cases and 1778 controls were included in the final association tests. Logistic models were adjusted for age, sex, BMI, lipids levels and the first 6 genetic principle components. **Results:** SNPs with suggestive association ( $p < 1 \times 10^{-3}$ ) were identified in the *LMF1* loci, which encodes for lipase mutation factor 1. The most significant SNP is rs3751666 ( $P = 4.056 \times 10^{-7}$ , OR = 0.5398, 95% CI [0.4253, 0.685]). *LMF1* has been shown to be associated with hypertriglyceridemia. In our analysis, *LMF1* remained associated with AVN after adjusting for LDL, HDL and TG, potentially indicating its direct role on AVN. **Conclusion:** Our results implicates a role of lipid metabolism in the pathogenesis of AVN of the hip. Future studies with a larger sample size are needed to replicate our findings.

**2322W**

**Using co-expression network analysis to inform genome-wide association studies for bone mineral density.** O.L. Sabik<sup>1,2</sup>, G.M. Calabrese<sup>1</sup>, C.L. Ackert-Bicknell<sup>3</sup>, C.R. Farber<sup>2,4</sup>. 1) Center for Public Health Genomics, School of Medicine, University of Virginia, Charlottesville, VA 22908; 2) Department of Biochemistry and Molecular Genetics, School of Medicine, University of Virginia, Charlottesville, VA 22908; 3) Center for Musculoskeletal Research, University of Rochester Medical Center, University of Rochester, Rochester, NY 14624; 4) Department of Public Health Sciences, University of Virginia, Charlottesville, VA 22908.

Osteoporosis is a disease characterized by reduced bone mineral density (BMD) and increased bone fragility. About half of the variation in BMD across the human population can be explained by genetic variation, and genome-wide association studies (GWASs) have identified over 200 regions of the human genome containing genetic variants influencing BMD. Despite the wealth of genetic signals identified, the genes and mechanisms through which these loci impact bone remain unknown. Here, we hypothesized that we could identify the causal genes underlying GWAS loci for BMD by analyzing GWAS data in the context of a co-expression network. Our approach was based on the idea that causal genes likely influence BMD through the same biological process (e.g. osteoblast-mediated bone formation) and genes involved in specific biological processes are often co-expressed. We applied weighted gene co-expression network analysis (WGCNA), to genome-wide gene expression profiles from mouse osteoblasts and identified 65 modules of co-expressed genes. Of these, one module was significantly enriched for genes located within BMD GWAS loci (odds ratio (OR) = 3.4,  $P = 4 \times 10^{-9}$ ) and its expression was significantly correlated with *in vitro* levels of mineralization ( $r = 0.49$ ; FDR = 0.012). This module was also enriched for skeletal development genes (OR = 8.58;  $P < 2.2 \times 10^{-16}$ ), and genes that result in a bone phenotype when knocked-out (OR = 4.06;  $P = 2.14 \times 10^{-9}$ ). Using independent gene expression profiles measured throughout osteoblast differentiation, we observed that genes in this module were expressed in two distinct patterns, either early or late in osteoblast differentiation, and the enrichments listed above were increased in the late differentiation group. Additionally, we observed that the mean connectivity of GWAS-implicated genes was significantly higher than non-GWAS genes, leading us to prioritize genes based on their degree of connectivity within the module. Of the 30 most highly connected genes in the module, 13 had not been previously linked to bone mass and three, *B4GALNT3*, *CADM1*, and *SLC8A3*, were located within GWAS loci for BMD. For all three genes, their expression in humans was influenced by expression quantitative trait loci (eQTL) that colocalized with the BMD associations and mouse knockouts demonstrated altered BMD. These data have identified three genes underlying BMD GWAS loci and provide a resource for understanding the complex network of genes directing bone mass.

**HLA-C\*06:02 genotype is a predictive biomarker of biologic treatment response in psoriasis.** N. Dand on behalf of the PSORT consortium. King's College London, London, United Kingdom.

Biologic therapies can be highly effective for the treatment of immune mediated inflammatory diseases, but some patients respond poorly to certain biologics. Predictive biomarkers to guide drug selection in clinical practice could significantly improve patient outcomes and reduce wasted healthcare expenditure. In psoriasis, *HLA-C\*06:02* has been established as the primary genetic susceptibility allele. Patients with and without this allele can exhibit clinical differences and there is some evidence associating *HLA-C\*06:02* status with response to ustekinumab (a biologic inhibiting IL-12/23 signalling). Using a large national psoriasis registry in the UK, we present the first pharmacogenetics study of comparative response to the two most commonly prescribed biologics for psoriasis: ustekinumab and adalimumab (anti-TNF $\alpha$ ). Specifically we sought to test whether *HLA-C\*06:02* is an effective predictive biomarker for treatment selection. The study includes longitudinal treatment and response observations and detailed clinical data on an unparalleled scale. HLA alleles were imputed from Illumina HumanOmniExpressExome genotype data for 1,326 patients for whom PASI90 response status (90% reduction in psoriasis area and severity index relative to baseline) was observed after 3, 6 or 12 months of treatment. We developed regression models of PASI90 response, examining the interaction between imputed *HLA-C\*06:02* dosage and drug type (adalimumab or ustekinumab) while accounting for potentially confounding clinical variables. A statistically significant interaction was observed at all time-points (most strongly at six months:  $P = 3.76 \times 10^{-5}$ ). Non-carriers of the *HLA-C\*06:02* allele were significantly more likely to respond to adalimumab than ustekinumab (odds ratio at six months 2.95,  $P = 5.85 \times 10^{-7}$ ), and this difference was greater when selecting patients with psoriatic arthritis, a common comorbidity (OR = 5.98,  $P = 6.89 \times 10^{-5}$ ). No significant difference in response was seen in *HLA-C\*06:02* carriers. Furthermore, results from HLA-wide analysis were consistent with *HLA-C\*06:02* itself being the mechanistically relevant allele. We conclude that reference to *HLA-C\*06:02* status could offer substantial clinical benefit when selecting treatments for severe psoriasis. Our study design provides a model that could facilitate more effective deployment of these expensive biologic therapies across immune-mediated disease more broadly.

**Genetic susceptibility to autoimmune diseases: The vitiligo model.** *L. T. Martins<sup>1</sup>, H.R. Frigeri<sup>2</sup>, C.C.S. Castro<sup>3</sup>, M.T. Mira<sup>1,3</sup>.* 1) Graduate Program in Health Sciences, Pontifícia Universidade Católica do Paraná, Curitiba, Brazil; 2) School of Life Science, Pontifícia Universidade Católica do Paraná, Curitiba, Brazil; 3) School of Medicine, Pontifícia Universidade Católica do Paraná, Curitiba, Brazil.

Vitiligo is an acquired, multifactorial pigmentary disease characterized by progressive loss of melanocytes. The reasons leading to melanocyte damage and its subsequent disappearance of the skin remain largely unknown and several hypotheses have been investigated; among them, the most explored by researchers assumes an autoimmune basis for the disease. Supporting this hypothesis is the frequent co-occurrence of autoimmune diseases with vitiligo. In addition, various genetic *loci* associated with vitiligo harbor key immune response genes. Symmetrically, genetic studies involving autoimmune pathologies have identified variants also associated with vitiligo. Our hypothesis is that vitiligo can be used as a model for the study of the genetic component controlling autoimmunity. To test this hypothesis, we investigated for association between vitiligo and genes *CYP27B1*, *REL*, *TNFAIP3* and *IL2/IL21*, all previously related to autoimmune diseases associated with vitiligo. The study was performed using two independent population samples: a discovery, family-based set of 211 trios and a replication set of 131 cases and 119 controls. A total of 14 genetic markers providing complete physical coverage of the candidate genes were genotyped using fluorescence-based platforms ABI 7500 or Thermo-Life QuantStudio 7 Flex. Statistical analysis was performed using the transmission disequilibrium test (for the family-based population) and multivariate logistic regression techniques. Statistically significant association with vitiligo was detected between rs6545836 of the *REL* gene and rs2069763 of the *IL2* gene in the family-based sample. Both association signals were concentrated among patients displaying autoimmune comorbidity and non-segmental vitiligo, consistently with our hypothesis. Evidence for validation was detected for rs2069763 in the case-control sample. Our findings suggest *REL* and *IL2* as new vitiligo susceptibility genes and reinforce the hypothesis of a shared genetic mechanism controlling vitiligo and other autoimmune diseases.

**Non-MHC loci associated with psoriatic arthritis reveal evidence of a potential mechanism for joint involvement.** *M.T. Patrick<sup>1</sup>, P.E. Stuart<sup>1</sup>, K. Raja<sup>1,2</sup>, G.R. Abecasis<sup>3</sup>, J.J. Voorhees<sup>1</sup>, T. Tejasvi<sup>4</sup>, J.E. Gudjonsson<sup>1</sup>, V. Chandran<sup>5,6,7,8</sup>, P. Rahman<sup>9</sup>, D.D. Gladman<sup>5,6,7</sup>, R.P. Nair<sup>1</sup>, J.T. Elder<sup>1,4</sup>, L.C. Tsoi<sup>1,3,10</sup>.* *An international group of investigators studying psoriasis genetics.* 1) Department of Dermatology, University of Michigan, Ann Arbor, MI; 2) Morgridge Institute for Research, University of Wisconsin, Madison, WI; 3) Department of Biostatistics, Center for Statistical Genetics, University of Michigan, Ann Arbor, MI; 4) Ann Arbor Veterans Affairs Hospital, Ann Arbor, MI; 5) Department of Medicine, Division of Rheumatology, University of Toronto, Toronto, Ontario, Canada; 6) Centre for Prognosis Studies in the Rheumatic Diseases, Krembil Research Institute, University of Toronto, Toronto, Ontario, Canada; 7) Institute of Medical Science, University of Toronto, Toronto, Ontario, Canada; 8) Department of Laboratory Medicine and Pathobiology, University of Toronto, Toronto, Ontario, Canada; 9) Memorial University, St. John's, Newfoundland, Newfoundland and Labrador, Canada; 10) Department of Computational Medicine & Bioinformatics, University of Michigan, Ann Arbor, MI.

The heritability of psoriatic arthritis (PsA) is higher than for psoriasis in general, yet no markers outside the major histocompatibility complex (MHC) have so far been found to distinguish PsA from cutaneous-only psoriasis (PsC) with genome-wide significance. Nevertheless, we showed in a recent meta-analysis of PsA vs. PsC associations, utilizing ~10 million markers from over 7,000 psoriatic patients across 6 cohorts, that non-MHC loci contribute significantly to the risk of psoriatic arthritis among psoriatic patients. We hypothesized that an integrative approach, utilizing additional chromatin accessibility, pharmacologic and transcriptomic data to study non-MHC genetic loci showing suggestive evidence of association ( $p < 1 \times 10^{-4}$ ), could provide valuable information about the mechanisms contributing to the pathogenesis of PsA. We first demonstrated that these suggestively associated markers are significantly enriched with active regulatory elements (predicted using H3K27ac chromatin marks) for chondrogenic differentiated cells ( $p = 3.99 \times 10^{-5}$ , OR=3.09) and osteoblasts ( $p = 3.33 \times 10^{-4}$ , OR=2.66). Furthermore, genes close to these markers are targets of existing anti-PsA drugs (e.g. the NSAIDs diclofenac, indomethacin and piroxicam) and have been implicated in Wnt signaling. For example, three of the most significant distinct loci (encompassing *FZD4*, *FUT8* and *RUNX1*, respectively) overlap with active enhancer marks, are potential PsA drug targets, and are involved in Wnt signaling. Previous research has suggested dysregulation in Wnt signaling can lead to the excessive bone formation seen in PsA, and we found that expression levels of several genes participating in the Wnt signaling pathway, including *WNT5A*, *DKK2* and *FZD8*, are elevated (FDR  $\leq 5\%$ ) in blood among psoriatic arthritis patients after they developed PsA, when comparing with pre-conversion ( $p = 5.26 \times 10^{-4}$ , OR=2.09). In fact, all six members of the Frizzled family of Wnt receptors that are differentially expressed in post-conversion blood manifest elevated, as opposed to decreased expression post-conversion ( $p = 0.0225$ ). Our study identifies testable mechanisms by which non-MHC loci may impact PsA risk via their effects upon bone and joint physiology.

**Association of MCP-1 and ACE genetic variants with osteoporotic population of Punjab: A pilot study.** M. Singh, P. Bhardwaj, G. Singh, H.S. Sandhu, V. Sambyal, A.J.S. Bhanwer. Guru Nanak Dev University, Amritsar-143005, Punjab, India.

Osteoporosis is a systemic skeletal disease, characterized by low bone mass and micro-architectural deterioration of bone tissue. The condition predisposes to an increased risk of fracture, is a major health problem worldwide and called as "silent disease" because it progresses without symptoms until a fracture occurs. Besides environmental correlates, twin and family studies showed that bone mineral density (BMD) and bone turn over are under strong genetic control. Monocyte chemoattractant protein-1 (*MCP-1*) is a member of the C-C chemokine family, and a potent chemotactic factor for monocytes. *MCP-1* has emerged as a potential genetic variant that plays a strong genetic role in skeletal homeostasis including acquisition and maintenance of bone mass. This study enrolled 221 subjects (116 osteoporotic cases and 105 healthy controls) from Punjab (North-West India). *MCP-1* (rs3917887) Ins/Del polymorphism was genotyped and analyzed in all subjects using PCR. No significant association of rs3917887 polymorphism was observed with osteoporosis. Furthermore, the data was analyzed on the basis of gender. In males, D allele [ $p=0.03$ ,  $1.81(1.05-3.15)$ ] and dominant model (ID+II vs DD) [ $p=0.02$ ,  $2.48(1.1-5.62)$ ] conferred increased risk towards pathogenesis of osteoporosis. However, females revealed no association with the osteoporosis etiology. Though, osteoporosis is most commonly found in post-menopausal women because of oestrogen deficiency and is thought of as a women's disease. Nevertheless fractures or bone loss also occur in men and majority of males with fractures remain undiagnosed. The progression of osteoporosis in males is scanty but cannot be overlooked as observed in this study. However, more SNPs on larger data set will be replicated to establish better association of *MCP-1* with osteoporosis. The financial assistance to M.S. by DST-PURSE, Gol is acknowledged.

**2327F**

**Association of knee osteoarthritis with Pvull polymorphism and serum levels of Col2a1 gene.** R.Nath, Srivastava<sup>1</sup>, A.C. Sharma<sup>1</sup>, S.R. Srivastava<sup>1</sup>, S. Raj<sup>2</sup>. 1) Orthopaedic surgery, King George's Medical University, Lucknow, Uttar Pradesh, India; 2) Westminster college, Salt Lake City, UT, USA.

**Objective:** To investigate the relationship between Pvull single nucleotide polymorphism (SNP rs1635560) and knee osteoarthritis (KOA) in North Indian Population **Methods:** A total of 300 cases that confirmed radiographic KOA and equal number of age- sex matched healthy controls were enrolled. In this study cases consisted of men and women  $\geq 40$  years that fulfilled American College of Rheumatology (ACR) clinical and radiographic criteria for KOA. Venous blood samples were obtained from all cases as well as controls for genetic and expression analysis. Polymerase chain reactions were performed for genetic analyses using specific primer. In addition, the effect of serum levels of SNP rs1635560 on cases and controls were examined by enzyme-linked immunosorbent assay (ELISA) for expression analysis. **Results:** SNP rs1635560 of Col2a1 was associated with KOA ( $P < 0.01$ ). TT genotype was significantly ( $p < 0.01$ ) associated with KOA as compared to CC genotype, However CT was not associated ( $p < 0.078$ ). In addition when alleles were compared, T allele was observed to be significantly associated with KOA ( $P < 0.002$ ). The level of Col2a1 in serum significantly increased in KOA group, compared with those in control group ( $P < 0.05$ ,  $\chi^2$ ), with  $30.2 \pm 7.8$  ng/ml (Mean  $\pm$  SD) in the OA group and  $15.6 \pm 4.2$  ng/ml in the control group. **Conclusion:** Our data indicate that genetic variation in the Col2a1 gene is involved in the risk of KOA in North Indian population, confirming the results from previous studies on the potential importance of this gene in the pathogenesis of KOA. .

**Identification of novel risk regions from TWAS and cross-trait genetic correlations for Dupuytren's disease.** *M. Major<sup>1</sup>, M. Ng<sup>2</sup>, D. Furniss<sup>2,3,4</sup>, B. Pasaniuc<sup>5,6</sup>, R. Ophoff<sup>7</sup>.* 1) Bioinformatics Interdepartmental Program, University of California Los Angeles, Los Angeles, CA; 2) Nuffield Department of Orthopaedics, Rheumatology, and Musculoskeletal Science, University of Oxford, Oxford, UK; 3) Department of Plastic and Reconstructive Surgery, Oxford University Hospitals NHS Foundation Trust, John Radcliffe Hospital, Oxford, UK; 4) NIHR Biomedical Research Centre, NDORMS, University of Oxford, Oxford, UK; 5) Department of Human Genetics, David Geffen School of Medicine, University of California Los Angeles, Los Angeles, CA, USA; 6) Department of Pathology and Laboratory Medicine, David Geffen School of Medicine, University of California Los Angeles, Los Angeles, CA, USA; 7) Center for Neurobehavioral Genetics, University of California Los Angeles, Los Angeles, CA, USA.

**Dupuytren's disease is the most common inherited connective tissue disorder, characterized by progressive and irreversible fibroblastic proliferation affecting the hand's palmar fascia, with an onset typically in the sixth decade of life. Previously, 24 risk regions for Dupuytren's disease have been identified from genome-wide association studies (GWAS). This study sought to expand understanding of this disease by: (1) identifying more risk regions via a transcriptome-wide association study (TWAS) and (2) understanding the genetic relationship between Dupuytren's disease and 38 other complex traits. We performed TWAS using expression from 47 different tissues from 6 consortia spanning ~15,000 unique genes. A novel risk region was identified from the 43 significant gene-tissue models (at least 0.5 MB away from the known 23 risk regions from GWAS). Testing 38 traits with Dupuytren's disease using cross-trait LD Score Regression, we identified that BMI, HDL, and TG had significant genetic correlation with Dupuytren's disease. Furthermore, we found that our results were consistent with previous epidemiological findings that lower BMI increases risk for Dupuytren's disease. We investigated these findings further with these traits using  $\rho$ -HESS, which uses local SNP-heritability to quantify local genetic correlation. Using  $\rho$ -HESS we identified 8 regions significantly correlated with BMI and 3 regions significantly correlated with HDL. From this study we have identified a novel disease associated gene on chromosome 17. We also showed novel genetic links to BMI, HDL, and TG, with specific genetically linked regions found for BMI and HDL. Biologically, these regions need to be researched further to understand the broader implications..**

**Investigation of CD207 and atopic dermatitis: Follow-up of a GWAS locus.** *L. Paternoster, A. Budu-Aggrey, M.S Babaei, T. Battram.* MRC Integrative Epidemiology Unit at the University of Bristol, Bristol, United Kingdom.

**Introduction:** A genomewide association study conducted by the EAGLE Eczema consortium in 2015 identified ten novel loci associated with atopic dermatitis (AD). One of the most interesting associations was at the 2p13.3 locus. The top SNP at this locus (rs112111458) is intergenic, but the nearby *CD207* was a promising candidate for the causal gene. *CD207* (langerin) is a transmembrane receptor, expressed in dendritic cells (e.g. Langerhan cells in the epidermis and mucosa) and is involved in antigen processing. **Aim:** We attempted to identify the causal gene at this locus using skin expression data and further sought to narrow the causal variant credible set at this locus. **Methods:** GTEx contains eQTL results from 414 sun-exposed and 335 non-sun-exposed skin samples. TwinsUK has skin RNAseq data, AD case/control information and genome-wide genotype data available for 672 individuals. Linear mixed models (in GEMMA) were used to test for cis-eQTL associations in TwinsUK between 25 genes and 5172 variants in the region. We also conducted eQTL analysis in controls only. We conducted colocalization analysis between the TwinsUK results and the GWAS results, to test if both signals were driven by the same underlying causal variant. We also undertook analysis to attempt to determine the causal variant at this locus, using GCTA-COJO and FINEMAP. **Results:** rs112111458 was a strong eQTL for *CD207* in both GTEx skin samples ( $p=7 \times 10^{-7}$  and  $2 \times 10^{-5}$ ), with the AD risk allele associated with higher levels of *CD207* expression. This SNP was not an eQTL for any other gene in GTEx. This was confirmed in the TwinsUK analysis ( $p=4 \times 10^{-10}$ ). Colocalization analysis confirmed that the eQTL and GWAS results shared a causal variant (posterior probability (PP)= 93%). There was far less evidence for colocalization with any of the other 25 genes tested (next greatest PP was 15% for *ANKRD53*). The association between rs112111458 and *CD207* expression was also present when restricting to controls only ( $p=3 \times 10^{-10}$ ), suggesting that this association is unlikely to be driven by disease-status altering expression of this gene. Our fine-mapping analysis suggested that there was only one causal variant, but the 95% credible set contained 511 SNPs. However, the PP for rs112111458 (67%) was far greater than the next best SNP (rs6723629, PP=4%). **Conclusion:** Our results suggest that *CD207* is likely to be the causal gene at the 2p13.3 locus. Our analyses were unable to determine the causal variant with any certainty.

**Association of CCL2 gene polymorphisms and their serum levels with susceptibility to knee osteoarthritis in North Indian population.** A.Chandra. Sharma<sup>1</sup>, R.N. Srivastava<sup>1</sup>, S.R. Srivastava<sup>1</sup>, S. Raj<sup>2</sup>. 1) Orthopaedic surgery, King George's Medical University, Lucknow, Uttar Pradesh, India; 2) Westminster College, Salt Lake city, Utah, USA.

**Objective:** To investigate the possible association between promoter polymorphisms rs1024611 and the polymorphism rs4586 in exon 2 of the chemokine (C–C motif) ligand 2 (CCL2) gene and knee osteoarthritis (KOA) in a North Indian population. **Methods:** DNA was obtained from 300 primary knee OA patients and 300 healthy controls. CCL2 genomic variants (rs1024611 and rs4586 polymorphisms) were detected by polymerase chain reaction restriction fragment length polymorphism (PCR-RFLP). In addition, the effect of serum levels of rs1024611 and rs4586 on cases and controls were examined by enzyme-linked immunosorbent assay (ELISA). **Results:** The rs1024611 A/G promoter polymorphism was associated with OA [genotype frequency,  $p=0.007$ ; allele frequency,  $p=0.01$ , odds ratio (OR) = 1.9, 95% confidence interval (CI) = 1.18–3.07]. Significant association was observed between the G carrier of the rs1024611 A/G promoter polymorphism and primary knee OA patients ( $p=0.01$ , OR=1.7, 95% CI= 1.12–2.7). However, no significant difference was found in the rs4586 polymorphism. Haplotype frequency analysis revealed a significant difference ( $\chi^2=8.01$ ,  $p=0.02$ ). The CCL2 serum level of subjects with the G carrier ( $285.0 \pm 86.5$  pg/mL) of the rs1024611 A/G promoter polymorphism was statistically higher than that of subjects with the non-G carrier ( $160.5 \pm 47.8$  pg/mL). Further in relation with clinical severity of OA, we observed significant association of the G carrier of the rs1024611 A/G promoter polymorphism with both Visual analogue scale (VAS) ( $p<0.01$ ) and Western Ontario and McMaster Universities (WOMAC) score ( $p<0.05$ ). **Conclusions:** The G carrier of the rs1024611 A/G promoter polymorphism was found to be associated with primary knee OA, and could be a susceptibility factor in the development of primary knee OA in the North Indian population.

**2331W**

**Targeted fine mapping and functional evaluation of chromosome 15q21-22 identifies AQP9 as a novel gene associated with keloid risk.** T.L. Edwards<sup>1</sup>, J.M. Keaton<sup>1</sup>, J.N. Hellwege<sup>1</sup>, S.M. Williams<sup>2</sup>, D.M. Supp<sup>3</sup>, S.B. Russell<sup>4</sup>, D.R. Velez Edwards<sup>5</sup>. 1) Division of Epidemiology, Department of Medicine, Vanderbilt Genetics Institute, Vanderbilt University Medical Center, Nashville, TN; 2) Division of Quantitative Sciences, Department of Obstetrics and Gynecology, Vanderbilt Genetics Institute, Vanderbilt University Medical Center, Nashville, TN; 3) Division of Dermatology, Department of Medicine, Vanderbilt Genetics Institute, Vanderbilt University Medical Center, Nashville, TN; 4) University of Cincinnati, College of Medicine Senior Investigator, Shriners Hospitals for Children - Cincinnati Burns Hospital; 5) Department of Population and Quantitative Health Sciences, Case Western Reserve University, Cleveland USA.

Keloids are benign dermal tumors that occur ~20 times more often in African versus European descent populations. While most keloids are sporadic, both familial aggregation and large differences in prevalence among populations support genetic risk. Prior studies identified variants at chromosome 15q21-22 associated with keloid risk in African and Asian ancestry populations without consensus for the causal variants. We conducted a fine mapping study using targeted next-generation sequencing of this region in 246 African-American samples using electronic health records ( $n=119$  cases, 121 controls), and also functionally assessed keloid cellular phenotypes in culture. Common variant (MAC>20) and nonsynonymous gene-based rare variant associations within this region were evaluated adjusting for sex and the first 5 principal components from the LASER method. Genetically predicted gene expression (GPGE) association analyses were performed with S-PrediXcan to identify keloid gene-tissue combinations. The strongest single variant association was at rs72073238 ( $P=2E-4$ ), odds ratio [OR]=2.4) near *POLR2M*, and a keloid risk-increasing association with increasing *POLR2M* GPGE was detected in transformed fibroblasts ( $P=5E-3$ ). The *ALDH1A2/AQP9* common variant rs55803039 was also associated ( $P=2E-4$ ), and *AQP9* was nominally significant in rare-variant gene-based SKAT analyses ( $P=0.02$ ). Increasing *AQP9* GPGE was negatively associated with keloid risk in lymphocytes ( $P=3E-3$ ). *AQP9* associations were robust to adjustment for BMI and the previously detected variants from this region, rs747722 (*MYO1E*) and rs8032158 (*NEDD4*). Characteristics of candidate genes identified from these and published association results were evaluated in keloid-derived and normal fibroblasts. We observed a 20-fold reduction in *AQP9* expression in keloid compared to normal fibroblasts ( $P=7E-6$ ), which is consistent with the GPGE result. We observed an approximate 2-fold decrease in *IGFBP5* expression in keloid cells after silencing *NEDD4* ( $P<0.05$ ), but no significant changes in the expression of other keloid markers. Silencing of either *NEDD4* or *MYO1E* decreased maximum culture density of both normal and keloid fibroblasts. These results suggest that nearest gene annotation for noncoding SNPs may not identify causal genes and that incorporating GPGE may improve gene identification. Our findings further support the chr15q21.2-22.3 region as containing keloid risk factors and that *AQP9* is a promising candidate.

## 2332T

**Whole-genome sequencing and genome-editing implicate missense variants in *LRRK2* and *NOD2* in early-onset leprosy.** M. Dallmann-Sauer<sup>1,2,3,4</sup>, Y.Z. Xu<sup>1,2,3</sup>, W. Correa-Macedo<sup>2,3,5</sup>, A.L.F. Costa<sup>6</sup>, G.E. Cambri<sup>4</sup>, A. Alcaïs<sup>7,8,9</sup>, J. Manry<sup>1,2,3</sup>, V.M. Fava<sup>1,2,3</sup>, C.M. Probst<sup>10</sup>, M. Mira<sup>4</sup>, E. Schurr<sup>1,2,3,4,5</sup>. 1) Departments of Human Genetics and Medicine, Faculty of Medicine, McGill University, Montreal, Quebec, Canada; 2) Program in Infectious Diseases and Immunity in Global Health, Research Institute of the McGill University Health Centre, McGill University, Montreal, Quebec, Canada; 3) McGill International TB Centre, McGill University, Montreal, Quebec, Canada; 4) Core for Advanced Molecular Investigation, Graduate Program in Health Sciences, School of Medicine, Pontifícia Universidade Católica do Paraná, Curitiba, Paraná, Brazil; 5) Department of Biochemistry, Faculty of Medicine, McGill University, Montreal, Quebec, Canada; 6) State University of Piauí, Teresina, Piauí, Brazil; 7) Laboratory of Human Genetics of Infectious Diseases, Necker Branch, Institut National de la Santé et de la Recherche Médicale U1163, Paris, France; 8) University Paris Descartes, Imagine Institute, Paris, France; 9) St. Giles Laboratory of Human Genetics of Infectious Diseases, Rockefeller Branch, Rockefeller University, New York, NY, United States of America; 10) Laboratory of Functional Genomics, Instituto Carlos Chagas-ICC-FIOCRUZ, Curitiba, Paraná, Brazil.

Despite the availability of an effective treatment, leprosy caused by the human pathogen *Mycobacterium leprae* still affects over 200,000 new patients annually. Leprosy has a long incubation period; hence, cases with age-of-onset younger than 4 years are rare and represent an extreme end of the age distribution. Here, we studied monozygotic twins exhibiting clinical symptoms of leprosy at the age of 22 months. The early onset of disease in the twins raised the possibility of a strong genetic effect on leprosy susceptibility. Moreover, both the father and the paternal grandmother were affected by leprosy. This familial aggregation of cases further supported the hypothesis of strong genetic effects acting on leprosy susceptibility in the family. To investigate the genetic contribution to leprosy susceptibility in this family, we performed whole-genome sequencing in six family members. After variant calling, stepwise procedures of filtering and variant prioritization were applied to identify those variants that were most likely to be causal. A number of different approaches were used to determine co-segregation of coding variants with leprosy susceptibility in the family, taking into account age-at-diagnosis and possible model of inheritance. A total of 95 and 37 candidate variants were identified assuming recessive or dominant genetic models of inheritance of a putative leprosy susceptibility gene, respectively. Two missense variants – N551K and R1398H – homozygous in the twins located to *LRRK2*, a gene previously associated with susceptibility to leprosy phenotypes. Interestingly, these variants have been associated with protection from Parkinson's disease and Crohn's disease. In addition, the strong Crohn's disease risk variants P268S and R702W of *NOD2* were carried heterozygously by the twins and father suggesting a joint effect of homozygosity at *LRRK2* and heterozygosity at *NOD2* on leprosy risk. To follow-up on the genetic results, RAW macrophages were genome-edited by CRISPR/Cas9 to carry one or both *LRRK2* candidate variants. *M. leprae* triggered production of microbicidal reactive oxygen species in RAW cells was lower for the ps1398 variant and the double mutant compared to wild-type cells. These results implicate *LRRK2*, an established risk factor for Parkinson's disease and Crohn's disease, in leprosy susceptibility.

## 2333F

**Genotype-first phenotyping of 32 patients with post-zygotic *GNAQ* or *GNA11* mutations.** M. Jordan<sup>1</sup>, V. Carmignac<sup>2</sup>, A. Sorlin<sup>2</sup>, P. Kuentz<sup>2</sup>, C. Philippe<sup>2</sup>, I. Investigators MUSTARD Cohort<sup>1</sup>, P. Vabres<sup>1,2</sup>. 1) CHU F Mitterrand, Dijon - FRANCE, France; 2) GAD team, INSERM UMR1231, Dijon, France.

Introduction: Post-zygotic mutations in *GNAQ/GNA11* genes account for mosaic conditions with vascular or pigmentary anomalies. We sought to delineate the phenotype of 32 patients harboring an activating post-zygotic mutation in *GNA11* or *GNAQ*. Method: All patients were studied because of cutaneous vascular anomalies suggestive of involvement of G-proteins. *GNAQ* and *GNA11* mutations were identified on ultradeep NGS on affected skin. A postzygotic *PIK3CA* mutation was ruled out in 9 patients. Cutaneous capillary malformations (CM) were subclassified as suggested by Happle: naevus flammeus, naevus roseus, cutis marmorata, and naevus anemicus. Patients with segmental asymmetry were classified as one of the six types defined by Oduber et al. Results: CM were observed in all patients, involving the face in 65.6% of cases (n=21), and were extensive with multiple affected segments in 71.8% (n=23). Naevus flammeus, segmental overgrowth, varicose veins (with deep vein thrombosis or venous agenesis) and macrocephaly were more common in patients with *GNAQ* mutations, whereas cutis marmorata (p=0.042), naevi anemicus (p=0.03), and segmental hypotrophy were more frequent in patients with *GNA11* mutations. Other features did not predominate in either *GNA11* or *GNAQ* patients. Pigmentary anomalies were observed in 11 patients and associated with skin types III-IV (p=0.006). Neurological anomalies (epilepsy, mental retardation, or MRI brain anomalies) in 9 and glaucoma in 8. Six patients had high blood pressure (HBP) (p=0.003). Among them, renal artery dysplasia and renal hypoplasia were found. Discussion: Hence, in addition to well-known features associated with mosaic G-protein mutations (e.g. Sturge-Weber syndrome), we found previously undescribed manifestations: segmental overgrowth, arterial hypertension and renal artery or kidney anomalies. Risk of thrombosis, HBP and renal anomalies should be considered in the follow-up of these patients. We also found distinct clinical features possibly allowing to discriminate between *GNAQ* and *GNA11* mutations.

**2334W****Multiscale causal network models identify VGF as an Alzheimer's**

**disease gene.** *N.D. Beckmann<sup>1</sup>, W.J. Lin<sup>1,2</sup>, M. Wang<sup>1</sup>, A.T. Cohain<sup>1</sup>, A.W. Charney<sup>1</sup>, M. Ehrlich<sup>1</sup>, B. Zhang<sup>1</sup>, S.R. Salton<sup>1</sup>, E.E. Schadt<sup>1</sup>.* 1) Icahn School of Medicine at Mount Sinai, New York, NY; 2) Medical Research Center of Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, Guangdong, China.

Though discovered over 100 years ago, the molecular foundation of sporadic Alzheimer's disease (AD) remains poorly understood. To further characterize the complex nature of this disease, large scale data integration and advanced modeling are necessary. Here, using cutting edge bioinformatics approaches, we built multiscale causal networks on a large multi-omics dataset of AD. We integrated DNA variation, gene and protein expression into models enabling the detection and prioritization of *VGF* as an important key driver of the disease. To validate this at the functional and molecular level, we overexpressed *VGF* in 5xFAD mice. We found that *Vgf* overexpression partially rescued the AD phenotype in mice and that genes differentially expressed in this model were enriched for genes our human *VGF* subnetwork predicted would change in response to changes in *VGF*. Our findings support a causal, protective role for *VGF* in regulating AD.

**2335T****Ascertainment and study design for the Resource for Early-Onset Alzheimer Disease Research (READR), a genomics resource for EOAD.**

Background: Genomic studies of Alzheimer disease (AD) have primarily focused on non-Hispanic White (NHW) participants affected by the late-onset form of the disease (AAO>65), or the study of early onset AD (EOAD; onset age <=65) cases from families showing Mendelian inheritance patterns associated with mutations in the *APP*, *PSEN1* and *PSEN2* genes. However, mutations in these three genes explain ~10% of EOAD cases, and among mutation carriers age at onset is often highly variable. To begin addressing this issue, we began the *Resource for Early-onset Alzheimer Disease Research* (READR) initiative to assemble and assess a large set of well-characterized multiplex EOAD families without known EOAD mutations from various ethnic groups as a resource for genomic studies. Methods: We have begun ascertainment of multiplex (2 or more affected) EOAD families using two methods. First, we utilized our existing community networks to identify families. This approach involves community outreach and collaborations with local neurology clinics. Our second approach involves collaborating with patient and caregiver support groups to identify families with positive family history who are interested in participating in genomics research studies. All families are being assessed using extensive neurological, medical and batteries neuropsychiatric batteries for deep cognitive endophenotyping. Results: Through our multipronged outreach approach we have identified nearly 175 possible/definite qualifying families (~50% non-Hispanic White, ~30% Hispanic, ~20% African American), validating our ascertainment methods. 40 of these families have already received whole-genome sequencing in a first batch; a second batch of 60 families is currently being prepared for sequencing. The remaining 75 families have been identified and contacted and will need to be thoroughly screened and ascertained. Through additional planned outreach efforts we expect to ascertain another eligible 20-30 families, yielding upwards of 200 families in total. Conclusion: We have established READR as a genomics resource for EOAD research. The substantial increase in sample size over existing EOAD efforts and the inclusion of minority populations will significantly enhance the ability to identify causative variants, validate variants across ethnic groups, and clarify the distinction of unexplained EOAD from EOAD with known mutations and late-onset AD.

**An Alzheimer's disease stem cell model of a rare *SORL1* mutation.** *H.N. Cukier*<sup>1,2,3</sup>, *F.S. Johnson*<sup>1</sup>, *C. Garcia-Serje*<sup>1</sup>, *J.M. Vance*<sup>1,2,3</sup>, *M.L. Cuccaro*<sup>1,3</sup>, *M.A. Pericak-Vance*<sup>1,2,3</sup>, *D.M. Dykxhoorn*<sup>1,3</sup>. 1) John P. Hussman Institute for Human Genomics, University of Miami, Miami, FL; 2) Department of Neurology, University of Miami, Miami, FL; 3) Department of Human Genetics, University of Miami, Miami, FL.

While genetics has been shown to play an integral role in Alzheimer's disease (AD) risk for over two decades, understanding the underpinning mechanisms which cause disease is still ongoing. We propose to focus this study on *SORL1*, a gene that has been implicated in both early and late onset AD. We have identified two siblings with late onset AD who carry a single base pair deletion (g.4292delG) that is predicted to result in a frameshift alteration and early termination of the protein (p.Cys143Ser\*1). To understand the mechanism by which the *SORL1* alteration may be acting to contribute to AD risk, induced pluripotent stem cells (iPSC) lines were developed to examine cellular consequences in neuronal tissue, which can otherwise only be collected post-mortem. Peripheral blood mononuclear cells (PBMCs) were extracted from the whole blood of two siblings bearing the *SORL1* change, as well as two aged, and ethnically matched control individuals. iPSC reprogramming was performed using Sendai virus. Each iPSC line generated was validated for pluripotency through immunocytochemical staining and shown to be negative for any large-scale chromosomal abnormalities via karyotyping. These iPSC lines will be promoted to generate excitatory neurons through the overexpression of *NGN2* and create a disease relevant tissue to assess. General characterization of the cellular viability and morphology will be performed. Alzheimer-specific phenotypes such as the levels of secreted beta amyloid and intercellular whole and phosphorylated tau will also be measured. The *SORL1* protein has been shown to act in APP trafficking and processing; therefore, this will be assessed in aged neurons. Utilizing patient-specific iPSC lines will permit assessing the cellular and molecular consequences of genetic alterations that may contribute to AD risk. We will present the morphological and cellular phenotypes of these lines carrying a potential risk factor for AD.

**Identification of novel noninvasive disease biomarkers for susceptibility to Alzheimer's disease progression.** *S. Esmaeeli Nieh*<sup>1</sup>, *Q. Guo*<sup>2</sup>, *A. Vasanthakumar*<sup>1</sup>, *J.W. Davis*<sup>1</sup>, *K. Idler*<sup>1</sup>, *R. Comley*<sup>2</sup>, *J. Waring*<sup>1</sup>. 1) Genomics Research Center, AbbVie, North Chicago, IL; 2) Translational imaging, AbbVie, North Chicago, IL.

Introduction Alzheimer's disease (AD) is a devastating neurodegenerative disorder. AD patients display hippocampal atrophy, memory impairment, and cognitive decline. Despite research efforts and a substantial unmet medical need, no effective cure has been identified and treatment remains symptomatic. Early diagnosis is essential to start treatment in a timely manner, and in treating the disease more effectively. However, reliable early molecular diagnosis has been a challenge, and current methods are invasive, time-consuming, and/or expensive. Objective In this study we sought to integrate DNA methylation data and brain endophenotypes within the very well-characterized Alzheimer's disease Neuroimaging Initiative (ADNI) dataset to identify novel noninvasive disease biomarkers for susceptibility to disease progression. Method We performed cross-sectional analysis on a cohort of ADNI patients who had both methylation and MRI data. We included a total of 260 samples comprised of 83 cognitively normal (CN), 140 mild cognitive impairment (MCI), and 37 Alzheimer's disease (AD) patients. Total gray matter and hippocampal volumes were used as endophenotypes for the association analysis. FreeSurfer was used to extract total gray matter and hippocampal volumes, as well as estimated total intracranial volume (eTIV). Differentially Methylated Positions (DMPs) were analyzed using routinely applied DNA methylation analysis pipelines. To study associations between peripheral blood methylation markers and brain endophenotypes, generalized linear mixed modeling regression was applied; these analyses were conducted using eTIV and age as co-variates. Results and Conclusion The cross-sectional analysis of differential DNA methylation yielded 483, 139, and 299 DMPs for the AD vs CN, AD vs MCI, and MCI vs CN comparisons respectively. We found DNA methylation changes in genes associated with neurodegeneration (e.g. BDNF), and in some novel genes associated with neurodevelopment and synaptic function (e.g. IQSEC1). In this study we integrated the DNA methylation dynamics with brain endophenotypes. Initial analysis of the association between DMPs and total gray matter and hippocampal atrophy revealed correlations with genes known to be involved in neuronal function. These findings may support the identification early biomarkers of disease progression, and shed light on the biological underpinnings of that progression, potentially helping identify novel drug targets.

**Whole-exome sequencing (WES) analysis of Alzheimer's disease in non-*APOE\*4* carriers.** K. Fan, S. Rosenthal, E. Feingold, F. Demirci, O. Lopez, M. Kamboh. University of Pittsburgh, Pittsburgh, PA.

The genetics of late-onset Alzheimer's disease (AD) is complex due to the heterogeneous nature of the disorder. *APOE\*4* is the strongest genetic risk factor for AD. Genome-wide association studies (GWAS) have identified more than 20 additional loci, each having relatively small effect size. Including *APOE\*4*, the known loci explain only about 30% of the genetic variance and thus much of the AD genetic variance remains unexplained. In an effort to identify some of the missing heritability of AD, we have performed whole-exome sequencing (WES) analysis focusing on non-*APOE\*4* carriers from two WES datasets. The first dataset was an AD case-control sample (n=773) biased against *APOE\*4* carriers. After quality control measures and removing subjects with *APOE\*4*, the non-*APOE\*4* sample consisted of 372 AD cases (mean age-at-onset (AAO): 75.95 ± 7.09 years, 62% female) and 348 controls (mean age: 78.59 ± 4.72 years, 66% female). The second dataset was derived from the Alzheimer's Disease Sequencing Project (ADSP) that was downloaded from dbGaP (phs000572.v7.p4) and the non-*APOE\*4* sample comprised 2,113 cases (mean AAO: 76.43 ± 7.98 years, 57% female) and 5,139 controls (mean age: 85.68 ± 3.93 years, 61% female). Following individual WES analysis, we performed WES meta-analysis for overlapping markers present in both datasets. Among the top five SNPs, two were from known AD loci (*APOE* and *MS4A6A*). The well-established protective *APOE/rs7412* SNP coding for *APOE\*2* was the top hit (odds ratio (OR)=0.39;  $P=1.34E-23$ ). *MS4A6A/rs12453* was the third most significant SNP (OR=0.82;  $P=1.16E-05$ ). The other three SNPs were from three novel loci. The second most significant association was seen on chromosome 8 in *PLEC* (OR=1.45;  $P=3.18E-06$ ) followed by *ABCD3* (OR=5.65;  $P=4.38E-05$ ) on chromosome 1 and *STK33* (OR=2.87;  $P=7.08E-05$ ) on chromosome 11. All three SNPs from these novel loci were synonymous mutations, and the top *PLEC* SNP was cis-eQTL for multiple genes in the GTEx data in the *PLEC* gene region, indicating its important biologic significance. In addition to affecting *PLEC* RNA expression in whole blood ( $P=3.17E-04$ ) and brain hippocampus ( $P=3.02E-02$ ), the top *PLEC* SNP was eQTL for nearby *PARP10* in the blood ( $P=3.62E-06$ ) and for *SLC52A2* in brain frontal cortex ( $P=9.61E-04$ ). Further characterization of the genes that are affected by this SNP may help to shed light on the roles of these genes in AD etiology. This study was supported by NIH grants AG030653 and AG041718.

**Mitochondrial variants and haplogroups associated with late-onset Alzheimer's disease identified by whole exome sequencing.** J.J. Farrell<sup>1</sup>, X. Zhang<sup>1,2</sup>, C. Zhu<sup>1</sup>, R. Mayeux<sup>3</sup>, J.L. Haines<sup>4</sup>, M.A. Pericak-Vance<sup>5</sup>, G. Schellenberg<sup>6</sup>, K. Lunetta<sup>2</sup>, L.A. Farrer<sup>1,2</sup> on behalf of the Alzheimer's Disease Sequencing Project (ADSP). 1) Section of Biomedical Genetics, Boston University School of Medicine, Boston, MA, USA; 2) Department of Biostatistics, Boston University School of Public Health, Boston, MA, USA; 3) Columbia University, New York, NY, USA; 4) Case Western Reserve University School of Medicine, Cleveland, OH, USA; 5) University of Miami Miller School of Medicine, Miami, FL, USA; 6) University of Pennsylvania, Philadelphia, PA, USA.

**Background:** Numerous studies suggest that mitochondrial dysfunction is involved in Alzheimer disease (AD) pathogenesis. **Methods:** The Alzheimer's Disease Sequencing Project (ADSP) performed whole-exome sequencing (WES) of 5,519 AD cases and 4,917 cognitively normal elderly controls of European ancestry (EA) and 218 cases and 177 controls of Caribbean Hispanic (CH) heritage. After mapping to the reference MT genome (NC\_012920), MT variants were called using the haploid option of GATK HaplotypeCaller. Low-quality, multi-allelic and monomorphic variants were excluded using a QC metric based on comparison with MT variants called in the Alzheimer Disease Neuroimaging Initiative WGS dataset and the 1000 Genomes project. HaploGrep2 software was used to classify mtDNA Haplogroups with Phylotree 17. The association of AD with MT single nucleotide variants (SNVs) with minor allele count (MAC) ≥10 and call rate ≥ 0.80 (802 SNVs in EA, 135 SNVs in CH) and with mtDNA haplogroups was evaluated in EAs and CHs separately. In gene-based tests, only SNVs with minor allele frequency (MAF) <0.05 were considered, and genes with ≥2 SNVs and cumulative MAC ≥10 were tested. Analyses were performed using single variant score tests and gene-based (SKAT-O) tests in seqMeta implemented in the R package, controlling for age, sex, and principal components of ancestry. Results were combined across ethnicities using meta-analysis. Bonferroni-corrected thresholds were used to determine study-wide significance (SWS) for single variant ( $P=6.2 \times 10^{-6}$ ) and gene-based ( $P=3.8 \times 10^{-3}$ ) associations. In EAs, association of AD with 47 mtDNA haplogroups was tested using logistic regression. **Results:** After variant-level and sample-level QC, 4,220 variants and 10,610 samples remained for association analyses. A missense SNV in *MT-ND4L* which encodes NADH dehydrogenase subunit 4L involved in ubiquinone activity and oxidoreductase activity (26:10733:C:T, rs28709356, Asp88Glu, MAF=0.002) was associated with AD risk in EAs at nearly the SWS level (OR=7.52;  $P=7.3 \times 10^{-6}$ ). One SWS gene-based association finding was identified with *MT-TI* ( $P = 3.0 \times 10^{-3}$ ). None of the mtDNA haplogroups were nominally associated with AD. **Conclusions:** A set of high quality MT variants and mtDNA haplogroups were called from the large ADSP sequencing data. We identified significant association of AD risk with a rare SNV in *MT-NDL4* and the *MT-TI* gene. A replication study of independent cohorts from the extension of ADSP WGS data is now underway.

Dozens of genetic variants conferring risk for and protection from Alzheimer disease (AD) have been identified. However, understanding the role of DNA variation directly on disease mechanisms, particularly in under-represented ethnic groups, is lacking. Because expression studies in readily available material, such as blood, can recapitulate transcriptional changes occurring in neuronal tissues, our goal was to identify transcriptomic changes related to AD from peripheral blood collected from 234 African American (AA) (115 AD, 119 cognitively normal, age matched) and 241 non-Hispanic Whites (NHW) (121 AD, 120 cognitively normal, age-matched). We performed RNAseq of all protein coding genes and identified differentially expressed genes between AD cases and cognitively normal individuals within each ethnicity adjusting for known covariates. A total of 419 genes (291 up-regulated, 127 down-regulated) and 490 genes (353 up-regulated, 137 down-regulated) were differentially-expressed in the AA and NHW datasets, respectively. Among genes previously implicated by genome-wide association studies in AD, two were differentially expressed in NHW (*SPI1* and *EPHA1*) and one in AA (*CR1*). Interestingly, only 16 genes were commonly differential in both ethnicities including upregulation of genes involved in Ab processing (*MMP9* and *APMAP*) and immune modulation (*LTB4R* and *PGLYRP1*). Despite the majority of significantly altered genes differing between ethnicities, pathway enrichment analysis revealed that immune response and RNA processing related pathways were enriched in both datasets. These results demonstrate that analysis of blood can reveal aspects of AD pathophysiology without the use of more invasive methods (e.g. PET scans and lumbar punctures). Furthermore, these data support the hypothesis that there is genetic heterogeneity for AD across racial/ethnic groups but a convergence of underlying processes representing a shared etiology. Studies such as this that identify common mechanisms across ethnically diverse individuals in a genetically heterogeneous disorder such as AD are critical to translating previous discoveries into diagnostic or therapeutic interventions.

**Population-based genome-wide association study of cognitive decline in older adults free of dementia.** M. Kamboh, Q. Yan, J. Beer, K-S. Fan, X. Wang, F. Demirci, B. Snitz, C-C. Chang, E. Feingold, M. Ganguli. University of Pittsburgh, Pittsburgh, PA.

Genome-wide association studies (GWAS) have identified over 20 risk loci for late-onset Alzheimer's disease (AD), but common variants at these loci account for only ~30% of the AD genetic variance. Alternative approaches are needed to identify additional genetic factors for AD. An attractive option is the use of AD-related quantitative endophenotypes. In this study, we used decline in cognitive function as a relevant endophenotype that is derived from different cognitive domains having high heritability estimates. We used longitudinal data on 5 cognitive domains (memory, executive function, language, attention and visuospatial ability) from two population-based cohorts, MYHAT (Monongahela-Youghiogheny Health Aging Team) and MoVIES (Monongahela Valley Independent Elders Survey), and conducted GWAS meta-analysis to: a) examine the association of previously reported AD loci with cognitive decline, and b) identify novel loci that affect cognitive decline. The MYHAT sample consisted of 767 participants with mean age of 77.1±7.3 years (61% women, all whites) and the MoVIES sample comprised 378 participants with mean age of 70.1±4.3 years (67% women, all whites). For decline over time in each cognitive domain, we normalized intra-individual slopes within each cohort, accounting for baseline age, sex and years of education. Normalized slope for each domain was used in individual GWAS analysis after including top principal components as covariates followed by GWAS meta-analysis. Among the known AD loci, *APOE\*4* showed the strongest association with memory ( $P=7.18E-06$ ) followed by language ( $P=1.65E-04$ ). Two other known loci showed associations with more than one domain at  $P<1E-03$ , including *EPHA1* with visuospatial and memory ( $P=1.24E-05$ ,  $5E-04$ ), and *ABCA7* with executive function, language, attention and visuospatial ( $P=3-7E-04$ ). A novel locus at genome-wide significant level was detected in *WDFY2* on chromosome 13 with attention ( $P=3.37E-08$ ). In the GTex eQTL analysis, the genome-wide significant SNP was associated with RNA expression levels of *WDFY2* in several brain regions: cerebellar hemisphere ( $P=1.07E-04$ ), cerebellum ( $P=6.92E-04$ ), hippocampus ( $P=2.18E-03$ ) and cortex ( $P=2.29E-02$ ) as well as in whole blood ( $P=4.41E-05$ ). In summary, our meta-GWAS analysis on >1,100 non-demented elderly subjects has identified a novel genome-wide significant locus for the attention domain. This study was supported by NIH grants AG023651, AG07562, AG030653 and AG041718.

**Chromatin accessibility profiling in hiPSC-derived neurons identifies functional noncoding GWAS risk variants of Alzheimer's disease.** A. Kozlova<sup>1,2</sup>, S. Zhang<sup>1,2</sup>, H. Zhang<sup>1</sup>, M. Streit<sup>1</sup>, J. Shi<sup>3</sup>, A.R. Sanders<sup>1,2</sup>, P.V. Gejman<sup>1,2</sup>, G. Thinakaran<sup>4</sup>, J. Duan<sup>1,2</sup>. 1) Center for Psychiatric Genetics, NorthShore University HealthSystem, Evanston, IL; 2) Department of Psychiatry and Behavioral Neurosciences, University of Chicago, IL; 3) Biostatistics Branch, Division of Cancer Epidemiology and Genetics, National Cancer Institute, Bethesda, MD; 4) Departments of Neurobiology, Neurology and Pathology, University of Chicago, IL.

Alzheimer's disease (AD) is the most common cause of dementia in the aged. Genome-wide association studies (GWAS) of the AD have identified more than 20 risk loci including the APOE locus. However, each GWAS locus typically spans several genes and many equally associated genome-wide significant SNPs; it thus remains challenging to identify which risk SNPs/genes are likely to be causal. Most GWAS risk variants are noncoding and likely affect gene transcription. A major determinant of transcription is chromatin accessibility (openness) to transcription factors. Here, we consider the allele-specific open chromatin (ASoC) assay as a functional readout of the regulatory variation by directly comparing within the same sample the effects of the two alleles of a heterozygous SNP on the measurements of open chromatin. Using human induced pluripotent stem cells (hiPSCs) as a cellular model, we carried out an open chromatin profiling by ATAC-seq in hiPSC-derived neural progenitor cells (NPCs) and NGN2-induced excitatory neurons (iNs) of 20 individuals with unknown AD status. We found that ~6% of the heterozygous SNPs (~100 K) showed ASoC in iNs and NPCs. ASoC variants were found significantly enriched (~4-fold) for AD GWAS risk variants, and can readily inform putatively regulatory risk variants at three AD loci (*CLU*, *BIN1*, and *CD2AP*). Although these ASoC variants were identified in NPCs and iNs, we have found that the mRNAs and the encoded proteins of *CLU*, *BIN1*, and *CD2AP* are also expressed in non-neuronal cell types such as microglia and oligodendrocytes in AD postmortem brains. To systematically examine their cell-specific gene expression, we used hiPSCs to derive other cell types including GABAergic neurons, microglia, and astrocytes. We found that hiPSC-derived neurons secreted Ab and accumulated Tau as neurons matured. By using CRISPR/cas9 epigenome editing, we are in the process of interrogating which genes are regulated by the putatively functional AD risk variants that exhibited ASoC. We are also extending the ASoC assay to other AD-relevant cell types (microglia and astrocytes) to identify which other AD GWAS risk variants are likely to be regulatory and causal. Our study provides a novel approach for identifying functional noncoding AD GWAS risk variants in hiPSC models. Identifying regulatory AD-risk SNPs and their regulated genes, together with cellular phenotypic characterization, will help bridge the AD GWAS findings to disease biology.

**Independent associations of the TOMM40 and APOE polymorphisms with risks of Alzheimer's disease.** A. Kulminski, Y. Loika, K. Arbee, O. Bagley, S. Ukraintseva, A. Yashin, I. Culminskaya. Biogerontology of Aging Research Unit, Social Science Research Institute, Duke University, Durham, NC.

Previous research reports that the *TOMM40* (Translocase of Outer Mitochondrial Membrane 40) rs2075650 SNP (single nucleotide polymorphism) and the *APOE* (Apolipoprotein E)  $\epsilon$ 4-allele-coding rs429358 SNP are strongly associated with Alzheimer's disease (AD) when they are analyzed separately. Because these SNPs are in moderate linkage disequilibrium in Caucasians ( $r^2 \sim 0.5$ ), the association of rs2075650 with AD is often attributed to linkage disequilibrium of rs2075650 with rs429358. This conclusion is supported by showing pivotal role of rs429358 in the association with AD in conditional statistical analyses using models with both these SNPs included. We performed meta-analysis of separate and additive associations of rs2075650 and rs429358 with risks of AD in a sample of N=2,518 AD cases and N=15,946 non-cases of Caucasians ancestry from four studies (the Framingham Heart Study, the Cardiovascular Health Study, the Health and Retirement Study, and the National Institute on Aging Late-Onset Alzheimer Disease Family Study) using the Cox proportional hazard regression model adjusted for age and sex. Minor alleles of rs2075650 and rs429358 SNPs were strongly associated with increased risks of AD in additive genetic models,  $\beta=0.82$ , SE(standard error)=0.04,  $p=1.08 \times 10^{-100}$  and  $\beta=1.02$ , SE=0.04,  $p=3.11 \times 10^{-164}$ , respectively, when they were analyzed separately. Conditional analysis with both rs2075650 and rs429358 SNPs in the model identified small-effect association of rs2075650 with the increased risk of AD,  $\beta=0.14$ , SE=0.06,  $p=1.00 \times 10^{-2}$ , which was independent of strong association of rs429358 with AD,  $\beta=0.92$ , SE=0.05,  $p=9.39 \times 10^{-85}$ . Meta-analysis using genotypic model with both rs2075650 and rs429358 SNPs identified 4-fold larger risk for carriers of the rs2075650 minor allele homozygotes ( $\beta=0.39$ , SE=0.13,  $p=2.84 \times 10^{-3}$ ) compared to heterozygotes ( $\beta=0.10$ , SE=0.07,  $p=1.28 \times 10^{-1}$ ) and 1.5-fold larger risk for carriers of the rs429358 minor allele homozygotes ( $\beta=1.67$ , SE=0.12,  $p=1.24 \times 10^{-43}$ ) compared to heterozygotes ( $\beta=1.06$ , SE=0.07,  $p=4.81 \times 10^{-85}$ ). In addition to confirming more pronounced role of rs429358 compared with rs2075650 in the associations with risk of AD, our analyses identified independent roles of these variants from the *TOMM40* and *APOE* genes in AD and suggested that carriers of the rs2075650 minor allele homozygous genotypes could be at nonlinearly increased risk of AD.

**Background.** The Alzheimer's Disease Sequencing Project (ADSP) was established in 2012 as a key initiative to meet the goals of the National Alzheimer's Project ACT to prevent and effectively treat Alzheimer's disease (AD) by 2025. Developed jointly by National Institute on Aging (NIA) and the National Human Genome Research Institute (NHGRI), the aims of the ADSP are to: 1) identify new genomic variants contributing to increased risk of developing late-onset AD, 2) identify new genomic variants contributing to protection against developing AD, 3) provide insight as to why individuals with known risk factor variants escape from developing AD, and 4) examine these factors in multi-ethnic populations as applicable in order to identify new pathways for disease prevention. **Methods.** The ADSP Data Flow Work Group (DFWG) and the NIA Genetics of Alzheimer's Disease Data Storage Site (NIAGADS) support data production for the Genome Center for AD (GCAD), sharing and management for the ADSP, and facilitation of data access to the community. Samples are contributed by the AD Genetics Consortium (ADGC) and Cohorts for Heart and Aging Research in Genomic Epidemiology Consortium (CHARGE). Sample plating and shipping is coordinated by the National Cell Repository for AD (NCRAD). Whole-exome and whole-genome sequencing data were generated by four sequencing centers, mapped to GRCh38 and processed by GCAD, and quality controlled by the ADSP. **Results.** The ADSP has completed whole-exome sequencing of 10,939 unrelated cases and controls, whole-genome sequencing of 854 members from 159 families, and whole-genome sequencing of 3094 unrelated cases and controls. These genomes along with 809 ADNI genomes will be available for qualified access in summer 2018 through the NIAGADS Data Sharing Service (DSS). Approved investigators can log in using eRA Commons authentication and download raw sequencing files through Amazon S3 and quality controlled VCFs and phenotype files directly through the Portal. As of June 2018, the Follow-up Study (FUS) phase has generated an additional ~2000 genomes and has ~14,000 ethnically diverse genomes planned for the next four years. **Conclusion.** The DFWG provides support to all ADSP work groups for data related issues, coordinates with NIAGADS, GCAD, and sequencing centers for data transfers, and reviews, posts, and notifies members of new results generated by other work groups. Additional information can be found on the ADSP website ([www.niagads.org/adsp](http://www.niagads.org/adsp)).

**2345F****Use of a genetically-based biomarker risk algorithm to design Alzheimer's disease clinical trials with outcomes based on neurocognitive measures.**

M.W. Lutz<sup>1,2</sup>, D.K. Burns<sup>3</sup>, C.L. Dunn<sup>4</sup>, J.S. Cranston<sup>4</sup>, D.J. Hatch<sup>2,5</sup>, A.M. Saunders<sup>5</sup>, G. Potter<sup>2,5</sup>, J.R. Burke<sup>1,2</sup>, B.L. Plassman<sup>1,2,5</sup>, K.A. Welsh-Bohmer<sup>1,2,5</sup>. 1) Department of Neurology, Duke University School of Medicine, Durham, NC; 2) Duke Bryan Alzheimer's Disease Research Center, Duke University School of Medicine, Durham, NC 27705; 3) Zinfandel Pharmaceuticals, Chapel Hill, NC 27517; 4) Duke University, Durham, NC 27708; 5) Department of Psychiatry, Duke University School of Medicine, Durham NC 27710.

The efficiency of clinical trials focused on the prevention of Alzheimer's disease (AD) is greatly increased by enrichment strategies that identify individuals likely to convert from normal cognition to AD or mild cognitive impairment (MCI) due to AD. A genetic biomarker risk algorithm (GBRA) has been developed to identify individuals at high risk of converting from cognitively normal status to MCI due to AD in a 5-year period. The GBRA is based on age and two genetic variants that are easily genotyped in blood: *APOE* and *TOMM40*<sup>'523</sup>. The GBRA is designed to allow study enrichment for cognitively normal individuals, between the ages of 65-83 years. The present report evaluates the GBRA's performance in predicting cognitive change in a community based AD prevention screening study. Of note, this length of follow-up is comparable to the length of AD prevention trials, 3-5 years. This trial duration is necessary for adequate power to detect a difference in effect between placebo and an intervention, e.g. the TOMMORROW trial (ClinicalTrials.gov identifier, NCT 01931566). GBRA performance was evaluated using data from two studies: the Duke Prevention Screening Study and Database/Repository (PREPARE) and The Measurement to Understand Reclassification of Disease of Cabarrus/Kannapolis (Murdock) study. Subjects were stratified into high or low risk groups at baseline. To account for differences in cognitive change based on age, sex and education, Montreal Cognitive Assessment (MoCA) and Trail making test (TrailsB) scores were standardized for these covariates using National Alzheimer's Coordinating Center UDS3 norms. For PREPARE/Murdock, individuals who had baseline and follow-up neurocognitive evaluations were included, (N=1255, mean age 67.7 years, sd 7.9, mean follow up time 3.7 years, sd 1.2). At baseline, a total of 949 individuals were classified as low risk and 306 as high risk. A statistically significant effect was observed for the GBRA association with change in MoCA scores (p=0.03) and with change in TrailsB scores (p=0.02). For both cognitive measures, direction of change was consistent with the risk category. When used in the context of a clinical trial using neurocognitive measures to assess MCI due to AD, the GBRA has strong potential to significantly reduce the numbers of study subjects required to accumulate sufficient conversion events.

**Brain expression of vascular endothelial growth factor genes relates to cognitive performance.** E.R. Mahoney<sup>1</sup>, L. Dumitrescu<sup>1</sup>, A.L. Jefferson<sup>1</sup>, D.A. Bennett<sup>2</sup>, J.A. Schneider<sup>2</sup>, T.J. Hohman<sup>1</sup>. 1) Vanderbilt Memory and Alzheimer's Center, Department of Neurology, Vanderbilt University Medical Center, Nashville, TN; 2) Rush Alzheimer's Disease Center, Department of Neurological Sciences, Rush University Medical Center, Chicago, IL.

Recent evidence suggests vascular endothelial growth factor (VEGF), an angiogenic factor, protects against neurodegeneration and cognitive impairment. However, the VEGF family includes multiple ligand and receptor genes that differentially influence angiogenesis and neurodegeneration. This study aims to identify which VEGF ligand and receptor genes are associated with cognitive performance. Autopsy data from 531 participants (normal cognition, n=180; mild cognitive impairment, n=148; Alzheimer's disease [AD], n=203) were acquired from the Religious Orders Study and Rush Memory and Aging Project. VEGF expression levels were obtained from the prefrontal cortex of postmortem brain tissue and quantified using RNAseq. RNA was isolated, reverse transcribed, and normalized as part of the Accelerating Medicine Partnerships AD project. A global cognitive composite score was calculated across 19 neuropsychological tests spanning multiple cognitive domains. Associations between the expression of 65 VEGF isoforms and longitudinal cognition were evaluated using mixed effects regression models co-varying for age and sex. Four genes, including six isoforms, were associated with longitudinal cognitive decline: *FLT4* (MIM 136352; *FLT4*-207  $\beta$ =-0.163,  $p$ <0.001; *FLT4*-201  $\beta$ =-0.053,  $p$ =0.002), *VEGFB* (MIM 601398; *VEGFB*-202  $\beta$ =-0.004,  $p$ <0.001; *VEGFB*-201  $\beta$ =-0.001,  $p$ =0.02), *NRP1* (MIM 602069; *NRP1*-204  $\beta$ =0.148,  $p$ =0.02) and *FLT1* (MIM 165070; *FLT1*-201  $\beta$ =-0.005,  $p$ =0.03). All but *VEGFB*-201 were differentially expressed in AD cases relative to controls ( $p$ <0.01). However, co-varying for diagnostic status and expression of cell-specific markers did not alter associations. When restricting to cognitively normal individuals, higher levels of *VEGFA*-209 (MIM 192240;  $\beta$ =0.11,  $p$ <0.001) were associated with better cognitive performance, consistent with previous proteomic findings. In summary, high levels of *VEGFB*, *FLT4*, and *FLT1* are associated with worse cognitive performance, perhaps due to their known upregulation in response to neural injury. In contrast, higher levels of *VEGFA* and *NRP1*, which act through kinase domain receptor (*KDR*), are associated with better cognitive performance, perhaps due to the angiogenic and neuroprotective properties of this pathway. These findings suggest that brain expression of VEGF ligand and receptor genes relates to cognitive performance and may have relevance in neurodegeneration. Future work will evaluate VEGF ligand and receptor genes in relation to neuropathology.

**CD33 and Alzheimer's disease: Functional and association analysis of a frame shift variant.** A. Mitchell<sup>1</sup>, C. Zhang<sup>1</sup>, S. McGrath<sup>1</sup>, H. Crehan<sup>1</sup>, T. Faust<sup>1</sup>, D. Felsky<sup>2</sup>, P. de Jager<sup>2</sup>, M. Mattijevic<sup>1</sup>, J. Arai<sup>1</sup>, M. Kinnunen<sup>3</sup>, A. Palotie<sup>3</sup>, J. Hutz<sup>1</sup>, Industry Partnership for Human Genetics (IPHG). 1) Eisai, Andover, MA; 2) Columbia University, New York, NY; 3) FIMM - Institute for Molecular Medicine, Helsinki, Finland.

CD33 (siglec-3) is a transmembrane receptor expressed on the surface of microglia and peripheral monocytes. The minor allele of a non-coding variant near CD33 (rs3865444) has been associated with reduced risk of Alzheimer's disease (AD). This association appears to be driven by increased skipping of CD33 exon two, which eliminates the protein's extracellular sialic acid binding domain and is thought to confer loss of function. Thus, reduced CD33 expression or function may be protective for AD. We sought to functionally characterize this and other CD33 variants in order to glean more insight into the role of CD33 in AD and to further elucidate the potential protective mechanism. We performed a pQTL study using plasma and CSF from 91 individuals, testing for association between each genotyped or imputed variant within 1 MB of the CD33 gene and soluble CD33 (sCD33) protein level in each fluid. We found that the protective allele at rs3865444 was associated with reduced sCD33 in both fluids ( $\beta$  = -0.53,  $p$  =  $8.7 \times 10^{-7}$  in plasma). In addition, we identified a 4 bp deletion in CD33 (rs201074739) with non-Finnish European population frequency 0.02 that was associated with sCD33 in both fluids. This association remained highly significant after adjusting for rs3865444 ( $\beta$  = -1.4,  $p$  =  $3.1 \times 10^{-11}$ ). Because frame shift leads to a premature termination codon in an early exon, it is expected that mRNA carrying the deletion allele will be subject to nonsense mediated decay. To investigate this, we isolated peripheral monocytes from a volunteer who is homozygous for the deletion allele and found no surface expression of CD33 on monocytes in that sample. If reduced CD33 expression or function reduces risk of AD, the deletion allele would be expected to confer a protective effect on carriers. To test this, we performed a meta analysis of 8 studies including a total of 25,651 individuals. We found that the deletion allele is associated with a 20% reduction in AD risk (with  $0.04 < p < 0.27$ , depending on the model used). In ongoing analyses, we are performing functional studies using PBMC-derived monocytes from volunteers with all three genotypes, as well as in cell lines lacking CD33 or expressing CD33 with reference sequence, with exon two deleted, or the carrying rs201074739 deletion allele. We will present results from a range of functional studies and from our meta analysis of rs201074739 and AD.

**Transcriptomic analysis of mouse models based on candidate genes associated with Alzheimer's disease.** R.S. Pandey<sup>1</sup>, L. Graham<sup>2</sup>, A. Uyar<sup>1</sup>, C. Preuss<sup>2</sup>, G.R. Howell<sup>1</sup>, G.W. Carter<sup>2</sup>. 1) The Jackson Laboratory For Genomic Medicine, Farmington, CT; 2) The Jackson Laboratory, Bar Harbor, ME.

New genetic and genomic resources are identifying genetic risk factors for late-onset Alzheimer's disease (LOAD) and characterizing this common dementia at the molecular level. Experimental studies in model organisms can validate these associations and elucidate the links between specific genetic factors and transcriptomic signatures. However, most transgenic animal models are based on rare, early-onset AD genes which may not reflect the full transcriptomic signatures and complete neuropathology of LOAD. Animal models based on LOAD-associated genes are necessary to connect common genetic variation with LOAD transcriptomes, thereby providing novel insights into basic biological mechanisms underlying the disease. We performed RNA-seq on whole brain samples from a panel of six-month-old female mice, each carrying one of the following mutations: homozygous deletions of *APOE* and *CLU*; hemizygous deletions of *BIN1* and *CD2AP*; and a transgenic *APOEε4*. We also included a transgenic *APP/PS1* model for comparison to early-onset variants. Weighted gene co-expression network analysis (WGCNA) was used to identify modules of correlated genes and each module was tested for differential expression by strain. We then compared mouse modules with human postmortem brain modules from the Accelerating Medicine's Partnership for AD (AMP-AD) to determine the AD relevance of risk genes. Mouse modules were significantly enriched in multiple AD-related pathways, including immune response, inflammation, lipid-processing, endocytosis and synaptic-cell-functioning. Various modules were significantly associated with *APOE*, *APOEε4*, *CLU*, and *APP/PS1* mouse models. *APOE*, *APOEε4*, and *APP/PS1* driven modules overlapped with AMP-AD inflammation and microglial modules; *CLU* driven modules overlapped with synaptic modules; and *APP/PS1* modules separately overlapped with lipid-processing and metabolism modules. Furthermore, we found that immune/microglia related genes are up-regulated and synaptic genes are down-regulated in early-onset carriers. This study of LOAD mouse models provides a basis to dissect the role of AD risk genes in relevant AD pathologies. We determined that different genetic perturbations affect different molecular mechanism underlying AD, and mapped specific effects to each risk gene. Our approach provides a platform for further exploration into the causes and progression of AD by assessing animal models at different ages and/or with different combinations of LOAD risk variants.

**Rare coding mutations in Alzheimer disease and other dementias.** D.

Patel<sup>1,2</sup>, J. Mez<sup>2</sup>, J. Chung<sup>1,2,7</sup>, X. Zhang<sup>2,3</sup>, R. Mayeux<sup>8</sup>, J.L. Haines<sup>9</sup>, M.A. Pericak-Vance<sup>10</sup>, G. Schellenberg<sup>11</sup>, K.L. Lunetta<sup>1</sup>, L. Farrer<sup>1,2,3,4,5,6</sup>. 1) Bioinformatics Graduate Program; 2) Departments of Medicine (Biomedical Genetics); 3) Neurology; 4) Biostatistics; 5) Ophthalmology; 6) Epidemiology, Boston University Schools of Medicine and Public Health, Boston, MA; 7) Massachusetts General Hospital, Boston, MA; 8) Columbia University, New York, NY; 9) Case Western Reserve University School of Medicine, Cleveland, OH; 10) University of Miami Miller School of Medicine, Miami, FL; 11) University of Pennsylvania, Philadelphia, PA.

**Background:** Much of the unexplained heritability of late onset Alzheimer disease (AD) may be due to variants that are too rare to be detected in genome-wide association studies. **Methods:** In a sample of unrelated European ancestry participants in AD Sequencing Project (5617 AD cases, 4594 controls), variants identified by whole exome sequencing were culled from 110 genes previously associated with AD or other dementias, as well as genome-wide, and then filtered for predicted functional impact and occurrence in AD cases, but not controls. **Results:** A total of 24 variants with moderate/high functional impact from 19 genes were observed in 10 or more AD cases. This includes a missense mutation (rs149307620, n=10) in *NOTCH3* for which several other coding mutations are associated with cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL), a diagnostically distinct disorder, marked by severe headaches in young adulthood and stroke and dementia later in life. Evaluation of clinical/autopsy data from 7 of these AD cases revealed classic AD symptoms with progressive memory loss, moderate to severe amyloid and tau pathology at autopsy and no evidence of stroke or severe microvascular disease. Protein modeling showed the AD *NOTCH3* mutation causes quantitative changes in H-bonding that impact the JAG1 binding site, whereas CADASIL *NOTCH3* mutations result in the gain or loss of Cysteine and di-sulfide bonds affecting overall protein structure. Further analysis revealed all 10 cases with rs149307620 share a 5 SNP haplotype with frequency of 15% in ADSP controls. We also identified in 4 AD cases the *TREM2* Q33X mutation that in homozygous form causes Nasu-Hakola disease, a rare disorder characterized by early-onset dementia and multifocal bone cysts, suggesting an intermediate inheritance model for the mutation with respect to dementia outcome. Other findings include an 8-SNP haplotype (0.3% in controls) spanning 12.9 kb that is shared by 10 AD cases and contains 3 rare mutations in *ABCD4* and a 12-SNP haplotype (0.1% in controls) spanning 77.6 kb that is shared by 8 of 10 AD cases and contains 4 rare mutations, two each in *CELSR1* and *GTSE1*. Notably, *ABCD4* encodes an ATP binding cassette transporter that is in the same family as well-established AD gene *ABCA7*. **Conclusions:** We identified several novel rare variants predicted to have high impact on protein structure which may alter AD risk and be potential therapeutic targets.

**2350T**

**Use of brain homogenate RNA expression data to identify novel cell-type specific alterations in Alzheimer's disease.** *I.S. Piras<sup>1</sup>, P.D. Coleman<sup>2</sup>, M.J. Huettelman<sup>1</sup>.* 1) Neurogenomics Division, Translational Genomics Research Institute, Phoenix, AZ, 85004, US; 2) Biodesign Institute, Neurodegenerative Disease Research Center, Arizona State University, Tempe, AZ, 85287, US.

Cell type resolution gene expression changes are critical to assess in neurological disease due to the heterogeneity within the brain. However, this requires labor and cost intensive approaches (i.e laser capture microdissection, LCM) reducing the sample size. We describe herein a bioinformatics approach that is able to leverage expression profiling data from brain homogenate to derive cell type specific differential expression. Our approach is able to identify expression differences that were previously only seen using LCM, demonstrating the utility of our method to expand the knowledge of brain disease gene expression changes without the need for generation of additional cell specific data. We utilized an LCM-derived RNA expression database from mouse cortex (Zhang et al. *J Neurosci* 34, 11929-47) to create a cell type enrichment expression score for each gene in the transcriptome. The database includes RNA profiling of 22,458 genes in: astrocytes (A), neurons (N), microglia (M), endothelial (E), and Oligodendrocytes (O). We classified the DEGs from: middle temporal gyrus (MTG), temporal cortex (TCX), BA22, BA10, BA44, hippocampus (HIP), and cerebellum (CBE) in AD and controls. We detected 50 gene classes from 11,994 DEGs. The "Mixed" genes (non specific cell expression), were the most represented (67.7%), followed by N (9.1%), E (5.8%), M (5.7%), A (4.6%) and O (3.1%). "N" genes were mostly downregulated in AD, and "E" genes were mostly upregulated, especially in the temporal area. "M" genes were upregulated in the temporal area and BA44, and slightly downregulated in BA10, HIP and CBE. "N" genes were enriched for the "GABAergic" pathway (MTG, TCX, HIP). Specific pathways for E were: "Angiogenesis" and "Hemostasis" (MTG and TCX). "M" genes were enriched for Immune Pathways (MTG, TCX, BA44, CBE), "O" genes were enriched for Glycosaminoglycan metabolism. We detected classes of cell-specific genes functionally related, observing pathways not identifiable from the homogenate results. For instance, "N" genes were mostly downregulated, and enriched for "GABAergic" pathway. The upregulation of "M" genes and the enrichment in Immune System processes seems specific to temporal area and BA44. Our approach affords the advantage of cell type level interrogation of the transcriptome using bulk RNA profiling which lends itself to more cost and time effective studies that should have increased statistical power.

**Whole genome sequencing-based rare variant analysis in 450 multiplex Alzheimer's disease families.** *D. Prokopenko<sup>1</sup>, L. Bertram<sup>2</sup>, S. Morgan<sup>3</sup>, S. Amberkar<sup>3</sup>, R. Kirchner<sup>4</sup>, I. Wolkers<sup>2</sup>, S. Hong<sup>2</sup>, B. Hooli<sup>1</sup>, K. Mullin<sup>1</sup>, J. Miller<sup>4</sup>, B. Chapman<sup>4</sup>, O. Hofmann<sup>5</sup>, C. Lange<sup>4</sup>, W. Hide<sup>2</sup>, R.E. Tanzi<sup>1</sup>.* 1) Genetics and Aging Research Unit, Department of Neurology, Massachusetts General Hospital, Boston, MA; 2) Lübeck Interdisciplinary Platform for Genome Analytics, Institutes of Neurogenetics and Cardiogenetics, University of Lübeck, Lübeck, Germany; 3) Department of Neuroscience Sheffield Institute of Translational Neuroscience University of Sheffield, Sheffield, UK; 4) Department of Biostatistics, Harvard T.H. Chan School of Public Health, Boston, MA; 5) Melbourne Centre for Cancer Research, The University of Melbourne, Melbourne, Australia.

Alzheimer's disease (AD) is one of the most common neurodegenerative disease in the world, being the 6<sup>th</sup> leading cause of death in the United States. It provides a huge burden on the healthcare system, and this burden is projected to grow in the following decades. Genome-wide association studies (GWAS) have been successful at identifying common and rare genomic loci associated with AD. Whole-genome sequencing (WGS) techniques allow a comprehensive analysis of the entire genome, specifically of rare variants, which cannot be well imputed. We sequenced 1,971 individuals from 450 multiplex AD families from NIMH and NIA cohorts as our discovery dataset. We further gained access to population-based AD sequenced ADNI and ADSP cohorts and used them as our replication dataset. We performed single variant analysis using the FBAT approach. We further performed a region-based analysis of rare variants, which were partitioned into nonoverlapping windows with a spatial clustering approach. In this analysis we specifically focused on variants with low minor allele frequency and their association to AD. Although none of our rare variants were genome-wide significant, we highlight 2 novel potential AD loci from single rare variant analysis and 5 novel loci from region-based analysis showing evidence of replication. Using pathway analysis we show that a subset of identified loci are involved in regulatory interactions with *APP* and *ADAM10*. Whole Genome Sequencing will serve as an important resource for identifying rare functional variants, although large sample sizes in family-based cohorts will be needed to finemap known signals.

**2352W**

**Genome-wide linkage analysis of Caribbean Hispanic Puerto Rican families supports evidence of linkage to chromosome 9.** *F. Rajabli<sup>1</sup>, B.E. Feliciano-Astacio<sup>2</sup>, K. Celis<sup>1</sup>, K.L. Hamilton-Nelson<sup>1</sup>, L.D. Adams<sup>1</sup>, A.R. Betancourt<sup>2</sup>, V. Rodriguez<sup>1</sup>, H. Acosta<sup>3</sup>, A. Chinea<sup>2</sup>, G.S. Bird<sup>4</sup>, J.M. Vance<sup>1,5</sup>, M.L. Cuccaro<sup>1,5</sup>, M.A. Pericak-Vance<sup>1,5</sup>, G.W. Beecham<sup>1,5</sup>.* 1) John P. Hussman Institute for Human Genomics, University of Miami Miller School of Medicine, Miami, FL, USA; 2) Universidad Central del Caribe, Bayamón, PR, USA; 3) Clinica de la Memoria, San Juan, PR, USA; 4) Center for Outreach in Alzheimer's, Aging and Community Health at North Carolina A&T State University, Greensboro, NC, USA; 5) 8.Dr. John T. MacDonald Foundation Department of Human Genetics, Miller School of Medicine, University of Miami, Miami, FL, USA.

**Background.** The majority of genomic studies of late-onset Alzheimer's disease (LOAD) focus on non-Hispanic White (NHW) population. Genetic studies in Caribbean Hispanic (CHI) populations are limited, despite evidence of higher incidence rates of AD (compared to NHW) among these ethnic groups. Moreover, the ancestral heterogeneity (admixture) of CHI makes studies of CHI population critical in the discovery of ancestry-specific genetic factors in AD. In this study, we analyzed twenty-five multiplex CHI Puerto Rican (PR) families using genome-wide linkage analysis with the goal of identifying genomic regions segregating with a disease that are likely to contain risk genes for PR AD. **Methods.** Genome-wide array genotyping (with IlluminaMEGA and GSA arrays) of 95 individuals (69 affected) from 25 families was used for linkage analysis. Models assuming autosomal dominant inheritance included: 1) parametric two-point affecteds-only and age-dependent penetrance models, and 2) parametric multipoint affecteds-only and age-dependent penetrance models, and 3) nonparametric multipoint model. Linkage disequilibrium pruning for the multipoint models was done using the 1000 Genomes Project PUR panel frequencies as a reference. Linkage analyses were implemented in the MERLIN software. **Results.** We identified linkage region with the LOD scores exceeding 2.6. A locus at 9p21 produced a linkage LOD score of 2.6 across all families in the nonparametric multipoint model. The highest linkage peak was observed at SNP marker rs7853053. The region for this locus is 17 centimorgans (cM) wide (46.8-63.7 cM). The region overlaps a previously reported linkage peak in NHW families (Zuchner et al. 2008). Genes located in this region, such as CDKN2A, C9orf72 were found as AD associated genes in other studies. CDKN2A involved in the process of neurodegeneration in AD. On the other hand, regions previously identified in AD linkage scans (PSEN1, PSEN2, APP, MAPT, APOE) showed no evidence of linkage in these analyses. **Conclusions.** Linkage analysis of CHI PR families extended evidence for a LOAD susceptibility gene on chromosome 9 and confirmed previously reported linkage to 9p21.3 in NHW families. Further, we will evaluate CDKN2A, C9orf72 and other potential candidate genes using ancestry-aware mapping methods. .

**RNA expression and DNA methylation in the Alzheimer's Disease Neuroimaging Initiative (ADNI) data.** *B. Riley-Gillis, S. Grosskurth, K. Idler, A. Vasanthakumar, J. Davis, J. Waring.* Genomics Research Center, AbbVie, North Chicago, IL.

The aim of this study was to integrate peripheral blood RNA expression & DNA methylation data within the well-characterized Alzheimer's Disease Neuroimaging Initiative (ADNI) dataset to understand the relationship between the two data types & to identify potential blood biomarkers of Alzheimer's disease (AD). The ADNI dataset is comprised of AD patients as well as mild cognitively impaired (MCI) & cognitively normal (CN) patients tracked longitudinally with data collected for WGS, expression analyses, imaging, CSF biomarkers & clinical data such as diagnostic & cognitive assessments (eg. MMSE). RNA expression data generated on the Affymetrix U219 array was obtained from the ADNI data portal where it had been normalized & quality controlled prior to upload. Differential expression analysis was performed for the comparisons AD vs CN, AD vs MCI & MCI vs CN employing a linear model incorporating disease status, gender, age, education, race & APOE e4 state as covariates. Overall, we identified nominal differential expression with adjusted p-values not meeting significance (<0.1). However, at a transcriptome-wide level we do see that differential gene expression changes for AD vs CN & AD vs MCI are more similar than MCI vs CN, indicating that broad gene expression changes may be occurring in the AD patients relative to MCI & CN. To investigate the relationship of RNA expression with DNA methylation, we utilized data generated on the Illumina EPIC methylation array. Differential DNA methylation yielded 483, 139 & 299 differentially methylated positions (DMPs) for the AD vs CN, AD vs MCI & MCI vs CN comparisons, respectively. The DMPs included 357, 113 & 225 individual genes when annotated based on a threshold of 50kb from the CpG. The top DMPs were overlapped with the differentially expressed genes (raw p-value < 0.1) & we focused on genes where the RNA expression was up-regulated & the DNA methylation was down-regulated, & vice-versa. Preliminary exploration of the overlapping genes identified biological connections to brain function & development; ongoing efforts to fully understand the application to AD include association of identified differential gene expression & methylation changes with CSF biomarkers & cognitive scores. **Disclosures:** All authors are employees of AbbVie. The design, study conduct, & financial support for this research were provided by AbbVie. AbbVie participated in the interpretation of data, review, & approval of the publication.

## 2354F

**Towards personalized health: Multimodal risk prediction models for dementia.** N. Shah<sup>1</sup>, C. Swisher<sup>1</sup>, N. Schenker-Ahmed<sup>1</sup>, P. Garst<sup>1</sup>, I. Shomorony<sup>1</sup>, D. Tkach<sup>1</sup>, C. Venter<sup>2</sup>, D. Karow<sup>1</sup>. 1) Human Longevity, Inc., San Diego, CA; 2) J. Craig Venter Institute, La Jolla, CA.

Current models for predicting onset of dementia rely primarily on single modality data (e.g. magnetic resonance imaging, genotyping, or cognitive assessment). However, it is necessary to include multiple modalities including imaging, genetic and clinical biomarkers to accurately assess an individual's lifetime and short-term risk. Furthermore, it requires genotyping beyond a single gene, analyzing imaging features beyond a single structure, and further investigation into mitigating risk factors. We describe a method that utilizes polygenic risk score for Alzheimer's disease, and 77 features from structural T1-weighted magnetic resonance imaging (MRI) including surface area, thickness, and volume of the brain regions to train multimodal models to predict the likelihood of cognitive decline as well as lifetime risk of dementia. The cumulative hazard from the lifetime risk model is then integrated with population-based incidence rate for dementia to calculate annualized lifetime risk personalized to the age and sex of an individual. For both models, respectively, using MRI and WGS data combined improves performance (1: AUC=0.95, 2: AUC= 0.92 within 3 years) in the prediction of dementia progression over either MRI (1: AUC=0.93 at the time of event and AUC=0.55 10 years prior to developing dementia, 2: AUC=0.90 within 3 years) or WGS (1: AUC=0.82, 2: AUC=0.75 within 3 years) alone. We validated the models using an independent cohort. In addition we show that our model outperforms commonly used markers to predict onset of dementia including amyloid plaque quantitative markers from PET scan in detection of dementia. Finally, we show how the results of these multimodal models would be visualized to help an individual achieve a better understanding of their risk.

## 2355W

**Investigation for a protective variant for the ApoEε4 allele in Alzheimer disease.** J.M Vance<sup>1</sup>, F. Rajabli<sup>1</sup>, B.E. Feliciano-Astacio<sup>2</sup>, K. Celis<sup>1</sup>, L.D. Adams<sup>1</sup>, K.L. Hamilton-Nelson<sup>1</sup>, A.R. Betancourt<sup>2</sup>, H. Acosta<sup>3</sup>, P. Bussies<sup>1</sup>, T. Starks<sup>4</sup>, N. Hoffman<sup>1</sup>, C. Reitz<sup>1</sup>, R. Mayeux<sup>1</sup>, G.S. Bird<sup>5</sup>, M.L. Cuccaro<sup>1</sup>, J.L. Haines<sup>6</sup>, G.W. Beecham<sup>1</sup>, M.A. Pericak-Vance<sup>1</sup>. 1) John P. Hussman Institute for Human Genomics, University of Miami Miller School of Medicine, Miami, FL, USA; 2) Universidad Central del Caribe, Caguas, PR, USA; 3) Clinica de la Memoria, San Juan, PR, USA; 4) Gertrude H. Sergievsky Center, Departments of Neurology, Psychiatry, and Epidemiology, College of Physicians and Surgeons, Columbia University, New York, NY, USA; 5) North Carolina A & T State University, Greensboro, NC, USA; 6) Department of Epidemiology and Biostatistics, Institute for Computational Biology, Case Western Reserve University School of Medicine, Cleveland, Ohio, USA.

**Background:** The risk for late-onset Alzheimer disease (LOAD) in ApoEε4 carriers differs between ethnic groups, with Japanese>Europeans>African-Americans (AA) >Africans. We hypothesized two possibilities for this difference: 1) differences in overall (global) ancestry (GA) that also reflects environmental pressures 2) differences due to local ancestry (LA) around the ApoE region. To investigate, we assessed GA and LA in our LOAD datasets in AA and Caribbean Hispanics/Latinos (CHI) for association and interaction with ApoEε4. **Methods:** Genotyping data were available on 2,229 AA (811 cases, 1,418 controls) and 267 Puerto Rican (PR) CHI samples (169 cases, 98 controls). LA was calculated using SHAPEIT and RFMix. Analyses included an interaction analysis between ApoEε4 and LA or GA using logistic regression and a haplotype-based analysis of LA using GEE. For sequence comparison, we used ApoEε4 carriers in African (Yoruban), European (CEU) and Japanese genomic DNA sequence data (1000 Genomes). Differences were screened for potential functional effect (insilico: GTEx, ROADMAP) and in vitro (massively parallel reporter assays (MPRA)). iPSC of each LA subtype are differentiated into neurons, astrocytes and microglia. **Results:** We identified a 2mB region of LA surrounding the ApoEε4 allele. Both haplotype and interaction analyses were significant for LA, but were not significant for GA. Interaction results: ApoEε4 x LA (AA<0.008, PR<0.04) and haplotype analysis showed that the CEU ApoEε4 haplotype was significantly different from the African haplotype (PR<1.3e-08, AA<2.2e-16) for AD risk. We identified 548 variants with significant frequency (Bonferroni corrected) differences between CEU and African populations in the LA region. A strong peak of sequence differences (p<e-12) lies within the strongest topologically associated domain of ApoE. MPRA clones have been created across the LA region and are being screened for regulatory potential. We have identified over 100 AA ApoEε4 brains for analysis as well. iPSC have been created for ApoEε4/4 homozygotes of each of the LA subtypes. **Conclusion:** LA surrounding the ApoEε4 allele is a primary contributor for population differences in LOAD risk. Identification of this variant could lead to therapeutic targets and provide greater insight into the mechanism in which ApoEε4 leads to AD. Counseling of risk for ApoEε4 carriers will differ depending on the origin of the patients ApoEε4 allele.

**Integrative functional genomics analysis of neuropathologic features of Alzheimer's disease and related cognition decline reveals novel insights on previously identified loci.** J. Yang<sup>1</sup>, S. Nagpal<sup>2</sup>, M. Epstein<sup>1</sup>, L. Tsoi<sup>3</sup>, M. Patrick<sup>4</sup>, A. Wingo<sup>5</sup>, T. Wingo<sup>5</sup>. 1) Department of Human Genetics, Emory University School of Medicine, Atlanta, GA; 2) Department of Bioinformatics, Georgia Institute of Technology, Atlanta, GA; 3) Department of Dermatology, University of Michigan School of Medicine, Ann Arbor, MI; 4) Department of Psychiatry, Emory University School of Medicine, Atlanta, GA; 5) Department of Neurology, Emory University School of Medicine, Atlanta, GA.

Alzheimer's Disease (AD) is a devastating neurodegenerative disease that has ~70% of risk believed to be genetic with polygenic architecture. Previous GWAS have identified 20 genetic risk genes of AD. However, most identified SNPs fall within the noncoding regions of the genome where the closest genes were reported as the genetic risk genes. Consequently, the molecular mechanisms underlying these identified risk genes are largely unknown. To provide further insights into the biology of these known loci, we conducted a novel integrative functional genomics analysis using the genotype and transcriptomic data from the Religious Orders Study and Memory Aging Project (ROSMAP) study, with 499 samples from the dorsolateral prefrontal cortex (dPFC) tissues. We first used the recently published Dirichlet Process Regression (DPR) method to estimate the genetically-regulated component of the gene expression respectively for all 20 loci. We took the assayed gene expression levels (adjusted for other non-genetic covariates) as the response variable and all SNPs within a 10<sup>6</sup> base pair window of the gene boundary as predictors. DPR nonparametrically models the genetic architecture by assuming a Dirichlet process prior for the effect-size variance, which significantly improved the regression over the alternative PrediXcan method (average R<sup>2</sup>=16.7% vs. 4.4%). Then we respectively tested the association between the estimated genetically-regulated components and the AD-related phenotypes — AD diagnoses, cognition decline, and two neuropathological features (CERAD, Braak). Interestingly, we identified significant associations for *SORL1* with respect to all four studied phenotypes, demonstrating that *SORL1* is likely to affect cognition decline (p=0.07) and AD (p=0.043) through CERAD (p=0.048) and Braak (p=0.014). Particularly, *CEFL1* was identified significant for both CERAD (p=0.004) and AD (p=0.032), showing that *CEFL1* is likely to affect AD through CERAD. In addition, *UNC5C* was identified significant for both cognition decline (p=0.0053) and AD (p=0.023), showing that *UNC5C* is likely to affect AD through the cognition decline. In summary, our study provides novel transcriptomic insights for the known loci of AD. Moreover, our fitted DPR models can be used to impute the genetically-regulated transcriptomic components (in dPFC tissues) for samples with genotype data only, which will significantly increase the study sample size and help illustrate the genetic etiology of AD.

**Genome-wide interaction study of brain and CSF measures of Alzheimer disease on memory impairment.** C. Zhu<sup>1</sup>, J. Chung<sup>1</sup>, J. Mez<sup>2</sup>, K. Lunetta<sup>3</sup>, G. Jun<sup>1,4</sup>, L. Farrer<sup>1,3</sup>, X. Zhang<sup>1,3</sup>. 1) Section of Biomedical Genetics, School of Medicine, Boston University, Boston, MA, USA; 2) Departments of Neurology, Boston University School of Medicine, Boston, MA, USA; 3) Department of Biostatistics, Boston University School of Public Health, Boston, MA, USA; 4) Neurogenetics and Integrated Genomics, Andover Innovative Medicines Institute, Eisai Inc, Andover, MA, USA.

**Background:** Although amyloid- $\beta$  plaques (A $\beta$ ) and neurofibrillary tangles (tau) are pathological hallmarks of Alzheimer disease (AD), ~10% of clinically diagnosed AD cases do not have AD pathology. Furthermore, a certain percentage of subjects with AD-like pathology do not have clinical AD symptoms (e.g., memory loss). Genetic factors that affect brain structure and cognition in cognitively normal adults may also influence AD pathogenesis later in life. In this study, we sought to identify genetic modifiers of the influence of AD-related endophenotypes on memory impairment. **Methods:** We evaluated the interaction of logical memory test scores including immediate (LMiT) and delayed (LMdT) recall, with single nucleotide polymorphisms (SNPs) across the genome on AD-related brain imaging and cerebrospinal fluid (CSF) endophenotypes including hippocampal volume (HPV), amyloid- $\beta_{42}$  (A $\beta_{42}$ ) and total/phosphorylated tau (t-/p-Tau) in cognitively normal (CN, n=315), mild cognitive impairment (MCI, n=611), and AD subjects (n=196) from the Alzheimer's Disease Neuroimaging Initiative (ADNI) study. LMiT and LMdT were considered as cognitive outcomes, and the interaction between SNP and endophenotypes were estimated after controlling for age, sex, and principal components of ancestry. HRC-imputed ADNI 1 (N=691) and ADNI GO/2 (N=431) data were analyzed separately. Results were combined across ADNI 1 and ADNI GO/2 using meta-analysis. P<5.0 $\times$ 10<sup>-8</sup> was used to determine genome-wide statistical significance for association. **Results:** In CN subjects, we identified significant interactions of *ATP8A2* SNP rs12385841 with A $\beta_{42}$  on LMiT score (P=1.08 $\times$ 10<sup>-8</sup>) and rs77369553 located near *ZNF804A* with ptau on LMdT score (P=4.66 $\times$ 10<sup>-6</sup>). No significant interactions were observed in MCI subjects. In AD subjects, significant interactions (P is 1.3 $\times$ 10<sup>-8</sup>~ 1.4 $\times$ 10<sup>-6</sup>) were observed for ptau with SNPs in *PCSK5*, *UNC79*, *CDYL*, and *ACSS3* on LMdT score, and for tau/A $\beta_{42}$  with SNPs in *DZIP1* (P=1.3 $\times$ 10<sup>-10</sup>) and *GPC5* (P=4.4 $\times$ 10<sup>-8</sup>) on LMdT score. In addition, we found consistent high expression patterns of *CDYL*, *DZIP1*, *GPC5*, and *UNC79* in human normal brains in GTEx. **Conclusions:** Our findings provide insight into the complex relationships between the amyloid and tau burden and memory impairment in stages preceding and after onset of AD symptoms. Further functional studies are required to elucidate the role of identified genetic variants in AD pathophysiology. A replication study using sequencing data is underway.

**Association of genetic variants/predicted gene regulatory scores with imaging-derived phenotypes in multiple sclerosis patients.** *K. Kim<sup>1</sup>, L. Madireddy<sup>1</sup>, C. Cordano<sup>1</sup>, R.G. Henry<sup>1</sup>, A.J. Green<sup>1</sup>, B.A. Cree<sup>1</sup>, S.L. Hauser<sup>1</sup>, J.R. Oksenberg<sup>1</sup>, S.E. Baranzini<sup>1,2</sup>.* 1) Department of Neurology, University of California San Francisco, San Francisco, CA; 2) Institute for Human Genetics, University of California San Francisco, San Francisco, CA.

Genome-wide association studies have identified 200 loci in addition to those in the MHC that confer susceptibility to multiple sclerosis (MS). However, a significant proportion of the heritability of MS remains to be explained. Relevant neuroimaging-derived phenotypes greatly empower the genetic analysis of complex diseases as they provide quantitative and reproducible indicators of disease activity, effectively linking the genotype and clinical phenotype. In MS, brain, spinal cord, and retinal imaging represent valuable quantitative assessments of CNS integrity and enable tracking of disease progression. In this study, we collected longitudinal neuroimaging-derived metrics from magnetic resonance imaging (n=466) and optical coherence tomography (n=363) in UCSF MS-EPIC cohort. To calculate a patient-specific rate of change of longitudinal metrics, we performed a linear mixed effect analysis using random slope model. Then, we conducted association studies in a different level of biological hierarchy using MS-susceptible genetic variants and predicted regulatory effects for 10 different cell types computed from the publicly available gene regulatory dataset. We found 2 variants with a significant effect on either phenotype. Rs2364482 (*LOC105369628*) was associated with gray matter volume change, and rs1250568 (*ZMIZ1*) with macular thickness (FDR < 0.05). We also tested an association of genes in 10 different cell types with imaging-derived metrics using predicted regulatory effects as a gene level analysis. A higher regulatory score of *EMR1* was associated with reduced brain atrophy change in CNS cell, on the other hand, a higher score of *EYA2* was associated with increased atrophy change ( $p < 0.001$ ). *IKZF1* and *CAMTA1* were significant in T cell for brain atrophy ( $p < 0.001$ ). Interestingly, *CAMTA1* has been found significant association with amyotrophic lateral sclerosis by GWAS but has not been reported in MS. For retinal thickness change, *MERTK* was significant for inner plexiform layer thinning in T or Treg cells. It has been reported that higher expression of *MERTK* was associated with risk of developing MS. We established an analytical pipeline to investigate the influence of genomic variation on neuroimaging-derived metrics. Then, we found candidate genetic variants and genes associated with phenotypic change using the pipeline. Our findings will provide more accurate disease pathogenesis and biomarkers for different disease progression in MS patients.

**2359T**

**A multiple sclerosis CD4+ T cell methylation QTL reference map identifies the proximal functional consequences of 18 MS susceptibility variants.** *T. Roostaei<sup>1</sup>, H.U. Klein<sup>1</sup>, N. Patsopoulos<sup>2</sup>, H.L. Weiner<sup>2</sup>, P.L. De Jager<sup>1</sup>.* 1) Center for Translational and Computational Neuroimmunology, Department of Neurology, Columbia University Medical Center, New York, NY; 2) Department of Neurology, Brigham & Women's Hospital and Harvard Medical School, Boston, MA.

Multiple sclerosis (MS) is a complex autoimmune disease of the central nervous system. To date, 140 non-MHC autosomal genetic loci are associated with MS risk. However, the functional consequences of the majority of these loci are not known. CD4+ T cells are strongly implicated in MS. Here, we sought to determine the effects of MS loci on DNA methylation of CD4+ T cells in MS patients. 180 relapsing-remitting MS patients were recruited. Imputation was performed on the whole-genome genotyping data. CD4+ T cells were isolated from frozen peripheral blood mononuclear cell samples. DNA methylation was measured using Illumina 850K array. After quality control, data from 156 individuals with European ancestry were used for analysis. Linear regression was performed to assess the association between genotypes and DNA methylation in cis ( $\pm 1\text{Mb}$ ) using M values, accounting for the effects of covariates including age and sex. From 769,634 tested CpG sites, we found evidence for the influence of cis genetic effects on the methylation of 107,925 CpGs (FDR-adjusted  $p < 0.05$ ). From the identified CpGs common between the Illumina 850K and 450K arrays (n=52,687), 64.8% were previously identified as having cis-methylation quantitative trait loci (mQTLs) in data from naïve CD4+ T cells of healthy participants (FDR-adjusted  $p < 0.05$ , BLUEPRINT epigenome project, performed using 450K array), therefore validating our findings. The top variants for 762 mQTLs were in  $\text{LD} > 0.2$  with 119 lead variants of MS-associated loci. Colocalization analysis was performed to find loci whose effects on MS risk and cis-DNA methylation are likely driven by a shared causal variant. 3 mQTLs showed strong evidence of colocalization (posterior probability  $> 0.95$ ) with 3 MS loci, affecting methylation levels of 12 CpGs in the body of *TNFSF14*, *ANKRD55* and *IL6ST* and the transcription start site of *CYP24A1* genes. 19 additional mQTL effects were colocalized with 15 other MS loci with posterior probability  $> 0.8$ . Of note, one of these mQTL effects was an association between rs4939490 and the methylation level of cg14130459 in the 1st exon of *SLC15A3*, suggesting a novel MS susceptibility gene that is influenced by this variant. Our new MS CD4+ T cell reference mQTL map therefore identifies the most proximal functional consequence of a large proportion of MS variants, refining the list of such loci with effects in healthy subjects (BLUEPRINT) and introducing novel loci for investigation in future functional studies.

**A genetic modifier model for SUDEP in SCN1A driven epilepsy.** P.J. Vandeverter, R. Domínguez Vidafía, A.R. Ghazi, E.S. Chen, A.M. Goldman, C.A. Shaw. Baylor College of Medicine, Houston, TX.

Sudden Unexpected Death in Epilepsy Patients (SUDEP) is a rare disorder that affects some individuals with SCN1A driven epilepsy as well as epilepsy patients with different genetic drivers. We have pursued a genetic modifier model of SUDEP in SCN1A cases. Under this model, concomitant variation – or genetic load – outside of SCN1A but in genes related to the SUDEP pathophysiology are expected to be elevated for individuals at high risk for SUDEP, while individuals that lack such variants are at lower risk. To pursue this hypothesis we have created a data set and computational approach to evaluate the modifier model. We identified individuals who underwent exome sequencing that have pathologic or potentially pathologic SCN1A variation from the Baylor Genetics laboratory who were also patients at Texas Childrens hospital. We also utilize exome data from SUDEP individuals with SCN1A driven epilepsy. Taken together, these data provide a set of positive control SCN1A SUDEP cases as well as a collection of test individuals that we can evaluate genomically and by chart review. The computational procedure considers the pathology and rate of occurrence of variation in genes related to the pathophysiology of SUDEP. The gene set used for load analysis was identified by expert review of the literature and publications of genetic models of SUDEP. The pathways and processes implicated include cardiac arrhythmia and spreading depression, as well as other phenotypes. Our preliminary results indicate significant evidence for increased load of Variants of Uncertain Significance (VUS) and potentially pathologic alleles in the candidate gene set among the SUDEP cases. The promising results of this study suggest a broader role for the modifier model in understanding the severity and variation in presentation observed in Mendelian disease. The results suggest that the spectrum between Mendelian and Complex disease could be viewed as a continuum, where the totality of alleles should be considered.

The anterior commissure is a nerve fiber bundle that interconnects the brain's hemispheres. It is important for higher-order cognitive functions and has a presumed role in neurodegeneration, but its genetic architecture remains elusive. Uncovering the genes underlying variation in the anterior commissure could aid understanding of its development and it potentially provides mechanistic insight into diseases that results from its dysfunction. We performed a two-stage genome-wide association study (N = 18,828) of the size of the anterior commissure and identified six independent variants at four loci (p-values ranging from  $4.1 \times 10^{-6}$  to  $9.4 \times 10^{-25}$ ). Using *in silico* and *in vitro* approaches, including gene expression analyses and Targeted Chromatin Capture (T2C) in human neural progenitor cells, we mapped the loci to probable causal genes involved in axon guidance (*EPHA3* and *SEMA6A*), cognitive disorders (*CTNND2*), and growth factor signaling (*RIT2*). Also, brain-wide morphometry studies revealed distinct associations of the variants with connected grey matter regions in the brain. Genome-wide analyses revealed an enrichment for H3K4me1 peaks (marking enhancer sites), introns, and conserved sequences, as well as cell-type-specific annotations from the central nervous system and cardiovascular system. Furthermore, we identify pleiotropy between genes known to increase risk of neurodegenerative diseases and loci of the anterior commissure, including frontotemporal lobar degeneration gene *TMEM106B*. These analyses shed light on the genetic architecture of commissural tracts and establish the size of the anterior commissure as a relevant marker of neurodegeneration.

**Multiple sclerosis genetic burden score in a systems biology study of MS patients from four countries.** S.D. Bos<sup>1,2</sup>, I.S. Brorson<sup>1,2</sup>, E.A. Høgestøl<sup>1,2</sup>, T. Berge<sup>2,3</sup>, J. Saez-Rodriguez<sup>4</sup>, A. Uccelli<sup>5</sup>, F. Paul<sup>6</sup>, P. Villoslada<sup>7</sup>, H.F. Harbo<sup>1,2</sup>. 1) Institute of Clinical Medicine, University of Oslo, Oslo, Norway; 2) Department of Neurology, Oslo University Hospital, Norway; 3) Department of Mechanical, Electronics and Chemical Engineering, Oslo Metropolitan University, Oslo, Norway; 4) Faculty of Medicine and University Hospital, University of Aachen, Aachen, Germany; 5) Ospedale Policlinico San Martino, Genova, Italy; 6) Department of Neurology, Charité – Universitätsmedizin Berlin, Berlin, Germany; 7) IDIBAPS, Neurosciences, Barcelona, Spain.

**Introduction:** Multiple Sclerosis (MS) is an auto-inflammatory disease which affects components of the nervous system. This results in neurological deficits of varying degree, depending on the affected site. In order to better study the complex interplay between genetics and the environment, which both are well-known risk factors a systems biology study (Sys4MS) was initiated in 2015. This study aims at applying systems medicine approach combining integrative omics, imaging and clinical data with computational tools, to develop personalized healthcare for people with MS. **Materials and Methods:** From four participating centres in total 328 MS patients and 90 healthy controls were included. DNA was extracted from whole blood for all participants and genotypes on the Illumina OmniExpress chip. Genotype data was then imputed, resulting in genotypes for 152 out of 200 MS-associated SNPs. Furthermore, variants at 17 out of 32 MS-associated HLA loci were imputed. The odds ratio was used to weight genotype on each of the 169 MS-associated loci, the sum of the genetic burden (MSGB) per individual was calculated. **Results:** The patients had a mean age of 41 years and 71% were women. The mean disease duration at the time of inclusion was 10 years (standard deviation 8 years). 83% of the patients had relapsing-remitting MS, whereas the remaining patients had primary progressive MS. The median expanded disability status scale (EDSS) score was 2.0 (range 0-8.0). The MSGB of patients was significantly higher as compared to the controls (respectively 4.23 vs 3.20 with a t-test p-value of  $3.4 \times 10^{-8}$ ). We did not observe a difference in the MSGB between patients from the participating centres (Norway, Germany, Spain and Italy). **Discussion:** MS patients in this systems biology approach have a higher MSGB as compared to controls, in line with earlier studies. We did not see a significant difference in the MSGB between the participating centres, although we may lack the power to detect subtle differences between the MSGB between countries in our modest sample size. Further investigations of the role of the MSGB in detailed phenotypes collected in the Sys4MS study, such as the response to treatment and immune cell profiles remains to be investigated.

## 2363F

**Neuropathological correlates and genetic architecture of microglial activation in elderly human brain.** D. Felsky<sup>1,2</sup>, T. Roostaei<sup>1</sup>, N. Kwangsik<sup>3</sup>, S.L. Risacher<sup>3</sup>, E.M. Bradshaw<sup>1,2</sup>, V. Petyuk<sup>4</sup>, J.A. Schneider<sup>5,6</sup>, A. Saykin<sup>3</sup>, D.A. Bennett<sup>5,6</sup>, P.L. De Jager<sup>1,2</sup>. 1) Center for Translational and Computational Neuroimmunology, Dept. of Neurology, Columbia University Medical Center, New York, NY; 2) Program in Population and Medical Genetics, Broad Institute of MIT and Harvard, Cambridge, MA; 3) Indiana Alzheimer's Disease Center, Center for Neuroimaging, Department of Radiology and Imaging Sciences, Center for Computational Biology and Bioinformatics, Indiana University School of Medicine, Indianapolis, IN; 4) Pacific Northwest National Laboratory, Richland, WA; 5) Department of Neurology, Rush University Medical Center, Chicago, IL; 6) Rush Alzheimer's Disease Center, Rush University Medical Center, Chicago, IL.

**Background:** Microglia, the resident immune cells of the brain, have important roles in brain health. However, little is known about the regulation and consequences of microglial activation in the aging human brain. **Methods:** We assessed the effect of microglial activation in the aging human brain by calculating the proportion of activated microglia (PAM), based on morphologically defined stages of activation in four regions sampled postmortem from up to 225 elderly individuals. **Results:** We found that cortical and not subcortical PAM measures were strongly associated with  $\beta$ -amyloid, tau-related neuropathology, and rates of cognitive decline. Effect sizes for PAM measures are substantial, comparable to that of *APOE*  $\epsilon 4$ , the strongest genetic risk factor for Alzheimer's disease. Mediation modeling suggests that PAM accelerates accumulation of tau pathology leading to cognitive decline, supporting an upstream role for microglial activation in Alzheimer's disease. Genome-wide analyses identified a common variant (rs2997325) influencing cortical PAM that also affected *in vivo* microglial activation measured by positron emission tomography using [<sup>11</sup>C]-PBR28 in an independent cohort. Finally, we identify overlaps of PAM's genetic architecture with those of Alzheimer's disease, educational attainment, and several other traits based on published GWAS summary data from over 1.7 million people. **Conclusions:** Active cortical microglia may cause worsening cognitive decline via an accumulation of tau pathology. We also identified and validated a novel genetic locus influencing postmortem microglial activation, providing strong biological rationale for further investigation. This locus may be clinically meaningful given its strong effect on *in vivo* TSPO imaging. Finally, genetic predisposition to microglial activation influences several other human traits including educational attainment, raising the intriguing possibility that genetic determinants of late life neuroinflammation may affect early life cognitive development.

Periconceptional maternal myo-inositol (MI) deficiency is one of the crucial risk factors of neural tube defects (NTDs), but the exact mechanism remains poorly understand. In the present study, we sampled 80 NTD pregnancies and 80 controls from a high-prevalence area of Shanxi Province in northern China. We found that maternal MI deficiency was associated with an increased risk of NTDs by gas chromatography–mass spectrometry (GC-MS) analysis ( $P < 0.05$ ). To further investigate the causality between maternal MI deficiency and the occurrence of NTDs, we established a maternal MI deficient mouse model using intraperitoneal injection of  $\text{Li}_2\text{CO}_3$ , which acts as an inhibitor of inositol 1-phosphatase (IMPase) and a key enzyme for the synthesis and recycling of inositol in vivo. The MI level of the pregnant mouse decreased significantly after  $\text{Li}_2\text{CO}_3$  injection, and reached to the lowest level at 8 hours after the injection (23.72mg/L vs 44.15 mg/L  $P < 0.05$ ). Repeat trials showed that the average incidence of NTDs was 26.7%. The NTD phenotypes included encephalocele (85.8%), anencephaly (5.7%) and spina bifida (8.5%). Using the phospho-protein array (PEX100 and PAB216, Full Moon Biosystems, Inc.), we intended to find the possible differential phosphorylated proteins between the NTD and control in MI deficiency human and mouse respectively. We performed pathway analysis on the differentially phosphorylated proteins using KEGG databases of human NTDs with MI deficiency. The result displayed that PI3K-Akt signaling pathway (hsa04151) was the most enriching pathway. We then validated the proteins involved in the PI3K-Akt signaling pathway using a mouse phospho-protein array. A total of 21 proteins were found to be differentially phosphorylated (Fold change  $> 1.5$ ), and 14 of them were differentially phosphorylated in both the human and mouse, including YWHAZ, AKT1, AKT2, BCL2, CCND1, NOS3, PTK2, IRS1, MTOR (mTOR), TP53, RPS6KB1 (p70S6K), PDPK1, PPP2CA and PTEN. Further pathway analysis on the 14 common differentially phosphorylated protein found that PI3K/Akt/mTOR/p70S6K pathway was the most disturbed signaling pathway induced by MI deficiency. Our study indicated that PI3K-Akt signaling pathway might be one of the important regulatory mechanisms of inositol deficiency-induced NTDs.

**Introduction:** Febrile seizures affect 2-5% of children in western countries including Denmark with an incidence peak around 16 months of age. While usually benign, in a minority of cases febrile seizures are later followed by epilepsy. **Materials and Methods:** We extended our previous genome-wide association study on febrile seizures to a total of 4304 cases and 48290 controls. The analysis was based on 8.5 million variants imputed from the 1000 genomes project phase III reference panel, using logistic regression on imputed SNP dosages for association testing. Replication testing was carried out in independent Danish and Australian cohorts (N cases, N controls). **Results:** The 4 loci from the previous GWAS were confirmed, and we tried to replicate all 7 new loci with variants associated at  $P < 5 \times 10^{-7}$ . Six loci turned out to be consistently associated with febrile seizures (replication  $P < 0.05$ , combined  $P < 5 \times 10^{-6}$ ). Subsequent genome-wide enrichment analysis suggested that pre-synaptic cytomatrix proteins were implicated in seizure etiology. The remaining loci suggested implication of prostaglandin signaling, endogenous interleukins, as well as GABAergic signaling. **Conclusion:** Our study identified novel genetic associations with febrile seizures implicating genes involved in neuronal excitability and fever response. **Grant support:** Lundbeck Foundation, Novo Nordisk Foundation, Oak Foundation and Carlsberg Foundation.

**Cytoskeletal scaffolding protein WHIRLIN loss of function mutation in familial frontotemporal dementia.** Y. Baradaran-Heravi<sup>1,2</sup>, L. Dillen<sup>1,2</sup>, C. Koçoglu<sup>1,2</sup>, C. Van Broeckhoven<sup>1,2</sup>, J. van der Zee<sup>1,2</sup> on behalf of the BEL-NEU Consortium and the EU EOD Consortium. 1) Neurodegenerative Brain Diseases Group, Center for Molecular Neurology, VIB, Antwerp, Belgium; 2) Laboratory of Neurogenetics, Institute Born-Bunge, University of Antwerp, Antwerp, Belgium.

**Background:** Unresolved frontotemporal dementia (FTD) and early-onset dementia (EOD) families are systematically collected within the context of the BELNEU and EU EOD Consortia. **Materials and Methods:** Whole-exome sequencing (WES) was performed in a Belgian autosomal dominant dementia family with 5 patients over 3 generations. The index-patient was diagnosed with FTD at the age of 53 years, the other patients from previous generations were diagnosed with Alzheimer's disease or dementia unspecified. DNA for WES was available for 3 patients over 2 generations. Additional DNA samples of 2 unaffected relatives were used for variant co-segregation analysis. Shared, rare (MAF<0.01%), heterozygous variants with predicted protein-modifying effect were prioritized for follow up. Multiplex amplification resequencing was used to validate selected variants and perform candidate gene screening in unrelated FTD patients (n=397) and control individuals (n=838). **Results:** WES of 3 affected relatives revealed 89,732 shared variants. Data analysis as outlined prioritized 24 variants, of which 16 had a CADD score >20. Based on functional relevance in neurodegeneration, type of mutation, protein expression in brain and absence from the healthy relatives, a frameshift mutation (p.Thr119Profs\*22) in *WHRN* was retained as the most promising candidate variant and gene. The generated premature stop codon is located in exon 1 and predicted to trigger nonsense-mediated RNA decay (NMD). Full exonic resequencing of *WHRN* identified a series of missense mutations in both patients and controls. Missense variants detected in patients often mapped to functional protein domains (PDZ1 and PDZ2 domains), whereas in controls all variants mapped outside the functional domains. This enrichment was significant (p=0.0018, SKAT-O). **Conclusion:** We identified a co-segregating frameshift mutation in the *WHRN* gene on chr9q32 in an autosomal dominant FTD family. Screening of *WHRN* in unrelated patients and controls, revealed a number of missense mutations affecting the PDZ domains - involved in anchoring receptor proteins to the cytoskeleton and hold together signalling complexes at cellular membranes - potentially also resulting in loss of protein function. The effect of the LoF mutations will be investigated in patient-derived biomaterials and the mutation screen expanded to a larger patient cohort to provide further supportive evidence for causal implication of *WHRN* in FTD and neurodegenerative dementias.

Myo-Inositol (MI) is a small organic molecule which plays important roles in a diverse array of cellular activities. MI deficiency is related with the etiology of many diseases. Previous studies have underlined the vital role autophagy plays during neural tube development, while the PI3K/Akt/mTOR/p70S6K signaling pathway are primarily involved in the regulation of autophagy. In the present study, using the commercially available PI3-kinase ELISA kit, we detected the activity of the PI3-kinase MI deficiency NE-4C cells which were treated with 6.25  $\mu$ M Li<sub>2</sub>CO<sub>3</sub> (the inhibitor of the key enzyme for MI synthesis and recycling). The results showed that PI3K activity was significantly higher in the Li<sub>2</sub>CO<sub>3</sub>-treated group ( $P<0.05$ ), and the increased kinase activity was abolished by additional treatment with MI ( $P<0.05$ ). Then in vitro enzymology experiment was performed, in which immunoprecipitated PI3K was treated with a gradient of inositol from 1 to 20 mg/L. We found that PI3K activity decreased dramatically with the increasing MI concentration in a dose-dependent manner when the inositol concentration was below 5 mg/L. The PI3K/Akt/mTOR/ p70S6K signaling pathway was significant activated in MI deficient NE-4C cells compare with the controls using the method of western blot. The level of LC3B and the number of autophagic vacuoles were analyzed by western blot and electron microscopy. We found that a significant impaired autophagy when the NE-4C cells were treated by Li<sub>2</sub>CO<sub>3</sub>, and the effects were abrogated by combining Li<sub>2</sub>CO<sub>3</sub> with MI or signaling inhibitor (Ly294002 and Rapamycin). Which suggested that MI deficiency induced autophagy impairment through the Akt/mTOR/p70S6K signaling. We next validate the above result in our previous established MI deficiency mouse model, and found PI3K activity in the MI deficient NTD mouse model was significantly elevated in heart, neural and placenta tissues 8 hours after Li<sub>2</sub>CO<sub>3</sub> injection. Furthermore, the maternal serum MI levels correlated with the PI3K activity in the mouse embryonic neural (MEN) tissue ( $P<0.05$ ). The activity of Akt/mTOR /p70S6K signaling and the LC3B level were detected by western blot in MEN tissue. The result was coincide with that in NE-4C cells that the activity of Akt/mTOR /p70S6K signaling was over activated accompanied by the reduced level of LC3B. These results indicated that inositol deficiency induce autophagy impairing via PI3K/Akt/ mTOR/p70S6K signaling.

**RAD9B variants identified in neural tube defects.** Y. Lei<sup>1</sup>, X. Cao<sup>1</sup>, S. Wadhwa<sup>1</sup>, R. Finnell<sup>1,2</sup>. 1) Center for Precision Environment Health, Department of Molecular & Cellular Biology and Medicine, Baylor College of Medicine, Houston, TX.; 2) Collaborative Innovation Center for Genetics & Development, School of Life Sciences, Fudan University, Shanghai, China.

Neural tube defects (NTDs) which are the result of the failure of neural fold fusion during the first 4 weeks of embryonic development, are among the most severe of all human structure malformations. The global average incidence of NTDs is 0.5-1 per 1,000 newborns. Both the genetics and environmental factors contribute to the etiologies of NTDs. Although over 400 genes have been identified as contributing to NTDs in the mouse, the genetic etiology of human NTDs remains unclear. To date, there is no published genome wide association study on NTDs. No large scale (sample size >1000) whole exome sequencing or whole genome sequencing on NTDs have been performed let alone published. In our phase I whole genome sequencing of 100 NTD samples, we identified two predicted to be loss of function (LoF) variants (Chr12: 110960044 delA; Chr12: 110968402 insC) and one predicted-to-be-damaging missense variant (p.Ser354Gly) in RAD9B and when compared with the EXAC and the genomAD database, there are significant (p<0.05) LoF variants enrichment in NTDs compared to public controls. In a phase II validation study, we re-sequenced 96 NTDs and identified three missense RAD9B variants (p.Ser10Gly, p.Gln146Glu and p.Gly221Arg). Two of the variants were predicted-to-be-damaging by SIFT software. RAD9B is a homolog of RAD9, which is an integral element of the PCNA-like HUS1-RAD1-RAD9(9-1-1) complex, that plays a role in genotoxin-induced CHK1 activation. Previous studies in mice found that heterozygotes of Rad9b mutant mouse exhibit abnormal neural tube closure, which is consistent with our finding that heterozygous RAD9B LoF variants are associated with NTDs. To explore the underlying mechanism by which RAD9B LoF variants contribute to NTDs, we performed functional analyses of the identified RAD9B variants in our WGS data. Two LoF variants disrupted RAD9B nucleus localization as well as DNA repair foci formation under oxidative stress. In a RAD9B knock out assay, we found that LoF variants could not counteract RAD9B siRNA effect on cell proliferation. In conclusion, our study indicates that RAD9B variants could contribute to the etiology of NTDs by adversely affecting normal RAD9B function. Our study is the first one to report RAD9B variants in human disease.

**A Truseq RNA exome capture method for two different brain regions of restless legs syndrome patients.** F. Sarayloo<sup>1,2</sup>, A. Dionne-Laporte<sup>2</sup>, D. Spiegelman<sup>2</sup>, P.A. Dion<sup>2,3</sup>, G.A. Rouleau<sup>1,2,3</sup>. 1) Human Genetics, McGill University, Montreal, Quebec, Canada; 2) Montreal Neurological Institute, McGill University, Montreal (QC), Canada; 3) Department of Neurology and Neurosurgery, McGill University, Montreal (QC), Canada.

**Introduction:** Restless legs syndrome (RLS) is a prevalent disorder and individuals who are affected experience unpleasant sensations (mainly in their legs while at rest during evenings or nights). Since only movements can partially relieve these sensations, these individuals often refer to themselves as “nightwalkers” since they typically stand up and walk during the night to get rid of their symptoms. Approximately 77% of RLS cases have a family history, thus suggesting an important contribution of genetic factors. Unfortunately, the genes thus far associated with RLS explain less than 10% of the heritability. Despite these genetic advances, the molecular mechanisms underlying RLS remain to be established. **Methods:** Our study proposes to use transcriptomes (RNA-Seq) to explore dysregulations associated with the transcription factor encoded by *MEIS1*; the gene showing the strongest association with RLS. In 2008, a risk haplotype of *MEIS1* was reported to lower its RNA and protein expression in lymphoblastoid cells and specific brain region of RLS cases. We have generated RNA-Seq data from two human cell lines (SKNSH a neuroblastoma cell line and HEK293) across which we both over-expressed or knocked out *MEIS1*. The differential expression analysis was made using the edgeR algorithm and a list of dysregulated genes was delineated. To follow up and validate the dysregulation of these genes in RLS, we have flash-frozen brain tissues obtained from RLS cases. RNA was prepared from 30 thalamus and 31 pons samples of patients harboring the risk or non-risk alleles of *MEIS1*, as well as patients with other RLS risk alleles. We used the Truseq RNA exome capture method, as it is known to improve the quality of RNA-Seq libraries that are prepared from samples that were frozen for a long period. **Outcome:** Our study will result in a precious list of genes dysregulated in RLS, some of which may have already been reported to be involved in the disease. Other genes might represent novel candidates that should be examined for the presence of risk variants through genotyping (e.g. burden study) in unrelated cases; or through high-throughput sequencing in multiplex families. Overall, this study will have an important impact on our understanding of RLS.

**Cerebral palsy gene discovery based on whole exome sequencing of multiplex consanguineous families.** S. Bakhtiari<sup>1,2</sup>, A. Tafakhori<sup>3</sup>, SC. Jin<sup>6</sup>, X. Zeng<sup>6</sup>, M. Corbett<sup>4</sup>, J. Liu<sup>1,2</sup>, J. Heim<sup>1</sup>, MM. Hockley<sup>2</sup>, B. Norton<sup>1,2</sup>, H. Magee<sup>1,2</sup>, C. Van-Eyk<sup>4</sup>, RP. Lifton<sup>6</sup>, AH. MacLennan<sup>7</sup>, J. Gecz<sup>7</sup>, S. Padilla-Lopez<sup>1,2</sup>, K. Bilguvar<sup>4</sup>, H. Darvish<sup>5</sup>, MC. Krueger<sup>1,2</sup>. 1) Cerebral Palsy & Pediatric Movement Disorders Program, Barrow Neurological Institute, Phoenix Children's Hospital, Arizona, USA; 2) Departments of Child Health, Neurology, and Cellular & Molecular Medicine, University of Arizona College of Medicine, Phoenix, Arizona, USA; 3) University of Arizona College of Medicine, Phoenix, Arizona, USA; 4) Department of Genetics, Yale University, Connecticut, USA; 5) Department of Medical Genetics, Semnan University of Medical Sciences, Semnan, Iran; 6) Laboratory of Human Genetics and Genomics, Rockefeller University, New York, USA; 7) Robinson Research Institute, The University of Adelaide, Adelaide, Australia; 8) Department of Neurology, School of Medicine, Imam Khomeini Hospital and Iranian Center of Neurological Research, Tehran University of Medical Sciences, Tehran, Iran.

Cerebral Palsy (CP) is a common neurodevelopmental disorder which impairs movement as a result of disruptions to the developing brain. CP has been attributed to several environmental conditions including preterm delivery, asphyxia, pre-/perinatal infection and pre-/perinatal stroke. However, in about one third of CP cases, none of these risk factors are present ('cryptogenic'). Our recent analyses in sporadic cryptogenic CP cases have demonstrated that CP is genetically heterogeneous. Here, we performed whole exome sequencing in eleven multiplex, consanguineous families in whom affected children met international consensus criteria for CP with a nonprogressive clinical course and onset before age 3. Most affected individuals were non-ambulatory (Gross Motor Functional Classification Scale 4-5/5). We focused our analysis on deleterious homozygous missense (with MetaSVM = D or CADD  $\geq$  20), non-frameshift insertions/deletions and loss of function (nonsense, canonical splice site, frameshift) variants. Variants segregating in affected siblings and absent in healthy family members were prioritized. In all, we identified 10 putatively causal genes, including *SLC25A23*, *RNF170*, *AP4M1*, *SIL1* (2 families), *ALG2*, *ASNS*, *MAN2B1*, *CACNA1A*, *ALS2*, and *HPRT1*. Among these genes, the association of *SLC25A23* with human disease is novel. We also report the new association of biallelic variants in *RNF170* with a cerebral palsy phenotype (heterozygous mutations in this gene cause neuroaxonal dystrophy affecting the dorsal columns; #MIM 608984). Clinical follow-up revealed that some patients experienced symptom progression from the time of initial ascertainment while others did not. Our findings indicate that studying multiplex, consanguineous families may be a valuable approach for cerebral palsy gene discovery, particularly in severe Mendelian forms of the disorder, but careful phenotyping is crucial in order to differentiate genetic forms of CP from progressive disorders. Although analysis of sporadic cases previously revealed an enrichment of deleterious *de novo* and X-linked variants, the current analysis also indicates a role for biallelic variants in CP.

**Utility of massively parallel targeted resequencing data for detection of copy number variants in developmental and epileptic encephalopathies.** M.G. Mehafeey<sup>1</sup>, B. Strobel<sup>1</sup>, H. Kaur<sup>1</sup>, I. Phelps<sup>1</sup>, J. Nguyen<sup>1</sup>, E.A. Fuerte<sup>1</sup>, A.L. Schneider<sup>2</sup>, G. Hollingsworth<sup>2</sup>, K. Boysen<sup>2</sup>, D. Doherty<sup>1</sup>, I.E. Scheffer<sup>2</sup>, H.C. Mefford<sup>1</sup>. 1) Department of Pediatrics, University of Washington, Seattle, WA; 2) Epilepsy Research Centre, Department of Medicine, Austin Health, The University of Melbourne, Heidelberg, Victoria, 3084, Australia.

**Objective:** Copy number variants (CNVs) are regions of the DNA that have either been duplicated or deleted with respect to the reference sequence. CNVs are defined as being > 1kb in length and can be up to dozens of megabases in size. CNVs can be benign population variants or may be disease-related. CNVs are most reliably detected using chromosome microarrays, but many efforts have been made to identify CNVs reliably from massively parallel sequence data. In the developmental and epileptic encephalopathies (DEEs), clinically detectable pathogenic CNVs account for 5-10% of cases. Smaller, intragenic CNVs may not be detected by traditional array methods, but are likely to explain a subset of cases. We have generated targeted sequencing data for a large cohort of patients with unsolved DEE. Here we present an approach using targeted massively parallel sequencing data to identify potentially pathogenic CNVs. **Methods:** We performed targeted capture using molecular inversion probes (MIPs) or single molecule MIPs (smMIPs) followed by sequencing of 267 known and candidate genes for DEE in a cohort of 1071 probands with DEEs. After BWA alignment, read depths for each resequencing probe for all samples were analyzed. Z-scores were calculated to give a unique deviation metric from the normal sampling distribution for each individual over each targeted resequencing probe as previously described (PMID 23160955). We used a test set (53 genes, 823 samples) to ensure we could accurately detect two previously validated CNVs (4.85Mb del and 4.05Mb dup). In-house scripts were then written to automatically scan the remaining genes for areas with 4 or more consecutive significant z-scores ( $x > 1.5$  for duplications or  $x < -1.5$  for deletions). These areas were also given a CNV score based on a summation of logistic function values from key metrics across the CNV being evaluated to create a graphical output of the results. **Results:** We identified 261 predicted rare or novel CNVs in 193 individuals ranging from ~500 bp (single exon deletion) to 46 Mb (multiple gene duplication). Ongoing custom array studies to validate putative CNVs will determine the accuracy of our calling algorithm. This method has the potential to identify small, intragenic CNVs that are missed by traditional array methods, increasing the efficiency of detecting pathogenic sequence and copy number variants using a single assay.

**2372F**

**A genome-wide DNA methylation analysis of CpG-polymorphisms reveals a genetic association between a chromosome 6 locus and age of onset in *C9orf72* carriers.** M. Zhang<sup>1</sup>, R. Ferrari<sup>2</sup>, M.C. Tartaglia<sup>1,3,4</sup>, J. Keith<sup>5</sup>, C. Sato<sup>1</sup>, J. Robertson<sup>1</sup>, L. Zinman<sup>5</sup>, E. Rogaeva<sup>1</sup>, the International FTD-Genomics Consortium. 1) Tanz Centre for Research in Neurodegenerative Diseases, University of Toronto, Toronto, Canada; 2) Department of Molecular Neuroscience, Institute of Neurology, University College London, London, UK; 3) Krembil Neuroscience Center, University Health Network Memory clinic, Toronto Western Hospital, Toronto, Canada; 4) Department of Medicine, Division of Neurology, University of Toronto, Toronto, Canada; 5) Sunnybrook Health Sciences Centre, University of Toronto, Toronto, Canada.

The G<sub>C</sub>-repeat expansion in *C9orf72* is the most common known cause of amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD). High phenotypic heterogeneity of *C9orf72* patients includes a wide-range in age of onset (AO), but AO modifiers are largely unknown. AO could be influenced by environmental and genetic factors both of which may trigger DNA methylation (DNAm) changes at CpG-sites. CpGs are the most mutable sites in the human genome because methyl-C can spontaneously deaminate to T (e.g., 35% of all coding mutations occur at CpG-sites). Allele-specific DNAm is largely attributed to CpG-SNPs, which have often been detected within promoter regions, transcription factor binding sites and DNase I hypersensitive sites, thus regulating the level of gene expression. We tested the hypothesis that AO in *C9orf72* patients is associated with some common single nucleotide polymorphisms (SNPs) causing a gain or loss of CpG-sites (CpG-SNPs) and thus resulting in DNAm alterations. First, we estimated the association between AO in *C9orf72* patients (n=46) and DNAm levels at all 7603 common CpG-SNPs available on the 450k BeadChip, which was followed by a genetic association study of the discovery (n=144) and replication (n=187) *C9orf72* cohorts. We found that AO was reproducibly associated with SNPs within a 124.7kb linkage disequilibrium block tagged by top-significant SNP and containing two overlapping genes (*LOC101929163* and *C6orf10*). A meta-analysis of 331 *C9orf72* carriers revealed that every A-allele of top-significant SNP reduced the Hazard ratio by 30% (p=0.0002); and the median AO of AA-carriers was 6 years later than GG-carriers. Gene expression studies of frontal cortex tissues from 25 ALS autopsy cases revealed that the G-allele of the top-significant SNP is associated with increased brain expression of a nearby gene *HLA-DRB1* (involved in initiating immune responses), while the A-allele is associated with their reduced expression. Our findings suggest that carriers of GG-genotype (linked to an earlier AO in *C9orf72* patients) might be in a more pro-inflammatory state (e.g., by microglia) than AA-carriers. Further investigating the functional links within the *C6orf10/LOC101929163/HLA-DRB1* pathway will be critical to better define age-dependent FTD-ALS pathogenesis.

**2373W**

**Whole exome sequencing in epilepsy reveals significant gene burden of ultra-rare deleterious variants.** Y. Feng<sup>1,2</sup> on behalf of the EPI25 Collaborative. 1) Stanley Center for Psychiatric Research, Broad Institute, Cambridge, MA, USA; 2) Analytic and Translational Genetics Unit, Massachusetts General Hospital, Boston, MA, USA.

Whole exome sequencing (WES) in rare, severe epilepsies have successfully identified gene targets that opens the opportunity for development of individualized treatments. For common epilepsy types, while family studies and genome-wide association studies have revealed a consistent genetic influence, the number of specific gene associations remains limited. As epilepsy is a highly heterogeneous disorder, large and well-phenotyped samples are required for the characterization of genetic contribution across epilepsy syndromes. In light of this, the Epi25 Consortium was formed, an international collaboration of multiple patient cohorts that aims to elucidate the genetic risk underlying rare and common epilepsies through WES. In our year 2 effort, WES data were generated for 1453 patients with epileptic encephalopathy (EE), 4443 with genetic generalized epilepsy (GGE), and 5486 with non-acquired focal epilepsy (NAFE). For comparison, 17668 controls without any known neuropsychiatric condition were aggregated from independent cohorts. All samples were jointly called at the Broad Institute and went through rigorous quality-control procedures, with ancestry matched and exome capture difference minimized. Overall burden analysis showed a significant enrichment of ultra-rare protein-truncating variants (PTVs) in loss-of-function intolerant genes for all three subtypes compared to controls (ORs=1.44, 1.38, 1.24, p-values=1e-07, 5e-12, 1e-06 for EE, GGE, and NAFE). An increased burden of ultra-rare PTVs and damaging missense variants in epilepsy patients was also observed in missense-constrained genes, brain-specific genes, known EE genes, and genes associated with intellectual disability. Gene-based burden tests re-captured several established epilepsy genes in EE patients, including *SCN1A*, *STXBP1*, and *KCNB1* (ORs=11.6, 18.4, 27.6, p-values=4e-09, 3e-06, 2e-05). No genes reached exome-wide significance for the two common epilepsies. However, for GGE, some channel or transporter genes were among the strongest associations, including *SLC6A1*, *CACNA1G*, and *GABRA1* (ORs=24.6, 4.2, 21.5, p-values=9e-05, 3e-04, 3e-04); for NAFE, two familial focal epilepsy genes also came up at the top (*LG11* and *DEPDC5*; ORs=11.35 and 3.53, p-values=4e-04 and 2e-03). These results confirm a crucial role of ultra-rare deleterious variants in both common and rare epilepsies and provide a strong replication to previous gene findings in the largest epilepsy sequencing study to date.

**A microRNA-328 binding site in PAX6 discriminates between rolandic and other epilepsies.** N. Panjwani<sup>1</sup>, F. Lin<sup>1</sup>, L. Addis<sup>2,3</sup>, S. Tang<sup>2,4</sup>, D.K. Pal<sup>5,6</sup>, L.J. Strug<sup>1,7,8</sup>. 1) Program in Genetics and Genome Biology, The Hospital for Sick Children, Toronto, Ontario, Canada; 2) Department of Basic and Clinical Neuroscience, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, SE5 9RX, UK; 3) Neuroscience Discovery Research, Eli Lilly and Company, Erl Wood, Surrey, GU20 6PH, UK; 4) Evelina London Children's Hospital, London, SE1 7EH UK; 5) King's College Hospital, London, SE5 9RS UK; 6) Northwick Park Hospital, Middlesex, HA1 3UJ UK; 7) The Centre for Applied Genomics, The Hospital for Sick Children, Toronto, ON, Canada; 8) Biostatistics Division, Dalla Lana School of Public Health, University of Toronto, Toronto, ON, Canada.

**Introduction** Rolandic epilepsy (RE) is a neurodevelopmental disorder characterized by seizures and centrottemporal sharp waves (CTS) on electroencephalogram (EEG). Fine-mapping of the CTS linkage region identified a variant in the 3'-UTR of *PAX6* (rs662702) known to disrupt microRNA-328 binding (Panjwani et al, 2016). The impact of this variant on other epilepsies, however, is not known. We investigated the relationship between rs662702 and Electrical Status Epilepticus during Slow Sleep (ESES), Myoclonic Astatic Epilepsy (MAE), Childhood Absence Epilepsy (CAE) and Juvenile Absence Epilepsy (JAE), and we replicated in an independent RE sample. **Methods** N=177 individuals with RE, ESES, or MAE were genotyped on the InfiniumOmni2.5 BeadChip and 126 patients with CAE and JAE on the HumanOmniExpress BeadChip. 263 passed QC and clustered with Europeans. We used the European unrelated subset of the 1000 Genomes Project (phase 3) genotyped on the HumanOmni2.5 as controls (N=522), and logistic regression to test for association between rs662702 and each epilepsy type. The rs662702 SNP was also assessed in a prediction model to discriminate between RE and other epilepsy diagnoses adjusted for sex and age of first seizure onset.

Diagnosis	CC	CT	TT	Total	MAF	Odds Ratio	P-value
1KG EUR Controls	462 (0.885)	56 (0.107)	4 (0.008)	522	0.061	-	-
RE Discovery (Panjwani et al, 2016)	115 (0.757)	31 (0.204)	6 (0.039)	152	0.141	1.97	1.50E-03
RE Replication	19 (0.63)	11 (0.37)	0	30	0.183	3.31	8.30E-04
ESES	66 (0.94)	4 (0.06)	0	70	0.029	0.47	0.14
MAE	36 (0.88)	5 (0.12)	0	41	0.061	0.98	0.96
CAE	84 (0.913)	7 (0.076)	1 (0.011)	92	0.049	0.84	0.62
JAE	27 (0.90)	3 (0.10)	0	30	0.05	0.83	0.75

**Results** In the replication RE sample the frequency of the rs662702 T allele is elevated (replication odds ratio=3.31; P=8.3e-4), whereas for all other epilepsies tested no significant difference from the 1KG control population was observed (P>0.05). A training set comprised of 60% of the RE, MAE and CAE samples and five-fold cross-validation was used to define a model comprised of rs662702 genotype, sex and age of first seizure onset, to discriminate RE from the other epilepsy diagnoses. External validation of the model on 91 (40%) of the remaining patients yielded an AUC of 0.690. **Discussion** The frequency of the T allele in rs662702 is elevated in two independent RE samples, while the frequency in the other epilepsy types tested was similar to the 1KG controls, suggesting specificity for RE. A model that includes this SNP shows promise as a diagnostic tool for RE.

**Genetic generalized epilepsies and parasomnias are linked to CLCN2, EFHC1 and GABRA1 genes in Colombian families.** N. Pineda Trujillo<sup>1</sup>, D. Cornejo-Sanchez<sup>1</sup>, J. Carrisoza-Moog<sup>1</sup>, R. Solarte-Mila<sup>2</sup>, D. Cabrera-Hemer<sup>3</sup>, C. Gomez-Castillo<sup>3</sup>, R. Thomas<sup>4</sup>, S-M. Leal<sup>5</sup>, W. Cornejo-Ochoa<sup>2</sup>. 1) Grupo Mapeo Genético, Facultad de Medicina, Universidad de Antioquia. Medellín 050010470, Antioquia, Colombia; 2) Grupo Pediciencias, Facultad de Medicina, Universidad de Antioquia. Medellín 050010470, Antioquia, Colombia; 3) IPS Univesitaria, Universidad de Antioquia. Medellín-Colombia; 4) Institute of Neuroscience, Newcastle University, United Kingdom; 5) Center for Statistical Genetics, Columbia University, New York, USA.

The genetic architecture of focal and genetic generalised epilepsies (GGE) remain cryptic. Endophenotypes, such as sleep-disorders, represent an attractive way of delineating the genetic factors. Epilepsy GWAS and exome sequencing studies have identified common and rare variants of importance. Epilepsy GWAS and exome sequencing studies have identified common and rare variants of importance. Here, we test the contribution of genetic variants in *CLCN2*, *EFHC1* and *GABRA1* genes in a set of extended Colombian families with seizures and sleepwalking (SW) or sleep paralysis (SP), or both. These families presented with GGE and at times focal seizures were also present, in combination with either SW or SP, or both. The three genes coding-region (*CLCN2*, *EFHC1* and *GABRA1*) was sequenced by Sanger in 60 affected individuals. After selecting tagSNPs, 39 variants were typed in 723 individuals (283 affected individuals) in 155 families. Genotypes were obtained by KASP methodology (LGC genomics). Statistical analyses included H-WE, non-parametric linkage and association tests, combining all convulsive affection status with/without sleepwalking and sleep paralysis. No discrimination between focal or generalized seizures were considered. Twenty-three out of 39 SNPs were successfully typed. All of the SNPs were found in H-WE (p>0.05/23). No Mendelian inconsistencies were found. After base calling rates criteria, 143 families were analysed. Suggestive association was found for SNP *rs11920716* (p=0.0063). When SW was added to epilepsy, significant linkage findings arose. Thus, thirteen gene variants at *CLCN2* (p=0.0003), including *rs2293603*, *rs92449317*, *rs11656822*, *rs11920716*, *rs9820367* among others; *rs41275339*, *rs4260711*, *rs12187575*, *rs6867604*, *rs2279020* at *GABRA1* (p=0.0007) and *rs3804505*, *rs2065144*, *rs62407897*, *rs1266787*, *rs17851770* at *EFHC1* (P=0.0001) were, respectively, linked to this phenotype. Extended phenotype (epilepsy + SW+ SP) was even more significantly linked to these gene variants (P< 0.0003) only for genes *CLCN2* and *EFHC1*. We suggest that it may be valuable to reappraise the importance of *CLCN2* and *EFHC1* in special populations, such those with sleepwalking and sleep paralysis comorbidities. This work also demonstrates the value of investigating families with epilepsy from outside of traditional European populations. In conclusion, our results suggest that *CLCN2* and *EFHC1* genes are linked to GGE + SW + SP; whilst *GABRA1* gene is linked to GGE + SW in Colombian families.

**Over 70% of pathogenic in Czech epilepsy cohort is propagated into protein domains.** *D. Stanek<sup>1</sup>, P. Lassuthova<sup>1</sup>, L. Sedlackova<sup>1</sup>, J. Neupauerova<sup>1</sup>, K. Sterbova<sup>2</sup>, A. Rebelo<sup>3</sup>, D. Bis<sup>3</sup>, C. Saghira<sup>3</sup>, S. Zuchner<sup>3</sup>, P. Seeman<sup>1,2</sup>.* 1) DNA laboratory, Department of Pediatric Neurology, 2nd Faculty of Medicine, Charles University in Prague and University Hospital Motol, Prague, Czech Republic; 2) Department of Pediatric Neurology, 2nd Faculty of Medicine, Charles University in Prague and University Hospital Motol, Prague, Czech Republic; 3) Department of Human Genetics and John P. Hussman Institute for Human Genomics, Miller School of Medicine, University of Miami, Miami, FL 33136, USA;

**Introduction:** Many studies that variation in conserved protein domains are less tolerated and thus are more likely connected to a clinical phenotype. These potentially significant consequences of DNA variation on domain structure and function makes them a valuable target for genomic studies. In the previous project, we created the database of protein domains published in PubMed, mapped to a chromosomal location. Our lab has long-time experience with NGS analysis in patients with neurodegenerative disorders. We are continuously implementing new approaches to optimize analysis workflow for NGS data. **Methods:** We performed analysis on 60 variants, which were evaluated as pathogenic or likely pathogenic according to ACMG criteria, gathered from the cohort of patients with epileptic encephalopathies. Variants were annotated by our custom database (manuscript in preparation), that provides information about all protein domains/features published in PubMed mapped on its chromosomal location. With this kind of information, we are able to determine whether is variant translated into the specific domain and how a change in this domain can affect the function of a protein. **Results:** Out of 60 variants, 71% (43) was propagated into 94 protein domains. Most common were Ion channel domains (34 occurrences), binding domains (9 occurrences) and transmembrane regions (7 occurrences). These regions are very conserved and changes in these structures can be harming the whole organism. **Conclusion:** Our result showed, that most of the pathogenic variants are translated into protein domains. This information about protein domain can help experts in evaluation of NGS. On the other hand, we can see that many of these variants are not connected to any protein domain. Based on this fact we cannot decide pathogenicity on variant only based on these criteria. Supported by: AZV 15-33041, GAUK 388217 and NINDS R01NS075764.

Parkinson's disease (PD) is a complex motor neurodegenerative disorder, affecting ~1% of the population over 65 years old. Genome-wide genotyping and sequencing based association studies have discovered several genes and pathways associated with causality or risk. However, they only explain a small proportion of the disease heritability, therefore others remain to be identified. Here we present an exome-wide burden analysis in PD in order to detect a set of variants that could help us to identify novel gene-sets and pathways. We have analyzed the International Parkinson's Disease Genomics Consortium (IPDGC) exome-wide study comprising, after QC, 1,530 unrelated individuals (1,078 cases and 452 healthy controls). Annotation and functional prediction of variants was done with ANNOVAR. Whole-exome burden analysis for different frequency of variants was performed using logistic regression, modeling the allelic counts for each individual with disease status and adjustment for gender, first 5 principal components and sequencing coverage. We have found a significant burden of loss-of-function low frequency variants in cases vs controls (CADD phred score > 20, MAF < 0.05;  $p=1.59 \times 10^{-4}$ ). The signal increases its significance for novel singleton variants ( $p=1.29 \times 10^{-20}$ , OR=1.125). We found a stronger effect within early onset PD cases (<40 years old age-at-onset,  $p=1.88 \times 10^{-28}$ , OR=1.192) and weaker for late-onset patients (>60 years old age-at-onset,  $p=1.4 \times 10^{-4}$ , OR=1.123). In a gene-set approach, we analyzed variants mapping to loss-of-function intolerant genes (ExAC pLI score > 0.9, N=3,043/18,224) and obtained an increased effect in all and early onset, compared to late-onset cases (OR=1.232, OR=1.349 and OR=1.180, respectively). Our results indicate that private loss-of-function variants are significantly enriched in PD patients, providing new insights into the genetic architecture of this disease. Expanded gene-set, pathway analysis and validation efforts are currently in progress in order to unravel underlying mechanisms of these variants and confirm our findings.

**A first-degree family history of Alzheimer's disease and apolipoprotein E genotype influences cognition.** *J.S. Talboom<sup>1,2</sup>, A.K. Haberg<sup>3,4</sup>, M. De Both<sup>1,2</sup>, M. Naymik<sup>1,2</sup>, A.L. Siniard<sup>1,2</sup>, L. Ryan<sup>2,3</sup>, E.L. Glisky<sup>2,3</sup>, C.L. Lewis<sup>1,2</sup>, M.A. Fritz<sup>1</sup>, M.J. Huentelman<sup>1,2</sup>.* 1) The Translational Genomics Research Institute, Phoenix, Arizona 85004 USA; 2) Arizona Alzheimer's Consortium, Phoenix, Arizona 85004 USA; 3) University of Arizona, Tucson, Arizona 85721 USA; 4) Norwegian University of Science and Technology, Trondheim 7491 Norway.

**Background** A first-degree family history Alzheimer's disease (FH) can be a proxy for heritable and non-heritable risk factors of dementia. However, the exact influence of FH on cognition across the lifespan is poorly understood. Further, the presence of FH specific interactions with genetics on cognition remains largely unexplored. We examined the influence of FH and a well-known Alzheimer's disease genetic risk factor, on paired associate learning (PAL).

**Methods** We developed a web-based PAL task (at [www.mindcrowd.org](http://www.mindcrowd.org)) and tested over 75,000 individuals between the ages of 18-85. Next, we examined the apolipoprotein E (APOE) genotype, in over 500 FH positive individuals, via dried blood spot collection from the cohort. **Results** FH was associated with significantly decreased PAL performance. This difference was larger in participants under the age of 60. Propensity score matching analysis revealed an effect size of approximately half a word pair deficit in FH positive individuals. Further, FH positive carriers of the APOE E4 allele also demonstrated a higher risk for decreased PAL performance. **Conclusions** This study suggests that FH and APOE genotype are important factors that modify the trajectory of an individual's cognitive performance across their lifespan.

**2379W**

**Genetic study in Taiwan's Hirschsprung disease.** *W. Yang<sup>1,2</sup>, J.C. Chen<sup>1</sup>, P.L. Chen<sup>2</sup>.* 1) Chang Gung Memorial Hospital, Linkou Branch, No.5, Fuxing St., Guishan Dist., Taoyuan City, Taiwan 333; 2) Graduate Institute of Clinical Medicine, National Taiwan University, No.7.Chung San South Road, Taipei 10002.

Introduction Hirschsprung's disease (HSCR, OMIM142623) is a disease caused by congenital absence of intrinsic ganglion cells in various length of the distal intestine and results functional bowel obstruction. HSCR has an incidence around 1 in 5000 to 1 in 10000 live births, differs with gender and race. Asian has the highest incidence, and male is affected 3.5 to 4 times more likely than female. According to the different length of aganglionic intestine, HSCR can be further divided into short (S-HSCR), long (L-HSCR), or total colon aganglionosis (TCA). S-HSCR accounts for more than 80% of the patients. Recurrence risk of a S-HSCR patient's sibling is 5% and increase to 10% to 20% for L-HSCR or TCA patients. We wish to find out the genetic variations of Taiwan's Hirschsprung disease and discuss the possibility to prevent disease pass down to the next generation. **Patient and Methods** Patients who was diagnosed as Hirschsprung's disease by pathology reports were included. A 31 genes NGS panel is designed according to previous literatures. All the genes are sequenced for the whole gene, except for NRG3. Due to the size limitation, NRG3 will be surveyed for the exons only. All the DNAs of the probands were send for NGS analysis to find any mutation genes in the panel. The mutations found in NGS were further confirmed by Sanger sequencing in all family members. **Results** Between 2014/07 to 2018/05, We included 42 families, 147 participants into our study. Half of the patients are L-HSCR, 8 are familial type and the male to female ration is 3 to 1. Mutations were found in 6 of the familial patients and 24 of the sporadic patients. The detection rate of a possibly pathogenic mutation is 75% in familial case and 63.16% for sporadic cases. *RET* is the most common found gene and was found in 11 patients. In the long segment group, 21.74%( 5 patients) has either frameshift or stop codon. Three frameshifts located in *RET* exon 7 or exon 11, 1 frameshift in *L1CAM* and a stop codon in *NRG1* exon 2. For short segment HSCR patients, one patient had stop codon in *EDNRB* exon 7, and the other had a frameshift in *ZEB2* exon7. They were all heterozygous, de novo mutations. **Conclusions** All long segment HSCR patients should receive at least a panel-based work up for gene mutations. In vivo fertilization for the patients found a de novo obvious deleterious mutation, such as frameshift or stop codon on a HSCR causative gene, might help avoid pass down the disease to their off springs.

**Meta-analysis of migraine with over 93,000 cases and 730,000 controls identifies 124 risk loci.** H. Hautakangas<sup>1</sup>, P. Gormley<sup>2,3</sup>, A. Auton<sup>4</sup>, N. Litterman<sup>4</sup>, A. Palotie<sup>2,3,5,6</sup>, M. Pirinen<sup>1,7,8</sup> on behalf of the 23andMe Research team and International Headache Genetics Consortium (IHGC). 1) Institute for Molecular Medicine Finland (FIMM), University of Helsinki, Helsinki, Finland; 2) Psychiatric & Neurodevelopmental Genetics Unit, Massachusetts General Hospital, Boston, MA, USA; 3) The Stanley Center for Psychiatric Research, The Broad Institute of MIT and Harvard, Cambridge, MA, USA; 4) 23andMe, Inc., Mountain View, CA, USA; 5) Analytic and Translational Genetics Unit, Department of Medicine, Massachusetts General Hospital, Boston, MA, USA; 6) Department of Neurology, Massachusetts General Hospital, Boston, MA, USA; 7) Department of Mathematics and Statistics, University of Helsinki, Helsinki, Finland; 8) Department of Public Health, University of Helsinki, Helsinki, Finland.

Migraine is a common brain disorder typically characterized by disabling episodes of severe headache accompanied by nausea and hypersensitivity to light, sound and smell. Its prevalence is around 15% worldwide and family and twin studies estimate a heritability of about 40%, pointing to a genetic component of the disorder. The largest genome-wide association study reported so far identified 38 loci and suggested that these loci are enriched for genes highly expressed in vascular and smooth muscle tissues (Gormley et al. Nat Gen 2016). In this meta-analysis, we increase the migraine sample size by 56% by adding to the earlier data 22,644 cases from 23andMe and 10,881 cases from the UK Biobank. This takes our total sample size to 93,199 cases and 733,977 controls. All the new samples have self-reported phenotype while a subset of the earlier data was ascertained through clinics. Using LD score regression (LDSC) we estimate that the genetic correlation between the new cohorts and the earlier data is above 0.99. Based on this observation we carried out a fixed-effects meta-analysis. We identified 124 genome-wide significant ( $P < 5 \times 10^{-8}$ ) autosomal single-nucleotide polymorphisms (SNPs) that were at least 250 kb apart from each other. Of these 124 loci, 92 are reported here for the first time while 32 loci overlap with the previously reported 37 autosomal loci. To investigate the biology behind migraine, we evaluated whether the polygenic migraine signal was enriched near genes with activating histone marks specific to a certain tissue or cell type by applying LDSC to specifically expressed genes (LDSC-SEG). We report enrichment in six central nervous system cell types and four cardiovascular cell types as well as one cell type of the digestive system at a false discovery rate of 5%. Our results point to both neuronal and vascular cell types, consistent with earlier evidence that both systems are important in migraine, but they potentially relate to different subtypes of migraine. We used information on migraine with aura (6,332 cases) and migraine without aura (8,348 cases) to further stratify the risk loci by migraine subtypes available to us. To conclude, we report the largest migraine GWAS to date, with 92 new loci and enrichment of association signal in both central nervous system and cardiovascular system. These data provide unprecedented possibilities to further disentangle the complex and heterogeneous genetic background of migraine.

**Genomic variants associated with cognitive impairment in Parkinson's disease.** S. Chung<sup>1</sup>, N. Choi<sup>1</sup>, J. Kim<sup>2</sup>, K. Kim<sup>1</sup>, M. Kim<sup>3</sup>, Y. Kim<sup>1</sup>, H. Ryu<sup>1</sup>, K. Park<sup>1</sup>. 1) Neurology, Asan Medical Center, Seoul, South Korea; 2) Neurology, Metro hospital, Anyang, South Korea; 3) Neurology, Bobath Memorial Hospital, Seongnam, South Korea; 4) Neurology, Kyungpook National University Hospital, Daegu, South Korea.

**Background:** Cognitive impairment is a frequent nonmotor symptom in Parkinson's disease (PD). There is substantial heterogeneity in the onset timing of symptom, severity, and long-term outcome of cognitive impairment in PD. Etiology of cognitive impairment in PD is still unclear and pathological features are highly variable. There is no convincing biomarker to predict the development of cognitive impairment in patients with PD. **Objectives:** We aimed to identify the genomic variants that are associated with cognitive impairment in patients with PD. **Methods:** Genomic data was produced in patients with PD (N=1,021), using the Korean Chip (K-CHIP), Affymetrix Axiom KORV1.1 (variants number of 827,400), which contains imputation genome-wide association study (GWAS) grid and other GWAS loci, functional variants of nonsynonymous exome, pharmacogenetics variants, variants in genes involved in absorption, distribution, metabolism and excretion (ADME) of drugs, and expression quantitative trait loci (eQTL). Genomic analysis was performed according to the scores of Mini-Mental State Examination (MMSE) and Montreal Cognitive Assessment (MoCA). **Results:** One upstream variant in Chromosome 17 (OR=0.54, CI=0.44-0.69,  $P=1.45 \times 10^{-7}$ ) and one intronic variant in Chromosome 3 (OR=0.31, CI=0.20-0.50,  $P=3.77 \times 10^{-7}$ ) were significantly associated with the lower scores of MMSE (score < 24) after Bonferroni correction. One intronic variant in Chromosome 10 (OR=0.53, CI=0.41-0.70,  $P=4.56 \times 10^{-6}$ ) was significantly associated with the lower scores of MoCA (score < 23). Several variants showed associations with lower scores of MMSE or MoCA, but they did not remain significant after Bonferroni correction. **Conclusions:** This study identified new loci associated with lower scores of cognitive screening tests in patients with PD. Further studies are needed to confirm our findings using more comprehensive cognitive tests.

**Deep mitochondrial sequencing in Parkinson's disease reveals possible genetic modifiers of reduced penetrance in Parkin/PINK1 mutation carriers.** J. Trinh<sup>1</sup>, A. Grunewald<sup>2</sup>, K. Wasner<sup>2</sup>, A. Hicks<sup>3</sup>, P. Bauer<sup>4</sup>, S. Imhoff<sup>5</sup>, K. Kandaswamy<sup>4</sup>, N. Ouzren<sup>4</sup>, M. Werber<sup>4</sup>, M. Weiss<sup>4</sup>, A. Rolf<sup>4,5</sup>, P. Pramstaller<sup>2</sup>, P. Seibler<sup>1</sup>, K. Lohmann<sup>1</sup>, C. Klein<sup>1</sup>. 1) Institute of Neurogenetics, Universität zu Lubeck, Luebeck, Germany; 2) Luxembourg Centre for Systems Biomedicine, University of Luxembourg; 3) EURAC, Bolzano, Italy; 4) Centogene AG, Rostock, Germany; 5) University of Rostock, 18147 Rostock, Germany.

**Background:** Biallelic mutations in *Parkin* and *PINK1* are fully penetrant and cause recessively inherited Parkinson's disease (PD). On the other hand, heterozygous mutations in these genes may be considered as a risk factor for PD or even act in a dominant manner with highly reduced penetrance. Since both *Parkin* and *PINK1* function in the removal of dysfunctional mitochondria, we hypothesize that mitochondrial DNA (mtDNA) mutations influence the age-dependent penetrance and thus the onset of disease. In other words, they may be regarded as a 'second hit' in affected *Parkin/PINK1* mutation carriers. **Method:** We performed deep mtDNA sequencing in 124 individuals with Illumina NextSeq in blood-derived DNA and brain tissue-derived DNA to assess mitochondrial mutational load including somatic mosaicism and individual mtDNA variants. Patients were recruited from Germany and Italy and comprised carriers of *PINK1* (n=89) and *Parkin* mutations (n=159), idiopathic PD patients (n=83) and controls (n=100). We also compared mtDNA variants between iPSC-derived neurons and post-mortem brain frontal cortex, occipital lobe, and substantia nigra of patients with *Parkin* mutations and controls. **Results:** A mean coverage of >10,000X was achieved with high sensitivity of detecting low level heteroplasmic (<15%) variants. *Parkin* mutation carriers have cumulatively more variants including both single nucleotide variants (SNV) and copy number variations (CNV) compared to controls and idiopathic PD (p<0.01). *PINK1* mutation carriers showed a non-significant trend (p=0.10). Comparing early and late onset *Parkin* mutation carriers, we identified a potential protective variant in *ATP6* (p.A177T). iPSC clones and differentiated neurons reveal a stable process in maintaining mtDNA integrity and postmortem brain tissues reveal differential cumulative mtDNA SNV and CNVs. **Conclusion:** *Parkin* and *PINK1* mutations may predispose to an increased mitochondrial mutational load. Replication and random segregation of heteroplasmic mitochondrial DNA may partially explain the variable expressivity (i.e. age at onset) and the reduced penetrance in (heterozygous) *Parkin/PINK1* mutation carriers.

**Phenotype-genotype characterization of a new intellectual disability syndrome with acroosteolysis: New roles for TMEM41B protein.** F.

Pirozzi<sup>1</sup>, A. Gevorgyan<sup>1,2</sup>, S. Swagemakers<sup>3,4</sup>, B.C.J. van der Eerden<sup>5</sup>, J.P.T. van Leeuwen<sup>5</sup>, A.R. Khan<sup>6</sup>, G. Neri<sup>7</sup>, P.J. van der Spek<sup>3,4</sup>, P. Chiurazzi<sup>1</sup>. 1) Center for Integrative Brain Research (CIBR), Seattle Children's Research Institute, Seattle (USA); 2) Department of Genetic and Genome Sciences, Case Western Reserve University School of Medicine, Cleveland (USA); 3) Department of Bioinformatics, Erasmus University Medical Center, Rotterdam (NL); 4) Department of Pathology, Erasmus University Medical Center, Rotterdam (NL); 5) Department of Internal Medicine, Erasmus University Medical Center, Rotterdam (NL); 6) Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin (IE); 7) Department of Medical Genetics, Catholic University of Rome, Rome (IT).

We describe a novel syndromic form of acroosteolysis (AOL, progressive osteolysis of hand and foot phalanges associated with recurrent ulcers of the fingers and soles), inherited as an autosomal recessive trait and characterized by intellectual disability, sensory neuropathy, hypogonadism and recurrent infections. Whole-genome sequencing, combined with SNP haplotyping of an affected family identified two variants residing in neighboring genes in 11p15.4 (*TMEM41B* and *DENND5A*) and resulting in two missense mutations (D107G and R772Q) of the respective proteins. Bioinformatic analysis of the two variants characterized the D107G variant in *TMEM41B* as likely pathogenic, while the R772Q variant in *DENND5A* is likely benign. *TMEM41B* encodes a SNARE-associated Golgi protein with a potential role in synapsis formation. This is the first reported association of variants of this gene with human disease. *DENND5A* encodes a DENN-domain-containing protein that functions as a RAB-activating guanine nucleotide exchange factor (GEF); it is also known as RAB6-Interacting Protein 1 (RAB6IP1) as it is recruited by RAB6 onto Golgi membranes. Frameshift mutations of *DENND5A* are associated to Early Infantile Epileptic Encephalopathy 49 (EIEE49). Using microscale thermophoresis of the wildtype and mutant *DENND5A*, we did not detect any differences in the ability to bind RAB6, potentially confirming the benign nature of this missense variant. Our experiments further showed that *TMEM41B* mRNA is markedly upregulated in patient-derived osteoclast cell cultures, while patients' blood mononuclear cell-derived osteoclasts exhibit significantly enhanced bone resorption activity, suggesting a causative role of the *TMEM41B* missense variant. In order to fully characterize the contribution of both the *TMEM41B* and *DENND5A* to the phenotype, we are using genome editing to generate induced Pluripotent Stem Cells (iPSCs) containing either one of the two homozygous mutations, or both. These iPSCs will then be differentiated in osteoclasts in order to investigate the bone resorption phenotype. At the same time, we will differentiate the mutant iPSCs to cortical neurons in order to elucidate each gene's contributions to the neuronal phenotype. Our study provides the first description of a novel disorder with a potential causative role for the *TMEM41B* gene. Our investigations will also help elucidate the physiological role of the *TMEM41B* protein in human disease for the first time.

**Mitochondrial DNA variants and headache.** *S. Børte<sup>1,2</sup>, B.S. Winswold<sup>2,3</sup>, L.G. Fritsche<sup>4,5</sup>, I. Surakka<sup>6</sup>, J.B. Nielsen<sup>6</sup>, W. Zhou<sup>7</sup>, C.J. Willer<sup>6,7,8</sup>, J.A. Zwart<sup>1,2,3</sup>.* 1) Research and Communication Unit for Musculoskeletal Health, Division of Clinical Neuroscience, Oslo University Hospital, Ullevål, Oslo, Norway; 2) Institute of Clinical Medicine, Faculty of Medicine, University of Oslo, Oslo, Norway; 3) Department of Neurology, Oslo University Hospital, Oslo, Norway; 4) HUNT Research Centre, Department of Public Health and General Practice, Norwegian University of Science and Technology, 7600 Levanger, Norway; 5) Michigan, Ann Arbor, Michigan, 48109, United States of America; 6) Department of Biostatistics, University of Michigan School of Public Health, Ann Arbor, MI 48109, USA; 7) Department of Internal Medicine, Division of Cardiology, University of Michigan Medical School, Ann Arbor, Michigan, 48109, United States of America; 8) Department of Computational Medicine and Bioinformatics University of Michigan, Ann Arbor, Michigan, 48109, United States of America; 9) Department of Human Genetics, University of Michigan Medical School, Ann Arbor, Michigan, 48109, United States of America.

**Background:** Mitochondria are, through oxidative phosphorylation, the main source of energy in the cells. Even though mutations in mitochondrial DNA and mitochondrial dysfunction have been implied in migraine no mitochondrial-wide analyses have been performed on any headache type yet. We aimed to explore whether there are associations between mitochondrial DNA variants and different headache diagnoses. **Methods:** We used a sample of 57,924 genotyped individuals from the population-based Nord-Trøndelag Health Study (HUNT) from Norway. Headache diagnoses were obtained by questionnaires. Genotyping was performed using Illumina HumanCoreExome chip, including 369 mitochondrial variants. In the first approach, we called and imputed the variants as male X chromosome, using 2,202 sequenced individuals from the same HUNT population as reference panel. In a second approach, we analysed frequency of the B-allele, to account for heteroplasmy. In a third approach, we assigned and analysed major European haplogroups. **Results:** No single mitochondrial variants or any of the haplogroups were significantly associated with any headache type. **Conclusion:** No single mitochondrial variants or haplogroups were associated with any headache types, indicating that inherited mitochondrial mutations do not play a major role in the major primary headache diagnoses.

**2385W**

**Variational autoencoder identifying clinically meaningful latent features in multiple sclerosis bases on blood gene expression and genetically regulated gene expression across tissue-types.** *L.J. Lancashire<sup>1</sup>, A.C. Provost<sup>1</sup>, P.L. De Jager<sup>2</sup>, M. Haas<sup>1</sup>, N.P. Daskalakis<sup>1</sup>.* 1) Cohen Veterans Bioscience, Inc., Cambridge, MA; 2) Columbia University.

Multiple Sclerosis (MS) is clinically heterogeneous and it has been challenging to predict progression or treatment response. A study of MS relapse included 362 patients that were untreated or treated with one first-line treatment at the time of blood sampling. Whole blood genome-wide gene expression was available together with genome-wide genotype data, which were used to predict genetically regulated gene expression using PrediXcan transcription imputation (average 5000 imputed genes across 48 tissues). A Variational autoencoder (VAE) was applied to the observed blood and imputed transcriptome based on genotype. VAE is a deep generative model that allows for automatic engineering of non-linear features while learning a reduced dimensional manifold capturing the gene expression in a way that can be interpreted. The most variable genes were selected by median absolute deviation. These input genes were encoded to 100 features and then decoded back to the original number of variable genes. Models were trained in the encoding stage using batch normalization, the Adam optimizer and rectified linear units. During the decoding stage a sigmoid activation function was used. We investigated state transitions from the latent dimensions of the model to determine the extent to which the approach learned a manifold representation that could be interpreted from a biological perspective. The latent features were able to capture i) patient gender, ii) previously discovered subtypes of MS (MSa/MSb) and interestingly were able to iii) stratify the cohort into distinct groups representing time to relapse. All of this was achieved in an unsupervised manner, meaning that the phenotypic information was not used in the modelling process. Further, the trained models weights were investigated to determine the contribution of the genes to each learned node in the encoded layer. Genes that contributed greater than 2 standard deviations above or below the mean within the nodes contributing to the three phenotypes above were selected for pathway enrichment using gene ontology terms. Here, the trained model captured relevant biological patterns and pathways. For example, genes driving gender were located on sex chromosomes, and those driving MS subtypes were overrepresented in immune signalling pathways, a finding previously reported in these groups. VAE show promise in identifying lower representations of high dimensional biological data and are interpretable.

The anti-HIV drug efavirenz (EFV) commonly causes central nervous system (CNS) adverse effects (AEs). Analyses included patients who were randomized to EFV-containing regimens in four AIDS Clinical Trial Group (ACTG) protocols and provided genetic consent. Cases had new onset grade  $\geq 2$  (moderate or greater) EFV-consistent CNS AEs within 48 weeks of study entry while receiving EFV. Controls had no EFV-consistent CNS AEs while receiving EFV for  $\geq 96$  weeks. Whole exome sequencing data was collected from 310 individuals (70 cases, 150 controls) using Agilent Sure Select Human All Exon kit V6. We used BioBin software to bin rare variants (minor allele frequency  $< 5\%$ ) by genes and tested for association between CNS AEs and binned variants using burden-based (logistic regression) and dispersion-based (sequence-kernel association test) methods with Madsen-Browning weighting. We adjusted for effects of age, sex, race and first 5 ancestry-derived principal components. We also applied different filters to bin rare variants based on functional annotation to detect loss-of-function and predicted deleterious non-synonymous variants using different scoring algorithms: SIFT 5.2.2, Polyphen 2, likelihood ratio test and MutationTaster. Fifteen genes known to be highly to moderately expressed in brain (based on Genotype-Tissue Expression Project portal) were nominally associated with EFV-consistent CNS AEs, including *DNER* (delta/notch-like epidermal growth factor repeat) on chromosome 2 (logistic regression p-value =  $4.9E-5$ ), *NECAB2* (N-terminal EF-hand calcium binding protein 2) on chromosome 16 (SKAT p-value =  $1.6E-4$ ), and *NKAIN4* (sodium/potassium transporting ATPase interacting 4) on chromosome 20 (SKAT p-value =  $3.4E-4$ ). None were statistically significant after correcting for multiple testing. Our findings suggest possible novel associations with EFV CNS AEs.

**The genetics of multiple sclerosis in the Northern Isles of Scotland.**

C.L.K. Barnes<sup>1</sup>, P.K. Joshi<sup>1</sup>, T.S. Boutin<sup>2</sup>, C. Hayward<sup>2</sup>, H. Campbell<sup>1</sup>, J.F. Wilson<sup>1,2</sup>. 1) Usher Institute of Population Health Sciences and Informatics, University of Edinburgh, UK; 2) MRC Human Genetics Unit, University of Edinburgh, Institute of Genetics and Molecular Medicine, Western General Hospital, Edinburgh, UK.

The prevalence of multiple sclerosis (MS) in the Northern Isles of Scotland is among the highest in the world, with Shetland having 229 cases / 100,000 individuals and Orkney having a significantly higher prevalence of 402 cases / 100,000 individuals<sup>1</sup>. Although the environmental and genetic influences for MS are largely established, the explanation for this excess prevalence of MS in the Northern Isles, particularly Orkney, is not clear. Previous investigations into possible influences, including vitamin D deficiency<sup>2</sup> and homozygosity<sup>3</sup> in Orkney, have been unable to provide an explanation. In 1981, Compston suggested<sup>4</sup> that Orkney may have a higher frequency of common risk variants due to the founders having higher frequencies of these variants by chance. We aimed to explore this suggestion by comparing the common risk variants in Shetland and Orkney to those in mainland Scotland to assess if there was a difference in common risk variant frequencies, and if so, how that translated into disease prevalence. We calculated the frequency of common risk variants and polygenic risk scores (PGRS) in non-MS cases in Orkney and Shetland (using the ORCADES and VIKING cohorts) and compared these to non-MS cases mainland Scotland (using a subset of the Generation Scotland cohort). A logistic regression model was then used to assess the relationship between PGRS and MS. We found there was a significant difference between the mean PGRS in Orkney, Shetland and mainland Scotland, however this did not translate into a significant "real world" difference in prevalence that would be expected if common risk variants were the cause of the excess prevalence of MS in Orkney. Additionally, we investigated if Orkney and Shetland had any unique, undiscovered common risk variants by conducting a genome-wide association study in the populations, however no unique variants were discovered. This suggests that another cause, possibly rare variants, are the cause of excess prevalence of MS in Orkney. **References** 1. Visser, E. M. et al. **Blood-based RNAs distinguish cases from controls and indicate *C9orf72* carrier status in amyotrophic lateral sclerosis (ALS).** *M.T.W. Ebbert<sup>1</sup>, M. Prudencio<sup>1</sup>, Y. Song<sup>1</sup>, B. Oskarsson<sup>1</sup>, J. Wu<sup>2</sup>, R. Rademakers<sup>1</sup>, M. Benatar<sup>2</sup>, J. Fryer<sup>1</sup>, L. Petrucelli<sup>1</sup>.* 1) Neuroscience, Mayo Clinic, Jacksonville, FL; 2) Department of Neurology, Miller School of Medicine, University of Miami, Miami, FL.

**Background.** Neurodegenerative diseases like amyotrophic lateral sclerosis (ALS), Alzheimer's disease, and others are particularly challenging to address clinically because, once symptoms onset, the disease has ravaged affected tissues beyond the body's ability to function normally. Identifying blood-based biomarkers that distinguish cases and controls is an ideal starting point for identifying biomarkers that track with disease longitudinally. We have identified >300 RNAs in whole-blood across 59 cases and 30 controls that distinguish ALS cases from controls, and indicate *C9orf72* (*C9*) carrier status. **Methods.** We performed total RNA sequencing from whole blood across 29 *C9* expansion carriers (*C9+*), 30 non-carriers (*C9-*), and 30 controls after rRNA and hemoglobin depletion. Individuals were clinically diagnosed with ALS, and were negative for *SOD1*, *TARDBP*, and *FUS* mutations. Groups were 55%, 53%, and 47% female for *C9+*, *C9-*, and controls, respectively, with median ages of 61, 61, and 56 years. Data were quality checked, aligned using STAR (hg38), and tested for differential expression (cases and controls) using DESeq2 after conditional quantile normalization. Similar analyses between *C9+* and *C9-* were performed. Statistical models controlled for sex and age at collection. Collection site ( $p=0.99$ ) and RNA RIN ( $p=0.42$ ) were not statistically significant. **Results.** There were >300 (FDR 0.1) coding and non-coding differentially-expressed RNAs between cases and controls, and several between *C9+* and *C9-*. Cases and controls were significantly different by hierarchical clustering (SigClust;  $p=1.48e-4$ ) with a positive-predictive value of 86.5%. Combining RNAs with an AUC  $\geq 0.8$  ( $n=8$ ), we attained  $\geq 90\%$  sensitivity/specificity using a linear model (AUC=97%). For *C9* status, we attained  $\geq 85\%$  sens/spec (AUC=92%). Approx. 81% of cross-validation (100x, 20-fold) results had  $\geq 50\%$  sens/spec, where 40% of results had 100% sens/spec. Top phenotype and gene ontology terms were statistically ( $7.257e-11 < p \leq 0.01$ ) and biologically significant, including ontology terms specific to documented ALS phenotypes and pathways. **Conclusions.** While effective therapies are essential, a pre-symptomatic disease diagnostic is equally critical to intervene before symptomatic neurological damage occurs. Our results may have important implications for future ALS clinical diagnostics and therapy, and potentially other neurodegenerative diseases, by allowing earlier diagnosis.

**Enrichment of rare protein truncating variants in patients with amyotrophic lateral sclerosis.** *S.M.K. Farhan<sup>1,2</sup>, D.P. Howrigan<sup>1,2</sup>, L.E. Abbott<sup>1,2</sup>, A.E. Byrnes<sup>1,2</sup>, C. Churchhouse<sup>1,2</sup>, M.J. Daly<sup>1,2</sup>, B.M. Neale<sup>1,2</sup>.* 1) Massachusetts General Hospital, Harvard Medical School, Boston, MA; 2) Stanley Center for Psychiatric Research, Broad Institute of MIT and Harvard.

Amyotrophic lateral sclerosis (ALS) is a genetically and phenotypically heterogeneous neurodegenerative disease. Genetic variation is an important risk factor for ALS. Known familial ALS gene mutations are found in 5-10% of patients reporting a positive family history but also in ~10% of sporadic patients, further eliminating the distinction between familial and sporadic disease. To search for novel genetic risk factors underlying ALS, we aggregated exomes from 3,864 cases and 7,839 ancestry matched controls, generating the largest ALS exome-based case-control study to date. We complemented our analysis by leveraging allele frequencies from large external exome sequencing databases such as DiscovEHR (>50,000 samples) and the non-brain related subset of ExAC (>45,000 samples). We observed a significant excess of ultra-rare and rare protein-truncating variants (PTV) among ALS cases, which was primarily concentrated in genes intolerant of truncating mutation (constrained genes); however, a significant enrichment in PTVs does persist in the remaining exome. There was no enrichment of rare PTVs in genes known to confer risk to ALS, genes associated with clinically overlapping diseases, or genes in which their expression is specific to the brain. We conducted gene level analyses, which highlighted three known ALS genes (*SOD1*, *NEK1*, and *FUS*) as the most strongly associated. We also observe suggestive statistical evidence for multiple novel genes including *DNAJC7*, which is a highly constrained gene and a member of the heat shock protein family (HSP40). HSP40 proteins, along with HSP70 proteins, facilitate protein maintenance and quality control, such as folding of newly synthesized polypeptides, and clearance of degraded proteins. When these processes are not regulated, misfolding and accumulation of degraded proteins can occur leading to aberrant protein aggregation, one of the pathological hallmarks of neurodegenerative diseases. This work reveals new insights in to the underlying genetic risk factors for ALS that would not be possible if conducting each study individually, and hints to novel signals that may be further queried as more data are collected in the future.

**Role of uric acid in multiple sclerosis risk and progression.** *M. Montierth<sup>1</sup>, J.C Denny<sup>2</sup>, M.F. Davis<sup>1</sup>.* 1) Department of Microbiology and Molecular Biology, Brigham Young University, Provo, UT; 2) Departments of Biomedical Informatics and Medicine, Vanderbilt University Medical Center, Nashville, TN.

Multiple sclerosis (MS) is a severe neurodegenerative that affects approximately 400,000 Americans. MS is also quite complex, with many genetic and environmental factors affecting disease risk and pathogenesis. Among many other factors, studies have indicated that oxidative stress plays a key role in the pathogenesis of MS. Uric acid, a natural scavenger of peroxynitrite, has been suggested as having a protective effect against MS. However, previous studies of uric acid in MS are affected by many confounding factors, and as such it is still difficult to draw conclusions regarding this association. In this study, we compared uric acid lab values between patients with MS and control patients in a large population of electronic medical records to better understand this difference. Additionally, Mendelian randomization studies can be used to lend power to epidemiological studies by using genetic variants as instrumental variables, and thus avoiding potential biases of an observational study. We performed a Mendelian randomization analysis to investigate the link between MS and uric acid. MS cases and controls were selected from the Vanderbilt University Medical Center's Synthetic Derivative (SD) database. The SD is composed of de-identified medical records used specifically for research purposes and includes more than 2 million individuals. Using lab values from 3803 individuals (500 cases, 3303 controls) with available uric acid tests, we determined that the mean uric acid level was significantly lower in patients with MS than in the control population (5.308 vs. 6.314,  $p=1.64E-13$ ). From the SD database, 1,625 cases and 6,187 controls were genotyped. In these individuals, we used 37 SNPs previously associated with uric acid levels to generate a weighted genetic risk score (wGRS) for each individual. We then regressed MS case status on the uric acid wGRS. Preliminary results show that alleles associated with higher uric acid levels were associated with decreased MS risk. A more powerful follow up analysis will better characterize this relationship. We also created an MS wGRS using 110 published SNPs associated with MS and regressed uric acid lab values on the MS wGRS. This regression analysis found MS wGRS to not have a significant influence on serum uric acid level ( $p=0.674$ ). In conclusion, we present evidence that suggests that SNPs associated with higher uric acid levels have a protective effect against MS.

**Genetic study of longitudinal brain atrophy in Multiple Sclerosis shows susceptibility loci are not influencing progression.** *P.G. Bronson<sup>1</sup>, A.R. Pine<sup>1</sup>, F.B.S. Briggs<sup>2</sup>, A. Dhroso<sup>2</sup>, B. Fisher<sup>2</sup>, S. John<sup>2</sup>, K. Estrada<sup>2</sup>.* 1) Statistical Genetics & Genetic Epidemiology, Biogen, Inc, Cambridge, MA 02142; 2) Department of Population and Quantitative Health Sciences, School of Medicine, Case Western Reserve University, Cleveland, OH 44106; 3) Value Based Medicine, Biogen, Cambridge, MA 02142; 4) Translational Biology, Biogen, Cambridge, MA 02142.

Multiple sclerosis (MS), a demyelinating autoimmune disease, affects 2.5M people. Susceptibility genetics has identified >100 loci, but we have a limited understanding of how these risk loci influence disease progression. There have been few large studies of MS progression, and none have used well-annotated longitudinal data. Identifying genetic predictors of progression is important for drug discovery and treatment decision-making. We conducted a GWAS of longitudinal brain atrophy in 3,446 MS cases collected in 9 randomized clinical trials. Cases were relapsing remitting at onset (15% secondary progressive; 68% female; mean age 38 years). We examined three additional traits: expanded disability status scale (EDSS; N = 4,352), nine-hole peg test (9HPT; N = 1,890) and timed 25-foot walk (T25FW; N = 1,006). All traits were analyzed by annualizing the difference between first and last time point (mean time range = 88 weeks; range 1 to 3 years). For 9HPT and T25FW, we compared the extremes of the annualized distributions (top vs. lowest quartile). There were no genome-wide significant results. We identified 99 regions with  $P < 1 \times 10^{-5}$  (43 PBVC, 32 EDSS, 13 9HPT, 11 T25FW); none were in the human leukocyte antigen (HLA) region. 12/111 susceptibility SNPs and 2/40 candidate progression SNPs had  $P < 0.05$  in our study, with same direction of effect. The two candidate progression SNPs with  $P < 0.05$  in our study were *RELN* (rs10487166\*T; EDSS beta = -0.03,  $P = 0.028$ ) and *CRTAC1* (rs11189446\*T; PBVC beta = -0.049,  $P = 0.014$ ). Both *RELN* and the alternate transcript of *CRTAC1* encode secreted extracellular matrix (ECM) proteins exclusive to the brain. The ECM is a functional, dynamic scaffolding that fills extracellular space, accounting for 15% of brain volume. In animal models, *RELN* overexpression boosts synaptic contacts and dendritic spine size. *CRTAC1* promotes axon growth by blocking interaction between a receptor for axon growth inhibitors (*NRG1*) and all four of its ligands (*RTN4*, *MAG*, *OMG*, *TNFSF13B*). In conclusion, this is the first large GWAS of progression to use well-annotated longitudinal data. Our study does not show an effect of susceptibility loci on progression. Interestingly, we have sufficient power to exclude HLA from influencing progression; in rheumatoid arthritis HLA is a predictor of progression. There was modest association with two candidate progression SNPs in *RELN* and *CRTAC1*, highlighting a potential role for these ECM proteins in MS progression.

**Prioritization of causal variants possibly associated with hippocampal volume using a massively parallel reporter assay.** Y. Cooper<sup>1</sup>, J. Davis<sup>2</sup>, A. Jasinska<sup>2</sup>, S. Service<sup>2</sup>, S. Kosuri<sup>3,4</sup>, N. Freimer<sup>1,2</sup>, G. Coppola<sup>2,5</sup>. 1) Department of Human Genetics, University of California, Los Angeles, Los Angeles, CA, USA; 2) Center for Neurobehavioral Genetics, Semel Institute for Neuroscience and Human Behavior, Department of Psychiatry and Biobehavioral Sciences, David Geffen School of Medicine, University of California Los Angeles, Los Angeles, CA, USA; 3) Department of Chemistry and Biochemistry, University of California, Los Angeles, Los Angeles, CA, USA; 4) UCLA-DOE Institute for Genomics and Proteomics, Molecular Biology Institute, Quantitative and Computational Biology Institute, Eli and Edythe Broad Center of Regenerative Medicine and Stem Cell Research, Jonsson Comprehensive Cancer Center, University of California, Los Angeles, Los Angeles, CA, USA; 5) Department of Neurology, David Geffen School of Medicine, University of California, Los Angeles, Los Angeles CA, USA.

The hippocampus is a conserved vertebral brain structure critical for episodic memory, cognition, and spatial reasoning. Hippocampal volume has been associated with a variety of neuropsychiatric disorders including Alzheimer's disease, schizophrenia, and bipolar disorder, and is highly heritable, with heritability estimates between 0.5-0.9. Therefore a better understanding of the genetic underpinnings of this complex trait is warranted. Our group previously identified a locus in a large pedigree of Caribbean vervet monkeys associated with both hippocampal volume and the quantitative expression (eQTL) of two long non-coding RNAs. However, this locus spans an extended region of linkage disequilibrium (LD) and contains thousands of variants tightly correlated with the three lead single nucleotide polymorphisms (SNPs) identified. We therefore sought to fine-map this locus to prioritize variants for subsequent downstream modeling and functional validation. We utilized a Massively Parallel Reporter Assay (MPRA) which allows for high-throughput interrogation of the effects of genetic variation on gene transcription. We assayed 1000 variants prioritized by LD with our lead SNPs, ultimately narrowing down our search space to 20 putative causal variants. We are validating these findings in vervet iPSC-derived neurons using a luciferase assay to determine the effect of these variants in neurons. These results indicate that MPRA is a suitable approach for the fine-mapping of eQTL loci and prioritization of variants in genome sequencing studies. We plan to model *in vitro* the effects of these putatively causal variants to interrogate novel molecular mechanisms regulating hippocampal volume.

**2393F**

**Associations of genetic risk variants for cognitive impairment and for Parkinson's disease (PD) with clinical features in PD.** A. Deuschlander<sup>1,2</sup>, T. Konno<sup>2</sup>, A. Soto<sup>1</sup>, R. Walton<sup>1</sup>, A. Strongosky<sup>2</sup>, M. Heckmann<sup>2</sup>, N. Diehl<sup>3</sup>, J. VanGerpen<sup>2</sup>, R. Uitti<sup>2</sup>, O. Ross<sup>1</sup>, Z. Wszolek<sup>2</sup>. 1) Human Genetics, Mayo Clinic Florida, Jacksonville, FL; 2) Neurology, Mayo Clinic Florida, Jacksonville, FL; 3) Division of Bioinformatics, Mayo Clinic Florida, Jacksonville, FL.

It was the aim of this study to analyse associations of genetic risk variants for cognitive impairment and for Parkinson's disease (PD) with clinical motor and non-motor features in PD including calculation of genetic risk scores. A large clinical heterogeneity is observed in PD (motor and non-motor features). Studies on associations of genetic susceptibility variants with PD features are limited and mostly analysed variants in only one gene (e.g., *SNCA*, *LRRK2*, *MAPT*, *GBA*). We included 862 Caucasian patients (550 male, mean AAO: 64 yrs) with PD, who had demographic and detailed clinical data available. Patients were classified into 4 distinct clinical subtypes based on their prominent motor feature. Genotyping was performed for 33 independent PD risk variants as identified in GWAS for PD and for several risk variants for cognitive impairment. Frequencies of variants were compared for motor and non-motor signs, subtypes, rate of progression, survival, and early cognitive decline. The tremor-dominant subtype was found most frequently, followed by akinetic-rigid, mixed, and gait difficulty subtypes. Orthostatic hypotension, rapid progression, visual hallucinations, resting tremor and REM sleep behavior disorder showed significant associations with PD risk variants. A polygenic risk score further correlated with PD features (e.g. age at onset of PD). The APOE4 genotype was significantly associated with risk for dementia; we present further data on genetic risk variants. Genetic susceptibility variants account for some of the clinical heterogeneity observed in PD in our large single site patient cohort. Clinicogenetic studies can provide a better understanding for this variability including parameters for prognosis. Further, a homogenous patient cohort, which takes genetic underpinnings of PD into account, is likely to be of importance for conducting clinical trials.

**2394W**

***FUS* p.P525L *de novo* mutation in sporadic juvenile ALS with aggressive progression and developmental delay.** O. Goldstein<sup>1</sup>, M. Gana-Weisz<sup>1</sup>, B. Nefussy<sup>2</sup>, S. Twito<sup>1</sup>, B. Vainer<sup>2</sup>, V.E. Drory<sup>2,3</sup>, A. Orr-Urtreger<sup>1,3</sup>. 1) The Genetic Institute, Tel Aviv Sourasky Medical Center, 6 Weizmann Street, Tel Aviv 64239, Israel; 2) Neuromuscular Diseases Unit, Department of Neurology, Tel Aviv Sourasky Medical Center, 6 Weizmann Street, Tel Aviv 64239, Israel; 3) Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel.

Amyotrophic lateral sclerosis (ALS) is a complex and heterogeneous neurodegenerative disease, characterized by loss of upper and lower motor neurons. Juvenile ALS is characterized by age at disease onset (AAO) before 25 years, with several genes identified as causative. More often than in non-juvenile ALS, these patients have a slower progression rate, and milder symptoms. Trio exome-sequencing (WES) of two unrelated juvenile ALS male patients with AAO at 18 and 19 years was done. Both patients had a fulminant disease that led to tracheostomy after only six months. They are still alive, locked-in and ventilated (for 1.5 and 5 years). None had history of ALS in their family, originated from mixed Ashkenazi-Balkan and Ashkenazi-North-Africa Jewish families. Both had a history of moderate learning and behavioral disabilities, and attended special classes for mentally disabled children, although functioned borderline well within a restricted social network. Trio analyses with 109X mean X-coverage included *de novo*-, rare-homozygosity-, and compound- heterozygosity-analyses. We identified the same *de novo* mutation in the Fused In Sarcoma (*FUS*) gene, p.P525L, in both. A TaqMan genotyping assay was used to genotype 3 ALS cohorts: early-onset (AAO  $\leq$ 40) and AAO >40 years from Ashkenazi and North-Africa Jewish origins (61, 320, and 94, respectively). Carriers were confirmed by Sanger sequencing. Among 8 other juvenile ALS patients, one carried the same mutation. This sporadic male patient had an AAO at 24 years and required tracheostomy after eight months. His past medical history was remarkable for mild mental retardation and need for a special school for mentally disabled. Paternal samples were not available, but both parents were neurologically and mentally unremarkable at the time of their son's diagnosis. All other ALS patients tested (467 with AAO >25 years) were negative for this mutation, suggesting full penetrance at an early age. Interestingly, all three patients reported learning disabilities/mild mental retardation, supporting previous observations of a possible connection between mutations in *FUS* and early life cognitive dysfunction. Our findings suggest that the *FUS* p.P525L mutation should be screened in ALS patients with early AAO, aggressive disease course and sporadic occurrence, especially when ALS is accompanied by developmental delay.

**2395T**

**Elucidating the role of genetic variants in known ALS-associated genes by means of targeted NGS analysis.** G. Marangi<sup>1</sup>, S. Lattante<sup>1</sup>, P.N. Doronzio<sup>1</sup>, S. Frangella<sup>1</sup>, A. Conte<sup>2</sup>, A.K. Patanella<sup>2</sup>, G. Bisogni<sup>2</sup>, M. Zollino<sup>1</sup>, M. Sabatelli<sup>2,3</sup>. 1) Institute of Genomic Medicine, Catholic University, Rome, Rome, Italy; 2) NEuroMuscular Omnicentre (NEMO), Serena Onlus Foundation, Policlinico universitario A. Gemelli; Foundation, Rome; 3) Institute of Neurology, Catholic University, Rome, Italy.

Amyotrophic lateral sclerosis (ALS) is a progressive, fatal neurodegenerative disease, whose etiology is not fully understood yet, but for which genetic variants in several genes have already been identified as causal factors in a consistent proportion of both familial and sporadic cases. The number of ALS-associated genes has been steadily increasing in recent years. Consequently, simultaneous screening of multiple genes is likely to be more efficient than gene-by-gene testing in order to identify possible causative variants in ALS patients. We designed a custom panel of 40 genes (including 5' and 3' UTRs) claimed to be associated with ALS and performed targeted next-generation sequencing in 500 consecutive Italian ALS patients (including about 10% familial and 90% sporadic cases) and 200 controls. We evaluated the following aspects of the results: 1) frequencies and relative impact of different categories of variants, including known pathogenic variants (found in 6% of cases), novel coding variants (12%), and variants with MAF <0.1% (28%); 2) frequencies and relative impact of variants in known genes, thus showing that patients were enriched for rare variants in previously neglected genes (i.e.: *OPTN*, *EPHA4*, and *MATR3* among the others); 3) co-occurrence of variants in specific genes; 3) association of certain variants with specific ALS phenotypes; 4) frequencies of variants in 5' and 3' UTRs of ALS-associated genes. Our panel has been proving to be a useful tool for evaluating and defining the relative contribution of genes, the effective role of specific coding variants and the possible involvement of variants in 5' and 3' UTRs in ALS. Furthermore, the integration of all genetic data we obtained allowed us to explore the oligogenic hypothesis in ALS etiopathogenesis, considering that we found a higher frequency than expected of patients carrying two or more rare variants in the studied genes.

**2396F**

**GWAS of broadly defined 'self-reported migraine' identify risk loci for tension-type headache.** *D.R. Nyholt.* Queensland University of Technology, Brisbane, Australia.

Migraine is one of the world's most prevalent, disabling, misdiagnosed, undertreated and underfunded disorders, and has an enormous socio-economic burden. The diagnostic criteria of the International Headache Society (ICHD) describe the two major varieties of migraine: i) *migraine without aura* (MO), and ii) *migraine with aura* (MA). MO is defined by at least five lifetime headache attacks (relaxed to two attacks for MA) lasting 4–72 hours, with at least two characteristics: unilateral location, pulsating quality, moderate or severe pain intensity, or aggravation by or causing avoidance of routine physical activity (e.g., walking or climbing stairs); and at least one of 'nausea and/or vomiting' or 'photophobia and phonophobia'. The most common MA requires headache, with or without MO characteristics, plus one or more aura symptoms of the following types: visual, sensory, speech and/or language, motor, brainstem, or retinal. Tension-type headache (TTH) is the most common form of headache and is defined by at least ten headaches lasting 30 minutes to 7 days, with at least two characteristics: bilateral location, pressing or tightening (non-pulsating) quality, mild or moderate intensity, or not aggravated by routine physical activity; and neither 'nausea and/or vomiting' and 'photophobia and phonophobia'. In 2016, the largest published genome-wide association study (GWAS) for migraine analysed 59,674 migraine cases and 316,078 controls, and reported 44 (34 new) risk variants for migraine. Subsequent tissue expression enrichment analysis of genes within 50 kb of credible SNP sets (i.e., having 99% probability of containing the causal SNP at each migraine locus) identified that vascular tissues were significantly enriched for expression of migraine-associated genes. Whereas the previously largest migraine GWAS of 23,285 migraine cases and 95,425 controls (published in 2013) utilised a majority (60%) of cases fulfilling ICHD criteria, the 2016 GWAS utilised more cases with broadly defined self-reported migraine status—in particular GWAS data from 23andMe contributed 30,465 self-reported cases which made up 51% of all migraine cases. Analysis of UK Biobank data indicates migraine GWAS utilising broadly defined 'self-reported migraine' identify risk loci for 'non-migraine' (TTH) headache. These findings indicate heterogeneous (and poor) diagnostic specificity has important implications for the interpretation of findings from large migraine GWAS.

**Tissue specific gene enrichment analysis reveals aberrant physiological regulations in ischemic stroke.** *H.N. Singh.* CSIR-Institute of Genomics & Integrative Biology, Delhi, Delhi, India.

**Background:** Ischemic stroke is a heterogeneous multifactorial complex neurological disorder. Treatment options are inadequate due to limited understanding of mechanisms that mediate neuronal injury. Therefore, pathway based genome wide expression analysis could be significant to understand the disease etiology and development of future medications. **Aim:** To assess expression patterns of groups of genes that share common biological function, chromosomal location, or regulation as well as identification of potential therapeutic targets. **Materials & Methods:** The microarray dataset GSE22255 was retrieved from the NCBI/GEO database, which includes mRNA expression data of peripheral blood mononuclear cells of 20 controls and 20 ischemic stroke patients. The bioconductor "affy" package was used to calculate mRNA expression and further pairwise ttest was applied to find the significant differential expression ( $p < 0.01$ ). Gene Set Enrichment Analysis was performed on deregulated genes and further drug targets were identified using Reactome FI Cytoscape Tool. **Results:** Out of 117 genes, majority of genes were found to be upregulated (67.5%) and showed 68.6% functional enrichment with disease phenotypes (Figure 1A). However, 32.5% genes were upregulated with 31.4% correlation in controls (Figure 1B). Additionally, homeostatic process ( $ES = -0.31$ ;  $NES = -0.89$ ;  $NOM\ p\text{-val} = 0.602$ ) and cell development pathway ( $ES = -0.31$ ;  $NES = -0.75$ ;  $NOM\ p\text{-val} = 0.813$ ) were identified as most dysregulated in the disease conditions (Figure 2B). The GSEA analysis suggested three markers (*SLC18A2*, *SLC12A5*, *RHAG*) from homeostatic process and five markers from cell development pathway (*ETV5*, *PARVA*, *SLC12A5*, *RHAG*, *BMPR1B*, *ROBO2*) are significant for the disease. Further, *SLC12A5* and *RHAG* were found as potential druggable target for stroke. **Conclusions:** Pathway based expression and gene set enrichment analysis showed cellular homeostasis and cell development pathways are mostly affected in ischemic stroke conditions. Seven markers and two druggable targets were identified, however further experimental validations are required.

**2398T****Mutations in *VPS13C* in a Belgian cohort of Parkinson disease patients.**

S. Smolders<sup>1,2</sup>, D. Crosiers<sup>1,2,3</sup>, P. Cras<sup>2,3</sup>, C. Van Broeckhoven<sup>1,2</sup>, BELNEU Consortium. 1) VIB Center for Molecular Neurology, University of Antwerp, Antwerp, Belgium; 2) Institute Born-Bunge, University of Antwerp, Antwerp, Belgium; 3) Department of Neurology, Antwerp University Hospital, Edegem, Belgium.

**Background** *VPS13C* was first identified as a novel risk gene for Parkinson Disease (PD) in a genome-wide association meta-analysis for PD (Nalls et al. Nature Genetics, 2014) and later as the fourth gene causative for autosomal recessive early onset PD (Lesage et al. Am J Hum Genet, 2016), alongside *PARK2*, *PINK1* and *PARK7*. **Materials and Methods** Targeted resequencing of all 86 exons and exon-intron boundaries of *VPS13C* was performed in an extended Belgian PD cohort of 641 unrelated patients (mean onset age 62.8 ± 11.5 years; 42.7 % female), 23.6 % of whom exhibit a familial history of PD. We focused on rare variants with an apparent impact on functional protein levels i.e. non-synonymous coding and splice site variants. **Results** We identified 1 patient with a homozygous missense variant, 1 patient with a homozygous splice site variant and 6 patients carrying 2 compound heterozygous missense variants in *VPS13C*. The overall mutation frequency in our Belgian PD cohort is 11.72 %. The homozygous p.A444P patient carrier had an onset age of 40 years and no known family history of PD. This p.A444P variant was present heterozygous in 2 other unrelated PD patients but absent in the Belgian control cohort of 1,181 unrelated, age- and geographically matched individuals. Since endogenous protein expression in lymphoblast cells of a heterozygous p.A444P carrier was reduced by 40 % (Philtjens et al., unpublished data), we expect a loss of protein expression by > 50 % in the homozygous carrier. A homozygous splice-site mutation, c.4166-8C>T, was identified in a patient with PD dementia at the age of 59 years. The effect on splicing of exon 37 is yet unknown. Of interest is the identification in a patient of heterozygous compound missense variants in *PARK2* and *VPS13C*, p.P437L/p.L239S, underscoring a role for multiple genetic factors in PD etiology. **Discussion** Our results confirmed *VPS13C* as a novel risk gene for PD. *Cis/trans* configuration for putative compound heterozygous mutations and the effect of novel splice site variants need to be investigated. Patient-derived biomaterials will be used to study the pathological relevance of the *VPS13C* mutations. Oligogenic inheritance of *PARK2/VPS13C* mutations could be explained by their essential roles in common mitochondrial quality control pathways.

**2399F****Longitudinal small RNA and whole transcriptome sequencing for over 1,500 individuals across 4,600 whole-blood samples as part of the Parkinson's Progression Markers Initiative.**

D.W. Craig<sup>1</sup>, M.R. Cookson<sup>2</sup>, I. Violich<sup>1</sup>, E. Hutchins<sup>2</sup>, E. Alsop<sup>1</sup>, E.M. Sullivan<sup>1</sup>, J. Mote<sup>1</sup>, S. Levy<sup>1</sup>, A. Keller<sup>3</sup>, K. van Keuren-Jensen<sup>2</sup>. 1) Department of Translational Genomics, University of Southern California, Los Angeles, CA; 2) Translational Genomics Research Institute, TGen; 3) National Institute of Aging, Bethesda, MA; 4) HudsonAlpha Institute, Huntsville, AL; 5) Saarland University, Center for Bioinformatics.

The Parkinson's Progression Markers Initiative (PPMI) is a landmark observational clinical study to comprehensively evaluate cohorts of significant interest using advanced imaging, biologic sampling and clinical and behavioral assessments to identify biomarkers of Parkinson's disease progression. We report on development of a comprehensive RNA resource from whole blood samples that can be accessed and utilized by the PD research community. Approximately 4,600 samples from 1,500 individuals enrolled within PPMI cohorts were expression profiled using two assays. These data complement existing whole-genome sequencing data and other genomic profiles on the same subjects, and will provide the community with a resource for development of novel integrative analytical approaches. We detail overall quality and utility of the resource, specifically examining informativeness of these whole-blood samples towards a neurological phenotype. We detail quality control and a pilot study comparing multiple platforms for a series of covariates. We describe finally development of a portal allowing end-users to interactively explore different facets of the data, both allowing for comparisons across phenotypic and clinical metrics. Together this portal and rich multi-omic data resource provides researchers an unparalleled resource for development and discovery of biomarkers predicting progression and/or suggesting new disease-modifying therapies.

Gaslini, Genoa, Italy.

**Rationale:** Pharmacoresistance and comorbid neurological disorders (NDs) are two key features of epilepsy, contributing to the negative impact of epilepsy on the quality of life, yet our understating of the genetics behind both features is limited. Pharmacoresistance may be of genetic etiology, but the exact degree of genetic contribution is unknown, with no robust evidence for association with any single gene. Whilst genetic overlap between NDs and epilepsy has been quantified epidemiologically, the role of comorbid NDs to genetic analyses and treatment solutions in epilepsy remains elusive. **Methods:** To identify risk factors for pharmacoresistance, a genome-wide association study (GWAS) was performed in 2354 individuals with pharmacoresistant and 1580 with pharmacoresponsive epilepsy of European ancestry. The nucleotide polymorphism (SNP) based heritability of pharmacoresistance was estimated in the same sample using LDSC. A linear mixed model GWAS (as implemented in BOLT-LMM) was performed using SHAPEIT/IMPUTE2 imputed Illumina OmniExpress SNP-chip data. To evaluate the predictive power of genetic risk factors for comorbid NDs, we used published ND-GWAS summary statistics in PLINK and R, following best-practices for allelic scoring. **Results:** The GWAS did not reveal any genome-wide significant associations with pharmacoresistance in epilepsy. In the same sample, the estimated observed-scale single nucleotide polymorphism (SNP) heritability  $h^2_{\text{SNP}}$  was 0.22 (standard error=0.13). Among four comorbid NDs (Alzheimer's disease, schizophrenia, major depressive disorder, attention deficit hyperactivity disorder) and two traits (educational attainment and neuroticism), genetic risk factors for Alzheimer's disease significantly predicted pharmacoresistance in epilepsy patients with  $P=1.3 \times 10^{-4}$ , explaining 0.05% of the trait variance. Interestingly, the best prediction was achieved, when considering only strong associations with Alzheimer's disease with  $P < 10^{-6}$ . **Conclusions:** This study provides evidence for a common genetic contribution to pharmacoresistance in epilepsy as a phenotype and implicates comorbid NDs in the biology of pharmacoresistance. Specifically, common variation associated with Alzheimer's disease might help predict each epilepsy patient's response to pharmacotherapy, potentially adding to the body of evidence increasingly implicating inflammatory processes in epilepsy.

## 2401T

**HLA risk alleles and CYP2C9 variant as predictor to prevent phenytoin hypersensitivity in Asians.** S. Su<sup>1,2</sup>, C. Chen<sup>2,3</sup>, W. Chung<sup>1,2,3</sup>. 1) Whole-Genome Research Core Laboratory of Human Diseases, Chang Gung Memorial Hospital, Keelung, Taiwan; 2) Department of Dermatology, Drug Hypersensitivity Clinical and Research Center, Chang Gung Memorial Hospital, Linkou, Taiwan; 3) College of Medicine, Chang Gung University, Taoyuan, Taiwan.

**Importance:** Phenytoin remains one of the most commonly used drugs to treat epilepsy. Although being effective in preventing provoked seizures, phenytoin can cause life-threatening, severe cutaneous adverse reactions (SCARs) like Stevens-Johnson syndrome (SJS), toxic epidermal necrolysis (TEN), and drug reaction with eosinophilia and systemic symptoms (DRESS). **Objective:** To implement a preemptive genetic test that comprises multiple predisposing alleles for the prevention of phenytoin hypersensitivity reactions, especially for SCARs. **Participants:** Three sets of patients with phenytoin-related SCARs and drug-tolerant controls, including 128 cases (65 SJS/TEN, 63 DRESS) and 376 controls from Taiwan, 129 cases (67 SJS/TEN, 62 DRESS) and 195 controls from Thailand, and 9 SJS/TEN and 94 controls from Japan, were enrolled for this study. **Main Outcomes and Measures:** Carrier rates of HLA-B alleles and a known genetic risk for phenytoin-related SCAR, *CYP2C9\*3*, were examined in Taiwanese cohorts to select associated alleles for composing a multiplex genetic testing. The clinical validity of the proposed test was further assessed by constructing receiver operating characteristic (ROC) curves and performing meta-analysis. **Results:** In addition to *CYP2C9\*3*, we found that *HLA-B\*13:01*, *HLA-B\*15:02* and *HLA-B\*51:01* were significantly associated with phenytoin hypersensitivity reactions with distinct phenotypic specificities (*HLA-B\*13:01* with DRESS; *HLA-B\*15:02* with SJS/TEN; *HLA-B\*51:01* linked to all phenotypes). Strikingly, we showed an increase in predictive sensitivity of concurrently testing *CYP2C9\*3/HLA-B\*13:01/HLA-B\*15:02/HLA-B\*51:01* from 30.5 to 71.9% for selecting the individuals with the risk of developing phenytoin-SCAR in Taiwanese cohorts, accompanied by a specificity of 77.7% (combined sensitivity, 64.7%; specificity, 71.9% for three Asian populations). Meta-analysis of the four combined risk alleles showed significant associations with phenytoin-SCAR in three Asian populations. **Conclusions and Relevance:** Combining the assessment of risk alleles of HLA and *CYP2C9* potentiated the implementation of predictive genetic tests to prevent phenytoin hypersensitivity in Asians.

## 2402F

**Association of common and rare *GCH1* variants with Parkinson's disease in European and Ashkenazi Jewish populations.** U. Rudakou<sup>1,2</sup>, J.A. Ruskey<sup>2,3</sup>, J.P. Fon<sup>2,8</sup>, Y. Dauvilliers<sup>9</sup>, R.N. Alcalay<sup>4,10</sup>, S. Hassin-Baer<sup>6</sup>, N. Dupré<sup>11,12</sup>, Z. Gan-Or<sup>1,2,3</sup>. 1) Department of Human Genetics, McGill University, Montreal, QC, Canada; 2) Montreal Neurological Institute, McGill University, Montreal, QC, Canada; 3) Department of Neurology and Neurosurgery, McGill University, Montréal, QC, Canada; 4) Department of Neurology, College of Physicians and Surgeons, Columbia University Medical Center, New York, NY, USA; 5) Joseph Sagol Neuroscience Center, Sheba Medical Center, Tel Hashomer, Ramat Gan, Israel; 6) Department of Neurology, Chaim Sheba Medical Center, Tel-Hashomer, Ramat-Gan, Israel; 7) Parkinson Disease and Movement Disorders Clinic, Chaim Sheba Medical Center, Tel-Hashomer, Ramat Gan, Israel; 8) Department of Experimental Medicine, McGill University, Montréal, QC, Canada; 9) National Reference Center for Narcolepsy, Sleep Unit, Department of Neurology, Gui-de-Chauliac Hospital, CHU Montpellier, University of Montpellier, Inserm U1061, Montpellier, France; 10) Taub Institute for Research on Alzheimer's Disease and the Aging Brain, College of Physicians and Surgeons, Columbia University Medical Center, New York, NY, USA; 11) Division of Neurosciences, CHU de Québec, Université Laval, Québec City, QC, Canada; 12) Department of Medicine, Faculty of Medicine, Université Laval, Québec City, QC, Canada.

**Background:** *GCH1* encodes the enzyme GTP cyclohydrolase 1, which is essential for dopamine synthesis in nigrostriatal cells. Loss-of-function mutations in *GCH1* lead to a severe reduction of dopamine synthesis in nigrostriatal cells and are the most common cause of DOPA-responsive dystonia (DRD). Co-occurrence of DRD and Parkinsonism has been reported in families with *GCH1* mutations, and a study on sporadic Parkinson's disease patients (PD) demonstrated an increased frequency of pathogenic *GCH1* mutations that were previously reported to cause DRD. *GCH1* is also implicated in genome-wide association studies of PD. While several studies replicated the association between rare or common *GCH1* variants and PD, other studies failed to replicate this association. **Methods:** First, *GCH1* and its 5' and 3' untranslated regions were sequenced in 1113 PD patients and 1147 controls, followed up by sequencing of additional 565 PD patients and 575 controls from Israel (92% Ashkenazi Jewish). Molecular inversion probes (MIPs) were designed in our lab for targeted capture of the regions of interest. To examine the association of rare *GCH1* variants with PD, optimized sequence kernel association test (SKAT-O) was performed using R. Common variants were analysed with logistic regression. **Results:** In the first cohort, three variants (p.R184C, p.M221T and p.K224R) that are considered to be pathogenic in DRD were found in five (~0.5%) PD patients, and none in controls (SKAT-O,  $p=0.024$ ). One variant (p.V204I) that was previously reported to have conflicting interpretation of pathogenicity in DRD was found only in 3 controls (~0.3%). A common variant, rs841, was associated with reduced PD risk in our data (OR=0.71, 95% CI=0.61-0.83,  $p=1.24 \times 10^{-4}$ ). This variant was associated with increased expression of *GCH1* in brain areas relevant for PD in the genome-tissue expression (GTEx) portal. The results of the analysis of the Israeli cohort are forthcoming. **Conclusions:** The association between *GCH1* variants and an increased risk for PD reported in this study provides further evidence that rare, pathogenic *GCH1* variants should be considered as a risk factor for Parkinson's Disease. Furthermore, common variants in the *GCH1* locus also affect the risk for PD, and the mechanism underlying this effect should be further studied. The study of the Israeli cohort will show if *GCH1* variants are associated with PD in a population of different ethnicity.

## 2403W

**Modeling the function of Parkinson's disease risk alleles using multiplexed differentiation of iPSC-derived dopaminergic neurons.** J.L. Jerber<sup>1,2</sup>, D. Seaton<sup>3</sup>, D. Pearce<sup>4</sup>, W. Chen<sup>4</sup>, O. Stegle<sup>5</sup>, F. Merkle<sup>5,6</sup>, D. Parkinson's disease (PD) is the second most common neurodegenerative disorder, affecting >3% of the population over the age of 75. PD is a multifactorial disease with genetic, age and environmental factors all playing a major role in disease pathogenesis. From the genetic standpoint, PD heritability is complex and Mendelian inheritance only account for 5-10% of the cases. Genome-wide studies (GWASs) have, to date, identified >41 PD risk loci however, the functional basis underlying risk mainly remains unknown. Functional characterisation of PD risk loci is challenging due to the inaccessibility of the affected cell types. Previous studies have been based on whole-tissue samples obtained from post-mortem donors, composed of many cell types with unknown specificity to the disease. Here, we used hiPSC technology to generate functional midbrain dopaminergic neurons (mDA), the cell type preferentially lost in this disease, in lines from 100 healthy donors derived by the Human Induced Pluripotent Stem Cell Initiative (HIPSCI). Our study used a "multiplexed" design, with lines from different donors pooled, differentiated and deconvoluted using single cell RNA-seq. This enabled us to control for between-differentiation batch effects, and efficiently collect samples across 4 differentiation time points, including a stimulation with the PD-associated compound, rotenone. We show that the representation of lines from different donors is maintained over the course of the differentiation, and identified different dopaminergic-like subpopulations and enrichment of Parkinson associated genes was clearly observed in a limited set of cells. Our study provides a novel framework for the discovery of novel disease pathways and for the efficient functional characterisation of disease risk loci across scores of cell subtypes and states in a single model system.

**2404T****Association of IL-16 gene with ischemic stroke in Sudanese patients:**

**A cross-sectional study.** H. Ahmed<sup>1,2</sup>, A. Gassoum<sup>2</sup>, O.A Seidi<sup>2</sup>, M. Arbab<sup>2,3</sup>, S. Eldeaf<sup>2</sup>, H. Musa<sup>2</sup>. 1) Faculty of Medical Laboratory Sciences, University of Khartoum, Sudan; 2) National Center of Neurological Sciences, Sudan; 3) Faculty of Medicine, University of Khartoum, Sudan.

**Background:** Stroke is the second leading cause of death after ischemic heart disease; IL-16 is identified as a pro-inflammatory cytokine that is a key element in the ischemic cascade after cerebral ischemia. **Objectives:** The aim was to study the association of IL-16 gene with ischemic cerebral stroke in Sudanese patients. **Methods:** A cross-sectional study was conducted for ischemic stroke patients at the National Center for Neurological Sciences (NCNS), Khartoum, Sudan, from March 2016 to September 2017. Demographic and clinical data was collected using structural questionnaire, hematological data including platelets count and D-dimer were estimated. Genomic DNA was extracted from blood, IL-16 gene was amplified using polymerase chain reaction (PCR). Thereafter, IL-16 PCR products were sequenced. **Results:** A 52.7% of the study population were males, 44% were at 65-82 year age and 29% were at 48-64 year age. Hypertension and heart disease were significantly ( $P < 0.05$ ) associated with ischemic stroke, and 83% of ischemic stroke patients have D. dimer  $\geq 0.3$  mg/l ( $P = 0.000$ ). High level of D. dimer was detected in 35.6% of hypertensive ischemic stroke patients, and 8.9% of heart diseases patients. The polymorphism rs11556218 T/G was detected in 75% of the patients (50% having TG allele, while 25% have GG allele). Mutation in IL-16 gene was associated with ischemic stroke risk factors including D. dimer ( $OR = 3.5$ ) and hypertension ( $OR = 1.6$ ). Moreover, it has significant relationship with ischemic stroke ( $OR = 3$ ). **Conclusion:** These findings indicated that the rs11556218 T/G can be used as indicator for ischemic cerebral stroke in Sudanese population. **Key words:** ischemic stroke, Sudanese patients; D. dimer, IL-16, SNP.

**2405F**

**Functional effects of damaging mutations in *RAI1* in neurons and astrocytes from patient-derived induced pluripotent stem cells.** J.L. Cross<sup>1</sup>, S. Detera-Wadleigh<sup>1</sup>, A.C.M. Smith<sup>2</sup>, F.J. McMahon<sup>1</sup>. 1) National Institute of Mental Health, National Institutes of Health, Bethesda, MD; 2) National Human Genome Research Institute, National Institutes of Health, Bethesda, MD.

Retinoic Acid Induced I (*RAI1*) encodes a transcriptional regulator involved in circadian rhythms and neuronal differentiation. *RAI1* is highly expressed in brain, and mutations or structural variants involving the gene cause neurodevelopmental disorders such as Smith-Magenis Syndrome (SMS) and Potocki-Lupski Syndrome (PTLS). Most SMS cases carry a ~3.7 MB deletion on chromosome 17p11.2 that involves *RAI1* and up to 14 additional genes, but point mutations in *RAI1* are sufficient to cause SMS in about 10% of cases. Clinical features of SMS include obesity, craniofacial abnormalities, sleep cycle disturbance, and intellectual disability; some patients also manifest mood disorders and autism spectrum symptoms. Several studies have investigated *RAI1* deletions in mice, but very few studies have examined the functional effects of *RAI1* mutations in patient-derived cells. We have generated induced pluripotent stem cells (iPSCs) from SMS patients with point mutations in *RAI1* to study the impact of these mutations at the cellular level. Two cell lines were derived from patients with missense mutations in exon 3, resulting in premature truncation of the protein. The third patient line carries a frameshift in the first 548 bases, resulting in a severe phenotype. All three mutations are predicted to disrupt the nuclear localization tag within the C-terminal end of RAI1 protein. We have differentiated the iPSCs into neural precursor cells, neurons, and astrocytes and our ongoing studies compare cellular phenotypes in these patient-derived and matched control cell lines. In addition to standard measures of neuronal growth and morphology, bulk RNA-seq, and ATAC-seq, we are using immunocytochemistry to investigate the sub-cellular localization of the RAI1 protein. Planned studies will also investigate expression of circadian pathway genes. We hypothesize that the *RAI1* mutations causing SMS will affect the sub-cellular localization of RAI1 and disrupt expression of genes involved in circadian rhythms, neuronal differentiation, and other key pathways, resulting in cellular phenotypes that may model aspects of SMS, bipolar, and autism spectrum disorders in vitro. Such cellular models may provide insights into mechanisms involved in SMS and other neuropsychiatric disorders, pointing toward novel treatments.

**2406W**

**APOE, Alzheimer's disease, and Hispanic populations.** *E.E. Blue<sup>1</sup>, A.R.V.R. Horimoto<sup>2</sup>, E.M. Wijsman<sup>1,2,3</sup>, T.A. Thornton<sup>2</sup>.* 1) Division of Medical Genetics, University of Washington, Seattle, WA; 2) Department of Biostatistics, University of Washington, Seattle, WA; 3) Department of Genome Sciences, University of Washington, Seattle, WA.

Although the relationship between *APOE* and both Alzheimer's disease (AD) risk and age-at-onset (AAO) is well-established in cohorts with European ancestry, there is debate regarding its effects in other ancestry groups. We compared the effects of *APOE* on AD risk and AAO among individuals with European and Hispanic ancestry from the National Institute on Aging's Late-Onset Alzheimer's Disease and the National Cell Repository for Alzheimer's Disease (NIALOAD) study with the Columbia University Study of Caribbean Hispanics with Familial and Sporadic Late Onset AD (CU Hispanics). Both Hispanic data sets represent admixed individuals, with proportions of African, European, and Native American ancestry varying between cases and controls and near *APOE*. Survival analyses revealed *APOE* had significant effects on AAO of AD across data sets. The effect of *APOE* genotype on AAO of AD among Europeans was nearly twice that observed among Hispanics. The count of *APOE* E4 alleles significantly increased the hazard of AD all data sets ( $p < 7e-05$ ), while the count of *APOE* E2 alleles significantly decreased the hazard of AD in the Europeans and CU Hispanics ( $p < 2e-16$ ) and approached significance in the NIALOAD Hispanics ( $p = 0.13$ ). *APOE* proved to be an important covariate for genome-wide association studies (GWAS). Across all data sets, *APOE* adjustment significantly improved model fit for AAO association testing ( $p < 0.01$ ), but not case-control analyses. The effects of *APOE* on GWAS results differed dramatically between European and Hispanic data. Although all GWAS adjusted for population structure and relatedness, the correlation between p-values from models with and without *APOE* adjustment was much weaker among the European data vs. the Hispanic data for both AD risk ( $r^2 = 0.49$  vs.  $r^2 = 0.97$  or  $r^2 = 0.81$ ) and AAO ( $r^2 = 0.58$  vs.  $r^2 = 0.87$  or  $r^2 = 0.83$ ). GWAS without *APOE* adjustment found significant association between the *APOE* region and both AD risk and AAO in the Europeans and CU Hispanics, and significant association between AAO of AD and 11p11.2 ( $p = 4.9e-08$ ) in the Europeans and 14q24.3 ( $p = 1.33e-10$ ) in the CU Hispanics. The association between AAO of AD and 11p11.2 and 14q24.3 were robust to *APOE* adjustment and correspond to genes implicated in AD risk or pathology. Our results indicate that ancestry informs the association between *APOE* and both risk and AAO of AD, and that GWAS results in samples with European ancestry are sensitive to *APOE* adjustment.

**2407T**

**Understanding genetic regulatory mechanisms of neurodegenerative and psychiatric disorders by cell-type specific deconvolution of gene expression profile in brain.** *L. He<sup>1,4</sup>, Y. Park<sup>1,4</sup>, J. Davila-Velderrain<sup>1,4</sup>, H. Mathys<sup>2</sup>, L. Hou<sup>1,4</sup>, P. De Jager<sup>3,4</sup>, L. Tsai<sup>1,4</sup>, M. Kellis<sup>1,4</sup>.* 1) Computer Science and Artificial Intelligence Laboratory, MIT, Cambridge, MA; 2) Department of Brain and Cognitive Sciences, Massachusetts Institute of Technology; 3) Department of Neurology, Columbia University Medical Center, New York, NY, USA; 4) Broad Institute of MIT and Harvard, Cambridge, Massachusetts, USA.

Cell-type specific RNA-seq information can help reveal regulatory mechanisms underlying complex traits and human disease, but is not readily available across large disease cohorts. To overcome this challenge, we developed a new method for deconvolution of bulk RNA-seq data using single-cell RNA-seq information for 80,000 cells in human frontal cortex across 48 AD and non-AD individuals, and bulk RNA-seq information across 482 individuals from the ROSMAP cohort. We focused on six major cell types, including excitatory and inhibitory neurons, oligodendrocytes, astrocytes, microglia and oligodendrocyte progenitor cells. We observed a significant reduction in excitatory neurons for AD ( $p = 10^{-6}$ ) and age ( $p = 10^{-6}$ ), and a converse expansion of microglia ( $p = 10^{-6}$ ,  $p = 10^{-27}$ , respectively). Both beta-amyloid and tau were significantly associated with fewer excitatory neurons ( $p = 10^{-6}$ ). Female individuals showed more inhibitory neurons than males ( $p = 10^{-6}$ ). The majority of AD GWAS genes showed altered microglial expression, highlighting the central role of microglia in AD. To recognize genetic variants underlying this association, we used the fraction of each cell type as the phenotype in a GWAS for each cell type, resulting in numerous significant SNPs. For excitatory neurons, we found that *TMEM106B*, a previously reported GWAS locus for frontotemporal dementia, was significantly associated ( $p = 10^{-7}$ ). We also estimated SNP-cell type interaction effects in relevant brain cell types for multiple brain-related diseases using a factorized QTL model. We found 39 independent factors with FDR < 1%, revealing transcription of ~600 protein coding genes are regulated in cell type specific manner. We then used the estimated SNP-cell type interaction effects to find cell-type specific causal genes. We applied multivariate effect sizes of these genes to summary-based transcriptome-wide association studies (TWAS) of multiple brain disorders. We found a significant association between oligodendrocyte expression of *HLA-DRB1* and *HLA-DQB1* and AD ( $P = 10^{-7}$ ) and with maternal history of AD in the UK Biobank ( $p = 10^{-6}$ ). We also discovered that *NP1PA2* gene in excitatory neuron is strongly associated in schizophrenia TWAS ( $p < 3.2e-7$ ) and autism spectrum disorder TWAS ( $p = 10^{-6}$ ).

**Blood total cholesterol polygenic score in Alzheimer's disease.** *N.I.V. Nilsson<sup>1,2</sup>, J. Poirier<sup>1,2</sup>*. 1) Department of Psychiatry, McGill University, Montreal, QC, Canada; 2) Douglas Mental Health University Institute, Montreal, QC, Canada.

Sporadic Alzheimer's disease (sAD) is considered a multifactorial disease caused by a combination of risk factors such as old age, genetics, and lifestyle factors. E.g. approximately half of the sAD phenotypic variance is explained by genetics, however most of these variants remain unknown. One of the suggested lifestyle factors in sAD is blood cholesterol. The results are somewhat conflicting, but a consensus is that high blood cholesterol levels specifically in midlife is associated with increased risk of developing sAD. Blood cholesterol levels are also influenced by genetics although not as strongly as for AD. Considering the genetic background of both conditions, and the fact that they are linked in terms of risk, we hypothesized that a polygenic score (pgs) based on blood total cholesterol (TC) levels would associate positively with sAD and its biomarkers. We used a previously published meta-analysis of GWAS for blood total cholesterol levels (Teslovich et al., 2010) to compute a TC pgs in the Alzheimer's Disease Neuroimaging Initiative cohort (ADNI,adni.loni.usc.edu). We found that the TC pgs indeed associates positively with blood TC levels. Logistic and linear regressions with sAD risk and with CSF levels of sAD biomarkers A $\beta$  and p-tau, respectively, did not reveal any significant associations. However, we did find a significant positive association with CSF t-tau, a biomarker typically associated with neuronal loss in the CNS. These results suggest that there is a very small, if any effect of genetics underlying cholesterol levels in sAD. However, the significant association between TC pgs and CSF t-tau levels suggests that genetics underlying cholesterol levels could have an effect on general neurodegeneration.

**Whole exome sequencing of DNA from a patient with bvFTD (behavioral variant of frontotemporal dementia) reveals a deleterious SNP in MAPT gene.** *M. Xi<sup>1</sup>, R. Zhang<sup>1</sup>, H. Wang<sup>1</sup>, Y. Cai<sup>2</sup>, A. Baskys<sup>3</sup>*. 1) Psychiatry, Xijing Hospital, Air Force Medical University, Xi'an, Shaanxi, Peoples Republic of China; 2) Neurobiology, Xuanwu hospital, Changchun street, NO.45, 100053 Beijing, People Republic of China; 3) Graduate College of Biomedical Sciences Western University of Health Sciences Pomona, CA 91766.

FTD is a significant clinical problem affecting younger individuals (ages 40-65) and often masquerading as a treatment resistant psychiatric disorder such as depression or psychosis. It is highly heritable and mutations in microtubule associated protein tau (MAPT), progranulin (PGRN) and chromosome 9 open reading frame 72 (C9orf72) expansion mutations have been found in familial FTD. It has been proposed that clinical presentations and treatment responsiveness of FTD patients vary depending on variant genes present (Young et al., 2017). Thus, MAPT mutation carriers tend to deteriorate when treated with ACh inhibitors and it has been suggested that PGRN mutation effects could be mitigated by small molecule drugs (De Muynck and Van Damme, 2015). To further explore the genotype-phenotype association, we performed whole exome sequencing (WES) of DNA extracted from a blood sample from a proband, a 56 year old Chinese female, with previously well characterized behavioral FTD (bvFTD) syndrome (Pospos et al. 2018), and her symptom-free son, 33. The Ethic's Committee of Xijing Hospital approved the study. SureSelect Human All Exon V6 64M (Agilent) was used to capture target DNA and HiSeq X Ten System (Illumina) was used for sequencing. Paired-end alignment to the 1000 genomes hg19/GRCh37 reference genome was performed using BWA ALN. SAM files were sorted, converted to BAM, and duplicates were marked with Picard. GATK was used for local realignment and base quality score recalibration, variants were called jointly in all samples using the GATK's HaplotypeCaller in the "GENOTYPE\_GIVEN\_ALLELES" mode. PROVEAN, SIFT, PolyPhen2 HDIV, PolyPhen2 HVAR, MutationTaster, M-CAP and REVEL were used to predict deleteriousness of amino acid changes. MaxEntScan was used for splicing defect prediction. Data showed a rare (MAF=0.014, China Thousand Human Genomes) missense single nucleotide variant c.689(exon 6)A>G in MAPT gene resulting in amino acid change (p.Q230R), which was deleterious by several predictors. Patient's son had no pathogenic MAPT variants. Our findings elucidate genotype-phenotype association in bvFTD and lend support to clinical applications of advanced technologies such as Next Generation Sequencing to improve diagnostic accuracy and minimize unnecessary investigations and treatments.

**Differences in the maternal and paternal contribution to inherited risk for autism.** D. Antaki<sup>1,2,3,5</sup>, W.M. Brandler<sup>1</sup>, M. Gujra<sup>1,2,3</sup>, P. Tandon<sup>1,2,3</sup>, J. Sebat<sup>1,2,3</sup>. 1) Beyster Center for Genomics of Psychiatric Diseases, University of California San Diego, La Jolla, CA 92093, USA; 2) Department of Psychiatry, University of California San Diego, La Jolla, CA 92093, USA; 3) Department of Cellular and Molecular Medicine and Pediatrics, University of California San Diego, La Jolla, CA 92093, USA; 4) Human Longevity, Inc., San Diego, CA 92121, USA; 5) Biomedical Sciences Graduate Program, University of California San Diego, La Jolla, CA 92093, USA.

The genetic basis of autism spectrum disorder (ASD) is known to consist of *de novo* and inherited loss of function mutations in haploinsufficient genes. Previous studies have reported that inherited risk is predominantly carried by mothers. However, the distinct contributions of each parent to inherited risk for ASD has not been explored. We investigated paternal and maternal contributions to ASD by analyzing the transmission of private deletions in coding and *cis*-regulatory (CRE-SVs) regions of haploinsufficient genes in whole genomes of 9274 individuals (2600 families). Consistent with previous findings, mothers over-transmitted exonic deletions in functionally constrained genes to affected offspring but not to control siblings (Affected Transmission Rate=63.0%, Control Transmission Rate=48.8%, Affected Binomial P=0.0091). Likewise, fathers transmitted more exonic deletions in the same genes to affected but not to control offspring (Affected Transmission Rate=68.1%, Control Transmission Rate=48.8%, Affected Binomial P=0.0001). Additionally, we found that fathers but not mothers significantly over-transmit CRE-SVs to affected offspring relative to control siblings (Paternal Affected Transmission Rate=63.0%, Paternal Binomial P=0.015, Maternal Affected Transmission Rate=51.1%, Maternal Binomial P=0.43). Taken altogether, paternally inherited structural variants in functionally constrained regions of the genome also contribute risk to ASD with CRE-SVs exhibiting a strong paternal origin effect, suggesting a complex genetic architecture of autism. We are currently expanding our analyses of transmission distortion to incorporate single nucleotide variants and insertions/deletions including the addition of whole genomes from 4712 subjects (1178 families). With over 10,000 whole genomes, we aim to discover distinct modes of inheritance conditioned on the genetic burden of parents. Consistent with our earlier finding of paternally derived exonic deletions, initial findings show an over-transmission of private loss of function single nucleotide variants in functionally constrained genes from fathers to affected children (Paternal Transmission Rate=53.1%, Binomial Pvalue=0.04). Our work demonstrates that the paternal origin effect of risk variants contributes genetic risk for ASD in more complex ways than previously thought.

Recent genomic studies have identified hundreds of genes and loci contributing to autism spectrum disorder (ASD) susceptibility, revealing the genetic complexity of ASD. Clinical morphology classification can help stratify ASD heterogeneity into more genetically meaningful subtypes. Using microarray and whole-exome sequencing, we previously determined a molecular diagnostic yield of 15.8% in 95 ASD cases, with the yield higher in the complex (significantly dysmorphic) ASD subtype (Tammimies *et al*, JAMA, 2015). Here, we aimed to examine the molecular diagnostic yield in a larger ASD cohort (n=329), and to dissect the genes and pathways involved in different ASD subtypes using whole-genome sequencing (WGS), with the advantage of detecting a full size spectrum of variants in a single experiment. A total of 329 children with ASD from Newfoundland, Canada were enrolled using a population-based recruitment strategy. Standardized dysmorphology assessments, including scoring for minor physical and major congenital anomalies, were completed and used to stratify the cohort into 193 essential (non-dysmorphic), 57 equivocal, and 79 complex ASD cases. We identified clinically significant single nucleotide variants, insertions/deletions and copy number variants (CNVs) in 15.2% of ASD cases. The yield was higher in the complex subgroup (38.0%; 30/79) compared to the essential subgroup (7.3%; 14/179) ( $p=1.06 \times 10^{-6}$ ). Clinically significant variants included 16p11.2 microdeletion and microduplication, and variants impacting *SHANK3*, *CHD8*, *NRXN1*, and *ASTN2/TRIM32*. Three ASD cases (~1%) had two clinically significant and/or ASD-risk variants. We compared global burden and gene-set enrichment of rare CNVs among ASD subtypes. We found that ASD cases with more dysmorphologies were associated with increased number of genes impacted by deletions ( $p=1.52 \times 10^{-6}$ ). These cases had a significant enrichment for rare deletions in neuronal genes, with the highest enrichment in genes responsible for neuron projection ( $p=0.0047$ ). Our findings show that WGS captures clinically significant variants with different size spectra for molecular diagnosis of ASD, and that differences in the genetic architecture among ASD subtypes can be characterized using a combination of rich genome-wide data and extensive clinical data.

**2412W****Replication of a risk haplotype on 1p36.33 for autism spectrum disorder.**

N.H. Chapman<sup>1</sup>, R.A. Bernier<sup>2,3</sup>, S.J. Webb<sup>2,3</sup>, J. Munson<sup>2,3</sup>, E.M. Blue<sup>1</sup>, D.H. Chen<sup>4</sup>, E. Heigham<sup>4</sup>, W.H. Raskind<sup>1,2,5</sup>, E.M. Wijsman<sup>1,5,6</sup>. 1) Division of Medical Genetics, University of Washington, Seattle, WA; 2) Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA; 3) Center on Human Development and Disability, University of Washington, Seattle, WA; 4) Department of Neurology, University of Washington, Seattle, WA; 5) Department of Genome Sciences, University of Washington, Seattle, WA; 6) Department of Biostatistics, University of Washington, Seattle, WA.

Hundreds of genes have been implicated in the genetics of autism spectrum disorders (ASDs). In genetically heterogeneous conditions, large families with multiple affected individuals can provide strong evidence implicating a rare variant, and replication of the same variant in multiple families is very unusual. We previously published linkage analyses and follow-up exome sequencing in 7 large families with ASDs, implicating 14 candidate exome variants. These included rs200195897, which was transmitted to 4 affected individuals in 1 family. In this paper, we attempted replication of those variants in the MSSNG database. MSSNG is a unique resource for replication of ASD risk loci, containing whole genome sequence (WGS) on thousands of individuals diagnosed with ASDs and their immediate family members. For each of the exome variants previously identified, we obtained all carriers and their relatives in MSSNG, using a TDT test to quantify evidence for transmission and association. We replicated the transmission of rs200195897 to 4 affected individuals in 3 additional families. rs200195897 was also present in 3 singleton affected individuals, and no unaffected individuals other than transmitting parents. The availability of WGS in parents of 4 affected individuals allowed us to identify 2 additional rare variants (rs566472488 and rs185038034) transmitted on the same background haplotype on 1p36.33. We sequenced these variants in the family in which rs200195897 was initially ascertained, confirming their presence. We have identified a haplotype carrying 3 rare variants (alternate allele frequency 0.0007 in Non-Finnish Europeans) transmitted to 8 individuals with autism in 4 families, and present in 3 other affected individuals. To our knowledge, this is the first example of a very rare haplotype being transmitted with ASD in multiple families. The candidate risk variants include a missense mutation in *SAMD11*, an intronic variant in *NOC2L*, and a regulatory region variant close to both genes. *NOC2L* is a transcription repressor, and several genes involved in transcription regulation have been previously associated with ASDs.

**2413T****Both rare and common genetic variants contribute to autism in the Faroe Islands.**

Andorsdóttir<sup>8</sup>, E. Billstedt<sup>9</sup>, C. Gillberg<sup>9</sup>, T. Bourgeron<sup>1,2,3,4</sup>, GenMed consortium. 1) Institut Pasteur, Human Genetics and Cognitive Functions Unit, Paris, France; 2) CNRS UMR 3571 Genes, Synapses and Cognition, Institut Pasteur, Paris, France; 3) University Paris Diderot, Sorbonne Paris Cité, Paris, France; 4) Centre de Bioinformatique, Biostatistique et Biologie Intégrative, Paris, France; 5) Centre National de Recherche en Génomique Humaine (CNRGH), CEA, Evry France; 6) Psychiatric Centre at Landssjúkrahús, Faeroe Islands; 7) Ministry of Health Genetic Biobank of the Faroes Tórshavn Faeroe Islands; 8) Institute of Neuroscience and Physiology, Sahlgrenska Academy, University of Gothenburg, Sweden; 9) Gillberg Neuropsychiatry Centre Göteborg, Sweden.

The number of genes associated with autism spectrum disorder (ASD) is increasing, but few studies have been performed on epidemiological cohorts and in isolated populations. Here, we investigated 357 individuals from the Faroe Islands including 36 patients with ASD, 136 of their relatives and 185 non-ASD controls. Data from SNP array and whole exome sequencing revealed that patients had a higher burden of copy-number variants ( $P < 0.05$ ), higher inbreeding status ( $P < 0.005$ ), higher load of homozygous deleterious mutations ( $P < 0.0005$ ), and a higher ASD polygenic risk score ( $P < 0.01$ ) compared to controls. Overall, for 11% of individuals with ASD, a known genetic cause was identified, for 39% at least one strongly deleterious mutation was identified in a compelling candidate gene and for 50% no obvious genetic cause was detected. Our analysis supports the role of several genes/loci associated with ASD (e.g. *NRXN1*, *ADNP*, 22q11 deletion) and identified new truncating (e.g. *GRIK2*, *ROBO1*, *NINL* and *IMMP2L*) or recessive deleterious mutations (e.g. *KIRELL3* and *CNTNAP2*) affecting ASD-risk genes. It also revealed three genes involved in synaptic plasticity, *RIMS4*, *KALRN* and *PLA2G4A*, carrying *de novo* deleterious mutations in patients without intellectual disability. In summary, our analysis provides a better understanding of the genetic architecture of ASD in isolated populations by highlighting the role of both common and rare gene variants and pointing at new ASD-risk genes. It also indicates that more knowledge about how multiple genetic hits affect neuronal function will be necessary to fully understand the genetic architecture of ASD.

## 2414F

**Genetic investigation of insistence on sameness in autism.** *M.L. Cuccaro<sup>1,2</sup>, E.R. Martin<sup>1,2</sup>, S. Luz<sup>2</sup>, H.N. Cukier<sup>2,3</sup>, A.J. Griswold<sup>2,4</sup>, D. Dykxhoorn<sup>1,2</sup>, J.M. Vance<sup>1,2</sup>, M.A. Pericak-Vance<sup>1,2</sup>.* 1) Human Genetics, University of Miami School of Medicine, Miami, FL., USA; 2) Dr. John P. Hussman Institute of Human Genetics, University of Miami, Miami, FL, USA; 3) Neurology, University of Miami School of Medicine, University of Miami, FL, USA; 4) Pathology, University of Miami School of Medicine, University of Miami, FL, USA.

**Background:** Restricted and repetitive behaviors (RRBs) are a defining feature of autism and fall into two groups: insistence on sameness (IS) and repetitive sensory motor behaviors (RSMB). IS is the more robust of the two and appears to have reduced overlap with intellectual disability phenotypes. To date, there has been limited study of the genetic basis of IS. **Objective:** We tested for genetic association with IS in a sample of individuals with autism with targeted sequence data. We hypothesize that multiple genetic variants will be associated with the IS score. **Methods:** Using Autism Diagnostic Interview-Revised (ADI-R) items (difficulties with minor changes, resistance to trivial changes, abnormal response to sensory stimuli, circumscribed interests, compulsions/rituals, sensitivity to noise), we calculated IS scores for our dataset of 1931 participants from the Hussman Institute for Human Genomics and Simons Simplex Collection. All individuals were sequenced with a 17Mb custom capture covering 681 genes within regions identified by GWAS of ASD. We conducted the SKAT-O gene-based test and single variant tests using IS scores as continuous outcomes. A Bonferroni correction for the number of genes tested was used as a significance threshold. **Results:** For the gene-based test our top four results were: *ATXN1*, *ARHGAP40*, *BICD1* and *GCOM1* with p-values of 5.6E-03, 5.8E-03, 6.2E-03 and 7E-03, respectively. When only missense variants were analyzed, the top three genes were *PANK1*, *TIMM22* and *ZNF397* with p-values of 1E-02, 1.2E-02 and 1.3E-02 respectively. *ATXN1*, located on the short arm of chromosome 6, is a protein coding gene and is associated with spinocerebellar ataxia type 1 (SCA 1). *ZNF397* is located on the long arm of chromosome 18 and is part of the zing finger family. This gene is well established for its role in and has shown prior association with autism. Overall, we identified 32 genes with p-values of less than 0.05. **Conclusions:** We did not find genome-wide association to the IS trait. Our top nominally significant results suggest several genes that may be associated with the IS trait in autism but need further study. Our findings serve as a first step in dissecting the genetic basis of the IS trait in autism. We propose follow up studies use a refined IS trait. Generally, our results suggest the value of identifying genes associated with phenotypic traits that are a part of autism as an alternative to the broader autism diagnostic phenotype.

## 2415W

**Analysis of convergent molecular pathways during neural development using ASD-specific induced pluripotent stem cells.** *D.M. Dykxhoorn<sup>1</sup>, B.A. DeRosa<sup>1</sup>, D. Van Booven<sup>1</sup>, C. Garcia-Serje<sup>1</sup>, M.L. Cuccaro<sup>1</sup>, J.M. Vance<sup>1</sup>, M. Nestor<sup>2</sup>, H.N. Cukier<sup>1</sup>, M.A. Pericak-Vance<sup>1</sup>.* 1) Hussman Institute for Human Genomics, University of Miami Miller School of Medicine, Miami FL; 2) Hussman Institute for Autism, Baltimore, MD.

Autism spectrum disorders (ASDs) are a phenotypically and etiologically complex group of neurodevelopmental conditions that are behaviorally defined based on the presence of social-communicative problems and restricted and repetitive behaviors. Recent studies have shown that ASD risk loci are highly enriched in genes expressed during early neocortical development and genes which encode proteins that function in biological pathways involved in regulating transcription, chromatin remodeling, cell adhesion, signaling complexes, and synapse function. The aim of this study is to use induced pluripotent stem cell (iPSC)-based approaches to identify key differences in important neurobiological processes by evaluating the expression of gene networks that regulate these processes, both in a temporal and neural-specific manner. This RNA-seq analysis was complemented by functional analysis of these neurons using electrophysiological, morphological, and biochemical analyses. Transcriptional analyses of ASD and control neurons at culture days 35 and 135 of their *in vitro* development showed ASD-specific transcriptional signatures mainly affecting pathways/networks involved in neuronal differentiation, the cytoskeletal matrix structure formation (i.e. axon guidance and cell migration), regionalization, patterning, DNA and RNA metabolism. Additionally, developing networks of neurons were analyzed using multi-electrode array (MEA) recordings, measurements of calcium transients, immunocytochemical analyses for important morphological markers, and cell migration assays at time-points aligning with the transcriptional analyses. Neurons from ASD individuals demonstrated significantly decreased network spiking activity from MEA recordings (40-80% decrease,  $p < 0.05$ ) as well as decreased numbers of calcium transients (30-60% decrease,  $p < 0.01$ ). Additionally, ASD lines showed significant differences in neurite morphology and decreased cell migration ( $p < 0.05$ ) at early neuronal differentiation times. The results of this study suggest that iPSC-derived neurons from individuals with ASD may have early deficits in network activity and morphology based on a combination of cell based assays, including MEA, calcium transients, and quantification of neurite outgrowth that complement with transcriptomic profiles. Taken together, these data suggests a convergence of pathophysiological processes that effect neuronal functionality in ASD.

S. Sutcliffe<sup>11</sup>, T. W. Yu<sup>12</sup>, J. J. Michaelson<sup>8</sup>, C. Lese Martin<sup>13</sup>, R. Gibbs<sup>6</sup>, E. E. Eichler<sup>3</sup>, B. J. O'Roak<sup>4</sup>, N. Volfovsky<sup>1</sup>, Y. Shen<sup>2</sup>, W. K. Chung<sup>2,1</sup>. 1) Simons Foundation, New York, NY; 2) Columbia University, New York, NY; 3) University of Washington, Seattle, WA; 4) Oregon Health Sciences University, Portland, OR; 5) University of California, Los Angeles, CA; 6) Baylor College of Medicine, Houston, TX; 7) Rush University Medical Center, Chicago, IL; 8) The University of Iowa, Iowa City, IA; 9) University of California, San Diego, CA; 10) University of California, Davis, CA; 11) Vanderbilt University, Nashville, TN; 12) Children's Hospital Boston, Boston, MA; 13) Geisinger, Danville, PA.

Autism spectrum disorder (ASD) is a phenotypically heterogeneous condition, and its genetic architecture involves a combination of rare de novo and inherited variants as well as common variants in at least several hundred genes. The heterogeneity in ASD increases the complexity of gene discovery and has led to challenges with reproducibility of clinical research findings. Although the largest genetic studies of ASD have included more than 16,000 individuals with ASD, significantly larger sample sizes are needed to identify genetic risk factors. SPARK (SPARKforAutism.org) is a new paradigm for scalable clinical and genomic research that combines convenient online access to participants, longitudinal collection of phenotypic data, return of meaningful individual-level genetic and phenotypic results and data sharing. All genomic and phenotypic SPARK data are available at sfarbase.org, and all SPARK participants are available for recontact and additional research studies. Since launching in 2016, SPARK has consented 42,848 individuals with ASD to participate in longitudinal research. Saliva for genetic studies has been collected from 22,283 individuals with ASD and 37,499 of their first-degree family members. In a pilot study of 462 families with ASD (12 of whom self-reported a known genetic diagnosis), we identified both pathogenic (14%) and probable (8%) genetic causes of ASD in 99 (22%) out of 450 families without a reported genetic diagnosis. Genetic causes consisted of de novo likely gene-damaging (dnLGD) variants in constrained genes ( $pLI \geq 0.5$ ) in 44 families, de novo predicted damaging missense ( $pLI \geq 0.9$ , REVEL Score  $\geq 0.75$ ) variants in 16 families, deleterious CNVs in 37 families and X-linked mutations in 2 families. Our analyses identified deleterious variants in genes known to be high-confidence risk genes for ASD, as well as in genes previously implicated in neurodevelopmental disorders, including *DPP6*, *MEIS2*, *QRICH1*, and *SETD1A*. We also identified two dnLGD variants in *BRSK2* (TADA q-value=0.002), supporting *BRSK2* as a new candidate gene for ASD. In one proband with a known 2 Mb deletion at 4q21, we also detected 2 de novo, predicted damaging missense variants in *MED13L* and *CLCN4*, providing support for multiple genetic contributions in some cases and demonstrating the value of both CNVs and sequence variants. Exome/genome sequencing and SNP-genotyping are in progress for 4,842 additional probands and their available first-degree family members.
