American Society of Human Genetics 71st Annual Meeting
Abstracts

Plenary Platform Poster talks Poster Presentations

PrgmNr 1012 Multi-trait Bayesian genome-wide association study identifies novel endometrial cancer risk loci at 7q22.1, 8q24.3 and 16q22.2

PrgmNr 1013 Novel basal cell carcinoma susceptibility loci identified from a multiethnic genome-wide meta-analysis

PrgmNr 1014 A fine-mapping study of over 254,000 Asian and European descendants identifies putative susceptibility genes for colorectal cancer

PrgmNr 1015 Assessment of genetic susceptibility to multiple primary tumors through whole-exome sequencing in two large cohorts

PrgmNr 1016 Validation of the BOADICEA multifactorial breast cancer risk prediction model in a large prospective cohort study

PrgmNr 1017 High resolution functional mapping credible causal variants to target genes at 54 common melanoma susceptibility loci

PrgmNr 1020 Analysis of PI3K-AKT-MTOR spectrum disorders through deep genomic and functional models reveals new clinical insights and distinct molecular pathomechanisms

PrgmNr 1021 Skewed X-chromosome inactivation in unsolved neurodevelopmental disease cases can guide re-evaluation for X-linked genes

PrgmNr 1022 Understanding trajectories of neuronal differentiation underlying neurodevelopmental disorders using single-cell technologies

PrgmNr 1023 De novo missense and truncating variants in ZMYND8 result in a distinctive neurodevelopmental disorder

PrgmNr 1024 Extremely rare variants in EIF4A2 are associated with a neurodevelopmental disorder characterized by hypotonia, intellectual disability and epilepsy

PrgmNr 1025 Autism spectrum disorder trios from consanguineous populations are enriched for rare biallelic variants

PrgmNr 1028 Long read sequencing to improve diagnostic rate in critically ill patients

PrgmNr 1029 Establishing nonhuman primate models of human disease using a publicly available rhesus macaque genomic variant database

PrgmNr 1030 Utilization of Dual-Label Optical Genome Mapping for genetic/epigenetic diagnosis

PrgmNr 1031 2D and 3D human neuronal cell models of CHD2-associated epilepsy

PrgmNr 1032 Long-read Sequencing Identifies Missing Disease-Causing Variants and Resolves Complex Structural Variants

PrgmNr 1033 Using CRISPR-based saturation genome editing to improve the diagnosis of neuro-developmental disorders

PrgmNr 1036 Single cell “whole embryo” phenotyping of developmental disorders

PrgmNr 1037 Identifying systematic variation at the single-cell level by leveraging low-resolution population-level data

PrgmNr 1038 Discovery of target genes and pathways of blood trait loci using pooled CRISPR screens and single cell RNA sequencing

PrgmNr 1039 SIMBA-single cell embedding along with features

PrgmNr 1040 Deciphering the variation of gene regulation among individuals via integrative single cell multi-omics analysis

PrgmNr 1041 scATAC.Explorer: A Single-Cell ATAC-Seq Database and Search Tool

PrgmNr 1044 A statistical framework to assess replicability of signals from trans-ethnic genome-wide association meta-analysis: Applications to smoking/drinking addiction traits using 3.4 million individuals

PrgmNr 1045 Pleiotropic decomposition regression to characterize multi-trait genetic architecture

PrgmNr 1046 DeepNull: Modeling non-linear covariate effects improves phenotype prediction and association power

PrgmNr 1047 SR-TWAS: Leveraging multiple reference panels to improve TWAS power by ensemble machine learning

PrgmNr 1048 Genetic and environmental correlations between complex phenotypes differ by race/ethnicity and sex

PrgmNr 1049 Enrichment for gene-by-environment candidate SNPs with variance locus analysis: Extension of vQTL to binary traits in the Pan-UK Biobank

PrgmNr 1058 Long-Term systemic expression and cross-correction ability of HMI-203: Investigational gene therapy candidate for mucopolysaccharidosis type II or Hunter Syndrome

PrgmNr 1059 Tasimelteon Safely and Effectively Improves Sleep in Smith Magenis Syndrome: results from a Double-Blind Randomized Trial Followed by an Open-Label Extension

PrgmNr 1060 Unravelling African genomes: Whole-genome sequencing of 1000 Nigerian samples spanning 50 tribal groups provides new insights into diversity and admixture

PrgmNr 1061 NOTCH3 p.Arg1231Cys is Present in 1 in 92 Pakistani and Associated with Stroke

PrgmNr 1062 A high-resolution panel for uncovering repeat expansions that cause ataxias

PrgmNr 1063 Deployment of clinical whole genome sequencing in support of more than 1,000 resource-limited patients: four years of the iHope Program

PrgmNr 1066 Accurate multi-cancer detection and typing by genome-wide cell-free DNA profile data mining

PrgmNr 1067 A novel method identifies liquid biopsy markers based on relative chromatin accessibility

PrgmNr 1068 Distinct intratumoral oncogenic mechanisms between single cells in primary Ductal Carcinoma In Situ exposed by Primary Template-directed Amplification

PrgmNr 1069 Full-length transcriptome analysis of liver cancer using a long-read sequencing technology

PrgmNr 1070 Functional genomics uncover novel regulatory genomic regions associated with gene expression and survival in multiple myeloma

PrgmNr 1071 Genetic map of human brain folding and links to developmental pathways and disease

PrgmNr 1074 Trans-ancestry imputation and exome sequencing of more than 1 million individuals identifies genetic variation protecting against SARS-CoV-2 infection and predicts individuals at risk for severe COVID-19 outcomes

PrgmNr 1075 Rare variant analyses in 239,395 whole exome and whole genome sequenced participants of the UK Biobank reveals novel genetic associations with renal function and chronic kidney disease

PrgmNr 1076 Novel genetic associations for rare diseases with GWAS and trans-ethnic analysis of self-reported medical data

PrgmNr 1077 Common and rare variant analysis of 21K psoriasis cases and 623K controls identifies novel, protective associations in several genes in the type 1 interferon pathway

PrgmNr 1078 Investigating genetic and phenotypic associations for 168 blood metabolites in 120K UK Biobank participants

PrgmNr 1079 Practical implementation of polygenic risk scores and absolute risk score estimation across diverse ancestry groups

PrgmNr 1103 Characterization of molecular and motor phenotypes in CGG knock-in mice with CRISPR mediated deletion of the trinucleotide repeat

PrgmNr 1104 Upregulation of disease compensatory gene via CRISPR activation in muscular dystrophy mice

PrgmNr 1105 Neuronal gene interaction:Scn8a, Kcna1 and Kcnq2

PrgmNr 1106 Adjunct treatment with glycogen synthase (GYS1) antisense oligonucleotides: Reduce glycogen in the Pompe disease mouse model

PrgmNr 1107 Transethnic evaluation of copy number burden in epilepsies from a genome-wide study of 34,132 subjects

PrgmNr 1108 Variant-to-gene-mapping of insomnia GWAS loci followed by a neuron-specific RNAi screen in Drosophila melanogaster implicates PIGQ at the ‘WDR90’ locus as a novel regulator of sleep

PrgmNr 1111 Somatic Mosaicism and Cardiovascular Disease: Uncovering Hidden Genetic Etiology with Clinical Implications

PrgmNr 1112 Identifying the role of alternative splicing during human heart organogenesis

PrgmNr 1113	Genetic deficiency of the AIM2 inflammasome mitigates JAK2p.V617F clonal hematopoiesis associated cardiovascular diseases risk
PrgmNr 1114	FHL5, a Novel Coronary Artery Disease Gene, Regulates Smooth Muscle Cell Contractility
PrgmNr 1115	Identifying causal protein-cardiometabolic trait relationships using whole genome sequencing
PrgmNr 1116	Network medicine-based multimodal omics discovery and iPSC-based validation of metformin for potential treatment of atrial fibrillation
PrgmNr 1119	The impact of evolutionary processes in shaping the genetics of complex traits in East Asia: A specific contribution from Denisovan introgression
PrgmNr 1120	The influence of Neanderthal introgression on human circadian biology
PrgmNr 1121	Systematic genomic investigation finds evidence of germline and somatic roles of Neanderthal introgression in liver cancer
PrgmNr 1122	Biobank-scale inference of ancestral recombination graphs reveals association to rare and common variants in complex traits
PrgmNr 1123	Local ancestry inference for ~7,000 genomes in the Genome Aggregation Database characterizes fine-scale allele frequencies within admixed American populations
PrgmNr 1124	Sex-specific effective population size inference in recent history
PrgmNr 1127	Local ancestry allows for improved genomic prediction in underrepresented and admixed populations
PrgmNr 1128	Polygenic risk prediction of obesity across the life course and in diverse populations
PrgmNr 1129	Improving Polygenic Prediction in Ancestrally Diverse Populations
PrgmNr 1130	A trans-ancestry polygenic test to predict severe hypercholesterolemia in diverse ancestry patients
PrgmNr 1131	Phenome-wide association study of polygenic risk for asthma in the UK Biobank highlights traits with shared genetic architecture and sex specific effects
PrgmNr 1132	Modelling hidden genetic risk from family history for improved polygenic risk prediction
PrgmNr 1135	A genome-wide mutational constraint map quantified from variation in 76,156 human genomes
PrgmNr 1136	Assessment of mitochondrial genome constraint in the gnomAD database of >50,000 individuals using a composite likelihood model
PrgmNr 1137	Quantifying negative selection on synonymous variants
PrgmNr 1138	Objective targeting of de novo loss of function variants in constrained genes improves diagnostic rates in the 100,000 Genomes Project
PrgmNr 1139	Biallelic noncoding regulatory mutations in autism spectrum disorder
PrgmNr 1140	Estimating the clinical diagnostic yield of whole-genome sequencing in 825 orofacial cleft trios
PrgmNr 1143	Modeling tissue co-regulation to quantify tissue-specific contributions to disease heritability
PrgmNr 1144	Uncovering context-specific genetic regulation of gene expression from single-cell RNA-sequencing using latent-factor models
PrgmNr 1145	Acetylated chromatin domains link chromosomal organization to cell and circuit level dysfunction in schizophrenia and bipolar disorder
PrgmNr 1146	Genetic determinants of alternative splicing in stimulated iPSC-derived macrophages enhance the understanding of immune-mediated disease risk
PrgmNr 1147	Leveraging single-cell ATAC-seq to identify disease-critical fetal and adult brain cell types
PrgmNr 1148	Computational and functional characterization of the hs737 enhancer in autism
PrgmNr 1151	CAPRIN1 haploinsufficiency causes a novel neurodevelopmental disorder associated with morphological and functional impairment in hiPSCs-derived cortical neurons
PrgmNr 1152	Biallelic ATG7 variants impair autophagy leading to neurological disease

PrgmNr 1153 --Bi-allelic variants in the autophagy gene ATG4D are associated with a pediatric neurological disorder characterized by hypotonia, joint laxity, and delayed speech and motor development

PrgmNr 1154 Large-scale, multi-ethnic resource of gene, isoform, and splicing regulation in the developing human brain

PrgmNr 1155 Biallelic variants in CELSR3 cause a syndrome comprising CAKUT, anorectal and CNS anomalies

PrgmNr 1156 Statistical framework uncovers deep intronic splice gain variants implicated in undiagnosed cases

PrgmNr 1159 The impact of copy number variants on complex human traits

PrgmNr 1160 PAV: An assembly-based approach for discovering structural variants, indels, and point mutations in long-read phased genomes

PrgmNr 1161 Classes of rare and common variants differentially contribute to variably expressive phenotypes in complex disorders

PrgmNr 1162 Modeling haplotype sharing powers CNV detection and reveals large-effect phenotype associations

PrgmNr 1163 Multi-tool discovery and joint genotyping of structural variations in 138,134 multi-ethnic TOPMed WGS samples

PrgmNr 1164 Sequencing individual genomes with recurrent deletions reveals allelic architecture and disease loci for autosomal recessive traits

PrgmNr 1167 Web-based analysis and collaboration tool, seqr, for rare disease genomics

PrgmNr 1168 Mendelian diseases and their role in a pediatric neurodegeneration cohort

PrgmNr 1169 A genome-first approach to rare variants in hypertrophic cardiomyopathy genes MYBPC3 and MYH7 in a medical biobank

PrgmNr 1170 Incomplete penetrance of disease variants in the UK Biobank

PrgmNr 1171 Biased pathogenic assertions of loss of function variants challenge molecular diagnosis of admixed individuals

PrgmNr 1172 Leveraging human phenotype ontology based similarity to further functional annotation of the human genome

PrgmNr 1175 Attitudes in four Latin American countries towards donation of personal genetic data for research

PrgmNr 1176 Patient completion of updated hereditary cancer genetic testing

PrgmNr 1177 Awareness and Use of Genetic Testing: An Analysis of the Health Information Trends Survey

PrgmNr 1178 Health Locus of Control, Belief in Genetic Transmission of COVID-19, and COVID-related Outcomes in a Global Sample

PrgmNr 1179 Identifying message design considerations to motivate cascade testing for familial hypercholesterolemia: Stakeholders' advice for healthcare providers

PrgmNr 1180 Usual care genetic counseling vs. ARIA: An RCT of an Accessible, Relational, Inclusive and Actionable model for sequencing results disclosure to historically underrepresented populations in the CSER CHARM study

PrgmNr 1183 Identification of clinically relevant variants in homologous regions in 41,755 exomes

PrgmNr 1184 Analytical validation of clinical whole genome sequencing across a diverse mutation spectrum

PrgmNr 1185 Genome sequencing as a first-line genetic testing in ill newborns

PrgmNr 1186 Genome-to-Treatment: A virtual, automated system for population-scale diagnosis and acute management guidance for genetic diseases in 13.5 hours

PrgmNr 1187 Large scale Cas9 mediated depletion of highly abundant transcripts to expand the interpretable genome and improve the diagnostic yield of clinical RNA Seq

PrgmNr 1188 Integration of proteomics with genomics, transcriptomics and phenomics increases the diagnostic rate of Mendelian disorders

PrgmNr 1191 Integrative analysis of human genetic association studies, single cell transcriptomics, and knockout mouse models identifies cell types and genes involved in skeletal disease

PrgmNr 1192 A modular massively parallel reporter assay uncovers context-specific allelic activity of GWAS variants

PrgmNr 1193 Understanding cell-type-specific drug effects while controlling for genotype

PrgmNr 1194 Modeling eQTLs at single-cell resolution identifies >2000 eQTLs with differential effects across continuous T cell states

PrgmNr 1195 Sex differences in the expression and genetic regulation of drug metabolism and transporter genes in human liver

PrgmNr 1196 Identifying disease-critical cell types and cellular processes across the human body by integration of single-cell profiles and human genetics

PrgmNr 1240 Interpreting Genome-Wide Association Studies of Inflammatory Bowel Disease Through the Lens of Single-Cell Sequencing

PrgmNr 1241 Identifying genetic determinants of transcriptional response dynamics at single cell resolution

PrgmNr 1242 Opposing evolutionary pressures drive clonal evolution and health outcomes in the aging blood system

PrgmNr 1243 Trans-ethnic meta-analysis and functional characterization highlights gene regulation underlying the genetic architecture of telomere length

PrgmNr 1244 Genetic associations from the COVID-19 Host Genetics Initiative highlight biology behind

PrgmNr 1245 Whole Genome Sequencing (WGS) based Association Study of 21 Inflammation Biomarkers in up to 38,473 Multi-Ethnic Individuals Identifies Novel Signals

PrgmNr 1248 Potential regulatory effect of the type 2 diabetes associated KCNQ1 locus on CDKN1C expression identified using induced pluripotent stem cell derived pancreatic islet-like cells

PrgmNr 1249 Single-cell gene expression and chromatin accessibility profiling of human pancreatic islets at basal and stimulatory conditions nominates mechanisms of type 1 diabetes genetic risk

PrgmNr 1250 The Kidney genome atlas reveals a novel locus on chromosome 14 associated with adult proteinuric kidney diseases

PrgmNr 1251 Computational and functional gene prioritization from a saturated GWAS of adult height in >5 million people

PrgmNr 1252 Genetic and functional characterisation of the Melanocortin 3 Receptor (MC3R) links nutritional state to growth, body composition and the onset of puberty

PrgmNr 1253 Causal signatures in skeletal muscle single nucleus multi-omics data across 287 individuals

PrgmNr 1256 A global biobank study of asthma identifies novel associations, illuminates shared genetic architecture, and improves polygenic prediction across diverse ancestry groups

PrgmNr 1257 Genome-wide polygenic risk score of prostate cancer in African and European ancestry men

PrgmNr 1258 Genetic association of phenotypes derived by self-supervised deep learning of retina fundus images reveals new genes for eye development

PrgmNr 1259 Fine-mapping across diverse ancestries drives the discovery of putative causal variants underlying human complex traits and diseases

PrgmNr 1260 Analysis across Taiwan Biobank, Biobank Japan and UK Biobank identifies hundreds of novel loci for 36 quantitative traits

PrgmNr 1261 The effects of demographic-based selection bias on GWAS results in the UK Biobank

PrgmNr 1264 HDAC9 structural variants disrupting TWIST1 transcriptional regulation lead to craniofacial and limb malformations

PrgmNr 1265 De-Novo Mutations identified in Nonsyndromic Cleft lip/Palate Families from Africa

PrgmNr 1266 Identification of novel molecular pathways in syndromic orofacial clefting

PrgmNr 1267 RERE deficiencycontributes to the development of orofacial clefts in humans and mice

PrgmNr 1268 Single cell transcriptomics-directed investigation of de novo mutations and rare inherited genetic variants in cleft lip and palate

PrgmNr 1269 A novel 3 MB deletion on 6p24 removes distant neural-crest enhancers controlling TFAP2A resulting in mild Branchiooculofacial syndrome in a multiplex family with orofacial clefting

PrgmNr 1272 Increasing Detection of Familial Hypercholesterolemia in an Academic Medical Center: The Familial Hypercholesterolemia Identification Registry (FHIRE).

PrgmNr 1273 Finding the Sweet Spot: Exploring patients' perspectives on the adoption of AI and Chatbots in genetic service delivery

PrgmNr 1274 A Step Towards Real-World Population Screening for Hereditary Cancer and Hypercholesterolemia

PrgmNr 1275 Using Supervised Machine Learning to Accelerate Variant Curation and Genomic Diagnosis in Suspected Mendelian Disorders

PrgmNr 1276 Design and implementation of genome interpretation for coronary disease - including monogenic and polygenic risk assessment - in a Preventive Genomics Clinic

PrgmNr 1277 Innovative approaches to optimizing the electronic health record for genomic medicine

PrgmNr 1280 Understanding clonal distributions during human cortical development deciphered through brain somatic mosaicism

PrgmNr 1281 MYCN gain-of-function variants induce excess proliferation of neurons and cause a novel megalencephaly syndrome

PrgmNr 1282 Gain and loss of function variants in EZH1 disrupt neuronal differentiation and lead to overlapping neurodevelopmental disorders

PrgmNr 1283 Genomic atlas of proteome from three tissues relevant to neurological disorders prioritizes proteins implicated in brain diseases

PrgmNr 1284 Single-cell RNA-sequencing of human brain regions identifies cell types and states relevant to disease

PrgmNr 1285 Joint transcriptome and chromatin accessibility profiling of the developing human brain cortex at the single cell level

PrgmNr 1335 Genotype first: Clinical genomics research through a reverse phenotyping approach

PrgmNr 1336 The knowledge gap between pharmacogenomics and medical genetics: Is there a bridge in between?

PrgmNr 1337 Population-based penetrance of clinical variants in individuals of diverse ancestries and ages

PrgmNr 1338 Common-variant dysregulation of Mendelian disorder genes contributes to complex disease

PrgmNr 1339 Understanding the importance of racial diversity in the development and implementation of pharmacogenomic guidelines in kidney transplant patients receiving tacrolimus

PrgmNr 1340 Genome-wide association of structural variations with lipid metabolism traits in TOPMed GOLDN study

PrgmNr 1343 Genetic mapping across autoimmune diseases reveals shared associations and mechanisms

PrgmNr 1344 Systematic discovery of gene-environment interactions for metabolic serum biomarkers

PrgmNr 1345 Global Biobank Meta-analysis Initiative: power genetic discovery for human diseases with > 2.6 million samples across diverse ancestries

PrgmNr 1346 Phenome-wide HLA association landscape of 235,000 Finnish biobank participants

PrgmNr 1347 Global discovery of genetic risk variant allelic enhancer activity in allergic eosinophilic esophagitis and atopic dermatitis

PrgmNr 1348 A genome-wide survey of recurrent repeat expansions in cancer genomes

PrgmNr 1351 Brain-specific succinyl-CoA synthetase deficiency leads to increased protein succinylation, abnormal neuronal metabolism, and altered chromatin accessibility

PrgmNr 1352 Aberrant posttranslational modifications contribute to MMA pathophysiology and identify new targets for therapy

PrgmNr 1353 The gnomAD database of mitochondrial DNA variation across 56,434 individuals

PrgmNr 1354 Clinician lead analysis of WGS data identifies missed diagnoses in suspected primary mitochondrial disease

PrgmNr 1355 Regulating PCCA gene expression by splice switching antisense oligonucleotide-mediated modulation of pseudoexon splicing to rescue propionyl CoA carboxylase enzyme activity in propionic acidemia

PrgmNr 1356 Multi-omics and functional studies in two cellular models of Barth Syndrome reveal novel mitochondrial defects and suggest new therapeutic approaches

PrgmNr 1359 Systematic functional interrogation of the Lynch Syndrome gene MLH1 by deep mutational

PrgmNr 1360 Comprehensive cell-type classification of tumor and normal cells from single cell RNA sequencing in pan cancer settings

PrgmNr 1361 Deep transcriptomic profiling with quantitative measures identifies high-risk multiple myeloma

PrgmNr 1362 Integrated somatic and germline assessment of PROACTIVE genomic data

PrgmNr 1363 Germline HOXB13 variant contributes to risk of prostate cancer in men of African Ancestry

PrgmNr 1364 Identification of mitochondrial DNA variants associated with risk of neuroblastoma

PrgmNr 1367 The genomic landscape of mosaic Y chromosome loss in the VA Million Veteran Program

PrgmNr 1368 Genome-wide gene expression analyses reveals ancestry-specific genetic architecture in Latino and African American children

PrgmNr 1369 Single-cell RNA-sequencing reveals pervasive but highly cell type-specific genetic ancestry effects on the response to viral infection

PrgmNr 1370 Chromatin accessibility differences between African and European Alzheimer Disease brains

PrgmNr 1371 Protein prediction for trait mapping in diverse populations

PrgmNr 1372 Multi-ancestry GWAS for venous thromboembolism identifies novel loci followed by experimental validation

PrgmNr 1375 Quantifying the developmental trajectory of autism associated brain overgrowth using 3D cellular resolution imaging

PrgmNr 1376 Genomic architecture of autism spectrum disorder from comprehensive whole-genome sequence annotation

PrgmNr 1377 Genotype-phenotype analyses in 10,000 individuals with psychosis highlights complex role of ultra-rare coding variants and common polygenic risk in presentation and etiology

PrgmNr 1378 Genome-wide association study of over 40,000 cases of suicide attempts yields eight genome-wide significant loci

PrgmNr 1379 Chromatin accessibility mapping reveals compound genetic effects at a schizophrenia GWAS risk locus impairing neurodevelopment and synaptic function in human neurons

PrgmNr 1380 Lineage-specific analysis of epigenome and transcriptome changes in postmortem brains from Schizophrenia and Bipolar Disorder

Poster Talk

296 - 379

PrgmNr 1407 Cancer Risk C, a functional genomics test, is a sensitive, specific, and rapid diagnostic for Lynch syndrome

PrgmNr 1408 Does it make sense to report single pathogenic alleles in cancer susceptibility genes for childhood cancer patients? Results from the BASIC3 and Texas KidsCanSeq studies

PrgmNr 1409 Breast cancer polygenic risk scores and rare variants in Latinas

PrgmNr 1410 Germline genetically predicted mammographic density is associated with breast tumor transcriptomic and proteomic features, CD8+ T cell infiltration, somatic mutational signatures, and tumor mutational burden in The Cancer Genome Atlas

PrgmNr 1411 Saturation Genome Editing of PALB2 Reveals Functionally Abnormal Missense Variants

PrgmNr 1412 Identify non-mutational TP53 loss of function in human cancers

PrgmNr 1413 Multiple germline events lead to cancer development in patients with Li-Fraumeni syndrome

PrgmNr 1414 Oncogenic mutations in the normal human brain

PrgmNr 1415 A human importin-ß-related disorder: Syndromic thoracic aortic aneurysm caused by bi-allelic loss-of-function variants in IPO8

PrgmNr 1416 Genotype-phenotype correlations in PIK3CA-related overgrowth spectrum (PROS) and overlapping phenotypes: a systematic review of 1007 patients with PIK3CA pathogenic variants

PrgmNr 1417 Exome CNV calling and analysis in a large cohort of families with undiagnosed rare genetic disease

PrgmNr 1418 Brazil enters the genome sequencing era: The Rare Genomes Project - interim results

PrgmNr 1419 Low-pass genome sequencing-based detection of absence of heterozygosity: validation in clinical cytogenetics

PrgmNr 1420 Advanced Diagnostics and Genotype-Phenotype Resolution using Functional Genomics in >500 Neuromuscular and Neurological Disorder Patients

PrgmNr 1421 Functional characterization of haplotype surrounding TOMM40-523' repeat to assess differential risk effects on European ancestry APOEε3 haplotypes

PrgmNr 1422 Telomere length analysis in amyotrophic lateral sclerosis using large-scale whole genome sequence data

PrgmNr 1423 Shared genetic aetiology of type 2 diabetes and knee osteoarthritis

PrgmNr 1424 Genetic control of mRNA splicing is affected by purifying selection and may be linked to incomplete penetrance

PrgmNr 1425 Rare variants affecting multi-omic measurements of gene regulation implicated in EKG traits

PrgmNr 1426 Systematic evaluation and Improvements for trans-eQTL Detection Methods Allows Identification of Novel trans-eQTLs in the GTEx data

PrgmNr 1427 Brain eQTL of East Asian, African American, and European Descent Explains Schizophrenia GWAS in Diverse Populations

PrgmNr 1428 Genome-wide inter-chromosomal epistatic associations identified across complex diseases in the ~300,000 participants from eMERGE and UK Biobank

PrgmNr 1429 Global Biobank Meta-Analysis Initiative: A genome-wide association meta-analysis identifies novel primary open-angle glaucoma loci and shared biology with vascular mechanisms

PrgmNr 1430 Systematic comparison of family history and polygenic risk across 27 common diseases

PrgmNr 1431 Systematic comparison of performance of over 50 PRS across ancestries for 14 diseases

PrgmNr 1432 Power-improved meta-QTL analysis reveals the complex regulation of molecular QTL associated with brain diseases

PrgmNr 1433 Single-cell RNA sequencing of lung identifies disease-associated cell type-specific eQTLs

PrgmNr 1434 The Musculoskeletal 3D Epigenome Atlas

PrgmNr 1435 Enhancer enhancer interaction networks involved in long-distance genome regulation link multiple non-coding variants to function

PrgmNr 1436 Escape from X-inactivation in twins exhibits intra- and inter-individual variability across tissues

PrgmNr 1437 ChromBPNet: Deep learning models of base-resolution chromatin profiles reveal cis-regulatory syntax and regulatory variation

PrgmNr 1438 NCBI ALFA Release 2for900 Million Variantsand Allele Frequencyfrom 200KdbGaPSubjects

PrgmNr 1439 Phenome-wide association analysis of rare and common variation in 455,000 UK Biobank

PrgmNr 1440 Integrated multi-omics analysis of thyroid cancer reveals key molecular pathways involved in tumor formation and metastasis

PrgmNr 1441 Whole Blood RNA Sequencing in a Cohort of Undiagnosed Pediatric Patients

PrgmNr 1442 Long read sequencing reveals extensive structural variation in diverse mouse genomes

PrgmNr 1443 MERSCOPETM reveals the transcriptional organization of the mouse brain

PrgmNr 1444 Identifying the genetic contributors of efficacy and adverse metabolic effects of thiazide diuretics in African Americans from the Genetics of Hypertension Associated Treatments (GenHAT) study

PrgmNr 1445 Paradigm Shift from Disease PRS to PGx PRS for Drug Response Prediction using PRS-PGx Methods

PrgmNr 1446 Utility of polygenic risk scores for colorectal cancer risk assessment across diverse populations

PrgmNr 1447 Dissecting 90 percent of lipoprotein(a) heritability in 487,571 UK Biobank participants

PrgmNr 1448 Polygenic score from a large GWAS predicts cases of heart failure with reduced ejection fraction (HFrEF) but not preserved ejection fraction (HFpEF)

PrgmNr 1449 Rare variant carrier status on risk of coronary artery disease among individuals with high polygenic risk

PrgmNr 1450 Expanded Genetic Clustering of Type 2 Diabetes Loci Using a High-throughput Pipeline Reveals Mechanistic Pathways of Metabolic Diseases

PrgmNr 1451 Mirror effects of OPRD1 variants on diabetes and obesity

PrgmNr 1452 The effect of obesity-related traits on COVID-19 severe respiratory symptoms and hospitalization and its mediation by socioeconomic status: a multivariable Mendelian randomization study

PrgmNr 1453 Comparative genetic architecture of the inflammatory bowel disease across East Asian and European populations

PrgmNr 1454 High-resolution genomic architecture of COVID-19 severe disease using multi-ethnic whole genome sequencing data

PrgmNr 1455 A de novo paradigm for male infertility

PrgmNr 1456 Genomic and Transcriptomic-wide Analysis Identifies Novel Genetic Risk Loci and Prioritization of Therapies for Myasthenia Gravis

PrgmNr 1457 Polygenic risk scores as a marker for lifetime epilepsy risk

PrgmNr 1458 Trans-ancestry GWAS meta-analysis of alcohol and tobacco addiction in 3.4 million individuals

PrgmNr 1459 A Genealogical Estimate of Genetic Relationships to Improve Detection of Population Structure Over Time

PrgmNr 1460 DNA methylation patterns underlying lifespan differences in mammals

PrgmNr 1461 Guaranteeing unbiasedness in selection tests based on polygenic scores

PrgmNr 1462 A cross-disorder and evidence-based tiered ranking of candidate genes for neuropsychiatric disorders

PrgmNr 1463 Dysregulation of Canonical and Alternative Replication Protein A Complexes in Huntington Disease and Spinocerebellar ataxia Type 1 brains is associated with CAG instability and phenotype

PrgmNr 1464 Genotypic spectrum and its clinical implication in disorders with epilepsy in Indian population: A preliminary experience

PrgmNr 1465 Identification of NDEL1 as a novel gene for lissencephaly

PrgmNr 1466 EFEMP1 rare variants cause juvenile-onset open angle glaucoma in families from the Philippines

PrgmNr 1469 Genetics Adviser: The development, usability and acceptance testing of a patient-centered digital health application to support clinical genomic testing

PrgmNr 1470 The cost of good health: Poverty association with differential gene expression

PrgmNr 1471 The impact of clinically relevant CNVs in the general population - the health consequences and personalized management of undiagnosed adult CNV carriers in the Estonian biobank

PrgmNr 1472 Uptake of cancer risk management strategies among women who undergo cascade genetic testing for breast cancer susceptibility: How do they compare to non-cascade testers?

PrgmNr 1473 Haplotyping SNPs for allele-specific gene editing of the mutant huntingtin allele using long-read sequencing

PrgmNr 1474 A mouse model recapitulating Bruck Syndrome provides insight into the role of Plod2 in bone

PrgmNr 1476 Mutations in DNA ligase III cause mitochondrial neurogastrointestinal encephalomyopathy

PrgmNr 1477 Significant burden of de novo damaging variants in novel genes in patients with congenital kidney malformations

PrgmNr 1478 Genome-wide genetic control of fetal placental genomics shows multiple associations with health and disease across the life course, informing the Developmental Origins of Health and Disease

PrgmNr 1479 Residual risk for clinically significant copy number variants in pregnancies with normal NIPS

PrgmNr 1480 A 100,000 Genome Project haplotype reference panel of 156,390 haplotypes and the improved imputation of UK Biobank

PrgmNr 1481 A powerful test of ancestral heterogeneity in the effects of gene expression on complex traits

PrgmNr 1482 Developing Trans-ethnic Polygenic Risk Scores Using Empirical Bayes and Super Learning Algorithm

PrgmNr 1483 Explainable and extendable machine learning models for identifying prognostic radiogenomic biomarkers from breast cancer multimodal imaging and genomic data

PrgmNr 1484 Identity-by-descent mapping in biobank-scale datasets

PrgmNr 1485 Incorporating family disease history and controlling case-control imbalance for population based genetic association studies

PrgmNr 1486 SUMMIT: An integrative approach for better transcriptomic data imputation improves causal gene identification

PrgmNr 1487 Allele-specific expression of SNPs involved in the immune response and gene transcription is associated with BMI

PrgmNr 1488 Genetic determinants of prostate-specific antigen levels improve cancer screening utility

PrgmNr 1489 Joint intron splicing-based transcriptome-wide association study identifies new candidate susceptibility genes for breast cancer

Poster Presentations

380 - 2225

PrgmNr 2001 ANGPT1 TEK signaling pathway and primary congenital glaucoma A likely impact in a female newborn glaucoma associated to a dup8q22

PrgmNr 2002 Chromosomal abnormality -17/17P- in acute B-lymphoblastic leukemia (B-ALL) implies loss of heterozygosity of TP53 gene

PrgmNr 2003 Clinical features and genetic analysis of pediatric pilomixoid astrocytomas

PrgmNr 2004 CYP polymorphisms and heart failure

PrgmNr 2005 Geographic differences of the distribution of the mutational spectrum of BRCA1 and BRCA2 genes in Algerian population

PrgmNr 2006 Germline mitochondrial DNA non-coding region variants among sporadic breast cancer patients of two Sri Lankan ethnic groups

PrgmNr 2007 Identification of RP gene and ERα gene polymorphism as genetic markers for the improvement of breast cancer management in cameroon

PrgmNr 2008 Low Prevalence of Large Genomic Deletions and Duplications Observed in the Sequential Use of MLPA after Negative NGS Result in Thai Breast Cancer Cohort

PrgmNr 2009 Renal cancer progression & contribution of chromatin remodeling complexes

PrgmNr 2010 Small nucleolar RNAs as potential predictive/prognostic markers for breast cancer

PrgmNr 2011 Studying the phenotypic variability of ERCC6L2 deficiency in a genetic island

PrgmNr 2012 The Immune-genetics landscape of brain metastases compared to their primary Tumors in a Saudi population

PrgmNr 2013 Timer CAR-T (TCAR-T): A paradigm shift in CAR-T cell therapy

PrgmNr 2014 A prospective Study Using Multigene Next Generation Sequencing panel to Evaluate the Prevalence of Familial Cancer in a Highly Consanguineous Population

PrgmNr 2015 Genetic factors of differentiated thyroid cancer in French Polynesian population after exposure to nuclear tests, A suggested role of 3 loci

PrgmNr 2016 Hereditary Bilateral Breast Cancer: role of the Multi-Gene Panel Testing for detection of Pathogenic Variants

PrgmNr 2017 Statistical Efficiency of Meta-analyses in Testing Gene-environment Interactions with Rare Variants

PrgmNr 2018 DNA repair genes in polyposis susceptibility

PrgmNr 2019 Bioinformatics analysis of gene expression profile in haematologic malignancies

PrgmNr 2020 Cancer informatics survey of different grades and subtypes of glioma

PrgmNr 2021 Chromatin domains affect the clustered breakpoint formation in complex chromosomal rearrangement

PrgmNr 2022 Deep generative neural network for accurate drug response imputation

PrgmNr 2023 Distinctive miRNA expression profiling of pediatric solid tumors in relation to doxorubicin treatment

PrgmNr 2024 Exploration of hypomorphic variants from VUS in multigene panel testing for Japanese breast cancer patients

PrgmNr 2025 Germline landscape of BRCAs by 7-site collaborations as a BRCA consortium in Turkey

PrgmNr 2026 HIVID2: an accurate tool to detect virus integrations in the host genome

PrgmNr 2027 Mutation profile of circulating cell-free DNA reflects the evolution of metastatic breast cancer

PrgmNr 2028 Reversal of Anthracycline Resistance in Colon Cancer cell lines using natural compound Curcumin

PrgmNr 2029 Single cell transcriptomics of Pituitary Neuroendocrine Tumors (PitNETs)

PrgmNr 2030 Spatial transcriptomics reveals unique molecular features of fluorescence sorted 5 minolevulinic acid positive infiltrative tumor cells associated with recurrence and poor survival in glioblastoma

PrgmNr 2032 LPA, KIV2, serum Lp(a), and the risk for Cancer and Cardiovascular disease related pathologies: A retrospective autopsy study

PrgmNr 2033 Trans-ancestry GWASs for ECG markers of ventricular depolarization and repolarization in 250,730 individuals identifies shared and distinct mechanisms

PrgmNr 2034 A Novel Method of Identifying Inherited High-risk Population of Atherosclerotic Cardiovascular Disease Using Polygenic Risk Scores of Metabolic Diseases

PrgmNr 2035 A translational bioinformatics investigation of the human gut microbiome and hypertensive diseases

PrgmNr 2036 Genome-wide association study of lipids in Greenlandic Inuit show large-effect size and independent associations and reveals a unique genetic architecture

PrgmNr 2037 Integration of biomarker polygenic risk score improves the prediction of coronary artery disease in UK Biobank and FinnGen

PrgmNr 2038 Multivariate genetic analysis of human plasma glycerophospholipids, glycerolipids, sphingolipids and sterols identifies novel associations near LPGAT1, GRIP1, SGPL1 and ERMP1

PrgmNr 2039 Rare Variant Analysis for Coronary Heart Disease Cases and Controls using Whole Genome Sequencing in a Middle Eastern Population Identifies Potential Novel Genes

PrgmNr 2040 Sex-stratified whole genome sequencing association study for coronary heart disease in a middle eastern population suggests differential loci

PrgmNr 2041 The penetrance of rare cardiomyopathy-associated DNA variants: a cross-sectional approach to estimate penetrance using large case series

PrgmNr 2042 Transferability of genetic loci and polygenic scores for cardiometabolic traits in ~22,000 British Pakistani and Bangladeshi individuals from a real-world healthcare cohort

PrgmNr 2043 Whole Genome Sequencing Association Study for Coronary Heart Disease in a Middle Eastern Cohort Validates Polygenic Risk Scores and Replicates Known Loci

PrgmNr 2044 A whole genome sequencing study in a three-generation consanguineous family with morbid obesity, learning difficulty and failure of weight loss surgery, to identify susceptibility variants for obesity

PrgmNr 2045 Deep shotgun metagenomic sequencing and functional profiling of the gut microbiota identifies associations with kidney function

PrgmNr 2046 Estimation of variance explained by polygenic risk score of Crohn's disease and ulcerative colitis using Korean versus European GWAS

PrgmNr 2048 HLA haplotype determines treatment response to GAD-alum immunotherapy in Type 1 diabetes: An applied example of a genetic precision medicine approach to pivotal clinical trial design

PrgmNr 2049 Selection pressures affecting Type 2 Diabetes in a South Indian and Scottish population

PrgmNr 2050 Validation and risk score applicability of T2D related variants in populations of East Asians and Europeans

PrgmNr 2051 Whole genome analysis of 342 adult cases of obesity and related metabolic disorders in highly consanguineous population

PrgmNr 2052 HLA-A*11:01:01:01, HLA*C*12:02:02:01-HLA-B*52:01:02:02, age and sex are associated with severity of Japanese COVID-19 with respiratory failure

PrgmNr 2053 Applying the regional heritability mapping method to primary biliary cholangitis in the Japanese population

PrgmNr 2054 Common, low frequency, rare and ultra-rare variants contribute to COVID-19 severity

PrgmNr 2055 Comprehensive analysis of HLA association in Japanese with childhood-onset nephrotic syndrome

PrgmNr 2056 Effective way that determining mild or severe COVID-19 patient only using T-cell receptor(TCR) sequencing data

PrgmNr 2057 Fine-mapping of novel susceptibility loci associated with eosinophil granule proteins (ECP and EDN) reveals five biologically relevant genes for asthma

PrgmNr 2058 Genetic diversity and epidemiology of human rhinovirus among children with severe acute respiratory tract infection in Guangzhou of China

PrgmNr 2059 Genetic Similarity Assessment of Qatar and Italy Populations in the context of COVID-19

PrgmNr 2060 High-resolution genomic architecture of COVID-19 severe disease using multi-ethnic whole genome sequencing data

PrgmNr 2061 Identification of causal genetic variants in invasive pneumococcal diseases by exome analysis in children

PrgmNr 2062 Identifying novel causative mutations forDOCK8 immunodeficiency syndromeusing whole exome sequencing

PrgmNr 2063 PADI4 and PADI2 enhance collagen-initiated inflammatory responses

PrgmNr 2064 rs1944919 on human chromosome 11q23.1 and its effector genes COLCA1 and COLCA2 confer susceptibility to primary biliary cholangitis

PrgmNr 2065 The impact of SARS-CoV-2 multiple spike protein variants on COVID-19 outcomes

PrgmNr 2066 Whole Exome Sequencing for Covid19 host in mild versus severe cases: A Saudi genome study

PrgmNr 2067 Advancing our understanding of genetic risk factors and potential personalized strategies in pelvic organ prolapse: currently largest GWAS reveals 19 novel associations

PrgmNr 2068 Explore the dynamic spatial and temporal regulation mechanism during embryonic sex development

PrgmNr 2069 Genetic characterization of the timing of human parturition unveils differential roles of maternal and fetal genomes on birth weight

PrgmNr 2070 Genome-wide polygenic risk scores for hypertensive disease during pregnancy identify women at risk for long-term cardiovascular disease

PrgmNr 2071 Large-scale GWAS meta-analysis unravels the genetic determinants of cervical biology and pathology

PrgmNr 2072 Meta-analysis of genome-wide association studies identified new loci associated with spontaneous preterm birth and gestational duration

PrgmNr 2073 Novel bi-allelic Mutations in DNAH10 cause multiple morphological abnormalities of the flagella

PrgmNr 2074 Disentangling migraine risk loci by fine-mapping and colocalization

PrgmNr 2076 Long-read sequencing analysis of Alzheimer risk geneABCA7 identifies risk-increasing novel alternative splicing events

PrgmNr 2077 Polygenic risk scores as a marker for lifetime epilepsy risk

PrgmNr 2078 Protein interaction network reveals enriched genetic variation across signaling networks in frontotemporal dementia

PrgmNr 2079 Trans-ethnic fine-mapping in the major histocompatibility complex region on Parkinson's disease risk

PrgmNr 2080 Using non-Autologous Wharton's Jelly Mesenchymal Stem Cells and Chitosan/Poly ethylene oxide as a Synthetic Scaffold inhibit SNI-Induced Apoptosis in Rat

PrgmNr 2082 Assessing association between polygenic risk scores for mood disorders and substance involvement in the Taiwan Biobank

PrgmNr 2083 Brain eQTL of East Asian, African American, and European Descent Explains Schizophrenia GWAS in Diverse Populations

PrgmNr 2084 Contribution of Glucoside Xylosyltransferase 1 gene variants in Schizophrenia

PrgmNr 2086 Is chronotype a risk factor for neuropsychiatric disorders? A two-sample, multivariable Mendelian randomisation study

PrgmNr 2087 Major depressive disorder and current psychological symptoms modify the polygenic predisposition to body mass index on obesity-related traits

PrgmNr 2088 A phenome-wide association study of Y-chromosomal haplogroups and 28 disease endpoints in 37,518 Finnish men

PrgmNr 2089 A selection pressure landscape for 870 human polygenic traits

PrgmNr 2090 Analysis of genetic variants of SARS-CoV-2 host factors ACE2, NRP1, TMPRSS2, and FURIN in Japanese population from IRUD whole-exome sequencing data

PrgmNr 2091 Analysis of the genetic components behind the chronic back pain

PrgmNr 2092 Association of confounding factors with Adolescent Idiopathic Scoliosis in the population of Jammu andKashmir, India

PrgmNr 2093 Can sex differences in GWAS variant effects be found with current sample sizes?

PrgmNr 2094 Challenges with X chromosome analyses and reporting in Genome-Wide Association Studies

PrgmNr 2095 Comprehensive genome-wide association study of different forms of hernia identifies more than 80 associated loci

PrgmNr 2096 Deep integrative models for large-scale human genomics

PrgmNr 2097 Genome-wide association study of chronotype in Japanese direct-to-consumer genetic testing data

PrgmNr 2098 Genome-wide association study of varicose veins identifies a protective low-frequency missense variant in GJD3 enriched in Finnish population and highlights connexins as potential therapeutic targets

PrgmNr 2099 Genome-wide phenome-wide association study for important diseases & quantitative traits based on the Taiwan Biobank data
PrgmNr 2100 Genotype-by-environment interactions for chronic back pain
PrgmNr 2101 Hierarchical topic modelling enables genetic analysis of electronic healthcare record data
PrgmNr 2102 Machine-learning SNP-based prediction for Primary Biliary Cholangitis: A proof-of-concept study
PrgmNr 2103 Phenome-wide association study of deleterious variant (shet) burden using exome sequencing of 394,694 UK Biobank participants
PrgmNr 2105 Quantifying concordant genetic effects of de novo mutations on multiple disorders
PrgmNr 2106 Sources of Inequality at Birth: The Interplay Between Genes and Parental Socioeconomic Status
PrgmNr 2107 Systematic comparison of family history and polygenic risk across 27 common diseases
PrgmNr 2108 Systematic comparison of performance of over 50 PRS across ancestries for 14 diseases
PrgmNr 2109 Web-based, participant-driven research platform discovered novel genetic associations for stress-related complaints and food-related behaviors in Japanese population
PrgmNr 2110 Epigenome-wide association study of DNA methylation in CD4- and CD8-positive T cells in narcolepsy
PrgmNr 2111 Functional characterisation of GJB2 cis-regulatory elements and WGS of heterozygous patients with NSHL
PrgmNr 2112 Genome-wide Analysis of DNA methylation in 106 Schizophrenia family trios in Han Chinese
PrgmNr 2113 Genome-wide DNA methylation profiling of leukocytes identifies CpG methylation signatures of treatment-resistant schizophrenia
PrgmNr 2114 High genetic load of the GREB1L gene and auditory rehabilitation in the severe form of cochlear malformation
PrgmNr 2115 Mapping the cis-regulatory landscape of ABCA4 in adult human retina
PrgmNr 2116 Methylation quantitative trait loci of type 2 diabetes in a middle eastern population
PrgmNr 2117 Mitochondrial-nuclear gene expression co-regulation is compromised in immune system cells of COVID-19 patients: rewiring towards glycolysis
PrgmNr 2118 UMI-4C chromatin interaction profiling, in vitro and in vivo enhancer assays to dissect the cis-regulatory mechanisms underlying North Carolina macular dystrophy, a retinal enhanceropathy
PrgmNr 2119 ZNF143, an important factor for CTCF-bound chromatin interactions
PrgmNr 2120 Epigenome-wide association study of the human IgG N-glycome composition
PrgmNr 2121 eQTL Catalogue: A compendium of uniformly processed human gene expression and splicing QTLs
PrgmNr 2122 Evaluation of the impact of genetic diversity on PIWI-interacting RNA analysis
PrgmNr 2123 Loss of PTEN disrupts 5-hydroxymethylcytosine landscape along mESC neuronal differentiation
PrgmNr 2124 Nuclease deficiencies alter plasma cell-free DNA methylation profiles
PrgmNr 2125 Regulon active landscape reveals cell development and function state changes of human primary osteoblasts in vivo
PrgmNr 2126 TDG contributes to male subfertility through dysregulation of male germline stem cell development
PrgmNr 2127 Whole-genome and small RNA sequencing-based microRNA-eQTL mapping in Japanese elucidates variant-microRNA-disease connections
PrgmNr 2128 Identification of hubb genes in retinoblastoma using network analysis
PrgmNr 2129 Detecting gene-gene interactions from GWAS using diffusion kernel principal components
PrgmNr 2130 Epigenetic and RNA profiling of cancer using multi-omics data on the Cancer Genomics Cloud powered by Seven Bridges
PrgmNr 2131 Implementation and evaluation of available methods for epimutation analysis

PrgmNr 2132 Pathway analysis enhances characterization of cell types and sample groups in single-cell RNA sequencing

PrgmNr 2133 Spatial changes in the human genome indicated by the consensus-based structural variants in selected human families

PrgmNr 2134 CNV characteristics in Chernobyl power plant catastrophe clean-up workers from Lithuania suggest unique genetic variation structure

PrgmNr 2135 Differentiation in Olfactory Receptor Genes in Worldwide Populations

PrgmNr 2136 Evaluating the accuracy of genotype imputation in the MHC region in selected African populations

PrgmNr 2137 Genetic diversity in host immune genes involved in responses against intestinal parasitic infections in the Orang Asli community in Malaysia

PrgmNr 2138 Genomic and ancestral variation underscores the severity of COVID-19 disease presentation

PrgmNr 2139 Gut microbiome analyses of ancient individuals, so called “Jomon”, lived in Japanese archipelago

PrgmNr 2140 Hematological, epigenetic and genetic adaptations in Tibetans

PrgmNr 2141 Historical Demography of Lithuania and Relationship to other Populations

PrgmNr 2142 Incidence of patients with methylenetetrahydrofolate reductase (MTHFR) gene mutations in a Tunisian population cohort

PrgmNr 2143 Population-specific adaptation to malaria infection in endemic regions of Asia

PrgmNr 2144 Positive selection to altitude and phenotypic associations in Papua New Guinean highlanders

PrgmNr 2145 TogoVar; providing integrated genomic information of Japanese population

PrgmNr 2146 Variations in genes associated with recurrent miscarriages in the HGDP CEPH dataset

PrgmNr 2147 Classifying uncertainty and impact of uncertainty on decision-making: How do medical students handle uncertainty in prenatal exome sequencing?

PrgmNr 2148 Population biobank participants’ response to a range of genomic results reported

PrgmNr 2149 Psychological burden of preimplantation genetic testing (PGT) on couples with multiple monogenic disorders and the role of genetic counselling in Saudi Arabia

PrgmNr 2150 Role of whole genome sequencing in detecting compound heterozygotes for single nucleotide variant and structural variant: Two illustrative patients

PrgmNr 2151 Stigma-power around Fragile X Syndrome: a tale of a royal family and a community in a rural village in Cameroon

PrgmNr 2152 The impact of clinically relevant CNVs in the general population - the health consequences and personalized management of undiagnosed adult CNV carriers in the Estonian biobank

PrgmNr 2153 Use of MOOCs for inclusive, flexible professional development and wider public engagement in human genomics and genetics

PrgmNr 2154 Novel CRISPR system with modified cas12 and nanoliposome based delivery can destroy SARS covid2 virus in human lung tissue

PrgmNr 2155 Targeted Therapies for Hereditary Peripheral Neuropathies: Systematic Review and Steps Towards a 'treatabolome'

PrgmNr 2156 A global omics data sharing and analytics marketplace: Case study of a rapid data COVID-19 pandemic response platform

PrgmNr 2157 An atlas of associations between polygenic risk scores from across the human phenome and circulating metabolic biomarkers

PrgmNr 2158 Human genetics is great: A genomic structural variant map of 945 Han Chinese individuals using long-read sequencing data

PrgmNr 2159 Measuring sensitivity of semi-automated Clingen-ACMG classification framework for CNVs through comparison with manual classification of 1437 clinical cases

PrgmNr 2160 SpliceAI algorithm identified potentially pathogenic variants in patients with hereditary hearing impairment

PrgmNr 2161 Towards a more usable database: MGeND 2021 update

PrgmNr 2162 Variations in Nomenclature of Clinical Variants between Annotation Tools

PrgmNr 2163 Two new patients with focal dermal hypoplasia: A novel PORCN variant and insights on the differential diagnostic considerations

PrgmNr 2164 A human importin-ß-related disorder: Syndromic thoracic aortic aneurysm caused by bi-allelic loss-of-function variants in IPO8

PrgmNr 2165 A novel NOTCH3 terminal exon variant causes the rare lateral meningocele syndrome in an Asian child

PrgmNr 2166 A novel variant in the WNT10A gene in a consanguineous Malian family with Odonto-Onycho-Dermal Dysplasia syndrome: First sub-Saharan African case

PrgmNr 2167 A Palestinian patient with Wiedemann-Rautenstrauch like syndrome: expanding the phenotypic spectrum of PYCR1 mutations

PrgmNr 2168 Acromesomelic skeletal dysplasia with severe short stature due to a biallelic KIF24 variant

PrgmNr 2169 Clinically actionable secondary findings in 390 whole genome sequence data from sub-Saharan African families with nonsyndromic orofacial clefts

PrgmNr 2170 Congenital bilateral anophthalmia: A case report

PrgmNr 2171 C-terminal and N-terminal truncating mutations of the MN1 gene lead to distinct developmental phenotypes

PrgmNr 2172 Delineation of the phenotype and genotype in ten individuals with de novo variants in ZBTB18

PrgmNr 2173 Expanding the phenotype of cerebello-facio-dental syndrome in female with a novel pathogenic variant

PrgmNr 2174 Long-read whole genome sequencing identified a partial MBD5 deletion in an exome-negative patient with neurodevelopmental disorder

PrgmNr 2175 Loss-of-Function mutations of USP9X as the differential diagnosis for CHARGE syndrome

PrgmNr 2176 Objective evaluation of dysmorphism by automated analysis of facial photographs

PrgmNr 2177 Say-Barber-Biesecker-Young-Simpson syndrome (SBBYSS) and the importance of Whole Exome Sequencing in finding the accurate diagnostic. A case report

PrgmNr 2178 The first East Asian adult case with rare NEPROrelated skeletal dysplasia caused by a novel missense homozygous variant in NEPRO

PrgmNr 2179 The genotypic and phenotypic spectrum of pycnodysostosis in Saudi Arabia: Novel variants and clinical findings

PrgmNr 2182 A novel variant in the GNE gene in a Malian with distal muscle weakness

PrgmNr 2183 A rare double diagnosis identified via exome sequencing in a patient with complex cerebellar ataxia

PrgmNr 2184 An exonic LINE-1 insertion and a novel missense variant in CC2D2A identified in siblings with Joubert syndrome using Long-Read Sequencing

PrgmNr 2186 Bi-allelic variants in neuronal cell adhesion molecule (NRCAM) lead to a novel neurodevelopmental disorder characterized by developmental delay, hypotonia, peripheral neuropathy or spasticity

PrgmNr 2187 Comprehensive genetic investigation of penta-nucleotide tandem repeats at RFC1 locus in Indian ataxia and ALS cohort

PrgmNr 2188 Delineating the spectrum of disorders with CNS white matter abnormalities in Indian population

PrgmNr 2189 Delineation of the phenotypic and genotypic spectrum of disorders with deficient myelination of central nervous system in 26 Indian families

PrgmNr 2190 Expanding the genotypic spectrum of Allan-Herndon-Dudley syndrome: Report of two novel mutations in the SLC16A2 gene

PrgmNr 2191 Genotypic spectrum and its clinical implication in disorders with epilepsy in Indian population: A preliminary experience

PrgmNr 2192 Identification of NDEL1 as a novel gene for lissencephaly

PrgmNr 2193 LRFN1- a novel candidate gene as a potential cause of autism spectrum disorder

PrgmNr 2194 Metabotropic glutamate receptor subtype 2 (GRM2) is a novel disease gene for developmental and epileptic encephalopathy

PrgmNr 2195 Mono- and bi-allelic variation of ABCA2 in individuals with different neurodevelopmental disorders

PrgmNr 2196 Multiple methodologies reveal novel picture of the genetic architecture of intellectual disability in Northern Finland

PrgmNr 2197 Mutational Landscape of a Bangladeshi Cohort of Neurodevelopmental Disorders

PrgmNr 2198 Novel PCDH19 frameshift variant in a girl with recurrent seizures and phenotype overlapping with SCN1A gene dysfunction: a case report and literature review

PrgmNr 2199 Preliminary studies on apparent Mendelian psychotic disorders in consanguineous families

PrgmNr 2200 Similar genotypes leading to different phenotype: expansion of the phenotype of UDP-Glucose-6-Dehydrogenase recessive neurodevelopmental disorder with or without epileptic encephalopathy, 2 new descriptions

PrgmNr 2201 The Genetic Architecture of Neurological Diseases in Khyber Pakhtunkhwa-Pakistan

PrgmNr 2202 A large deletion in EVER1 gene: Identification and validation through amplicon-based Next Generation Sequencing

PrgmNr 2203 A novel deletion causes SLC25A42-associated mitochondrial encephalomyopathy in a Saudi patient: Report of additional founder cases and functional characterization study

PrgmNr 2204 An MRM2 splicing variant in a complex dystonic syndrome: a second report and incomplete penetrance

PrgmNr 2205 Associate professor of clinical genetics

PrgmNr 2206 Bi-allelic missense variant p.Thr368Ala in DLST is associated with 2-oxoglutarate dehydrogenase complex deficiency related neurometabolic disorder

PrgmNr 2207 Drug repurposing based on multi-omics data for osteoporosis

PrgmNr 2208 Exome sequencing in 13 families with monogenic forms of rickets

PrgmNr 2209 Further delineation of RPL13-related skeletal dysplasia

PrgmNr 2210 Genetic linkage analysis identifies nuclear regions that modify the phenotype of m.3243A>G-related mitochondrial disease

PrgmNr 2211 High prevalence of DMD gene mutations in Duchenne muscular dystrophy in South Indian population

PrgmNr 2212 Identification of novel candidate genes and expansion of the phenotypic spectrum in a large skeletal dysplasias cohort

PrgmNr 2213 Long-term prognosis and genetic background of cardiomyopathy in 223 mitochondrial disease children

PrgmNr 2214 Lysosomal storage disorders at a tertiary care centre in a developing country

PrgmNr 2215 Mechanism of WRN loss for causing short stature in Werner syndrome

PrgmNr 2216 Molecular diagnostic challenges related to mutations in the low-complexity domain of heterogenous nuclear ribonuclearprotein A1 (HNRNPA1)

PrgmNr 2217 Mutations in DNA ligase III cause mitochondrial neurogastrointestinal encephalomyopathy

PrgmNr 2218 NTBC efficacy in alkaptonuria

PrgmNr 2219 Outcome of Clinical Genetic Testing in Patients with Features Suggestive for Ehlers Danlos Syndrome

PrgmNr 2220 Phenotypic Spectrumof DihydrolipoamideDehydrogenase Deficiencyin Saudi Arabia

PrgmNr 2221 The p.L3P (p.Leu3Pro) variant in GLA is not associated with Fabry disease

PrgmNr 2222 Association analysis of rare variants identified risk genes with neonatal respiratory distress syndrome

PrgmNr 2223 Combined immunodeficiency and increased cellular sensitivity to radiation due to a novel DNA Ligase 1 mutation

PrgmNr 2224 Functional characterization of a Xenopus tropicalis knockout and a human cellular model of RCBTB1-associated inherited retinal disease shows involvement of RCBTB1 in the cellular response to oxidative stress

PrgmNr 2225 Genetic and clinical characteristics of inherited retinal dystrophies in Northern Finland

PrgmNr 2226 Genetic variants influencing penetrance to iron overload disorder hereditary haemochromatosis: evidence from UK Biobank

PrgmNr 2227 Identification of variants associated with moderate to severe hearing loss

PrgmNr 2228 Inborn errors of immunity: Novel insights from four unrelated Indian families

PrgmNr 2229 Progressive familial intrahepatic cholestasis type3: two novel pathogenic variants in a cohort of Egyptian children with cholestatic disorders of infancy

PrgmNr 2230 Targeted exome sequencing identifies novel variants associated with non-syndromic hearing loss in an Indian family

PrgmNr 2231 A Novel Variant in RAP1GDS1 gene in a child with developmental

PrgmNr 2232 Beta-Ketothiolase deficiency in a patient with coexistence of homozygous ACAT1 gene mutation and homologous constitutional translocation t(4;11)(q13;q23) and father with XYY syndrome

PrgmNr 2233 Biallelic VPS35L pathogenic variants cause 3C/Ritscher-Scinzel-like syndrome: Description of two novel cases confirming the pathogenicity and clinical diversity

PrgmNr 2234 First reanalysis highlighting the increasing role of multiple molecular diagnoses in the field of rare diseases

PrgmNr 2235 Helsmoortel-van der Aa syndrome in a 14-year-old girl demonstrates intellectual impairment, facial dysmorphism and morbid obesity

PrgmNr 2236 Importance of genetic diagnosis on the PICU: case series during COVID-19 pandemic

PrgmNr 2237 MLPA mediated molecular characterization of associated syndromes with orofacial cleft patients

PrgmNr 2238 Pulmonary valvular stenosis missed Rasopathies in two asymptomatic adults

PrgmNr 2239 The identification of microduplications in 17q21.31 locus that might disrupt the KANSL1 gene

PrgmNr 2240 Clinical whole genome sequencing as an efficient first-tier diagnostic test for patients withrare diseasesfrom a resource-limited setting in the Democratic Republic of Congo

PrgmNr 2241 Current status of genetic diagnosis laboratories and frequency of genetic variants associated with cystic fibrosis through a newborn-screening program in Turkey

PrgmNr 2242 Detection of pathogenic CNVs in isolated and non-isolated congenital heart defects (CHD) by MLPA and CMA (retrospective cohort study)

PrgmNr 2243 Genetic determinants of mosaic loss of the X chromosome in peripheral leukocytes of 395,036 women from 3 biobanks

PrgmNr 2244 Low-pass genome sequencing-based detection of absence of heterozygosity: validation in clinical cytogenetics

PrgmNr 2245 Multilocus disease-causing genomic variations for Mendelian disorders: role of systematic phenotyping and implications on genetic counselling

PrgmNr 2246 The high-risk phenotypes of genetic disease in a Neonatal Intensive Care Unit population from the China neonatal genomes project

PrgmNr 2247 A novel splice site variant causes SLC13A5-related developmental and epileptic encephalopathy in large consanguineous family

PrgmNr 2248 Apolipoprotein E4 and meningeal lymphatics in Alzheimer disease: a conceptual framework

PrgmNr 2249 ----ASL deficiency in ALDH1A1+- neurons in the substantia nigra metabolically promotes neurodegenerative phenotypes

PrgmNr 2250 Compound heterozygousATMvariants cause late onset cerebellar and extrapyramidal disease in the absence of telangiectasia in a consanguineous Pakistani family

PrgmNr 2251 Dysregulated expression levels of APH1B in peripheral blood are associated with brain atrophy and amyloid-β deposition in Alzheimer’s disease

PrgmNr 2252 IMMP2L gene and Gilles de la Tourette syndrome a new case & review of the literature

PrgmNr 2253 Lipid transporter TMEM24/C2CD2L plays critical roles in ensuring the survival of retinal rod cells

PrgmNr 2254 Novel variants in UBE3B lead marfonoid body habitus of blepharophimosis ptosis intellectual disability syndrome

PrgmNr 2255 Phenotypic variability of MEGF10 variants in a consanguineous population

PrgmNr 2256 Second report of SHMT2 related neurodevelopmental disorder with cardiomyopathy, spasticity, and brain abnormalities

PrgmNr 2257 Simultaneous screening for SMN copy numbers and 2+0 silent carrier genotypes for Spinal Muscular Atrophy

PrgmNr 2258 The suppressive role for the splicing regulator, PTBP1, in the production of neuron-specific Agrin isoform

PrgmNr 2259 Transcriptomic profiling of chromatin-related neurodevelopmental disorders in human induced pluripotent stem cell -based models

PrgmNr 2260 Ultra rare truncating mutations of GRIK family genes associated with schizophrenia disrupt the interaction with PSD95 protein

PrgmNr 2261 Whole-genome sequencing analysis identifies rare Alzheimer's disease risk variants among Chinese individuals

PrgmNr 2262 Microtubule-Associated Serine/Threonine Kinases family genes (MAST) involved in the pathogenesis of seborrheic dermatitis may be related to Parkinson disease

PrgmNr 2263 RNAseq characterization of the effect of titin truncating variants

PrgmNr 2264 Automated prediction of the clinical impact of copy number variants: The power of combining expert and machine learning approach

PrgmNr 2265 Coding DNA numbering errors occurring in multiple pipelines

PrgmNr 2266 Copy number variation analysis with targeted next generation sequencing in patients with inherited metabolic disorders

PrgmNr 2267 Evaluating RNA-seq gene expression profiles for disease prediction using machine learning

PrgmNr 2268 Human Genome Topology for Selected Trios from the 1000 Genomes Project

PrgmNr 2269 Mining risk regulatory variants of Tetralogy of Fallot using deep learning models

PrgmNr 2270 Reanalysis of population cohort WGS revealed considerable minor allele frequency differences

PrgmNr 2271 VulExMap: Detection of exons which are vulnerable to exonic splicing mutations

PrgmNr 2272 A metagenome-wide association study revealed disease-specific landscape of the gut microbiome of systemic lupus erythematosus in Japanese

PrgmNr 2273 A multi-disciplinary approach to solving undiagnosed patients - Unsolved Cases Unit Groningen

PrgmNr 2274 An atlas of genetic scores to predict multi-omic biomolecular traits in blood

PrgmNr 2275 Enzymatic DNA synthesis (EDS) enables rapid and broad-based access to synthetic oligos needed for the genetic analysis and functional characterization of the SARS-CoV-2 virus

PrgmNr 2276 Impaired type I interferon activity of subjective cognitive decline in preclinical Alzheimer's disease

PrgmNr 2277 Molecular Cartography: a multiplexed high resolution transcriptomics approach to spatially analyze rare events demonstrated in an infection model of SARS-CoV-2

PrgmNr 2278 Translational diagnostics program -TDP-, an innovative intramural approach for hospital-based functional genomics of undiagnosed and rare diseases

PrgmNr 2279 An automated workflow for high-throughput qPCR

PrgmNr 2280 An integrated pipeline for genome analysis and phenotype-based gene prioritization with GenDiseak

PrgmNr 2281 Implementation of heart disease-associated cellular heterogeneity in vivo with Gene-Disease Integrative Systems Transgenesis (GENISYST) and Molecular Cartography

PrgmNr 2282 scDetect: A rank-based ensemble learning algorithm for cell type identification of single-cell RNA sequencing in cancer

PrgmNr 2283 Allelic and genotypic frequencies of CYP2C19*2, CYP2C19*3, and CYP2C19*17 alleles in the healthy South Indian population and their phenotypic prediction

PrgmNr 2284 Assessment of cytochrome P450 polymorphism for personalized therapy in acute coronary syndrome

PrgmNr 2285 Association between HLA-DRB1*15:01 and DQA1*01:02 frequencies and Lumiracoxib-induced DILI in healthy Thai Population

PrgmNr 2286 Association of a single nucleotide polymorphism rs12496846 in the C3orf20 gene region, identified to be associated with postoperative analgesia after mandibular sagittal split ramus osteotomy, with postoperative analgesia after major abdominal surgery

PrgmNr 2287 Comprehensive analysis of the genetics of clozapine-induced adverse effects

PrgmNr 2288 CYP2D6 genetic variants and their metabolic efficacy - insight from Molecular Dynamics Simulations

PrgmNr 2289 Distribution of HLA-B*13:01 allele related with dapsone-induced severe cutaneous adverse reaction in Thai and Asian population

PrgmNr 2290 Distribution of HLA-B*58:01 allele associated with allopurinol-induced SCARs in healthy Thai population

PrgmNr 2291 Experience and expectations of pharmacogenetic tests in France

PrgmNr 2292 Integration of genetically regulated gene expression and pharmacological library provides therapeutic drug candidates

PrgmNr 2293 Pharmacogenomics Marker of HLA-A*33:01 Allele Frequency in Healthy Thais

PrgmNr 2294 Practical guidelines of genomics-driven drug discovery from Global Biobank Meta-analysis Initiative

PrgmNr 2295 The frequency of HLA-B*57:01 allele in healthy Thai population

PrgmNr 2296 Association between relative telomere length in umbilical cord tissue and PCB congeners in maternal blood and cord blood in a birth cohort in Chiba, Japan

PrgmNr 2297 Distinct roles of ADAM10 and ADAM17 for testicular germ cell apoptosis

PrgmNr 2298 Exploring the factors affecting classification and reporting uncertain CMA findings, using a "virtual fetus" model

PrgmNr 2299 Genome-wide association analysis implicates dysregulation of Wnt signaling pathway in biliary atresia

PrgmNr 2300 Genomic sequencing in critically ill newborn infants shows high diagnostic rate in neurometabolic phenotypes and positive impact on clinical management

PrgmNr 2302 Residual risk for clinically significant copy number variants in pregnancies with normal NIPS

PrgmNr 2303 The potential of RNAsequencing for fetal malformation syndromes

PrgmNr 2304 3DeepMHC : 3D structure based Deep learning model for MHC-peptide binding prediction

PrgmNr 2305 A 100,000 Genome Project haplotype reference panel of 156,390 haplotypes and the improved imputation of UK Biobank

PrgmNr 2306 A weighted selection probability to locate rare variants associated with highly correlated multiple phenotypes

PrgmNr 2307 Accurate imputation of human leukocyte antigens with CookHLA

PrgmNr 2308 An explainable machine learning method for polygenic scores using whole UK biobank genotype dataset

PrgmNr 2309 Association tests of gene-environment interactions for time-to-event traits in family studies

PrgmNr 2311 Correction for sample overlap, winner's curse and weak instruments bias in two-sample Mendelian Randomization

PrgmNr 2313 Genome-wide classification of epigenetic signal reveals regions of enriched heritability in complex immune traits

PrgmNr 2314 Integrating facial and genomic data for subtyping individuals in the presence of confounders via individual-specific network analysis

PrgmNr 2315 Mendelian Randomization with repeated measurement using Taiwan Biobank

PrgmNr 2316 Significance in individual-specific networks: assessment, methods and characteristics

PrgmNr 2317 SNPs tagging structural variations help to reveal widespread role of CNVs in complex traits and gene expression

PrgmNr 2318 Statistical selection method to identify pleiotropic variants associated with both quantitative and qualitative traits

PrgmNr 2319 The Alpha variant: A comparison for risk for hospitalization and case-mortality rate for younger and older patients

PrgmNr 2320 Time to mortality and time to discharge from the hospital in Covid-19 data: A Turkish study

PrgmNr 2321 TransformerPRS: a deep learning-based polygenic risk model using bidirectional transformers derived from a language model

PrgmNr 2322 Using a digital health tool to analyse UK primary care electronic health records to identify potential cases of undiagnosed Marfan syndrome

PrgmNr 2323 A machine-learning-based prediction of disease endpoints from administrative health data accounts for misclassification and disease liability in GWAS

PrgmNr 2324 Characterization of the human ABO genotypes and their association to inflammatory and cardiovascular disease

PrgmNr 2325 Effects of GLP1R coding variation on random glucose levels and functional responses to GLP-1R agonists using whole exome sequencing data

PrgmNr 2326 Genetic and environmental determinants of drug adherence and drug purchasing behaviour

PrgmNr 2327 Higher adisposity, depression and wellbeing: causal inference using Mendelian randomization

PrgmNr 2328 HLA Fine Mapping and Genetic Risk Factors in Tuberculosis

PrgmNr 2329 Secondary findings from exome sequencing of 15,000 South Asians

PrgmNr 2330 Separating the effects of cardiometabolic risk factors from type 2 diabetes on coronary and peripheral artery disease

PrgmNr 2331 Transcriptome and GWAS identified rs2238678 as a critical SNP for eosinophilia in primary biliary cholangitis

PrgmNr 2332 Development of a novel, instrument-free, single-cell RNA sequencing technology (PIPseq) and its application to drug pathway discovery in lung cancer

PrgmNr 2333 Diversity of germline mutations in a cohort of unselected Brazilian pancreatic carcinoma patients

PrgmNr 2334 Effect of return of unknown significance on surgical variant of decision making in women with invasive breast cancer

PrgmNr 2335 Exome sequencing of 500 Brazilian patients with rare diseases: what we have learned

PrgmNr 2336 Human genetics isgreat:Incidental karyotype finding of aBRCA1translocation explaining family cancer history

PrgmNr 2337 Searching for epigenetic markers with prognostic value in Acute Myeloblastic Leukemia patients of Uruguay

PrgmNr 2338 Translocation t(8;14)(q11;q32) in Leukemia, a literature review

PrgmNr 2339 BRCA1 and BRCA2 variants of unclear significance in hereditary breast and ovarian cancer patients. Looking for novel pathogenic variants

PrgmNr 2340 Breast and prostate cancer risks for male BRCA1 and BRCA2 pathogenic variant carriers using recently-developed polygenic risk scores

PrgmNr 2341 Breast cancer risks associated with missense variants in breast cancer susceptibility genes

PrgmNr 2342 Copy number variation (CNV) analysis identifies variants in 1p36 in African American and Caucasian hereditary prostate cancer cases

PrgmNr 2343 Genetically Predicted Serum Insulin-like Growth Factor-1 (IGF-1) Levels and Risk of Multiple Primary Cancers in the Prostate, Lung, Colorectal and Ovarian Cancer Screening Trial

PrgmNr 2344 Germline PALB2 mutations found in NGS multigenetic panels from breast-ovarian cancer patients in Argentina

PrgmNr 2345 Germline genetically predicted mammographic density is associated with breast tumor transcriptomic and proteomic features, CD8+ T cell infiltration, somatic mutational signatures, and tumor mutational burden in The Cancer Genome Atlas

PrgmNr 2346 Identification of copy number variants in hereditary lung cancer families

PrgmNr 2347 Immune-related intra-tumoral gene expression and survival by BRCA1/2 mutation status in high grade serous ovarian cancer cases: an Ovarian Tumor Tissue Analysis (OTTA) study

PrgmNr 2348 Malignant pleural mesothelioma: germline variants may steer tailored treatment

PrgmNr 2349 On cross-ancestry cancer polygenic risk scores

PrgmNr 2350 Rates of mutations in DNA repair genes are low in localized prostate cancer patients, particularly among non-White individuals

PrgmNr 2351 The IMPACT study Lynch Syndrome cohort - results after first round of screening

PrgmNr 2352 Wood stove use interacts with genetic variants to alter risk of gastric cancer in a high altitude Central American population

PrgmNr 2353 ACSL VI:A Novel Variation Results in Structural Modification and Multiple Neoplasia in a 46-year-old Female

PrgmNr 2355 Functional study of the 2q22 renal cancer susceptibility locus

PrgmNr 2356 Inflammatory and oncological processes contributing to the increased susceptibility to Barrett's esophagus in adults born with esophageal atresia

PrgmNr 2358 Utility of altered nuclear expression of the BAP1 for assessment of pathogenicity of Variants of Unknown Significance

PrgmNr 2359 Chromatin accessibility mapping in T-cell Prolymphocytic Leukemia

PrgmNr 2360 DNA Methylation Profiles of Ovarian Clear Cell Carcinoma

PrgmNr 2361 From genetics to immune system: the dynamic crosstalk in a wide cohort of completely resected Gastrointestinal Stromal Tumors (GISTs)

PrgmNr 2362 Genome Variation Analysis on Accelerated Framework

PrgmNr 2364 Germline variants associate with the presence of somatic TP53 and PIK3CA mutations in breast tumors

PrgmNr 2365 Identify non-mutational TP53 loss of function in human cancers

PrgmNr 2366 Integrated Transcriptomic Profiling with Deep Learning Classification Applied to Prostate Cancer Tissue Images

PrgmNr 2367 Integrative genomic analysis reveals new insights on complex mutational landscape in T-cell prolymphocytic leukemia

PrgmNr 2368 Investigating associations of common ATM missense variants with neoplasms in the UK Biobank exome sequencing data - a conditional analysis

PrgmNr 2369 JBrowse 2: an extensible open-source platform for modern genome analysis

PrgmNr 2370 Oncogenic mutations in the normal human brain

PrgmNr 2371 Paired DNA and RNA genetic testing improves variant detection and classification independently of personal history of cancer

PrgmNr 2372 Role of circulating immune checkpoints in KIT-mutated metastatic gastrointestinal stromal tumor (GIST) patients

PrgmNr 2373 Single cell consensus clustering (SC3) with REVEALTM: SingleCell on neuroblastoma and fetal gene expression data

PrgmNr 2374 Targeted NGS-based molecular profiling of conjunctival squamous cell carcinomas

PrgmNr 2375 The landscape and clinical relevance of somatic mutations in a cohort of patients with myelodysplastic syndrome

PrgmNr 2377 Using single-cell transcriptomics to fit a multi-level computational model of cancer

PrgmNr 2379 WGTS insights in a cancer patient: a tale of two primaries

PrgmNr 2380 Whole-genome sequencing of phenotypically distinct inflammatory breast cancers reveals similar genomic alterations to non-inflammatory breast cancers

PrgmNr 2381 A phenome-wide association scan reveals novel associations between genetically increased blood lipid levels and the risk of cholelithiasis

PrgmNr 2382 Assessing the contribution of rare variants to human complex traits by whole-genome sequencing

PrgmNr 2383 Assessing the role of rare pathogenic variants in heart failure progression in the UK Biobank

PrgmNr 2384 Chromosome X Inactivation is associated with cardiovascular risk and monocyte abundance in an ageing cohort

PrgmNr 2385 Discovery of rare variants associated with resting heart rate

PrgmNr 2386 Epigenetics of Single and Multisite Atherosclerosis in African Americans from the Genetic Epidemiology Network of Arteriopathy (GENOA)

PrgmNr 2387 Estimating the causal effects of cardiometabolic factors on coronary artery disease in British Pakistanis and Bangladeshis: A trans-ancestry Mendelian Randomisation study

PrgmNr 2388 Exploring causal relationships between cardiometabolic traits and cancers using pathway-specific genetic instruments

PrgmNr 2389 Gene-SCOUT: gene-based biomarker signatures can assist identification of novel genes from phenome-wide association analyses

PrgmNr 2391 Polygenic risk and its interaction with lifestyle for cardiovascular mortality

PrgmNr 2392 Polygenic score from a large GWAS predicts cases of heart failure with reduced ejection fraction (HFrEF) but not preserved ejection fraction (HFpEF)

PrgmNr 2393 The impact of polyunsaturated fatty acids biosynthesis on the risk of cardiovascular diseases: A Mendelian randomization study in up to 1,153,768 European ancestry individuals

PrgmNr 2394 The transcriptional landscape of human atria and its role in atrial fibrillation: the RACE-V Consortium

PrgmNr 2395 A glomerular transcriptomic landscape of APOL1 in Black patients with focal segmental glomerulosclerosis

PrgmNr 2396 Assessment of the Genetic Risk Scoring Algorithm GRS2 for Type 1 Diabetes in African American Children

PrgmNr 2397 Causal association between circulating metabolites and age at menarche: A two-sample Mendelian randomization study

PrgmNr 2398 Discovery of Type 2 Diabetes genes using an accessible tissue

PrgmNr 2399 Evaluation of genetic prediction and differential expression of genes in non-alcoholic fatty liver disease (NAFLD)

PrgmNr 2400 Gene-based analyses in population based data identify MTTP as associated with nonalcoholic fatty liver disease

PrgmNr 2401 Genetics of osteopontin in patients with chronic kidney disease: the German Chronic Kidney Disease study

PrgmNr 2403 Mirror effects of OPRD1 variants on diabetes and obesity

PrgmNr 2404 Mutation Burden Analysis Reveal Genetic Differences between Obesity and non-Obesity Asthma patients in African American Population

PrgmNr 2405 N6-methyladenosine methylation regulatory genes modified the effect of APOL1 risk genotype on progression of chronic kidney disease

PrgmNr 2406 Random glucose GWAS in 493,036 individuals provides evidence for reduced lung function as a novel complication of type 2 diabetes

PrgmNr 2407 The association of fasting glucose with sweetened beverages consumption is greater in Latin Americans with a high polygenic risk score for type 2 diabetes mellitus

PrgmNr 2408 The genetic architecture of BMI in infancy and early childhood is characterized by age-specific effects and overlap with pathways involved in Mendelian obesity

PrgmNr 2410 Whole-exome sequencing study identifies rare and low-frequency coding variants associated with diabetic nephropathy

PrgmNr 2411 Defining the Regulatory Mechanism for Helios in Autoimmune Disease

PrgmNr 2412 Evaluate mitophagy/autophagy modulators and FDA-approved drugs to prevent or ameliorate the autoimmune, lipodystrophic and neurodegenerative phenotypes observed in Clec16a KO mice

PrgmNr 2413 Expanded genome-wide association study of IBD identifies novel loci and implicates new genes in disease susceptibility

PrgmNr 2414 Risk HLA alleles in South America and potential new epitopes for SARS-CoV2

PrgmNr 2415 SARS-CoV-2 as a trigger of autoimmune diseases: brazilian experience

PrgmNr 2416 Whole-exome sequencing of hundreds of microbiopsies reveals the somatic evolutionary landscape of psoriatic skin

PrgmNr 2417 A de novo paradigm for male infertility

PrgmNr 2418 Analysis of transcriptional changes associated with pubertal development

PrgmNr 2419 Construction of copy number variation map identifies small regions of overlap and candidate genes for atypical female genitalia

PrgmNr 2420 Genetic architecture of severe spermatogenic failure and male infertility: time to advance standard of care

PrgmNr 2421 Idiopathic hypogonadotropic hypogonadism in the Maltese island population: A spectrum of phenotypes and genotypes

PrgmNr 2422 Challenging diversity in precision medicine through large-scale exome sequencing and genome wide genotyping in South Asians: Analyses of quantitative red blood cell traits

PrgmNr 2423 Clonal myelopoiesis and risk of adverse events in chronic kidney disease

PrgmNr 2424 A Haptoglobin (HP) Exon Deletion Polymorphism Associates with Alzheimer's Disease Status with Stratification of APOEe4 Status

PrgmNr 2425 Deep learning-based feature extraction in neuroimaging genetics for Alzheimer's Disease

PrgmNr 2426 Evaluation of the role of common variant burden in the familial aggregation of epilepsy

PrgmNr 2427 Exploring genome wide association signals in mesial temporal lobe epilepsy

PrgmNr 2428 Investigating the contribution of common variants to neurodevelopmental disorders: Expression-modifying variants and polygenic scores

PrgmNr 2429 Mendelian Randomization analysis reveals a potential causal relationship for lipids in amyotrophic lateral sclerosis risk

PrgmNr 2430 Polygenic risk score in Multiple Sclerosis: understanding the challenges of the post-GWAS era for complex diseases

PrgmNr 2431 Whole genome sequencing association analysis of general cognitive function in a multi-ethnic sample from the Trans-Omics for Precision Medicine (TOPMed) Program

PrgmNr 2432 An IQ-matched genetic comparison between cases with ASD and typically-developing controls

PrgmNr 2433 Analysis of age- and sex-specific comorbidity patterns among brain disorders

PrgmNr 2434 Exome reanalysis of 242 Brazilian trios reveals NPAS3 as a new possible novel autism risk locus

PrgmNr 2435 Family-based whole-genome sequencing studies of psychiatric disorders in youth

PrgmNr 2436 Genome-wide rare variant score associates with morphological subtypes of Autism Spectrum Disorder

PrgmNr 2437 Integrating Brain Imaging Phenotypes, Genomics, and Substance Use

PrgmNr 2438 Interactions between variants in detoxification and permeability barrier genes and xenobiotics in Autism Spectrum Disorder

PrgmNr 2439 Polygenic scores for cortical and subcortical brain structures are associated with cognition

PrgmNr 2441 Trans-ancestry GWAS meta-analysis of alcohol and tobacco addiction in 3.4 million individuals

PrgmNr 2442 A genome-wide association study of Ménière disease in the UK Biobank cohort reveals one genome-wide significant locus and genetic correlation with mood/anxiety-related traits

PrgmNr 2443 A phenotype-driven machine-learning model to assess the pathogenicity of digenic variant combinations: a case study on ciliopathies

PrgmNr 2444 Associated anomalies in cases with oral clefts

PrgmNr 2445 Characteristics of keratoconus corneal epithelium in multi-omic approach

PrgmNr 2447 Extreme Expression Genotypes revealed regulatory effects on gene expression linked to traits and footprints of positive selection

PrgmNr 2448 From GWAS to GWANN: Genome Wide Artificial Neural Networks and the interpretability of non-coding associations

PrgmNr 2449 Fusion of multiplex whole-exome and low-depth whole-genome sequencing for cost-effective rare variant assessment in the genome-wide association studies

PrgmNr 2450 Genetically independent phenotype analysis identifies LPA and VCAM1 as drug targets for human ageing

PrgmNr 2451 Genome-wide investigation of the interplay between age-related hearing loss, tobacco smoking, and noise

PrgmNr 2452 Global Biobank Meta-Analysis Initiative: A genome-wide association meta-analysis identifies novel primary open-angle glaucoma loci and shared biology with vascular mechanisms

PrgmNr 2453 GWAS and ExWAS of blood Mitochondrial DNA copy number identifies 71 loci and highlights a potential causal role in dementia

PrgmNr 2454 Higher BMI causes lower odds of depression in individuals of East Asian Ancestry

PrgmNr 3157 Whole mitochondrial genome analysis of a single trophectoderm biopsy - heteroplasmy dynamics and selection in human embryos
PrgmNr 3158 TESLA: super-resolution Tumor Edge Structure and Lymphocyte multi-level Annotation from spatial transcriptoms
PrgmNr 3159 A fast and robust Bayesian nonparametric method for prediction of complex traits using summary statistics
PrgmNr 3160 A fresh look at the role of Hardy-Weinberg disequilibrium in association testing
PrgmNr 3161 A novel regression-based method for X-chromosome-inclusive Hardy-Weinberg equilibrium test
PrgmNr 3162 A sparse high-dimensional generalized varying coefficient model for identifying genetic variants associated with regional methylation
PrgmNr 3163 AFA Computationally efficient Ancestral Frequency estimation in Admixed populations: the Hispanic Community Health Study/Study of Latinos
PrgmNr 3164 Applying Recurrent Weighted Replanting to detect gene-gene interaction in case-parent trios
PrgmNr 3165 Approaches for detection of epistatic interactions of causal variants in genome-wide data: Comparison of Recurrent Weighted Replanting with other machine learning methods
PrgmNr 3166 Characterizing homozygous loss of function variants in 454,782 whole exome sequences from the UK Biobank
PrgmNr 3167 Conditional resampling improves calibration and sensitivity in single-cell CRISPR screen analysis
PrgmNr 3168 COVID19 symptoms vary by HLA haplogroup in a well typed crowd cohort
PrgmNr 3169 Deconvoluting sex-specific effects using GWAS summary statistics and biobank datasets across
PrgmNr 3170 Developing Trans-ethnic Polygenic Risk Scores Using Empirical Bayes and Super Learning Algorithm
PrgmNr 3171 Ethnicity-specific high-risk gene variant profiling unmasks diabetes associated genes
PrgmNr 3172 Exact and flexible, conditional and joint analysis of association summary statistics using linkage disequilibrium
PrgmNr 3173 Fast and scalable polygenic risk modeling with Variational Inference
PrgmNr 3174 Fine-mapping robustness in real data

PrgmNr 3175 Functional Response Regression Model on Correlated Longitudinal Microbiome Sequencing Data
PrgmNr 3176 Genealogical models of LD for Bayesian applications in GWAS
PrgmNr 3177 Genetic association analysis of a binary trait detects more than just the genetic effect: implications for pleiotropy and replication studies
PrgmNr 3178 GenoToolKit: A convenient and accessible R package for genetic data preparation and analysis
PrgmNr 3180 Novel Bayesian TWAS method using eQTL summary statistics
PrgmNr 3181 Polygenic risk prediction using gradient boosted trees captures non-linear genetic effects and allele interactions in complex phenotypes
PrgmNr 3182 Polygenic transcriptome risk scores improve cross-ethnic portability for COPD and lung function in the NHLBI Trans-Omics for Precision Medicine (TOPMed) Program
PrgmNr 3183 Predicting overweight and obese with genome-wide, epigenome-wide gene-gene and gene-diet interactions using machine learning
PrgmNr 3184 Prioritizing disease genes by integrating GWAS and WES with gene-level functional and perturbation data
PrgmNr 3185 Rare variant effect sizes are associated with variant pathogenicity
PrgmNr 3186 Reproducible analyses of petabytes of Heart Lung Blood and Sleep (HLBS) data in the cloud using NHLBI BioData Catalyst, the data analysis ecosystem for HLBS researchers
PrgmNr 3187 Single-cell allele-specific expression analysis and comparison using mixture models
PrgmNr 3188 Sister haplotype association based on recombination disequilibrium
PrgmNr 3189 SUMMIT: An integrative approach for better transcriptomic data imputation improves causal gene identification
PrgmNr 3192 TIGAR-V2: Efficient TWAS Tool with Nonparametric Bayesian eQTL Weights of 49 Tissue Types from GTEx V8
PrgmNr 3194 Trans-Ancestry Fine-Mapping using 3.4 Million Individuals from diverse ancestries elucidates the genetic architecture of tobacco and alcohol use and addiction
PrgmNr 3195 Using (Natural) Direct and Indirect Effects of Intermediate Risk Factors between Genotype and Disease to Inform Polygenic Risk Scores
PrgmNr 3196 Allele-specific expression of SNPs involved in the immune response and gene transcription is associated with BMI
PrgmNr 3197 Causal gene-to-trait effect estimation for schizophrenia and bipolar disorder using MRLocus
PrgmNr 3198 Common and rare genetic risk for autism have opposing effects on cognition at autism-associated genes
PrgmNr 3199 Comparing Gene Expression Across Paired Human Airway Models for Cystic Fibrosis Precision Medicine
PrgmNr 3200 Current methods integrating variant functional annotation scores have limited capacity to improve the power of genome-wide association studies
PrgmNr 3201 Determining disease co-occurrence architecture of Hypertensive Heart Disease in Penn Medicine Biobank using longitudinal EHR data linked with PMBB participants
PrgmNr 3202 Genome-wide association study and heritability of Gulf War illness
PrgmNr 3203 Genome-wide study on longitudinal MRI outcomes in 3,513 multiple sclerosis cases across six clinical trials highlights a potential role for MS susceptibility loci in progressive biology
PrgmNr 3204 High quality phased whole genome sequence across patient cohorts is achievable and informs genetic understanding of complex traits
PrgmNr 3205 Leveraging Genetics and Genomics Data to Identify Potential Transcriptional Pathways of Body Mass Index: The Framingham Heart Study
PrgmNr 3206 Major sex differences in allele frequency for X-chromosome variants in the 1000 Genomes phase 3 data
PrgmNr 3207 Maternal and parent-of-origin gene-environment effects on the etiology of orofacial clefting

PrgmNr 3208 Mining biopsychosocial attributes in major depressive disorder by a multi-modal latent topic model

PrgmNr 3209 Patterns of consanguinity and associations between autozygosity and clinical phenotypes in British South Asians

PrgmNr 3210 Prioritizing risk factors of heart failure from UK Biobank using explainable artificial intelligence

PrgmNr 3211 Stability of polygenic scores across discovery genome-wide association studies

PrgmNr 3212 Systematic Comparisons for Composition Profiles Taxonomic Levels and Machine Learning Methods for Microbiome based Disease Prediction

PrgmNr 3213 Two large-scale genome sequencing studies show a consistent association between mitochondrial DNA copy number and personality traits

PrgmNr 3214 Unexpected somatic mosaicism and reduced penetrance: NF1 pathogenic variants are found in 1 in 850 individuals

PrgmNr 3215 Variants in nicotinic acetylcholine receptor and dopaminergic genes in relation to smoking relapse and proportion of time in relapse throughout adulthood in female nurses

PrgmNr 3216 NUDT15 Variants Associated with Thiopurine Toxicity in 1,643 Pediatric Leukemia Patients

PrgmNr 3217 A case report of rare t(8;22)(p11.2;q13) positive AML

PrgmNr 3218 A case study of AML in a patient with an additional RUNX1T1 signal and a loss of one 3' CBFB signal in 88% of the nuclei examined

PrgmNr 3219 A rare inv(14)(q11.2q32.3) in Acute Lymphoblastic Leukemia

PrgmNr 3220 Does it make sense to report single pathogenic alleles in cancer susceptibility genes for childhood cancer patients? Results from the BASIC3 and Texas KidsCanSeq studies

PrgmNr 3221 Heterogeneity in cytological presentation of gene amplification and concurrent amplification of MYC and PVT1 in therapy related acute myeloid leukemia (AML)

PrgmNr 3222 Imputing missing genotypes and examining rare genetic variants in families with high risk of lung cancer

PrgmNr 3223 Serial cytogenetic studies showing evolution of trisomy 8 positive CMML to AML with a complex karyotype characterized by deletion 7q and a jumping 1q translocation without evidence of trisomy 8

PrgmNr 3224 Somatic Mutation Profiling of Basal Cell Carcinoma in a Population Exposed to Arsenic

PrgmNr 3225 The g-quadruplex stabilizing agent GQC-05 inhibits LINE-1 retroelement activity in human bronchial epithelial cells

PrgmNr 3226 Underutilization of germline testing for prostate cancer patients: Are genetic testing criteria a tool or an obstacle?

PrgmNr 3227 Age-specific transcriptional risk scores (TRS) link GWAS to eQTLs and predict therapeutic response across 8 common cancer types

PrgmNr 3228 Broadly pleiotropic effects of pathogenic variants in tumor suppressor CHEK2

PrgmNr 3229 Genome-wide interaction analysis identified low-frequency variants with sex disparity in lung cancer risk

PrgmNr 3230 GWAS of Uveal Melanoma Reveals Novel Genome Wide Significant Locus

PrgmNr 3231 Predicted gene expression identifies novel genes associated with lung cancer in African Americans

PrgmNr 3232 SNPs at SMG7 associated with time from biochemical recurrence to prostate cancer death

PrgmNr 3233 Cisplatin induced gene expression across three different cancer cell line types reveal common and distinct molecular regulatory effects

PrgmNr 3234 Computational evidence of BRCA1-NC3 receptor interaction and druggability analysis in BRCA1-related oncogenesis

PrgmNr 3235 Identifying functional melanoma risk variants and susceptibility genes via massively parallel reporter assays and multi-QTL in normal melanocytes and malignant melanomas

PrgmNr 3236 A deep learning approach for efficiently incorporating genomic data into ovarian cancer prognosis prediction

PrgmNr 3237 An improved approach leveraging MRI and genomic information for classification and segmentation of glioma lesions
PrgmNr 3238 Analyses of breast cancer microbiome data
PrgmNr 3239 Building multi-omics classifier to improve phenotype prediction in heterogeneous cancer data
PrgmNr 3240 Characterization and prediction of DNA methylation instability across human cancers
PrgmNr 3241 Diagnosing Li-Fraumeni syndrome from the somatic genome
PrgmNr 3242 Epigenomic landscape and 3D genome structure in pediatric high-grade glioma
PrgmNr 3243 MDC1 restrains ATR-mediated resection of DNA double-strand breaks in human cells
PrgmNr 3244 Single cell transcriptome analysis maps aneuploidy to mesenchymal phenotypes during thyroid cancer progression
PrgmNr 3245 Statistical analysis of breast cancer co-methylation patterns
PrgmNr 3246 Subtype-associated epigenomic landscape and 3D genome structure in bladder cancer
PrgmNr 3247 Survival analysis and evaluation of germline genomic patterns across multiple cancers using boosted trees and model interpretability
PrgmNr 3248 The clinical impact of somatic variants in AGT, MGMT and TP53 in Mexican patients with astrocytoma
PrgmNr 3249 Tumor spectrum of FLCN gene mutation carriers in an unselected pan-cancer patient population
PrgmNr 3250 Up-regulation of chromatin remodeling genes contributes to chemoresistance and tumorigenesis in PDAC
PrgmNr 3251 Assessment of population-appropriate polygenic risk scores for lipid traits in African Americans
PrgmNr 3252 Bivariate genome-wide association study of circulating fibrinogen and C-reactive protein (CRP) levels
PrgmNr 3253 Blood Pressure Polygenic Score Associations in a Pediatric Cohort Requiring Surgery for Congenital Heart Defects
PrgmNr 3254 Detecting blood-pressure regulatory mechanisms with tissue specific CRE maps and biobank scale datasets
PrgmNr 3255 Epigenetic age acceleration predicts subclinical atherosclerosis among participants of the Bogalusa Heart Study
PrgmNr 3257 Identification of genetic variants that confer susceptibility to familial combined hyperlipidemia
PrgmNr 3258 Phenotypic features of TGFB3 disease-causing variants in a group of North Americans
PrgmNr 3259 Polygenic risk for atrial fibrillation across ancestry: the Electronic Medical Records and Genomics (eMERGE) Network
PrgmNr 3260 Polygenic risk score for coronary artery disease worsens disparity by HIV status in clinical prediction of coronary artery calcium
PrgmNr 3261 The genetic determinants of body mass index & fasting glucose are mediators of grade 1 diastolic dysfunction development
PrgmNr 3262 The genetics of coronary artery calcification in individuals with type 2 diabetes
PrgmNr 3263 An exposome-wide association study (ExWAS) and comparison of clinical, environmental and polygenic risk scores for Type 2 Diabetes
PrgmNr 3264 Assessment of Polygenic Risk Score for Predicting Type 2 Diabetes Risk in Asian Indians: Results of the Asian Indian Diabetic Heart Study/Sikh Diabetes Study
PrgmNr 3265 Do methods of inclusion and presentation of non-European ancestry data in GWAS allow for novel discoveries?
PrgmNr 3266 Expanded Genetic Clustering of Type 2 Diabetes Loci Using a High-throughput Pipeline Reveals Mechanistic Pathways of Metabolic Diseases
PrgmNr 3267 Genetic Regulation of Obesity Explains Cardiovascular Sex Differences in Polycystic Ovary Syndrome for Predisposed Individuals
PrgmNr 3268 Genotype-Phenotype Analysis in African Americans with Inflammatory Bowel Disease

PrgmNr 3269 Identification of hepatocellular gene expression phenotypes influencing fatty liver disease in Hispanics

PrgmNr 3270 Investigating the Causal Role of Reduced Vitamin D Levels With Type 2 Diabetes Risk in South Asians and Europeans

PrgmNr 3271 Pediatrics and proteins: Molecular discovery in the Hearts & Parks study of children with obesity

PrgmNr 3272 Phenome-wide investigation of health outcomes associated with the genetic correlates of 25 hydroxyvitamin D concentration

PrgmNr 3274 Rare variants associated with serum creatinine in 350k UK Biobank whole exome sequences

PrgmNr 3275 The effect of obesity-related traits on COVID-19 severe respiratory symptoms and hospitalization and its mediation by socioeconomic status: a multivariable Mendelian randomization study

PrgmNr 3276 Whole exome sequencing analyses of BMI and obesity in a multi-ancestry cohort of > 300,000 individuals

PrgmNr 3277 Whole Genome Sequence Analysis of Dyspnea in Current and Former Smokers in COPDGene

PrgmNr 3278 Association of CXCR6 with COVID-19 severity: host genetic factors underlying transcriptomic regulation in 3p21.31 locus

PrgmNr 3279 Asthma-associated genetic variants induce IL33 differential expression through a novel regulatory region

PrgmNr 3280 Complex Architecture of COVID-19 Host Genetics from Whole Genome Sequencing of a Multi-Ethnic Hospitalized Cohort

PrgmNr 3281 Fine-mapping studies distinguish genetic risks for childhood- and adult-onset asthma in the HLA Region

PrgmNr 3282 Infinity Biologix - A Biorepository Answers the Call and Becomes a Leading COVID-19 Assay Development and Testing Center

PrgmNr 3283 Integrative analysis of DNase-I footprinting and genome-wide association data uncovers transcription factors involved in nine autoimmune diseases

PrgmNr 3284 MHC class II alleles are associated with rare dermatologic autoimmune diseases in an analysis of over 200,000 participants of the UK Biobank

PrgmNr 3285 mRNA expression analysis reveals degenerative phenotype and immune cell infiltration in spleen, thymus and pancreas of Clec16a knockout (KO) mice

PrgmNr 3286 Role of theFYVE and Coiled-Coil Domain Autophagy Adaptor 1 in severity of COVID-19 infection

PrgmNr 3287 The long-term effect of SARS-CoV-2 infection on host genetic regulation

PrgmNr 3288 Trans-ethnic association analysis of HIV viral load and Chromosome X markers in individuals living with HIV

PrgmNr 3289 Whole-genome sequencing association study reveals methylation-mediated genotype association with decreased lung function in urban children

PrgmNr 3290 APOL1 and biobanking in the West African terrain-challenges and successes

PrgmNr 3291 A Myasthenia Gravis genomewide association study implicates AGRN as a risk locus

PrgmNr 3292 Cognitive trajectories diverge by genetic risk in the Wisconsin Registry for Alzheimer's Prevention

PrgmNr 3293 Concordance of genetic variation that affects neuroinflammatory biomarkers for Alzheimer's disease and that influences brain volumes

PrgmNr 3294 Creating sex-specific phenome risk classifiers to identify under-documented cases of developmental stuttering in electronic health records

PrgmNr 3295 Genetic correlations between resilience and UK Biobank traits differ by biological sex

PrgmNr 3296 Genetic variants in the SHISA6 gene are associated with delayed cognitive impairment in two family datasets

PrgmNr 3297 Genomic and Transcriptomic-wide Analysis Identifies Novel Genetic Risk Loci and Prioritization of Therapies for Myasthenia Gravis

PrgmNr 3298 Identification of novel genetic associations of epilepsy with functional validation in a zebrafish model

PrgmNr 3299 Linkage and association of cognitive resilience to chromosomes 4 and 18 in Midwestern Amish

PrgmNr 3300 Measuring similarities and differences between EOAD and LOAD trough genome-wide association study, colocalization and heritability analysis

PrgmNr 3301 APOE gene associated with dementia related disorders and neuropsychiatric diseases in the Hispanic population

PrgmNr 3302 Association between polygenic risk for substance use and music engagement across multiple cohorts

PrgmNr 3303 Dimensional traits in genetic research of autism show greater heritability and generalization than case-control traits

PrgmNr 3304 Identify high risk individuals for Alcohol use disorder using polygenic risk scores

PrgmNr 3305 Identifying potential environmental influences on clinical comorbidities of schizophrenia through integration of electronic health data and genetics

PrgmNr 3306 Investigating shared genetic liability between recurrent major depression and cardiometabolic traits in East Asian populations

PrgmNr 3307 Pilot targeted gene analysis of resting heart rate variability in individuals with anxiety disorders and healthy controls

PrgmNr 3308 Targeted sequencing of genes most likely to harbor rare causal variants in schizophrenia

PrgmNr 3309 MS4A gene cluster variant modifies CSF sTREM2 associations with AD biomarkers of pathology

PrgmNr 3310 Analysis of genome-wide associations, exposome and lifestyle factors of skin-aging using medical proxies in the UK BioBank

PrgmNr 3311 Associated phenotypic and genotypic characteristics in a cohort of patients with infantile hemangiomas: a case series

PrgmNr 3312 Association of whole-person polygenic component scores with Alzheimer's disease pathology

PrgmNr 3313 Candidate causal variants affecting tissue-specific regulatory mechanisms in the GWAS catalog

PrgmNr 3314 Curated catalog of 309 functional GWAS non-coding variants across 125 diseases: a systematic review

PrgmNr 3315 Determining the Genetic risk of Complex Disorders in Global populations

PrgmNr 3316 DNA-methylation quantitative trait loci in Asian populations

PrgmNr 3320 Genomic approaches to identify shared genetic architecture among comorbid phenomes of eye disease

PrgmNr 3321 Individual Imputation of Genetically Regulated Gene Expression in the Million Veteran Program

PrgmNr 3322 Investigation of a complex phenotype involving craniosynostosis and cataracts leads to identification of a novel mutation related to Galactosemia type II

PrgmNr 3323 Modeling the longitudinal changes of ancestry diversity in the MVP cohort: systematic comparison of methods

PrgmNr 3324 Novel Osteoarthritis Genetic Variants Identified using Multi-Ancestry Analyses from 473,388 Participants in the MVP and the UK Biobank

PrgmNr 3325 Novel phenotyping approaches: Empirical Bayes methods improve heritability of dietary phenotypes from repeat diet questionnaire data

PrgmNr 3327 Programming biobank-scale relatedness analysis improvements

PrgmNr 3328 Reanalysis of exome data via Diagnosticator identifies significant variant reclassification with updated ClinGen SVI-WG recommendations
PrgmNr 3329 Study of over one million people finds that novel and previously reported familial genetic effects impact stuttering risk at a population-level
PrgmNr 3330 The contribution of common versus low-frequency variation to hearing loss heritability
PrgmNr 3331 Transcriptome-wide association study and eQTL colocalization identify potentially causal genes responsible for bone mineral density GWAS associations
PrgmNr 3332 Whole-exome sequencing of a family with specific language impairment suggests BUD13 as a novel SLI candidate gene
PrgmNr 3333 Year of birth and polygenic scores in the Electronic Health Records
PrgmNr 3334 A global transcriptomic approach reveals sex-specific differences in a middle-aged frailty cohort
PrgmNr 3335 A single cell chromatin accessible and transcriptome atlas of the human heart facilitates identification of risk variants and genes of Atrial Fibrillation
PrgmNr 3336 Blood-based differential DNA methylation and gene expression at the TREM locus in mild traumatic brain injury and Alzheimer's disease
PrgmNr 3337 Comparing gene expression imputation resources in a diverse Latin American Parkinson's disease cohort
PrgmNr 3338 Cross-omics analysis of DNA methylation and gene expression in post-mortem 41 brain tissues of opioid use disorder patients and controls
PrgmNr 3339 Identifying and characterizing superhypomethylation in head and neck cancer: drivers and transcriptional effects
PrgmNr 3340 Integrative meta-analysis of blood and brain epigenome-wide association studies of Alzheimer's disease
PrgmNr 3341 Methylation Profiling using Reduced Representation Bisulfite Sequencing for Basal Cell Carcinoma in a Population Exposed to Arsenic
PrgmNr 3342 Methylome-Wide Association Study Identifies Candidate DMRs for Carotid Bifurcation Intima-Media Thickness in Dominican Republic Families
PrgmNr 3344 PTSD, major depression, and advanced transcriptomic age in neural tissue
PrgmNr 3345 Role of differential DNA methylation in Mexican Americans & their risk for Alzheimer's disease & type 2 diabetes
PrgmNr 3348 Transcriptomic and epigenomic signatures associated with autoimmunity in Parkinson's Disease
PrgmNr 3349 A cryptic splice acceptor as a cause of X-linked heterotaxy
PrgmNr 3350 Adipose eQTL meta-analysis of 2,256 samples identifies 517 conditionally distinct signals colocalized with 426 cardiometabolic trait GWAS loci
PrgmNr 3351 Characterization of neonatal epigenetic markers associated with elevated stress from the COVID-19 pandemic
PrgmNr 3352 Defining the effects of noncoding genetic variation on human regulatory element activity
PrgmNr 3353 DNA-binding consequences of human homeodomain missense variants
PrgmNr 3354 Genome-wide association studies identify novel genetic loci for epigenetic age acceleration among survivors of childhood cancer
PrgmNr 3355 Genome-wide detection of enhancer-hijacking and reconstructing complex SVs in cancer genome
PrgmNr 3356 Automated localization and quantification of RNA transcripts from RNA-fluorescent in situ hybridization imaging data
PrgmNr 3357 Deep Learning Study to Predict Ribosome Binding from RNA-seq Data
PrgmNr 3358 Interpreting Epigenetic Aging with Deep Neural Networks Using High Dimensional DNA Methylation Data
PrgmNr 3359 Investigating the utility of sex-informed PrediXcan models in whole blood
PrgmNr 3360 A site-specific mutation rate model uncovers signatures of localized hypermutability

PrgmNr 3361 Assessment of the rates of pathogenic variants across the All of Us Research Program cohort

PrgmNr 3362 Cataloging human PRDM9 allelic variation using long-read sequencing reveals PRDM9 population-specificity and two distinct groupings of related alleles

PrgmNr 3363 Characterization of the Evolutionary Forces Acting on Genomic Regions Associated with over 600 Human Complex Traits

PrgmNr 3364 Core promoter similarity in ancient and modern human and in chimpanzee genomes

PrgmNr 3365 Estimating average height among populations from polygenic risk scores

PrgmNr 3366 FastRecomb: Fast inference of genetic recombination rates in biobank scale data using positional Burrows Wheeler transform

PrgmNr 3367 Flexible, scalable inference with tree sequences and Pyro

PrgmNr 3368 Guaranteeing unbiasedness in selection tests based on polygenic scores

PrgmNr 3369 GWAS on birth year infant mortality rates provides new evidence of recent natural selection

PrgmNr 3370 Increasing Portability of Predictive Gene Expression Models Across Ancestral Populations Using Genetic Variant Fixation Indices

PrgmNr 3372 The genetic diversity reduction due to background selection increases the disease prevalence under the liability threshold model

PrgmNr 3373 A comprehensive genomic test report for communicating cancer and incidental findings

PrgmNr 3374 A novel model for the management of clinically relevant incidental findings

PrgmNr 3375 Addressing the Direct-to-Consumer Genetic Testing Knowledge Gap for Non-Genetics Healthcare Professionals

PrgmNr 3376 BorderDNA Resources Project: Strategies for the development and disseminationof educational materials on nonmedical DNA applications in immigration contexts

PrgmNr 3377 Evaluation of genetic services in the care for adults with tetralogy of Fallot

PrgmNr 3378 Exploring the Use of Family Health History in Black Communities in the Deep South

PrgmNr 3379 Genetic service provision for men with prostate cancer within a safety-net setting: A qualitative study

PrgmNr 3380 Genetic-first diagnoses and disease predispositions: Implications for follow-up care

PrgmNr 3381 Grandmothers save the day: The power of grandmothers to improve care of families with history of cardiomyopathy

PrgmNr 3382 Integrating Ethical, Legal, and Social Implications (ELSI) considerations in the All of Us Research Program:Experiences of the ELSI Brain Trust

PrgmNr 3383 Measuring genetic literacy through familiarity, skills, and knowledge: A longitudinal assessment

PrgmNr 3384 Patient perspective on return of incidental findings in Africa

PrgmNr 3385 Patients demonstrate high motivation to enhanced cancer screening following genetic counselling

PrgmNr 3386 Recruitment of diverse participants into a trial of polygenic risk scoring: Enrollment metrics and reasons for decline in the Genomic Medicine at VA (GenoVA) Study

PrgmNr 3388 Should laboratories report small regions of homozygosity?

PrgmNr 3389 Strategies to increase clinicians in medical genetics: Establishing a pipeline to attract and prepare diverse clinical researchers

PrgmNr 3390 The Texome Project: Special considerations for developing a rare and undiagnosed disease program for underserved communities in Texas

PrgmNr 3392 Uptake of cancer risk management strategies among women who undergo cascade genetic testing for breast cancer susceptibility: How do they compare to non-cascade testers?

PrgmNr 3393 Colchicine: A Potential Therapy for the HSPB8-related Rimmed Vacuole Myopathy

PrgmNr 3394 Genome-wide integration assay for rAAV mediated homologous recombination (HR) in human hepatocytes demonstrated precision of in vivo gene editing approach

PrgmNr 3395 A New Paradigm for Coordinate-Based, Multipanel Genomic Plotting in R

PrgmNr 3396 All of Us Researcher Workbench: Bringing Researchers to Genomics Data

PrgmNr 3397 Annotation of genetic variation in 5134 cystic fibrosis cases with OpenCRAVAT and VEP

PrgmNr 3398 FusionGDB 2.0, fusion gene annotation update aided by deep learning

PrgmNr 3400 Genomics4RD: An integrated platform to share Canadian deep-phenotype and variant level data for international rare disease gene discovery

PrgmNr 3401 HGRepo - A comprehensive repository of clinical, lab assay, and genetic data for studies of innate and adaptive immune responses during acute COVID-19 infection and convalescence

PrgmNr 3402 New genomic data deposited in dbGaP cross-referenced against NINDS Repository Tourette Syndrome biospecimens

PrgmNr 3403 A Finnish-enriched functional DNA variant in an enhancer for IRF6 is associated with cleft palate

PrgmNr 3404 Analysis of genetic investigations in newborns with VACTERL spectrum of malformations

PrgmNr 3405 Biallelic variants in KARS1 are associated with neurodevelopmental disorders and hearing loss recapitulated by the knockout zebrafish

PrgmNr 3406 Congenital heart defects caused by FOXJ1

PrgmNr 3407 Loss of Zic3 impairs planar cell polarity leading to abnormal left-right signaling and heart defects

PrgmNr 3408 Novel pathogenic variants, evidence for involvement of DVL2, and quantitative phenotypic analyses of Robinow syndrome: WNT signaling perturbation and phenotypic variability

PrgmNr 3409 De novo TNPO2 variants are associated with developmental delays, neurological issues and dysmorphic features in humans and alter TNPO2 activity in Drosophila

PrgmNr 3410 De novo damaging variants in the microRNA processor DROSHA are associated with a severe progressive neurological disorder

PrgmNr 3411 De novo variant in MRTF-B is associated with intellectual disability, minor dysmorphic features, expressive language delay, impulse control issues, and fine motor delay

PrgmNr 3412 SLC6A1 Portal: Genetic variant analysis and educational resource for SLC6A1-related disorders

PrgmNr 3414 A novel de novo variant in PPP2CA affecting the 5'UTR region causes a syndrome characterized by global developmental delay with specific structural brain abnormalities, congenital microcephaly and dysmorphic features

PrgmNr 3415 Allelic frequency and distribution of M98Kvariant associated with adult-onset open angle glaucoma in Puerto Rico

PrgmNr 3416 An integrated machine learning and functional analysis approach for resolution of variants of uncertain significance (VUS) inSTXBP1

PrgmNr 3417 Biallelic NAV2 truncating variants cause a neurodevelopmental disorder with cerebellar cortical dysplasia

PrgmNr 3418 Delineation of a neurodevelopmental syndrome caused by PAX5 haploinsufficiency

PrgmNr 3419 Diagnostic rate and clinical implications of exome sequencing in adults with intellectual disability

PrgmNr 3420 Expanding the Genotypic and Phenotypic Spectrum of CTCF-Related Disorders: 19 new patients andreviews of published literature

PrgmNr 3421 Expanding the phenotypic spectrum of EXOSC8-related neurological disease: Presentation of an Egyptian family with neurodevelopmental disorder due to a novel EXOSC8 missense variant

PrgmNr 3422 Genetic heterogeneity in SARS2 gene in a patient with global developmental delay and spastic paraplegia

PrgmNr 3423 Genomics of early onset CNS autoimmune demyelinating diseases: Role for deleterious, rare variants in common immune pathways

PrgmNr 3424 Identifying variant specific phenotypes for SLC6A1 related disorders

PrgmNr 3425 KBG Syndrome: Prospective Videoconferencing and Use of AI Facial Recognition in 25 new patients

PrgmNr 3426 Loss of function variants in PUS7 dysregulate protein synthesis and are associated with neurodevelopmental delay, microcephaly, and hyperuricemia

PrgmNr 3427 Maternal mosaicism for a missense variant in the SMS gene that causes Snyder-Robinson syndrome

PrgmNr 3428 Novel PRUNE1 A (p.Thr311=) synonymous splice variant induces exon 7 skipping and leads to an atypical presentation of NMIHBA syndrome: Case report and review of the literature

PrgmNr 3429 Role of VRK1 defects in spinal muscular atrophies like patients with negative SMN1 finding

PrgmNr 3430 Role of exome testing in autism spectrum disorder

PrgmNr 3431 The phenotypic trajectory of 16p12.1 deletion is determined by family history of disease

PrgmNr 3432 The Use of Acetazolamide for Apneic Episodes in a Patient with EEF1A2 Mutation: A Case Report

PrgmNr 3433 Triple knockout ofFmr1,Fxr1andFxr2in Purkinje neurons results in mild behavioral phenotypes and a dramatic reduction of testis weight

PrgmNr 3434 Variation of Serum Metabolome and Exosomal Transcriptome in Acute Ischemic Stroke: Results of the Metabolome in Ischemic Stroke Study (MISS)

PrgmNr 3435 A heterozygous gain-of-function variant in KIF5B causes osteogenesis imperfecta by disrupting the Golgi-primary cilia axis

PrgmNr 3436 Biallelic variants in LDB3: A new inheritance pattern for an old cardiomyopathy gene

PrgmNr 3437 Combined PMM2-CDG and hereditary fructose intolerance in a child with mild clinical presentation: a case report

PrgmNr 3438 Implementing genome and transcriptome sequencing methods to improve the diagnosis of Mendelian myopathies

PrgmNr 3439 Intravenous fish oil emulsion and fatty acid profiles

PrgmNr 3440 Lessons learned from a severe Isovaleric acidemia (IVA) patient from hyperammonemia

PrgmNr 3441 Mutational spectrum in a sample of mexican patients with Hunter syndrome

PrgmNr 3442 Mutations in COL5A1 lead to heritable thoracic aortic disease

PrgmNr 3443 Oculocutaneous Albinism: Compound heterozygote genotype-phenotype correlation

PrgmNr 3444 Sengers syndrome: Novel pathogenic variant in the AGK gene and analysis of phenotypic variability and clinical outcomes

PrgmNr 3445 Whole genome sequencing of mitochondria: A powerful tool for clinical diagnosis of human mitochondria diseases

PrgmNr 3446 EFEMP1 rare variants cause juvenile-onset open angle glaucoma in families from the Philippines

PrgmNr 3447 FOXP1 haploinsufficiency contributes to the development of congenital diaphragmatic hernia

PrgmNr 3448 A multidisciplinary nephrogenetic referral clinic for children and adults - diagnostic achievements and insights

PrgmNr 3449 Carrier Prevalence of 302 genetic diseases in the Mexican Jewish Community

PrgmNr 3450 Congenital diarrhea is a common cause of neonatal crisis and up to ~60% of cases among neonates may be inherited

PrgmNr 3451 Diagnostic rate of clinical exome sequencing for CAKUT phenotypes

PrgmNr 3452 Exome sequencing further implicates disruption of the NODAL signaling pathway in laterality defects

PrgmNr 3453 Identifying susceptibility genes for congenital diaphragmatic hernia (CDH) using a machine learning algorithm

PrgmNr 3454 Increased Expression of ZFPM2 Bypasses SRY to Drive 46,XX Testicular Development: A New Mechanism of 46,XX DSD

PrgmNr 3455 Patient with novel compound heterozygous variants in NCKAP1L presents Immunodeficiency 72 with autoinflammation and novel features

PrgmNr 3456 Precision medicine models for undiagnosed and rare disease

PrgmNr 3457 Rapid CRISPR/Cas9-based method for functional validation of human disease genes

PrgmNr 3458 Refined SNP haplotype analysis uncovers a potential founder deletion mutation in the Cerebral Cavernous Malformations 2 gene

PrgmNr 3459 Significant burden of de novo damaging variants in novel genes in patients with congenital kidney malformations

PrgmNr 3460 Complex congenital heart defect in a patient with a pathogenic mutation of TLK2 gene: Coincidental findings or part of the phenotype of TLK2 syndrome?

PrgmNr 3461 Partial trisomy of 8q and partial monosomy of 10q as a result of unbalanced translocation in an infant with multiple congenital anomalies - A Case Report

PrgmNr 3462 A rapid and low cost NGS-based cytogenomics platform using proximity ligation technology

PrgmNr 3463 A Retrospective Review of Dominant Variants Identified from the HorizonTM Carrier Screening Test

PrgmNr 3464 Contiguous domains of differentially-accessible, single copy sequences along metaphase chromosomes are conserved among multiple tissues

PrgmNr 3465 Detection of near constitutional genome-wide uniparental disomy in a patient presenting with Beckwith-Wiedemann syndrome and cholestasis

PrgmNr 3466 Inverted genomic triplication structures: two breakpoint junctions, several possibilities

PrgmNr 3467 Library preparation for DNAseq: The next generation of automation

PrgmNr 3468 A novel intragenic deletion removing the secondary coiled-coil (CC2) domain of SOX6 in a patient with neurodevelopmental disorder

PrgmNr 3469 Analysis of single nucleus sequencing in rat amygdala reveals transcriptional and regulatory mechanisms associated with vulnerability to cocaine addiction

PrgmNr 3470 Arimoclomol's effects on Rimmed Vacuole myopathy caused by HSPB8 gene mutation

PrgmNr 3471 Characterization of APOE Christchurch carriers in 239,390 participants of the UK Biobank with whole exome and/or whole genome sequencing data

PrgmNr 3472 Drosophila functional screening of de novo variants in autism uncovers deleterious variants and facilitates discovery of rare neurodevelopmental diseases

PrgmNr 3473 Evaluation of chromosomal copy numbers in the 5'UTR of MBD5

PrgmNr 3474 Functional characterization of 400 acid α-glucosidase variants and analysis of phenotype-genotype relationships in Pompe disease

PrgmNr 3475 Genetic regulation of gene co-expression in human prefrontal cortex

PrgmNr 3476 Identifying novel evolutionarily conserved regulators of dopamine metabolism using a forward genetic screen in Drosophila melanogaster

PrgmNr 3477 Interrogating strategies to link CRISPR screens to neurodegenerative disease

PrgmNr 3478 Lessons learned from genomics studies of a large recessive NDD cohort: High prevalence of multilocus pathogenic variation, candidate novel genes, and extreme genetic heterogeneity

PrgmNr 3480 Molecular Dynamics Simulations and Markov State Models Reveal Metastable States and Isoform-Dependent Kinetics in Apolipoprotein E Risk and Resilience Alleles

PrgmNr 3481 Mutations Near the N- or C-Terminus of AHDC1 are Associated with More Mild Xia-Gibbs Syndrome Phenotypes

PrgmNr 3482 Personalized structural biology reveals the molecular mechanisms underlying heterogeneous epileptic phenotypes caused by de novo KCNC2 variants

PrgmNr 3483 MPDZ, a potential causal gene for the bone mineral density association at chromosome locus 9p23, regulates in vitro osteoblast function and in vivo bone mass accrual

PrgmNr 3484 A Novel Role for HAPLN1 in Skeletal Development

PrgmNr 3485 A SNP associated with risk for non-syndromic orofacial cleft affects expression of FOXE1 in an oral epithelium cell line

PrgmNr 3486 Clinical application of long-read sequencing technology for unsolved cases of neurodevelopmental disorders

PrgmNr 3487 Functional interpretation of TAB2 missense variants

PrgmNr 3488 Germline variation in the human immunoglobulin heavy chain locus contributes to inter-individual variability in the expressed antibody repertoire

PrgmNr 3489 High Throughput Trafficking Assay Identifies Novel Loss and Gain of Function Variants in the Potassium Channel Gene KCNE1

PrgmNr 3491 Hyperproliferative lymphatic sprouting caused by an NRAS mutation can be rescued by targeting PI3K/AKT and RAS/MAPK signaling pathways in cell-based modeling systems

PrgmNr 3492 Seeking answers for ocular disease: Characterizing intronic variants of uncertain significance using a minigene system

PrgmNr 3493 Single-cell RNA sequencing of red and black melanocytes uncovers new pathways in pigmentation and disease

PrgmNr 3494 A computational approach for detecting physiological homogeneity in the midst of genetic heterogeneity

PrgmNr 3495 A statistical analysis framework to test the presence of allelic imbalance from a genomic region using allelic count data

PrgmNr 3496 Assessing Short-Read Utility for SVs

PrgmNr 3497 Copy-Number Variation of CTCF Binding Sites Associates with Diverse Clinical Phenotypes

PrgmNr 3498 Evaluation of long-reads across challenging medical relevant genes and its implications for All of Us

PrgmNr 3499 Framework and analysis of cell-specific expression contributions to Mendelian Disease

PrgmNr 3500 Haplotype resolved LPA and Kringle repeats to study minorities across the USA

PrgmNr 3501 Identification of allele-specific KIV-2 repeats among multi-ethnic groups and association with LP(a) measurements

PrgmNr 3502 Knowledge based artificial intelligence for variant pathogenicity prediction for Mendelian disorders

PrgmNr 3503 MetaRNN: Differentiating rare pathogenic and rare benign missense SNVs and InDels using deep learning

PrgmNr 3504 Participation of rs9138 and rs1126616 of SPP1 gene in gender-specific predisposition in the development of systemic lupus erythematosus

PrgmNr 3505 Polygenic enrichment distinguishes disease associations of individual cells in single-cell RNA-seq data

PrgmNr 3506 Resolving the landscape of human genetic variation at the protein domain level using 454,803 exomes from the UK Biobank

PrgmNr 3507 The Genetic Architecture of Genome-scale Metabolic Networks

PrgmNr 3508 The structural landscape of constrained sites in the human proteome

PrgmNr 3509 Transposable element mediated rearrangements are prevalent in human genomes

PrgmNr 3510 Ultra-fast genome-wide association analysis for Alzheimer's Disease in 200,000 exomes from UK Biobank

PrgmNr 3511 Unique Sequence Detection: a novel variant genotyper spanning the full spectrum of genetic variants

PrgmNr 3512 Analysis of concordance of genetic variants across sample types

PrgmNr 3513 Automating Illumina RNA Prep With Enrichment Using Beckman Coulter i7 Hybrid Automated Workstation

PrgmNr 3514 Automating Twist Bioscience Modular Library Preparation and Targeted Enrichment Protocols Using Beckman Coulter Automation

PrgmNr 3515 Automation of NGS library preparation: Generate high quality libraries with less hands-on time

PrgmNr 3516 Germline and somatic protein quantitative trait loci from the tumor proteome in high grade serous ovarian cancer identify candidate biomarkers and connections between germline risk and disease biology

PrgmNr 3517 Impact of DNA contaminants on next-generation library preparation

PrgmNr 3518 Integrated multi-omics analysis of thyroid cancer reveals key molecular pathways involved in tumor formation and metastasis

PrgmNr 3519 Mitigating effects of blood disease pathologies that compromise specificity of gene expression signatures for radiation exposure

PrgmNr 3520 Untargeted metabolomics on the diet behaviors and their genomic interaction among Mexican Americans

PrgmNr 3521 Best practices for trans-ethnic, meta-analytic transcriptome-wide associations: lessons from the Global Biobank Meta-Initiative

PrgmNr 3522 Accurate profiling of forensic autosomal STRs using the Oxford Nanopore Technologies MinION device

PrgmNr 3523 Development of a highly multiplexed RNA in situ hybridization assay for spatial transcriptomic mapping of formalin-fixed paraffin-embedded tissue

PrgmNr 3524 DRIVE: Distant relatedness for identification and variant evaluation

PrgmNr 3525 Enabling faster and more cost-effective drug discovery through flexFSTM: A highly durable, elastic, and scalable cloud-native file system

PrgmNr 3526 Enabling Real Time Analysis of Single-Cell Genomic Data with Accelerated Computing

PrgmNr 3527 Improving rare variant calls from genotype array data: the Million Veteran Program Return Of Actionable Results (MVP-ROAR) Study

PrgmNr 3528 Integration of WGS & RNA-seq as an efficient approach for novel variant discovery in complex genetic cases

PrgmNr 3529 Introduction of a walk-away automated Roche NGS workflow solution: Integrated KAPA library preparation, KAPA target enrichment and the AVENIO Edge instrument

PrgmNr 3530 Investigation of a dysmorphic facial phenotype in patients with Gaucher type 2 and 3

PrgmNr 3531 Multiple de novo copy number variant (MdnCNV) driven mirror traits and blended phenotype

PrgmNr 3532 Rapid endpoint PCR: Improving amplification speed without sacrificing specificity

PrgmNr 3533 Sequence-based assessment of mitochondrial DNA oxidative damage in cognitive impairment: Shedding light on health disparities in Mexican Americans

PrgmNr 3534 TowardsIsoform Resolution Single-Cell Transcriptomicsfor Clinical Applications Using Highly Accurate Long-Read Sequencing

PrgmNr 3535 Attitudes on pharmacogenetic results as secondary findings among medical genetics providers

PrgmNr 3536 Connectivity Map Analysis of a Single-Cell RNA-Sequencing Derived Transcriptional Signature of mTOR Signaling

PrgmNr 3537 Explainable machine learning for adverse drug reactions

PrgmNr 3538 Identifying the genetic contributors of efficacy and adverse metabolic effects of thiazide diuretics in African Americans from the Genetics of Hypertension Associated Treatments (GenHAT) study

PrgmNr 3539 Investigation of matrisome genes within the druggable genome

PrgmNr 3540 Long-read amplicon sequencing of the polymorphic CYP2D6 locus

PrgmNr 3541 Targeting Alzheimer’s Disease drug development via network analysis of GWAS data

PrgmNr 3542 Worse COVID-19 outcomes in patients with the hemoglobin beta sickle allele due to existing comorbidities and new acute events

PrgmNr 3543 A Single-Assay Solution for Expanded Carrier Screening Relieves Existing Workflow Constraints and Provides More Comprehensive Analysis

PrgmNr 3544 Cord blood DNA methylation gestational age estimation applied to dried blood spot DNA methylation

PrgmNr 3545 Developmental genomics of congenital limb malformations: further evidence for gene dosage effects

PrgmNr 3546 Potential additive effect of fetal HRAPOL1genotype and micronutrient deficiencies

PrgmNr 3547 A novel polygenic score for microglial activation enhances models of Alzheimer's disease neuropathology

PrgmNr 3548 A novel test for parent-of-origin effects in population samples leveraging multiple phenotypes

PrgmNr 3549 A powerful and resource-efficient pipeline for association analysis of large-scale whole-genome sequencing studies
PrgmNr 3550 A quantile integral linear model to quantify genetic effects on phenotypic variability
PrgmNr 3551 A resource-efficient tool for phenome-wide rare variant association analysis in large-scale whole-genome sequencing studies, with application to TOPMed metabolomics data
PrgmNr 3552 An extended fine-mapping framework to identify causal genes from transcriptome-wide association studies (TWAS)
PrgmNr 3553 An iterative approach to adjustment for covariates in genetic association studies using GWAS summary statistics
PrgmNr 3554 Ancestry-matching cases to controls from the GLAD database to accelerate genetic research in under-represented populations
PrgmNr 3555 Bayesian estimation of Allele-Specific Expression (ASE) in the presence of phasing uncertainty for identifying genes with aberrant expression
PrgmNr 3557 Consistent summary counts based rare variant analysis for discovery of germline predisposition genes using public genotype summary data as controls
PrgmNr 3558 DeepRsq: an improved imputation quality metric via a machine learning method
PrgmNr 3559 ExPheWas: a browser for gene-based pheWAS associations
PrgmNr 3560 Gene-based association approach in family samples using GWAS summary statistics
PrgmNr 3561 Gene-burden tests, gene-environment interactions and time-to-event data analysis within an efficient whole genome regression framework for large-scale biobanks
PrgmNr 3562 Gene-environment interaction testing using machine learning approaches and robust test statistics: a sex-specific risk score component for lung function
PrgmNr 3563 HaploSoup: IBD-based encoding for improved PCA genome matching
PrgmNr 3564 High-dimensional regression of continuous secondary traits under extreme phenotype sampling
PrgmNr 3565 Human Genetics Structure Activity Relationship (HG-SAR): A novel methodology to link human genotype-phenotype associations to high throughput functional activity data and validate targets for human disease
PrgmNr 3566 Identity-by-descent mapping in biobank-scale datasets
PrgmNr 3567 Individuals with limited healthcare interactions may degrade polygenic risk score analyses
PrgmNr 3568 Interactive Visualization of Relatedness and Ancestry Inference
PrgmNr 3569 Interpretable prioritization of causal genes in unsolved GWAS loci
PrgmNr 3570 LD Score regression (LDSC) with more comprehensive catalogs of LD scores
PrgmNr 3571 Leveraging functional annotation in a fast and powerful eQTL weighted gene-based association test
PrgmNr 3572 Leveraging Health Systems Data to Characterize a Large Effect Variant Conferring Risk for Liver Disease in Puerto Ricans
PrgmNr 3573 Leveraging simulations in extended pedigrees for population genetic analysis
PrgmNr 3574 MAST-Decon: Smooth Cell-type Deconvolution Method for Spatial Transcriptomics Data
PrgmNr 3575 Methods for genetic association analysis of mother-child pairs
PrgmNr 3576 Multiethnic joint analysis of summary statistics from genome-wide association studies
PrgmNr 3577 Multi-trait analysis of gene-environment-wide association using MAGENTA
PrgmNr 3578 Multivariate modeling of direct and proxy GWAS indicates substantial common variant heritability of Alzheimer's disease
PrgmNr 3579 Novel Global Quantile Regression Based Method for Differential Gene Expression Analysis of Quantitative traits
PrgmNr 3581 Reconstructing SNP Allele and Genotype Frequencies from GWAS Summary Statistics
PrgmNr 3582 SparsePro: an ultra-efficient Bayesian fine-mapping method integrating summary statistics and functional annotations
PrgmNr 3583 The power of pathway-specific polygenic risk scores

PrgmNr 3585 Using metagenomics to assess global levels of antimicrobial resistance

PrgmNr 3586 Utility of admixed individuals in genome wide association studies: A test case in COVID-19

PrgmNr 3587 Utilizing phenotype risk scores and genetically-regulated expression in a clinical biobank to investigate the genetic architecture of Mendelian disease genes

PrgmNr 3588 A phenome-wide Mendelian randomization study of plasma triglycerides and more than 6,000 diseases and traits

PrgmNr 3589 Assessing the difference in multiple sclerosis age of onset amongst different racial populations through the use of electronic health records

PrgmNr 3590 Bayesian analyses of variant-specific features enable penetrance estimates across cardiac channelopathies

PrgmNr 3591 BrainXcan identifies brain features associated with Alzheimer's disease using large scale genetic and neuroimaging data

PrgmNr 3592 Circulating proteins to predict adverse COVID-19 outcomes

PrgmNr 3593 Detecting DHCR7 variants consistent with Smith-Lemli-Opitz syndrome in autism patients

PrgmNr 3594 Dissecting the causal relationships between obesity and multiple sclerosis risk

PrgmNr 3595 Evaluation of genetic risk scores for incisional surgeries in primary open-angle glaucoma patients

PrgmNr 3596 Genetic Variation in Genes Associated with GERD in COPD

PrgmNr 3597 Genome-wide survival analysis of dental caries incidence

PrgmNr 3598 GWAS of self-report and imputed phenotypes capture distinct but complementary genetic architecture of stuttering

PrgmNr 3599 Identification of Genetic Loci Associated with Cognitive Preservation in the Midwestern Amish

PrgmNr 3600 Investigating White Blood Cell Count and Platelet Biology as a Possible Driver of the Comorbidity Between Coronary Artery Disease and Major Depressive Disorder

PrgmNr 3601 Joint intron splicing-based transcriptome-wide association study identifies new candidate susceptibility genes for breast cancer

PrgmNr 3602 Overwhelming numbers of patients who carry pathogenic familial hypercholesterolemia variants are predicted to have low clinical risk in the UK Biobank

PrgmNr 3603 Polygenic risk score analysis provides evidence of unique genetic architecture of Alzheimer’s disease in an Amish population

PrgmNr 3604 Prioritizing causal risk factors for severe COVID-19: an exhaustive Mendelian randomization study

PrgmNr 3605 Rare Variants in Non-coding Regulatory Regions and Non-syndromic Orofacial clefts

PrgmNr 3606 Sex-specific analyses in inflammatory bowel disease in African Americans reveal new loci on chromosomes 4, 5, 6, and 13

PrgmNr 3607 The Smoking Independent Causal Effects of Alcohol and Socioeconomic Traits on Lung Cancer Development

PrgmNr 3608 Today’s genetic risk scores for primary open-angle glaucoma underperform in African-descent participants from the Veteran Administration’s Million Veteran Program (MVP)

PrgmNr 3609 Transcriptome-wide association studies identify genetic determinants of brain-imaging phenotypes

PrgmNr 3611 Utilizing PrediXcan to detect Crohn's disease susceptibility genes in African Americans

PrgmNr 3612 A Translocation t(12;22) in Myxoid/Round Cell Liposarcoma

PrgmNr 3613 Amplification of CCND1 in Invasive High Grade Urothelial Carcinoma

PrgmNr 3614 Amplification of NMYC in Neuroblastoma

PrgmNr 3615 An amplification of EGFR (7p12) in a patient with Glioblastoma

PrgmNr 3616 An automated classification system for copy number variants based on 2019 ACMG guidelines

PrgmNr 3617 Characterizing tumor-infiltrated immune cells with spatial context using RNAscope-immunohistochemistry co-detection workflow in FFPE tissues

PrgmNr 3618 Monosomy 21, a rare finding in an elder patient with non-CLL-like monoclonal B-cell lymphocytosis

PrgmNr 3620 Outcomes from integrating an accessible delivery model for hereditary cancer risk assessment and genetic testing in populations with barriers to access

PrgmNr 3621 Patients with Birt-Hogg-Dubé syndrome and papillary renal cell carcinoma reveal a rare intragenic deletion in FLCN

PrgmNr 3622 Rapid whole genome sequencing (rWGS) on a novel digital microfluidic system: “on demand” personal automation for diagnosis of critically ill infants

PrgmNr 3623 Simplified and robust library construction for high-throughput HiFi sequencing for human variant detection

PrgmNr 3624 Utilizing Somatic Tumor Profiling To Identify Candidate Patients For Germline Genetic Testing In A Community Setting Reveals Barriers To Referral To Genetic Counseling

PrgmNr 3625 Verification of an EZH2 mutation test from formalin-fixed paraffin-embedded (FFPE) follicular lymphoma tumor tissue specimens

PrgmNr 3626 A large genome-wide association study for melanoma-specific survival reveals two novel loci linked to PSEN2, and ADCK3 genes

PrgmNr 3627 A segregation analysis of 17,425 population-based breast cancer families: Implications for breast cancer genetic susceptibility and risk prediction

PrgmNr 3628 Associations between tumor inflammation, survival, and somatic mutations in colorectal cancer patients

PrgmNr 3629 Associations of genetically predicted blood protein biomarkers with prostate cancer risk: a study using comprehensive protein genetic prediction modes

PrgmNr 3630 Breast cancer polygenic risk scores and rare variants in Latinas

PrgmNr 3631 Genetic risk of second primary cancer in breast cancer survivors: the Multiethnic Cohort Study

PrgmNr 3632 Improving risk prediction: Validation and exploration of breast cancer PRSs in a Midwest-American population

PrgmNr 3633 Increased burden of pathogenic variants in cancer predisposition genes in minority Americans with a cancer diagnosis between age 0-26: Use of linked California health registries

PrgmNr 3634 Inherited TP53 variants are associated with an increased risk of prostate cancer

PrgmNr 3635 The immuno-genetics of viral antigen response influence glioma susceptibility and survival in a subtype-specific manner

PrgmNr 3636 CDH1 and CTNNA1 variants with incomplete penetrance in Hereditary Diffuse Gastric Cancer Chilean families

PrgmNr 3637 Saturation Genome Editing of PALB2 Reveals Functionally Abnormal Missense Variants

PrgmNr 3638 A scalable deep learning framework for breast cancer prediction using DNA methylation data

PrgmNr 3639 Cell-type specific methylation changes from bulk whole genome bisulfite sequencing of matched primary and recurrent high grade serous ovarian cancers indicates stability of methylation landscape through tumor progression and chemoresistance

PrgmNr 3640 Exome-wide rare variant association study in lymphoid cancers

PrgmNr 3641 Identifying non-coding drivers of ovarian cancer by converging germline variants and somatic mutations

PrgmNr 3643 Spatial molecular profiling of Triple-Positive Ductal Carcinoma In Situ of the Breast using Visium Spatial Gene Expression for FFPE

PrgmNr 3644 Tracing intratumoral genetic heterogeneity using genetic barcoding in small cell lung cancer

PrgmNr 3645 Transcriptome-wide association study identifies novel genes associated with the immune traits in cancer

PrgmNr 3646 Epigenome-wide association study (EWAS) for soluble CD14 level in African Americans from the Jackson Heart Study

PrgmNr 3647 Exploring the genetic architecture of spontaneous coronary artery dissection using whole genome sequencing

PrgmNr 3648 Gene expression analysis of lipid traits in multi-ethnic population

PrgmNr 3649 Investigating a potential causal relationship between maternal blood pressure during pregnancy and future offspring cardiometabolic health

PrgmNr 3650 Investigating exposure mediated genetic scoring for coronary artery disease

PrgmNr 3651 Investigation of eQTLs in the CELSR2/ PSRC1/SORT1 gene cluster for independent effects in the liver and skeletal muscle that influence LDL levels and energy expenditure in American Indians

PrgmNr 3652 Methylome-wide association analysis identified novel CpG sites for lipid concentrations in ancestral-diverse populations from the PAGE Study

PrgmNr 3653 Polygenic risk score analysis of congenital heart disease phenotypes: elucidating the contribution of common variants to congenital heart defects

PrgmNr 3654 Response to Polygenic Risk: Results of the MyGeneRank Mobile Application-Based Coronary Artery Disease Study

PrgmNr 3655 Trans-ancestry PRSs of lipid traits to predict cardiovascular disease in the ancestrally diverse PAGE study

PrgmNr 3656 Biometric trait sex heterogenous SNPs disproportionately influence predicted gene expression and diverse traits later in life

PrgmNr 3657 Clinically impactful non-glycemic genetic effects on HbA1c yield missed detections of pre-diabetes, especially in African ancestry

PrgmNr 3658 Genome-wide association study of sphingolipid traits in diabetic patients reveals distinct cis-regulatory regions for sphingolipid pathway-associated genes

PrgmNr 3659 Grip strength, adiposity, and genetic risk of non-alcoholic fatty liver disease: Findings from the UK Biobank study

PrgmNr 3660 Integration of transcriptome genetics, metabolic perturbations, and trait associations identifies high-confidence cardiometabolic risk genes

PrgmNr 3661 Investigation of Rapid-onset Obesity with Hypothalamic dysfunction, Hypoventilation and Autonomic Dysregulation (ROHHAD) by comprehensive whole genome sequencing

PrgmNr 3662 Trans-ancestry meta-analysis of the X chromosome for obesity-related traits in over 600K individuals

PrgmNr 3663 Ancestry-aware polygenic risk scores identify host factors behind susceptibility and disease outcomes associated to SARS-CoV-2 infection from a nationwide longitudinal direct-to-consumer survey of 30,000 individuals

PrgmNr 3665 Common and rare variant analyses combined with single-cell multiomics reveal cell-type-specific molecular mechanisms of COVID-19 severity

PrgmNr 3666 Genome-wide association analyses of common infections in a large practice-based biobank

PrgmNr 3667 Mid-density Gene Expression Profiling of SARS-COV-2 infected samples using Applied Biosystems TaqMan Flexible Array Panels

PrgmNr 3668 Multi-ancestry GWAS reveals association between absolute neutrophil count and SETD1B

PrgmNr 3669 Predicting host response to Covid-19

PrgmNr 3670 Identification of Gene Expression Patterns Associated With Polycystic Ovary Syndrome

PrgmNr 3671 Mendelian randomization analyses reveal no evidence of causal relationships between chronic health conditions and sporadic and recurrent miscarriage

PrgmNr 3672 Development of a discovery pipeline for structural variation contributing to the cause of amyotrophic lateral sclerosis

PrgmNr 3673 First joint exome and metabolome analysis in dyslexia implicates immune system deficits and dysregulated sensory perception

PrgmNr 3674 Genome Wide Association Study of QSM brain measures in UK biobank to undercover the genetic basis of brain iron load

PrgmNr 3675 Integrated gene analyses of de novo mutations from 46,612 trios with autism and developmental delay

PrgmNr 3676 Multivariate genomewide associations on microstructural compartments of human brain highlight the consistent neurodevelopmental molecular pathways from adolescent to late adulthood

PrgmNr 3677 Pairwise contributions of 16p11.2 CNV genes to brain-related traits

PrgmNr 3678 Association between complement component 4 variation and childhood brain and behavioral phenotypes: Multiethnic PheWAS in the Adolescent Brain and Cognitive Development (ABCD) Study

PrgmNr 3679 Polygenic risk and causal inference of psychiatric comorbidity in inflammatory bowel disease

PrgmNr 3680 Polygenic risk scores for Bipolar Disorder predict age of diagnosis and the number of lifetime psychiatric diagnoses experienced by participants in the Australian Genetics of Bipolar Disorder Study

PrgmNr 3681 A GWAS of atopic dermatitis in African American individuals

PrgmNr 3683 A repetitive request: for the genome wide study of short tandem repeats in human phenotypic variation

PrgmNr 3684 Enabling biobank-scale GWAS data sharing with efficient compression and indexing

PrgmNr 3685 Genetic burden of cardio-metabolic diseases on women's health outcomes from a study of multi-ancestry population

PrgmNr 3686 Genetic variants affecting the expression of two Mendelian deafness genes are associated with age-related hearing impairment

PrgmNr 3687 Low-Coverage Whole Genome Sequence Genotyping Pipeline on Heterogeneous Stock Rats

PrgmNr 3689 Accelerated epigenetic aging in newborns with Down syndrome

PrgmNr 3690 Characterizing molecular mechanisms of the oncogene transcription factor FOXM1 in lung and breast cancer to suppress cell proliferation

PrgmNr 3691 Comparative analysis of bulk RNA versus single-cell RNA sequencing to profile gene expression in cellular subgroups within peripheral blood mononuclear cells

PrgmNr 3692 Genome-wide effects of sex chromosome aneuploidy on gene expression and DNA methylation in isogenic neural precursor lines

PrgmNr 3693 Interrogation of allergy associated regulatory variants for GATA3 in human T cells

PrgmNr 3694 Novel insight into the etiology of ischemic stroke gained by integrating human transcriptome wide association study with rodent expression data

PrgmNr 3695 Prediction of genetically regulated expression of asthma target tissues for African-ancestry populations

PrgmNr 3696 Regulatory landscape of CD4+ T cells with implications for asthma

PrgmNr 3697 Single-cell RNA sequencing of lung identifies disease-associated cell type-specific eQTLs

PrgmNr 3698 Association between the tobacco-specific carcinogen metabolite NNAL and DNA methylation in a multiethnic population

PrgmNr 3699 Automated High-throughput IP Workflows using Covaris Adaptive Focused Acoustics (AFA) System for Accelerated Epigenomic Mapping

PrgmNr 3700 Black Representation in Genomics Research (BRGR) Study of eQTLs in venous blood of 23andMe research participants with African ancestry

PrgmNr 3701 Circular RNAs preferentially localize to synapses in the human brain implying critical functions for synaptic plasticity and may be important components of neurodegeneration

PrgmNr 3702 Dissecting the evolutionary and functional architecture of human enhancer sequences with multiple ancestral origins

PrgmNr 3703 Enhancer enhancer interaction networks involved in long-distance genome regulation link multiple non-coding variants to function

PrgmNr 3704 Human-specific structural variants alter cis-regulation and chromatin structure

PrgmNr 3705 Integrative single cell analysis of cardiogenesis identifies developmental cellular trajectories and prioritizes noncoding mutations in congenital heart disease
PrgmNr 3706 Investigating conservation of chromatin accessibility signatures during iPSC reprogramming across human and mouse ATAC-seq data
PrgmNr 3707 Systematic reconstruction of the cellular trajectories of mammalian embryogenesis
PrgmNr 3708 Telomere-to-telomere map of a human epigenome
PrgmNr 3709 The landscape of alternative polyadenylation in single cells of the developing mouse embryo

PrgmNr 3710 Universal DNA methylation age across mammalian tissues
PrgmNr 3711 Using Taqman assays to analyze eQTL loci arising from GWAS Studies
PrgmNr 3712 A statistical framework for single-molecule transcription factor footprinting
PrgmNr 3713 Analyzing the Effects of GWAS Fine-Mapping on PGS Analyses for Type 2 Diabetes
PrgmNr 3714 ChromBPNet: Deep learning models of base-resolution chromatin profiles reveal cis-regulatory syntax and regulatory variation
PrgmNr 3715 Deep Learning Modeling of Transcription Factor Binding Specificity Using DNA Biophysical Properties
PrgmNr 3716 DMRscaler: A scale-aware method to identify regions of differential DNA methylation spanning basepair to multi megabase features
PrgmNr 3717 Outlier gene detection to improve biological validation and classification performance in RNA sequencing
PrgmNr 3718 A Genealogical Estimate of Genetic Relationships to Improve Detection of Population Structure Over Time
PrgmNr 3719 Causal variant effect sizes of complex traits differ between populations
PrgmNr 3720 Codon bias analysis of wildtype SARS-CoV-2 and prevalent variants indicates a mutational trajectory independent of human pulmonary tissue and genomic bias
PrgmNr 3721 Coevolution is pervasive between unrelated glycosylation pathways and points to potential disease modifiers
PrgmNr 3722 DNA methylation patterns underlying lifespan differences in mammals
PrgmNr 3723 Gnomix: local ancestry inference for whole genome sequences and large datasets
PrgmNr 3724 Human-specific evolution at multiple scales and dimensions
PrgmNr 3725 Identification of ancestry specific health risks in a large cosmopolitan biobank
PrgmNr 3726 Inferring negative natural selection at short tandem repeats in the human genome
PrgmNr 3727 Inferring population structure in biobank-scale genomic data
PrgmNr 3728 Population level study of tandem repeats using an ensemble call-set
PrgmNr 3729 Reconstructing spatio-temporal patterns of admixture in human history using present-day and ancient genomes
PrgmNr 3730 Reconstructing the 3D chromatin organization of archaic hominins reveals that genome folding shaped human-Neanderthal phenotypic divergence and introgression
PrgmNr 3731 The mutational dynamics of short tandem repeats in large, multigenerational families
PrgmNr 3732 The waiting distance distribution in ancestral recombination graphs
PrgmNr 3733 A retrospective study of health issues being discussed in a prenatal setting with female carriers of fragile X syndrome
PrgmNr 3734 Analysis of Financial Barriers Experienced by Prospective Genetic Counseling Students
PrgmNr 3735 Attitudes towards polygenic risk testing for glaucoma in an Australian population
PrgmNr 3736 Authorship Guidelines and Implementation: Promoting Equity and Inclusion
PrgmNr 3737 Clinical Sequencing Evidence-Generating Research (CSER) consortium Diversity and Inclusion Statement: development, revision, and adoption
PrgmNr 3738 Cloud-based biomedical data storage and analysis for genomic research: landscape analysis of data governance in emerging NIH-supported platforms

PrgmNr 3739 Conducting clinical genomic medicine research during the COVID-19 pandemic: Lessons learned from the CSER consortium experience

PrgmNr 3741 Designing and launching a pilot race and genetics seminar series for public health genetics students

PrgmNr 3742 Ethnic Differences in the Frequency of Cancer Reported from Family Pedigrees in the Prenatal Genetic Counseling Setting

Obesity is a major global public health problem, yet most genome-wide association studies (GWAS) for obesity traits have been performed in European ancestry populations. This lack of diversity impedes genetic discovery and limits the utility of genetics in obesity therapeutics. Here we report the first trans-ancestry meta-analysis for body mass index (BMI) involving continental Africans, and evaluate its utility in this population group. We aggregated GWAS of BMI in 678671 individuals from the United Kingdom Biobank (Europeans), Japan Biobank , African Partnership of Chronic Disease Research (APCDR), and the Population Architecture and Genetic Epidemiology (PAGE) who are representative of diverse global populations through inverse variance weighted, fixed-effects trans-ancestry meta-analysis implemented in Metasoft. We identified 660 loci at genome-wide significance (p -8), 164 of which have not been previously reported for BMI in any population. We compared the correlation of the effect sizes of lead variants from the trans-ancestry meta-analysis and those in the European GWAS in UK Biobank with ones found in a GWAS of 10900 continental Africans from the AWIGen study.For lead variants that were nominally significant in AWIGen, the effect size correlation of the trans-ancestry meta-analysis vs continental Africans was stronger (Pearson correlation = 0.45; p =0.0085) and significant compare to that with the European GWAS vs continental Africans (Pearson correlation = 0.35; p =0.084) . Trans-ancestry meta-analysis improved fine-mapping resolution over European ancestry participants in the UK Biobank as indicated by median 99% credible set sizes of 39 and 64, respectively. A polygenic risk score (PRS) derived from the trans-ancestry meta-analysis was more predictive of BMI in the continental Africans than the European ancestry-specific score. The mean difference in weight and BMI in the first and last deciles of the trans-ancestry PRS was 16.00kg and 6.45kg/m^2, respectively . The trans-ancestry PRS appeared to convey sex-specific effects (P_{int}=1.44 x10^{-66}) in continental Africans, such that the difference in BMI between first and last deciles was three-fold the magnitude in women (8.78kg/m^2; p =1.69 x10^{-92}) than men (2.90kg/m^2; p =4.86 x10^{-18}). Such an aspect has not been reported in Europeans.Our findings demonstrate that the inclusion of diverse populations in trans-ancestry meta-analyses improves fine-mapping resolution and enhance the transferability of PRS to African populations

PrgmNr 1053 - Investigating relative contributions to complex trait architecture from sequence elements originating across multiple evolutionary time-scales

View session detail

Author Block: **M. Sohail**[1,2], J. Novembre[3,4]; [1]Ctr. for Genomic Sci., Natl. Autonomous Univ. of Mexico (UNAM), Cuernavaca, Mexico, [2]Human Genetics, Univ. of Chicago, Chicago, IL, [3]Univ. of Chicago, Chicago, IL, [4]Dept. of Ecology and Evolution, Univ. of Chicago, Chicago, IL
Disclosure Block: **M. Sohail:** None.
Regulatory genomic elements have been found to be enriched for heritability across complex traits but can have different ages with respect to when they originated and became functionally constrained. We ask whether specific regulatory elements or sequences that have gained novel function during human evolutionary history are enriched in heritability for complex traits, and if this is enrichment is variable within and among trait domains. We partition heritability along the genome using S-LDSC and previously published genomic annotations from different periods of our evolutionary history. These are fetal and adult brain human-gained (HG) enhancers and promoters (H3K27as and H3K4me2 histone modification peaks in the cerebral cortex gained in humans compared to mouse and rhesus macaque), human accelerated regions, ancient selective sweeps, Neanderthal introgressed regions, and Neanderthal and Denisovan depleted regions. Meta-analyzing across 41 independent traits analyzed in Hujoel et al (2019) from UK Biobank and other GWAS, we find a significant heritability enrichment for fetal human gained enhancers and promoters expressed in the cerebral cortex at 7 post-conception weeks (pcw) and at 8.5 pcw, and those expressed in the occipital cerebral cortex (visual processing center) at 12 pcw (FDR

PrgmNr 1054 - Rare variant associations from exome sequencing of 454,787 individuals in the UK Biobank

View session detail

A major goal in human genetics is to use natural variation to understand the phenotypic and biological consequences of each of the protein coding genes in the genome. Towards that goal, we generated and analyzed exome sequencing of 454,787 participants of the UK Biobank (UKB) study, representing the largest catalog of protein-coding variation identified to date (~12 million variants, including ~8 million missense variants and ~1 million putative loss-of-function [pLOF] variants), exceeding the combined total of gnomAD and TOPmed reference datasets (~9 million variants). Using these data, we first evaluated genomic constraint at a resolution not previously possible in humans. For example, we identified exons depleted of nonsynonymous variation in genes such as *KCNQ2* and *U2AF2* (concordant with previous findings), suggesting that mutations in these highly constrained regions are likely to have deleterious phenotypic consequences. Conversely, we observed an enrichment of nonsynonymous variation in genes associated with clonal hematopoiesis of indeterminate potential (CHIP; eg. *DNMT3A*, *TET2*), most of somatic origin and consistent with positive selection.

We then assessed the impact of rare (MAFâ¤1%) pLOF and deleterious missense variants on 3,998 health- and behavior-related traits, testing the effect of variants individually and also on aggregate, through gene burden tests. We identified 8,865 significant associations with 492 traits at a Bonferroni-corrected significance threshold of Pâ¤$2x10^{-11}$. Key findings from these analyses include: 1) 564 genes associated with at least one trait; 2) 16% of associations identified with a burden of ultra-rare variants (MAFâ¤0.001%); 3) ~90% of associations remained significant after conditioning on nearby common variants identified through GWAS; 4) associations were highly concordant between European and other ancestries; 5) associations with rare variants were enriched in GWAS loci, and so can help prioritize genes underpinning common, non-coding variant associations; 6) significant associations with quantitative traits helped identify 13 protective sub-threshold (Pâ¤10^{-4}) associations with genetically-correlated diseases, such as between a burden of pLOF and deleterious missense variants in *SLC22A12*, lower serum urate, and protection from gout.

Overall, we show that the wealth of high-quality phenotype data available in the UKB study, in conjunction of whole-exome sequencing, provides an unprecedented opportunity to elucidate gene function through association studies of protein-coding variants.

PrgmNr 1055 - High-resolution structural and temporal mapping illuminates relationships between 3D chromatin structure, enhancer activity, and gene regulation during macrophage activation

View session detail

Author Block: **K. Reed**[1], E. S. Davis[1], D. Phanstiel[2]; [1]Univ. of North Carolina, Chapel Hill, Chapel Hill, NC, [2]UNC, Chapel Hill, NC
Disclosure Block: **K. Reed:** None.
DNA loops physically connect enhancers to the promoters of target genes, which can be over a million base pairs away. Many of these loops are cell-type specific, forming during differentiation and activation. While these condition-specific contacts are often accompanied by changes in gene expression and chromatin accessibility, the causal relationships are still unclear.
To address this gap, we have conducted a multi-omics time course to map structural and regulatory changes with high temporal resolution, focused on eight time points in the early stages of human macrophage activation. Integration of these datasets revealed the order of events, providing many insights into the relationships between genome architecture, enhancer activity, protein binding, and gene expression.
Deeply sequenced in situ Hi-C revealed significant rewiring of DNA loops during cellular activation, including some transient loops found only at intermediate time points, and others that changed as quickly as 30 minutes after treatment. RNA-seq, H3K27ac ChIP-seq and ATAC-seq identified massive changes in gene expression and chromatin accessibility.
In general, chromatin accessibility changed faster than most loops and genes. Among stable three-dimensional contacts, enhancers looped to genes showed significantly correlated patterns of activation when compared to un-looped matched pairs, with enhancer activation preceding gene activity by approximately 1 hour. Newly formed and strengthened loops correlated with increased internal and anchor gene expression. Surprisingly, we saw a striking anticorrelation between internal gene expression and contact frequency at loops that declined over the course of activation, suggesting that increased gene transcription may be disrupting loop extrusion in some circumstances.
On a coarser level, gene expression correlated with A/B compartmentalization as predicted, but changes in transcription appear to drive changes in compartmentalization to a lesser extent than expected. We found that a possible cause for this discrepancy is apparent poising of regions in the A compartment prior to gene activation in the region.
The integrated data from this study provides a deep resource for the continued exploration of structural and functional changes in the genome.

PrgmNr 1199 - Early detection of cancers using plasma cell-free DNA methylomes up to 7 years prior to clinical diagnosis

View session detail

Author Block: **N. Cheng**[1,2], D. Soave[3], K. Skead[4,2], T. Ouellette[1,2], S. Bratman[5,2], D. DeCarvalho[5,2], P. Awadalla[4,2]; [1]Ontario Inst. for Cancer Res., Toronto, ON, Canada, [2]Univ. of Toronto, Toronto, ON, Canada, [3]Wilfrid Laurier Univ., Waterloo, ON, Canada, [4]Ontario Inst. Cancer Res., Toronto, ON, Canada, [5]Princess Margaret Cancer Ctr., Toronto, ON, Canada
Disclosure Block: **N. Cheng:** None.
Cancer survival rates are significantly improved when detected at early stages, particularly when the tumour is still localised to the tissue of origin. However, effective screening tools for early cancer detection is currently limited to a subset of cancer types. Profiling cell-free DNA (cfDNA) patterns has emerged as a prominent non-invasive biomarker for detection and subtyping of cancers. However, owing to difficulties in observing the early development of human malignancies as cancers are often detected once they become symptomatic, most cancer biomarker and evolution studies to date have primarily examined the genomics from solid tumour or liquid biopsies following a diagnosis. Utilizing cfDNA as a screening tool for early cancer detection requires profiling of blood plasma samples collected from asymptomatic individuals prior to the diagnosis of cancers to enable assessment of the earliest detectability and predictive performance of potential biomarkers. Here, we leverage the Canadian Partnership for Tomorrowâ□□s Health Project (CanPaTH), to profile blood plasma collected prior to the clinical detection of underlying cancers. Specifically, we use cell-free methylated DNA immunoprecipitation and high-throughput sequencing (cfMeDIP-seq), a highly sensitive assay for profiling cfDNA methylomes, to profile over 300 blood plasma samples collected up to 7 years prior to the detection of a breast, prostate or pancreatic cancer, in addition to matched controls with no history of cancer free through follow-up. We demonstrate using machine learning that not only can cfDNA methylation markers indicative of breast cancers be detected up to 7 years prior to clinical detection, predictive models classifying these individuals with an undetected cancer can achieve AUROC of 0.76 (95% CI: 0.72 - 0.81). We further highlight that cfDNA methylation markers in blood plasma collected close to diagnosis differ from those collected over 2 years prior to diagnosis revealing potential novel markers at the earliest stages of cancer development. In our current studies, we focus specifically on breast, prostate and pancreatic cancer cases, and are extending this to further pan-cancer applications in subsequent investigations.

PrgmNr 1200 - Genetic regulation of DNA methylation across tissues reveals thousands of molecular links to complex traits

View session detail

Author Block: **M. Oliva**[1], K. Demanelis[2], F. Jasmine[1], Y. Lu[1], GTEx Consortium, H. Hahsan[1], K. G. Muhammad[1], L. S. Chen[1], B. L. Pierce[1,3,4]; [1]Dept. of Publ. Disclosure Block: **M. Oliva:** None.
Epigenetic modifications play a fundamental role in gene regulation in humans. **We generated DNA methylation (DNAm) data for 987 samples from the Genotype-Tissue Expression (GTEx) project, from 9 tissues** (breast, colon, kidney, lung, muscle, ovary, prostate, testis and whole blood) and 424 subjects. We mapped DNAm quantitative trait loci in *cis* (mQTLs), contrasted mQTLs with expression QTLs (eQTLs) features, and assessed their relative contributions to complex traits. We observed that while eQTL enrichment in transcription factors involved in basal transcription, **mQTLs tend to occur in binding sites of proteins involved in 3D organization of the genome**. Only 21% of mQTLs were identified as suggestively colocalized (PP4 > 0.5) with at least one eQTL. These results suggest that **mQTLs and eQTLs diverge in their underlying biological mechanisms** and that genetic co-regulation of DNAm and gene expression is not pervasive.
We integrated QTLs with genome-wide association study (GWAS) summary statistics of 87 GWASs and observed that **mQTL colocalizations are abundant and complementary to eQTL-GWAS colocalizations**: only 27% (749/2734) of GWAS hits colocalized with both QTL types, while 55% of hits colocalized with mQTLs exclusively. Among those, we identified an ovary-specific mQTL colocalized with a breast cancer GWAS signal in the known cancer-associated TERT locus, although TERT expression is generally undetectable in adult tissues. These results emphasize the importance of integrating multiple -omics to maximize the expectation of identifying molecular links to inheritable traits, and suggest that DNAm may be genetically co-regulated with gene expression in a particular context which causally impacts the trait; but unlike gene expression, only methylation is identifiable beyond the causal context. We observed that mQTL-GWAS colocalizations are enriched in pleiotropic variants regulating multiple CpG sites (mCpGs) (OR = 2.65, Fisherâ□□s exact test P 0.5) with ovarian cancer risk. These findings indicate that **mQTLs that exhibit regulatory pleiotropy have increased chances to impact a complex trait**, and that genetic variants can drastically modify the DNAm and gene expression landscape in a tissue-specific manner, impacting disease risk. The DNAm dataset generated herein enhances existing GTEx resources and enables the research community to investigate the inherited susceptibility to human disease from both cross-tissue and cross-omics perspectives.

PrgmNr 1201 - Widespread evidence of systematic bias in estimates of genetic correlation due to assortative mating

View session detail

Positive genetic correlation estimates are commonly interpreted as evidence that two traits share overlapping biological underpinnings. With the increasing availability of large consortium and biobank datasets, considerable research activity has focused on cataloging the genetic correlation structure of complex human traits to better understand shared etiology and transdiagnostic risk factors. In the present work, we demonstrate that primary-phenotypic cross-trait assortative mating (AM) induces substantial genetic correlations among traits with independent genetic effects, which are then overestimated by widely-used marker-based estimators, including genomic-relatedness residual maximum likelihood and linkage disequilibrium score regression (LDSC). For example, a single generation of AM for two 50% heritable traits correlated across mates at r=0.5 will lead to LDSC genetic correlation estimates > 0.2 in the complete absence of pleiotropy. Using empirical cross-mate phenotypic correlation and heritability estimates across a broad array of previously studied anthropometric, metabolic, psychosocial, and psychiatric phenotypes measured in multiple large samples (n ranging between 44,686 and 500,000 individuals), we estimate the extent to which AM alone might plausibly account for previously published genetic correlation estimates. With respect to psychiatric disorders, we demonstrate that even small misdiagnosis errors together with cross-trait AM could account for previous genetic correlation estimates (i.e., without out any true pleiotropy) between some disorders (e.g., Schizophrenia and anxiety disorders), but not others (e.g., Schizophrenia and Bipolar Disorder). Averaging across disorders, AM alone would result in genetic correlation estimates 38.9% as large as those reported by previous studies. Finally, we provide evidence congruent with AM at the genetic level by examining cross-trait cross-chromosome polygenic score correlations. We discuss our results, which indicate that the genetic correlation is an unreliable indicator of shared etiology for the numerous trait-pairs subject to cross-trait AM, in the context of the widespread application of the genetic correlation as a direct measure of biological overlap or shared pathogenesis.

PrgmNr 1202 - Benefits and cost-effectiveness of cascade testing for pediatric cancer predisposition syndromes: Findings from the PreEMPT Model

View session detail

Author Block: **K. D. Christensen**[1,2], G. O'Brien[3], P. M. McMahon[1], N. K. Stout[1,2], J. M. Yeh[3,2], A. C. Wu[1,2,3]; [1]Harvard Pilgrim Hlth.Care Inst., Boston, MA, [2]Harvard Med. Sch., Boston, MA, [3]Boston Children's Hosp., Boston, MA

Disclosure Block: **K.D. Christensen:** None.

Background

Newborn population-based genetic screening may reduce mortality associated with pediatric cancers and could be cost-effective, especially as costs decline. Cascade testing of siblings of newborns with pathogenic variants could further improve population health.

Methods

The Precision Medicine Prevention and Treatment (PreEMPT) Model projects the incremental benefits, costs, and cost-effectiveness of newborn genetic screening. Using the model to estimate outcomes associated with a 11-gene panel of pediatric cancer predisposition syndromes (*RET, RB1, TP53, DICER1, SUFU, PTCH1, SMARCB1, WT1, APC, ALK,* or *PHOX2B*), we projected outcomes associated with cascade testing of siblings of newborns identified to be a pathogenic variant carrier via newborn screening. We assumed each newborn had one newborn sibling with a 50% chance of harboring the same variant. Benefits were modeled via reductions in advanced disease, cancer deaths, and treatment-related late mortality, assuming 100% adherence to surveillance.

Results

In a cohort of 3.7 million newborns, the model estimated 1,584 newborns had pathogenic variants and 792 siblings would have the same variants. An estimated 115 siblings with these variants would develop cancer before age 20 years. If these siblings underwent surveillance for early detection, 15 (95%UI, 11 to 20) cancer deaths would be averted, a reduction of 52% (95%UI, 45% to 59%). Compared with usual care, sibling cascade testing had an incremental cost-effectiveness ratio (ICER) of $17,950 per LY gained (95%UI, $7,070 to $31,450). Even if only 10% of mutation carriers identified in newborn screening had inherited mutations from parents (and therefore 5% of siblings were therefore expected to be carriers), the ICER increasing only to $23,800/LY gained (95% UI, $11,770 to $40,160).

Conclusion

Sibling cascade testing could potentially avert half of predicted cancer deaths and be a high-value intervention. Testing of siblings of newborns with pathogenic variants is likely an effective way to enhance cancer outcomes. Findings also highlight how targeted approaches can dramatically improve the value of genetic screening and be more reasonable strategies to achieve population-level benefits.

PrgmNr 1288 - Interplay between longitudinally-measured gene expression and metabolite levels in whole blood in the MultiMuTHER study

Multi-omic datasets represent a snapshot of the systemâ□□s physiological state, and are increasingly being considered for health monitoring and earlier identification of disease risk. Deeper understanding of the cross-sectional and longitudinal interplay between concurrently-measured â□□omics is critical to enabling a systems-wide approach to health monitoring.

We therefore explored univariate and multivariate cross-sectional and longitudinal patterns of variation in the MultiMuTHER study, which comprises gene expression (RNASeq - 16,292 genes) and metabolomics (Metabolon-1,197 metabolites) data in whole blood at three or more timepoints over up to eight years per individual from 335 TwinsUK subjects [age range 32-80; median=61yrs]. TwinsUK is a deeply-phenotyped cohort of twins with extensive â□□omics data and repeat phenotypic measures.

We assessed association between gene expression and metabolites, and identified 105,629 gene-metabolite associations significant at a 5% false discovery rate. Approximately 81% of genes and 99% of metabolites were found to have at least one significant gene-metabolite association. Expression of each gene was associated with a mean (1^{st}-3^{rd} quartiles) of 8 (2-10) metabolites, while each metabolite was associated with a mean (1^{st}-3^{rd} quartiles) of 116 (13-119) genes. Striking examples of hub metabolites and genes with extensive associations were identified, including nicotinamide, which was associated with expression of 5,081 genes, as well as a number of genes involved in fatty acid metabolism, including CPT1A, whose expression levels were associated with 309 metabolites, and ACAA2, whose expression levels were associated with 182 metabolites.

Longitudinal gene expression association analyses (GEAS) revealed expression levels of ~40% of 16,292 genes showed significant change over time (FDR 5%), while ~5% of 915 metabolites showed significant longitudinal variation (FDR 5%). Genes showing longitudinal change over time were found to have a higher number of gene-metabolite associations than those exhibiting stable expression over time (P -16), while metabolites exhibiting longitudinal variation did not.

In summary, we have performed one of the largest multi-omic longitudinal studies of concurrently-measured gene expression and metabolite levels in whole blood, identifying over 100,000 gene-metabolite associations. This study provides novel insight into the interplay between gene expression and metabolites, and may inform systems-wide approaches to projection of temporal progression of age-related diseases.

PrgmNr 1289 - Integrative single-cell eQTL analysis of 2.3 million cells elucidates causal gene expression mechanisms and relevant cellular contexts in 34 brain GWAS traits

Gene expressions in the human brain are maintained and orchestrated by regulatory-genomic models in multiple neuronal and glial cell types. Although common genetic variation may not immediately cause disease phenotypes, polygenic effects of cis-regulatory models of relevant cell types can accumulate over time and eventually alter the disease propensity.
To understand cell-type-specific regulatory mechanisms, we profiled single nucleus RNA-seq data of 2.3 million cells across 429 postmortem human brain samples, of which 396 individuals are genotyped by whole genome sequencing. After adjusting batch-specific effects, fitting a von Mises Fisher mixture model, we hierarchically annotated the cells into 16 distinctive cell types, which include (1) four cortical layers of excitatory neurons, (2) four types of inhibitory neurons, (3) four glial cell types, and (4) four vasculature cell types. In comparison with observed covariates, we found significant negative correlations between the fraction of somatostatin(SST)-expressing interneurons with Alzheimer's disease (AD) pathology (p=0.01) and cognitive decline score (p=0.03), and the microglial proportions are positively correlated with AD pathology (p=0.04) and APOÎµ E4 genotypes (p=0.01).
We estimated cell-type-specific multivariate models by regressing pseudo-bulk gene expression profiles on thousands of cis-regulatory variants. For the 45% of 26k genes, we identified 2-3 independent causal eQTLs per gene within 2Mb window (posterior probability > .9), and these independent variants correspond to 2-3 different cell types (correlation > .8). On a thousand individuals, we directly compared observed AD-related variables with gene expression variation imputed by cis-regulatory genotypes (TWAS). The significant examples include TOMM40 in pericytes associated with amyloid-beta, RAB2A in pericytes and IDI1 in excitatory neurons (L5/6) with tau protein level (FDR

PrgmNr 1290 - Accounting for coordinated regulatory activity allows to refine genetic regulation of gene expression in schizophrenia

View session detail

Author Block: **M. Alver**, N. Lykoskoufis, A. Ramisch, H. Ongen, E. T. Dermitzakis; Dept. of Genetic Med. and Dev., Univ. of Geneva, Geneva, Switzerland

Schizophrenia (SCZ) is a heritable and highly polygenic neurodevelopmental disorder that oftentimes leads to a lifetime of chronic disability. While research has revealed numerous genomic loci predisposing to disease and identified dysregulation of gene expression in affected brain regions, causal mechanisms how genetic variants affect gene regulation in SCZ remains to be determined. Assessing the interplay between genetic variants, coordinated activity of regulatory elements (REs) and gene expression allows to fill that gap and gain insight into SCZ-specific gene regulatory mechanisms.
We used genotype, RNA-seq and ChIP-seq (histone mark H3K27ac) data collected within Human Brain Collection Core from post-mortem prefrontal cortex of 98 SCZ cases and 174 controls. To study the coordination of REs, we systematically measured interindividual correlation between proximal open chromatin peaks. Variability in nearby regulatory activity was structured into 10,938 and 10,376 well-delimited domains (cis-regulated domains, CRDs), in SCZ cases and controls, respectively, of which 42% were shared. Changes in 3D structure of the genome, rather than differential activity, were responsible for SCZ-specific CRDs. Differentially expressed genes were significantly enriched at differentially active CRDs (Fisher PTo interrogate deviations in regulatory signature patterns affecting gene expression in SCZ cases, we applied Bayesian Networks to infer the most likely causal relationship for QTLs affecting both CRDs and genes (QTL-CRD-gene triplets common to SCZ cases and controls (n=1,100)). While 2/3 of the triplets displayed the same direction of effect from QTL onto gene/CRD in both states, 1/3 of studied triplets showed change in directional effect from QTL variant onto gene expression (i.e., not mediated via associated CRD) in opposite state. These directional change-associated triplet genes clustered in molecular functions related to small GTPase binding, filopodium assembly and cellular lipid catabolic process, indicating changes in synaptic function and plasticity, and dendritic spine morphology in SCZ.
The established multi-level analysis accounting for coordinated activity between REs allowed to discriminate patterns of correlation structure between REs specific to SCZ, identify SCZ-specific QTLs as well as discover and refine perturbations in the molecular machinery underlying eQTL function in SCZ.

Osteogenesis Imperfecta (OI), a Mendelian disorder of bone and connective tissue presents with low bone mass, recurrent fractures, bone deformities, as well as extraskeletal manifestations. To date, there are no disease-specific or FDA-approved therapies for OI. In preclinical studies, we have previously shown that excessive TGF-Î² signaling is a key driver of pathogenesis in OI. In this study, we evaluated TGF-Î² signaling in human OI bone and translated this discovery by conducting a phase 1 clinical trial of TGF-Î² inhibition in adults with OI. We first assessed signaling abnormalities in human OI bone using a multi-omic approach. Histology and RNASeq were performed on bones obtained from children with (n=10) and without (n=4) OI. Gene Ontology (GO) assay, gene set enrichment assay (GSEA), and Ingenuity Pathway Analysis (IPA) were used to identify key dysregulated pathways. Reverse-phase protein array, western blot, and immunohistochemistry were performed to evaluate changes at the protein level. We show that OI bone has woven structure, increased osteocyte density, high turnover, and reduced bone maturation. SMAD phosphorylation was the most significantly up-regulated GO molecular event. GSEA identified TGF-Î² to be the top activated pathway in OI. IPA showed that TGF-Î² was the most significant activated upstream regulator mediating the global changes identified in OI bone.

A phase 1 study with a single administration of two doses (1 mg/kg and 4 mg/kg) of a pan-anti-TGF-Î² neutralizing antibody, fresolimumab, was conducted in 8 adults with OI. The effect of fresolimumab on bone was assessed by measuring blood bone remodeling markers, and areal bone mineral density (aBMD). Treatment with fresolimumab was well-tolerated. Use of 4 mg/kg of fresolimumab was associated with suppressed bone remodeling compared to the 1 mg/kg dose. The percent change in osteocalcin (Ocn) was significantly different between the two doses (p=0.0045). Whereas there were no significant changes in C-terminus telopeptide (CTX) and Procollagen 1 Intact N-Terminal Propeptide (P1NP) between the two dose groups, similar to the results with Ocn, the percentage change of CTX from baseline was lower in the 4 mg/kg dose cohort. In 2 out of 4 individuals in each dose cohort, a robust increase in lumbar spine aBMD (6.7% and 8.6% in 1 mg/kg and 7.6% and 3% in 4 mg/kg dose) was observed compared to baseline. Our study, the first to comprehensively asses signaling abnormalities in human OI bone, confirms that TGF-Î² signaling is a driver pathogenic mechanism and that anti-TGF-Î² therapy could be a potential disease-specific therapy

PrgmNr 1383 - A cystic fibrosis lung disease modifier locus harbors tandem repeats associated with gene expression

View session detail

Hlth., Univ. of Toronto, Toronto, ON, Canada

Disclosure Block: **D. Roshandel:** None.

Introduction: The largest genome-wide association study (GWAS) of cystic fibrosis (CF) lung disease identified two independent signals on chromosome 5 (Chr5:403,462-686,129) in 5â□□ and 3â□□ of a previously reported CF modifier gene, *SLC9A3*. The locus displays a high density of CpG islands and variable number of tandem repeats (VNTRs). The exact boundaries of these VNTRs have not been well defined as they often expand hundreds of bps difficult to capture by short-read sequencing.

Methods: We used long-read PacBio phased data and multiple alignment to identify the boundaries of common (> 2%) VNTRs in the region (N = 22). Association between the identified VNTRs and gene expression in the region (*AHRR*, *EXOC3*, *SLC9A3*, *CEP72* & *TPPP*) was then investigated using RNA-seq of CF nasal epithelia (NE; N = 46). Subsequently, the lengths of VNTRs were estimated in 10X Genomics (10XG) linked-read technology by dividing the number of reads aligned to the location of each VNTR by the average sequencing depth: we confirmed a high correlation between estimated lengths from short-read (10XG) sequencing and lengths from long-read (PacBio) sequencing in 53 subjects with both 10XG and PacBio. Therefore, the same strategy was used to estimate the VNTR lengths using short-read sequencing from the Genotype-Tissue Expression (GTEx) to investigate VNTR associations with gene expression in all 49 GTEx tissues. **Results:** At the locus, 54 VNTRs were identified. A VNTR in the last intron of *SLC9A3* overlapping a CpG island was associated with *SLC9A3* expression in NE (p = 5E-4) and forty GTEx tissues including lung (p = 8E-15). This VNTR was partially tagged by rs72711364, the top associated GWAS SNP 3â□□ of *SLC9A3* (Spearman correlation coefficient = 0.28). Its repeat sequence was â□□100bp including 7 CpGs. Subjects had 2-10 copies of the repeat (mean = 5) per haplotype. Another VNTR in the 3â□□ UTR of *TPPP* also overlapping a CpG island was associated with both *TPPP* (p = 9E-5) and *SLC9A3* (p = 2E-3) expression in NE, and multiple GTEx tissues. This VNTR had a 31 bp repeat sequence including 1-4 CpGs and multiple SNPs some changing CpG count. Subjects had 3-21 copies of the repeat per haplotype (mean = 9). The long/short version of this VNTR was perfectly tagged by C/T alleles of rs72703083, a GWAS SNP 5â□□ of *SLC9A3*. These two VNTRs together explained 22% and 9% of variation in *SLC9A3* expression in CF NE and GTEx lung, respectively. **Conclusion:** We used long-read sequencing to identify the precise boundaries of common VNTRs at the *SLC9A3* locus. Two of these VNTRs, tagged by genome-wide associated CF lung disease SNPs from two independent GWAS peaks in the region, account for almost a quarter of *SLC9A3* expression in the NE model of CF airway.

PrgmNr 1384 - Genome-wide somatic mutation rate maps uncover drivers of cancer

Identifying cancer driver elements - genomic loci that can cause cell proliferation, tissue invasion, and immune evasion - is a critical challenge, particularly in the noncoding genome. We developed a probabilistic deep learning framework that integrates tissue-of-origin epigenetic patterns with cancer mutational spectra to learn a map of the neutral somatic mutation rate across the genome of a cancer of interest. These browsable maps allow dynamic retrieval of the mutation rate at any genomic locus and enable tests for positive selection by comparing the expected to observed mutation rate in a cancer cohort. We applied this approach to identify driver elements genome-wide in 2,583 tumor samples from the Pan-Cancer Analysis of Whole Genomes resource.

-

Predicted cryptic splice SNVs in the introns of tumor suppressor genes (TSGs) were observed significantly more often than expected under neutrality ($P=2.6Ã□10^{-5}$) with the majority (79.3%) outside the 20bp splice region bordering exons. These cryptic splice SNVs, which are usually overlooked by computational pipelines, accounted for 4.5% (95% CI: 1.6-7.3%) of driver SNVs in TSGs and recurrently disrupted 8 genes in 14 tumor types including *CIITA* (blood tumors) and *SMAD4* (pan-cancer). Of the 7 predicted cryptic splice SNV carriers with available tumor RNA-seq data, 6 had evidence of alternative splicing consistent with predictions.

-

A search for positive selection in noncoding regulatory elements revealed that the 5â□□ UTR of *TP53* carried a significant burden of indels (7 observed vs. 0.08 expected; $P=3.3Ã□10^{-12}$). These indels - all deletions - were larger than most indels (median: 17 bp) and recurrently disrupted regulatory sequences such as the transcription start site and a splice region within the UTR (*TP53* 5â□□ UTR spans multiple exons). The six *TP53* 5â□□ UTR mutation carriers with available tumor RNA-seq data exhibited 1-2 s.d. decreases in *TP53* expression ($P=1.6Ã□10^{-4}$, adjusted for tissue and copy number).

-

We also searched for driver mutations in infrequently mutated (â□□long-tailâ□□) genes in whole-exome and targeted sequencing of 14,018 tumors from 10 cancer types. Across these cancers, 1-5% of samples carried excess activating SNVs in oncogenes and 3-6% of samples carried excess protein-truncating SNVs in TSGs not associated with that cancer in recent pan-cancer driver gene databases. We identified 142 specific driver gene-tumor pairs not reported in these pan-cancer databases, detailing the rich, shared landscape of common and rare cancer driver genes. These results highlight the promise of genome-wide somatic mutation rate maps to uncover underappreciated coding and noncoding drivers of human cancers.

PrgmNr 1385 - Developmental Venous Anomaly: A genetic primer to *PIK3CA*-related neurological disease?

View session detail

Author Block: **D. A. Snellings**[1], R. Girard[2], R. Lightle[2], A. Srinath[2], S. Romanos[2], A. A. Ren[3], M. L. Kahn[3], I. A. Awad[2], D. A. Marchuk[1]; [1]Duke Univ., Durham, NC, [2]The Univ. of Chicago Med. and Biological Sci., Chicago, IL, [3]Univ. of Pennsylvania, Philadelphia, PA

Disclosure Block: **D.A. Snellings:** None.

Developmental Venous Anomalies (DVAs) are common vascular malformations present in up to 3% of the population and are generally considered to be benign. Despite being considered benign, DVAs have long been known to be directly associated with sporadic Cerebral Cavernous Malformations (CCMs)â□□a rarer, more aggressive type of vascular malformation that grow from the branches of a DVA. Recent work from us and others have shown that CCMs develop through co-occurring gain of function mutations in *PIK3CA* and *MAP3K3*. We hypothesize that DVA are the product of somatic *PIK3CA* mutation during developmental angiogenesis, creating field of mutant cells that may develop into a CCM upon a subsequent mutation in *MAP3K3*. To test this hypothesis, we used Droplet Digital PCR and targeted sequencing to detect somatic mutations in surgically resected sporadic CCMs in addition to paired samples of associated DVA discretely dissected from the DVA bed during surgery. We find that the *PIK3CA* mutation is present in both the DVA and the CCM, but that the *MAP3K3* mutation is exclusively present in the CCM suggesting that the *PIK3CA* mutation occurs first. Furthermore, we performed single-nucleus DNA sequencing on 3 CCM samples and found in each case that *PIK3CA* and *MAP3K3* mutations co-exist in the same clonal population of cells supporting a cell-autonomous synergy between *PIK3CA* and *MAP3K3* mutations. As *PIK3CA* is a commonly mutated oncogene and has been implicated in numerous cancer and non-cancer diseases, we wondered if DVA are also associated with diseases other than CCM. There are several clinical case reports that note a link between DVA and various brain tumors, however the strongest evidence comes from a recent study showing that DVA were present in 24.1% of a series of 162 diffuse intrinsic pontine gliomaâ□□a class of tumor reported to have *PIK3CA* mutations in up to 27% of cases. Notably, association with DVA is also present in the literature of other diseases related to PI3K activation including: hemimegalencephaly, focal cortical dysplasia, and Cowden syndrome. Taken together these data support a model where DVA serve as a genetic primer for the formation of CCM, glioma, and other *PIK3CA*-related disease.

Defects in embryonic patterning resulting in craniofacial abnormalities account for approximately 1/3 of birth defects. The regulatory programs that build and shape the face require precisely controlled spatiotemporal gene expression, achieved through tissue-specific enhancers. Large regions with coactivation of enhancer elements and co-regulation of multiple genes, referred to as superenhancers, are important in determining cell identity and perturbation could result in developmental defects. Building upon a previously published epigenomic atlas of human embryonic craniofacial tissue in which we identified over 75,000 putative embryonic craniofacial enhancer regions, we have identified 581 superenhancer regions, including 36 which fall in completely non-coding regions and not directly adjacent to known craniofacial relevant genes. To demonstrate the utility of this data for the understanding of craniofacial development and the etiology of craniofacial abnormalities, we focused on a craniofacial-specific superenhancer in a ~600kb non-coding region located between *NPVF* and *NFE2L3*. This region harbors over 100 individual putative craniofacial enhancer segments and 7 in vivo validated craniofacial enhancers from primary craniofacial tissue as well as strong enhancer activation signatures in a culture model of cranial neural crest cell (CNCC) development. However, none of the directly adjacent genes have been implicated in neural crest specification, craniofacial development, or abnormalities. To identify potential regulatory targets of this super enhancer region, we characterized three-dimensional chromatin structure of this region in CNCCs and mouse embryonic craniofacial tissues using multiple techniques (4C-Seq, HiC). We identified long range interactions that exclude most intervening genes and specifically target the anterior portion of the *HOXA* gene cluster located 1.2 to 1.8 Mb away. We demonstrate the specificity of the enhancer region for regulation of anterior *HOXA* genes through CRISPR/Cas9 editing of human embryonic stem cells. Mice homozygous for deletion of the superenhancer confirm the specificity of the enhancer region and demonstrate that the region is essential for viability. At fetal stages homozygotes develop at the same rate as heterozygous and wild type littermates but die at P0-P1 and have high penetrance of orofacial clefts that phenocopy previously described *Hoxa2* knockout mice. This evidence suggests we have identified a critical non-coding locus control region that specifically regulates anterior *HOXA* genes and whose deletion could be pathogenic in human patients.

Anatomically modern humans evolved around 300 thousand years ago in Africa. Modern humans started to appear in the fossil record outside of Africa about 100 thousand years ago though other hominins existed throughout Eurasia much earlier. Recently, several researchers argued in favourof a single out of Africa event for modern humans based on whole-genome sequences analyses. However, the single out of Africa model is in contrast with some of the findings from fossil records, which supports two out of Africa, and uniparental data, which proposes a back to Africa movement. Here, we used a deep learning approach coupled with Approximate Bayesian Computation and Sequential Monte Carlo to revisit these hypotheses from the whole genome sequence perspective. Our results support the back to Africa model over other alternatives. We estimated that there are two successive splits between Africa and out of African populations happening around 60-90 thousand years ago and separated by 13-15 thousand years. One of the populations resulting from the more recent split has to a large extent replaced the older West African population while the other one has founded the out of Africa populations.

Introduction Copy number variation (CNV) is responsible for a large component of normal human variation and has been implicated in the cause/genetic aetiology of several rare diseases. Population reference databases containing CNV information from all global populations is critical in disease genetics research, but current resources lack diversity, especially from the African continent. This makes such databases of limited use in studies looking at genetic diseases in African individuals. This study therefore aims to address this knowledge gap by producing a map of CNV using whole-genome data from several, previously unstudied African populations

Methods 1027 high coverage whole genome sequences obtained from individuals across west, central, southern and east Africa, were analysed using Manta and Graphtyper2. Additionally, 919 of the samples were also analysed using Genome STRiP to detect multi-allelic CNV. Quality control specific to each tool was performed in order to achieve high quality variant call sets.

Results 56 816 CNVs were detected by the Manta pipeline, consisting of 44 671 deletions and 12 145 duplications. Due the ability of Manta to detect small variants (5% allele frequency. 50% of these variants are novel compared to 27% of the remaining variants >100bp. Overall, 32% of the variants identified were novel. A comparison between central, west, east and southern African regions yielded a number of variants unique to each region. We find deletions tend to have lower allele frequencies compared to duplications. The majority of variants were found in the non-coding genome, with only 8% of variants overlapping coding transcripts. An additional 5% of variants overlapped regulatory features. Genome STRiP detected 3991 multi-allelic variants with 99% having a copy number between 3-20. There were also variants with copy numbers greater than 20, some of which appear to be incidences of excessive runaway duplications not previously described.

Conclusion The amount of novel variation found demonstrates the importance of including African individuals from multiple African regions when producing reference databases and the rich genomic diversity of African genomes. Work is currently being performed to combine the full Genome STRiP and Manta call sets to produce a robust combined dataset. The variant database produced in this study will provide a valuable resource as a reference of normal CNV for the study of diseases in African populations.

PrgmNr 1006 - Integrative genomic analyses identify key interethnic differences in immune response to malaria

Host responses to infection with the malaria parasite *P. falciparum* vary between individuals for reasons that are poorly understood. Here we reveal metabolic perturbations as a consequence of malaria infection in children and identify an immunosuppressive role of endogenous steroid production in the context of *P. falciparum* infection. We perform metabolomics on matched samples from children from two ethnic groups in West Africa, before and after infection with seasonal malaria. Analyzing 306 global metabolomes we identify 92 parasitemia-associated metabolites with impact on the host adaptive immune response. Integrative metabolomic-transcriptomic and causal mediation-moderation analyses reveal an infection-driven immunosuppressive role of parasitemia-associated pregnenolone steroids on lymphocyte function and the expression of key immunoregulatory lymphocyte genes in the Gouin ethnic group. In children from the less malaria-susceptible Fulani ethnic group we observe opposing responses upon infection, consistent with the immunosuppressive role of endogenous steroids in malaria. These findings advance our understanding of *P. falciparum* pathogenesis in humans and identify potential new targets for antimalarial therapeutic interventions.

PrgmNr 1007 - GWAS of complex traits in a multi-population African cohort

The diversity among present-day African populations is the result of a deep and complex history of admixture, migrations, and regional adaptations to local environments and diseases. Little is known about the impact of this evolutionary history on the genetics underlying complex traits. Here I present recent work on genetic associations for a panel of anthropometric, cardiovascular, and metabolic biomarker measurements paired with dense genotyping data. For some traits, the variation among populations is expected to reflect local adaptations, such as short stature in western Cogo rainforest hunter-gatherers. The study cohort of several thousand individuals is drawn from an ancestrally diverse set of populations from western, eastern, and southern sub-Saharan Africa. Populations include current or recent hunter-gatherers, traditional agriculturalists, and semi-nomadic pastoralists, from rural regions of Cameroon, Nigeria, Ethiopia, Kenya, Tanzania, and Botswana. For many of these traits, this marks the first genotype/phenotype analysis to include these ethnic groups. The high degree of population structure presents both challenges and opportunities for genetic analysis. Genetic structure analysis indicates genetic clustering by geographic location, language family, and regional hunter-gatherer lineages. Examples include the hunter-gathers from the Serengeti, western Congo, and Kalahari, and clusters that correlate with Niger-Congo, Afroasiatic, and Nilo-Saharan language families. We observe substantial population-level variation for many traits, such as height, skin pigmentation, and blood pressure. The proportion of the trait variance that is due to the genetic population structure varies by trait and tends to be greater for anthropometric traits like height and skin pigmentation than for metabolic biomarkers like LDL. From genotype/phenotype association tests we find numerous independent associations at genome-wide significance for several traits, including circulating triglyceride levels and BMI. The population structure of the total additive genetic effects is also examined. European GWAS associations replicate poorly in this African cohort, while associations discovered in the African cohort show comparatively better replication in Europeans.

PrgmNr 1008 - Genotype-by-infection interactions: Single cell RNASeq profiling of in-vivo host immune response to malaria reveals cell type and infection-specific eQTLs

Disclosure Block: **O. Bayaraa:** None.
The disease burden of malaria remains a significant global public health challenge. *Plasmodium falciparum* is responsible for more than 99% of malaria cases in Africa and for >400,000/year malaria-related deaths worldwide. Inter-individual differences in susceptibility to malaria is multifactorial and has a significant heritable component but our understanding of the effect of infection on gene regulation of immune response at the transcriptional remains very limited. Here we use longitudinal matched sampling, single cell RNAseq profiling of PBMCs and whole-genome sequencing data of malarial children before and after natural *P. falciparum* infection in Banfora, Burkina Faso, West Africa. In total, we generated ~90,000 single cell RNASeq profiles and identified PBMC cell types affected by infection. Single cell RNASeq eQTL analysis revealed cell type specific eQTLs and genome-wide significant genotype-by-infection interaction effects implicating key immune genes. These results provide the first genome-wide picture of host in vivo regulatory variation events in malaria at the single cell level and highlight the implication of regulatory interaction effects in modulating host immune response in-vivo.

PrgmNr 1009 - Returning secondary genetic findings: Provider perspective in Africa

Objective: Previous research has shown that lack of resources and knowledge significantly impact the return of genomic test results. However, not much is known about the level of expertise and knowledge of clinicians providing cleft care in Africa on genetic diseases, despite the vast genetic diversity in this population.
Methods: Providers in participating cleft-craniofacial clinics in Ethiopia, Ghana, and Nigeria were sent the link to a 63-question online survey. This survey assessed the providers' experience with genetic testing, genetics education and return of genetic results, provider knowledge, clinician comfort with returning results, available resources to assist with genomic findings, and potential barriers.
Results: As of June 2nd, 2021, 246 providers completed the survey. Only 2% had been involved in the delivery of Exome or Genome sequencing; 78.6% had no formal genetic education, 49.6% agreed that all secondary findings should be disclosed to patients. Regarding the comfort level, 89.4% were somewhat to extremely comfortable discussing genetic risk factors with patients, and 81.8% were somewhat to extremely comfortable with returning genetic results. Sixty-three percent believed that resources were currently available to enable them to access needed genetic information.
Conclusion: Providers were aware that genetic testing could help in the clinical management of diseases from the returned responses. However, the lack of knowledge about genomic medicine, uncertain clinical utility, and lack of available resources were cited as barriers that significantly impacted incorporating genetic testing into their practice. Data collection is ongoing and will continue till July 31st, 2021. This is the first Ethical, Legal, and Social Implications (ELSI) study to document the knowledge and comfort level of cleft providers in Africa. This study will help determine the most beneficial information to equip providers with the return of secondary genetic findings.

PrgmNr 1012 - Multi-trait Bayesian genome-wide association study identifies novel endometrial cancer risk loci at 7q22.1, 8q24.3 and 16q22.2

Endometrial cancer is the most common gynecological tumor in developed countries, and its prevalence and mortality are increasing worldwide. Current genome-wide association studies (GWAS) of endometrial cancer, performed by the Endometrial Cancer Association Consortium, have identified 16 genetic risk regions for this disease. To identify additional risk variants for endometrial cancer, we leveraged summary statistics from the largest GWAS meta-analysis for endometrial cancer performed to date (12,906 cases and 108,979 controls) and publicly available GWAS datasets of endometrial cancer risk factors using a recently developed multi-trait Bayesian GWAS (bGWAS) framework. Using LD score regression, we assessed the genetic correlation between >2,500 phenotypes and endometrial cancer risk to identify potential endometrial cancer risk factors. Significantly genetically correlated phenotypes (FDRThe bGWAS findings suggest that the three novel loci affect endometrial cancer risk through altered sex-hormone levels or effects on obesity. Consistent with this hypothesis, several genes with established roles in these pathways (*CYP11B1*, *CYP3A7*, *IRX3* and *IRX5*) were prioritized as candidate endometrial cancer risk genes by interrogation of quantitative trait loci data and chromatin looping assays in endometrial cell lines. The findings of this study identify additional opportunities for hormone therapies and further support weight loss to reduce the risk of developing endometrial cancer.

PrgmNr 1013 - Novel basal cell carcinoma susceptibility loci identified from a multiethnic genome-wide meta-analysis

View session detail

Author Block: **H. Choquet**[1], J. Yin[1], Y. Kim[2], T. J. Hoffmann[3], E. Jorgenson[4], M. M. Asgari[5]; [1]Kaiser Permanente, Oakland, CA, [2]Harvard Med. Hosp., Harvard Med. Sch., Boston, MA
Disclosure Block: **H. Choquet:** None.
Purpose: Basal cell carcinoma (BCC) is one of the most common malignancies worldwide and has a moderate genetic component with an array-heritability estimate of up to 17.0%. Previously published genome-wide association studies (GWAS) have reported more than 70 loci associated with BCC, explaining up to 11.0% of BCC heritability, suggesting that additional loci remain to be discovered. Most published studies have exclusively utilized European descent populations, and the impact of genetic factors on BCC risk in a multiethnic population has not been explored. **Methods:** We conducted GWAS analyses, followed by a meta-analysis, including 526,432 individuals (34,616 BCC cases and 491,816 controls) from two cohorts: the Kaiser Permanente Genetic Epidemiology Research in Adult Health and Aging (GERA) and the UK Biobank (UKB). First, a logistic model GWAS for BCC was carried out separately in each ethnic group of GERA (non-Hispanic whites, Hispanic/Latinos, East Asians, and African-Americans), and UKB (European, South Asian, African British, and mixed Ancestries), adjusting for age, sex, and ancestry principal components. Then, the results from each ethnic group, and each cohort were meta-analyzed. We tested novel loci discovered in the combined multiethnic meta-analysis in an external replication cohort. To prioritize genes and biological pathways, and highlight gene-set and tissue/cell enrichments within the associated loci identified, we used DEPICT (Data-driven Expression-Prioritized Integration for Complex Traits) integrative tool. **Results:** Our multiethnic GWAS meta-analysis identified 78 genome-wide significant (*P*â□□8) BCC-associated loci, of which 20 were novel. Most of them replicated in an external independent sample at Bonferroni significance with the same direction of effect. Identified novel loci are implicated in the normal cell function (*SENP7*), adhesion of platelets and other cell types to the extracellular matrix (*ITGA2*), or DNA repair (*ATM*). Interrogation of loci uncovered by our multiethnic meta-analysis GWAS using DEPICT integrative tool also prioritized novel biological pathways underlying BCC. **Conclusions:** In this work, we present the largest and most ethnically diverse genetic study of BCC susceptibility conducted to date to our knowledge. Study findings provide new insight into the genetic basis of BCC susceptibility and may help identify individuals at higher BCC risk.

Over 150 genetic susceptibility loci have been identified for colorectal cancer (CRC) through genome-wide association studies (GWAS). To uncover potential independent association signals and identify putative target genes in these loci, we conducted a fine-mapping analysis using GWAS summary statistics data from 72,272 subjects of East Asian (EAS)- and 182,518 subjects of European-ancestry (EA). We performed stepwise conditional analyses by race using the GCTA-COJO with adjustment for the top association signal in each region. Results from EAS and EA were combined using a fixed-effects model. To identify race-specific associations, similar analyses were performed with adjustment for the race-specific top association signal in each region. At conditioned *P* -6, we identified 219 independent risk signals, including 142 from combined analyses of EA and EAS, 9 from EAS analyses, and 68 from EA analyses. Using a conditioned *P* value within two orders of magnitude of the most statistically significant variant for each signal, we identified 6,131 credible causal variants (CCVs). Using a modified INQUSIT pipeline to score each gene-CCV pair by integrating functional genomic data, we identified 168 potential target genes. We conducted cis-eQTL analysis using transcriptome data derived from colon transverse tissues of EA from GTEx and of tumor-adjacent normal tissue of EAS. At Bonferroni-corrected *P* P P

Disclosure Block: **T.B. Cavazos:** None.
Approximately 10-20% of individuals diagnosed with one cancer will face another cancer diagnosis in their lifetime. Multiple cancer diagnoses will likely become more common with earlier detection and improving survival. While some pleiotropic drivers of hereditary cancer syndromes, such as BRCA1/2 and TP53, have been discovered, the genetic factors contributing to the development of multiple primary tumors within single individuals are not well understood. To characterize the genetic susceptibility to multiple malignancies we conducted a pan-cancer, whole-exome sequencing study of two large prospective cohorts: Kaiser Permanente (KP) and the UK Biobank (UKB). The former cohort included 3,111 individuals with two or more primary cancers and 3,126 cancer-free controls, and the latter included 2,126 cases and 173,779 controls. In KP, we used SAIGE to conduct gene-based tests of predicted functional/pathogenic rare (MAF significant associations after Bonferroni correction (p

Background The BOADICEA breast cancer (BC) risk prediction model has been extended to incorporate questionnaire-based risk factors (QRFs), mammographic density (MD), explicit family history (FH) and the effects of known rare and common BC genetic susceptibility variants. Here, for the first time, we assessed its clinical validity in predicting the 5-year BC risks, using an independent, prospective cohort. **Methods** We used data from the Swedish KARMA screening cohort, which included 66,415 women (816 incident BCs) without a previous cancer diagnosis, recruited between 2011 and 2013. All participants had information on QRF, FH, and categorical MD (BIRADS). A sub-cohort of 15,502 women (676 incident BCs) had a validated BC polygenic risk score (PRS) based on 313-SNPs, and 5,693 women (280 incident BCs) had gene-panel testing information for the 5 major BC susceptibility genes: *BRCA1*, *BRCA2*, *PALB2*, *CHEK2*, and *ATM*. We assessed the model calibration and discriminatory ability in predicting 5-year BC risks, using a weighted cohort analysis approach. Calibration was assessed using the ratio of expected versus observed BC cases in deciles of predicted risk and the calibration slope. The discriminatory ability was assessed using the area under the curve (AUC). **Results** BOADICEA was well calibrated in the full cohort on the basis of QRF, MD and FH (calibration slope=0.98, 95%CI: 0.96-1.00). In the subcohort with PRS information, the largest discrimination was achieved by the PRS (AUC=0.665, 95%CI:0.644-0.686), followed by QRF (AUC=0.626, 95%CI:0.605-0.647), FH (AUC=0.612, 95%CI:0.591-0.633) and MD (AUC=0.626, 95%CI: 0.605-0.646). When all four risk factors were considered, AUC was 0.685 (95%CI:0.666-0.705). The model was well calibrated in deciles of predicted risks (overall calibration slope 0.98, 95%CI:0.96-1.00). AUC was 0.688 (95%CI:0.651-0.724) in pre-menopausal women and 0.665 (95%CI:0.641-0.690) in post-menopausal women. In the subcohort with gene-panel testing information, addition of pathogenic variant status in the 5 BC susceptibility genes improved discrimination with an AUC=0.696 (95%CI: 0.660-0.732) and the model remained well calibrated in deciles of predicted risk (overall calibration slope 0.97, 95%CI: 0.95-0.99). **Conclusion** The study shows that the multifactorial BOADICEA model (version 5.0) provides valid BC risk predictions, and that incorporating all risk factors provides significantly better discrimination than any one factor. BOADICEA, which is implemented in the CanRisk tool (www.canrisk.org) for use by healthcare professionals, provides a powerful basis for personalised decisions on disease prevention and screening.

Quantitative Trait Locus (QTL) studies have been useful for nominating candidate causal genes (CCGs) for genome-wide association study (GWAS) loci. However, melanocyte-specific expression (eQTL) and methylation (mQTL) QTLs nominate CCGs for only 37% of all known melanoma GWAS loci by colocalization. To complement these QTL data and conduct variant to gene mapping at a higher resolution, we performed region-focused chromatin conformation capture assay (capture-C) to identify physical interactions between Credible Causal Variants (CCV) and target genes in primary human melanocytes. We baited the regions of association for all independent signals from a recent melanoma GWAS (n=36,760 cases; Landi et al. 2020) and capture-C interactions were called using HiCUP and CHiCAGO. Capture-C data identified physical interactions between CCVs and CCGs at 57% of the loci with no QTL support; collectively QTL and capture-C data nominated CCGs for 94% of loci. We performed sequencing assay for transposase-accessible chromatin (ATAC-seq) in primary melanocytes and observed interactions between CCVs located within open chromatin to CCG at 70% of the loci. These findings were in concordance with the ATAC-seq data from melanoma cell lines and interactions from CCVs in melanoma open chromatin regions were observed for 60% of loci. Furthermore, we annotated CCV to CCG interactions using the available ChromHMM data from primary melanocytes and melanoma cell lines and observed that these interactions formed enhancer-promoter loops at 50% and 38% of loci in melanocytes and melanoma cell lines respectively. Biological pathway enrichment analyses of capture-C-nominated CCGs identified embryonic development, aryl hydrocarbon receptor signaling, interferon signaling, and DNA repair pathways, including multiple targets involved in the neural crest lineage. Notably, we observed interactions from two independent loci (separated by ~1.6Mb) to the promoter of *SOX4*, a gene that regulates neuronal differentiation. The first independent locus near *HDGFL1* showed multiple loops from the region of association to the *SOX4* promoter, one of which included CCV rs16886790. The second locus, located in a melanocyte enhancer within the *CDKAL1* gene, also showed direct interaction between a region harboring multiple CCVs and the *SOX4* promoter. Integration of these results with MPRA and CRISPR screening data are currently underway. In summary, we developed a high-throughput cell-type specific analysis framework for high-resolution functional mapping CCVs to CCGs and highlighted the added utility of capture-C for identifying high-confidence CCGs at melanoma susceptibility loci.

PrgmNr 1020 - Analysis of PI3K-AKT-MTOR spectrum disorders through deep genomic and functional models reveals new clinical insights and distinct molecular pathomechanisms

Megalencephaly (MEG), Hemimegalencephaly (HMEG) and Focal Cortical Dysplasia (FCD) are neurodevelopmental disorders characterized by brain overgrowth and cortical abnormalities, associated with significant pediatric morbidity and mortality including epilepsy, autism and intellectual disability. Gain and loss of function mutations in the PI3K-AKT-MTOR pathway have been identified in this spectrum, with variable levels of mosaicism and distribution of causal mutations. We aimed to better define the genotype-phenotype correlation among the most common hotspot mutations in the pathway. We analyzed a cohort of 58 patients (144 samples, 114 epilepsy brain tissue) and tested them using droplet digital PCR (ddPCR). We were able to solve 29% of our cohort, with a diagnostic yield of 90% in HMEG and 24% in FCD. Interestingly, individuals with FCD mostly had mutations in *MTOR*, while those with HMEG had *PIK3CA* mutations. Our data highlighted an inverse correlation between age of onset for seizure and mutational burden (level of mosaicism), with individuals presenting a Variant Allele Fraction (VAF) >5% having seizure at day of life 1-30, and individuals with VAFin vitro using patient-derived and genome edited induced pluripotent stem cells carrying the common $PIK3CA^{H1047R}$ and $MTOR^{T1977I}$ mutations and differentiated them to Neuronal Progenitor Cells (NPCs) and cerebral organoids. We performed functional assays including population doubling time, analysis of cellular morphology and size, differentiation and cortical layering.Our results show overlapping and exclusive cellular phenotypes in *PIK3CA* and *MTOR* mutant cell lines. Specifically, both mutant lines had increased NPCs proliferation and hypertrophy, albeit *PIK3CA* mutants displayed the most severe phenotype. *MTOR* and *PIK3CA* mutant organoids had an average area at least double that of controls, recapitulating MEG *in vitro*.Eventually, we treated NPCs with 3 different MTOR pathway inhibitors to investigate their potential in rescuing the cellular phenotypes identified. Inhibition of MTOR activity *in vitro* effectively reduced hypertrophy and hyperplasia, providing a proof of concept for novel therapies for individuals with FCD and HMEG.In summary, our results show that distinct mechanisms underlie *PIK3CA*- and *MTOR*- related MEG and FCD during human embryonic development, and that inhibition of MTOR pathway might be sufficient to restore cellular homeostasis. This work will help characterize mechanisms of MEG and FCD caused by mutations in MTOR pathway and guide the design of future clinical trials.

PrgmNr 1021 - Skewed X-chromosome inactivation in unsolved neurodevelopmental disease cases can guide re-evaluation for X-linked genes

In females, random X-chromosome inactivation (XCI) results in an approximate equal ratio of cells expressing maternal or paternal X chromosome genes. When XCI is non-random, this proportion can vary from mildly skewed XCI (e.g., 70:30) to completely skewed XCI (e.g., 0:100). Non-random XCI can be associated both to unaffected females (XCI favors the expression of the normal allele) or affected females. This latter case is explained by skewing towards a deleterious allele which reaches toxicity threshold or skewing away from a deleterious allele that decreases expression below lethality or an extreme phenotype.We explored the excess XCI in a clinically heterogeneous cohort of unsolved neurodevelopmental disease (NDD) cases - either the mothers of male patients or affected females - negative at FRAXA, array-CGH and Trio Whole Exome Sequencing (WES). We set up a fluorescent-PCR based screening for XCI on blood extracted DNA, amplifying three different microsatellites (AR, PCSK1N and SLITRK4 genes) after HhaI digestion. Currently, we analyzed 23 mothers of affected males and 45 female probands. We found a skewed XCI >80% in five of the 23 mothers (22%), and in ten of the 45 female patients (22%), far beyond the expected XCI in normal population (8%; p=0.0023, Chi square test). To search for a possible genetic mechanism determining XCI, we reanalyzed WES and clinical data. We possibly solved 5/15 cases (33%) whose causative gene was previously missed. In a boy, whose mother was 100% skewed, we found a previously missed causative deletion involving exons 3-4 in the ATRX gene (Mental retardation-hypotonic facies syndrome; MIM 309580). In two monozygotic twins (mother: 80% skewed XCI), we identified a possible causative c.-23C>A splicing variant in RLIM, associated with Tonne-Kalsheuer syndrome (MIM 300978), whose protein is involved in initiating XCI. In two brothers (mother: 100% skewed XCI), we identified a [c.1526C>T; p.(P509L)] missense variant in OTUD5, recently associated with X-linked multiple congenital anomalies-neurodevelopmental syndrome (MCAND; MIM 301056). Finally, we found a boy (mother: 100% skewed XCI) with a [c.2491C>T; p.(R831C)] missense variant in RBM10, associated with TARP syndrome (MIM 311900). Among affected females, we found the [c.1204G>A; p.(D402N)] likely pathogenic variant in KDM5C segregating in three other family members. Our work suggests to evaluate skewed XCI as an easy assay to further study cases without a diagnostic exome, to guide molecular re-evaluation for X-linked NDD. This approach may improve diagnostic yield and allow identifying new disorders with molecular mechanisms related to X chromosome inactivation.

PrgmNr 1022 - Understanding trajectories of neuronal differentiation underlying neurodevelopmental disorders using single-cell technologies

The mechanisms behind severe neurodevelopmental disorders (NDDs) such as Kabuki syndrome (KS) are still elusive, despite their large impact in modern society. The main reason for this lack of knowledge is the complexity of the chain of events during development that lead to these conditions. Large genetic studies of severe NDDs have shown that they are commonly caused by highly penetrant de novo mutations that are frequently observed in genes encoding for chromatin modifying enzymes. In KS, the KDM6A and KMT2D genes have been shown to cause the majority of cases. To study how mutations in these genes might cause NDDs on the cellular level, we used induced pluripotent stem cells (iPSC) together with single-cell technologies to model the mutation effects on early neuronal development in vitro.
First, we differentiated iPSC lines obtained from 8 healthy individuals and 4 KS samples to neuronal precursor cells (NPC). We collected single-cell transcriptomic and chromatin accessibility profiles from these cells before and after differentiation and used the data to compare cell type composition and gene regulatory differences between patient and control cells. Second, to control for genetic background effects, we used CRISPR-Cas9 to create isogenic control iPSC lines as well as wild-type lines carrying engineered disease mutations. Third, to determine when KS-specific cellular phenotypes first appear, we profiled the cells daily over the course of NPC differentiation using immunocytochemistry and qPCR to identify a time point when KS-specific changes in cell identity and morphology start appearing. The experiment will then be repeated using additional cell lines and time points.
Collectively, these complementary data will be used to reconstruct the gene regulatory networks underlying Kabuki syndrome. With a better understanding of the molecular pathways and key developmental stages underlying this disorder, it may be possible to re-purpose existing drugs associated with these pathways to treat KS.

PrgmNr 1023 - *De novo* missense and truncating variants in *ZMYND8* result in a distinctive neurodevelopmental disorder

ZMYND8 encodes a protein that serves as a central interactive hub for coordinating critical roles in transcription regulation, chromatin remodeling, regulation of super-enhancers, DNA damage response and tumor suppression. Through exome sequencing and an international collaboration, we assembled genotype and phenotype data for 15 affected, unrelated individuals with *de novo* variants in *ZMYND8*, of which 12 are missense, three are truncating and one is recurrent. This novel neurodevelopmental disorder is characterized by moderate to profound intellectual disability, non-familial facial features, cardiovascular, ophthalmologic and minor skeletal anomalies. Molecular modelling and yeast two-hybrid assays suggest that missense variants in the PWWP domain of ZMYND8 abolish interactions

with Drebrin, which translocates the ZMYND8 protein from the nucleus to the cytoplasm of neurons, while missense variants in the MYND domain abolish interactions with GATAD2A, a key component in the NuRD complex. Based on available human brain transcriptomic data, we demonstrate that ZMYND8 is broadly expressed across all cell types in all brain regions and shows higher expression in the early stages of brain development compared to the postnatal period. Neuronal knockdown of the *Drosophila ZMYND8* ortholog results in decreased habituation learning, consistent with a role of the gene in cognitive function. In conclusion, we present genomic and functional evidence for disruption of *ZMYND8* as a novel etiology of syndromic intellectual disability.

PrgmNr 1024 - Extremely rare variants in *EIF4A2* are associated with a neurodevelopmental disorder characterized by hypotonia, intellectual disability and epilepsy

Eukaryotic Initiation Factor-4A2 encodes EIF4A2, an ATP-dependent RNA helicase subunit of the eIF4F complex, which recognizes the 5â□□cap structure of mRNAs and is required for mRNA binding to the ribosome. The fruit fly homolog *eIF4A* mediates the negative regulation of Decapentaplegic (Dpp) signaling. In the fly, Dpp-signaling regulates embryo patterning, eye and wing morphogenesis, and stem cell identity determination. The vertebrate homolog of Dpp, TGF-Î²/BMP, is a key regulator of neuronal differentiation, development, and function. Dysregulation of TGF-Î²/BMP signaling is associated with various neurological disorders. Prior fly studies revealed that both gain and loss of function (GOF and LOF) *eIF4A* alleles modulate the rough eye and wing serration phenotypes associated with Dpp GOF and LOF, respectively. Despite the role of EIF4A2 homologs in key developmental processes, human disease-causing variants have not previously been identified. Here, we report eleven individuals with *extremely rare* variants in *EIF4A2* who all present with global developmental delay or intellectual disabilities, significant hypotonia, and epilepsy in most cases. To determine the pathogenicity of the *EIF4A2* variants *in vivo*, we generated transgenic flies expressing human *EIF4A2* wild-type (WT) and variants with a C-terminal HA tag for four *de novo* variants. We used the GAL4-UAS system to selectively express human EIF4A2 in fly neurons, wing, or eye. First, we conducted climbing assays to determine the impact of neuronal expression of EIF4A2 p.L344F, p.G364E, and p.T243I. We found that expression of these variants resulted in motor defects. Second, we found that the wing specific expression of EIF4A2 p.T216I caused wing serration, which is consistent with loss of Dpp signaling. This finding indicates that p.T216I is a GOF variant. Third, we found that the eye specific overexpression of EIF4A2 p.L344F exacerbates the rough eye phenotypes associated with Dpp GOF, suggesting that p.L344F is a LOF variant. Together, these findings reveal that these *de novo EIF4A2* variants are pathogenic and alter fruit fly development in a dominant

manner through either LOF or GOF mechanisms. Our work establishes a role for EIF4A2 dysfunction in human neurodevelopmental disorders.

PrgmNr 1025 - Autism spectrum disorder trios from consanguineous populations are enriched for rare biallelic variants

View session detail

Author Block: **R. S. Harripaul**; Ctr. for Addiction and Mental Hlth., Ajax, ON, Canada
Disclosure Block: **R.S. Harripaul:** None.
Autism spectrum disorder (ASD) is a severe neurodevelopmental disorder that affects about 1 in 55 children worldwide and imposes enormous economic and socioemotional burdens on families and communities. Genetic studies of ASD have identified de novo copy number variants (CNVs) and point mutations that contribute significantly to the genetic architecture of ASD, but the majority of these studies were conducted in outbred populations, which are not ideal for detecting autosomal recessive (AR) inheritance. However, several studies have investigated ASD genetics in consanguineous populations and point towards AR as an under-appreciated source of ASD variants. Here, we used trio whole-exome sequencing (WES) to look for rare variants for ASD in 115 proband-mother-father trios from populations with high rates of consanguinity, namely Pakistan, Iran, and Saudi Arabia. In total, we report 93 candidate sequence variants, with 57% biallelic, 24% dominant/de novo, and the rest X-linked. 52% of the variants were loss of function (LoF) or putative LoF (splice site, stop loss) and 47% non-synonymous. Our analysis indicates enrichment of previously identified and candidate AR genes. These include variants in genes previously reported for AR ASD and/or intellectual disability (ID), such as AGA, ASL, ASPA, BTN3A2, CC2D1A, DEAF1, HTRA2, KIF16B, LINS1, MADD, MED25, MTHFR, RSRC1, SHH, TECPR2, VPS13B, ZNF335, and 36 previously unreported candidates, including LoF variants in genes such as DAGLA, EFCAB8, ENPP6, FAXDC2, ILDR2, PKD1L1, SCN10A, and SLC36A1. We also identified likely causative CNVs in N individuals, and candidate biallelic exonic loss CNVs in four trios, implicating the genes SEMG1, DNAH7, DHRS4L2, and SIRPB1 Gene expression and cell-typing analysis indicated that the cortical plate, subplate and ventricular and excitatory and inhibitory neurons in critical learning and developmental regions such as the hippocampus and cerebral cortex were significantly enriched.

PrgmNr 1028 - Long read sequencing to improve diagnostic rate in critically ill patients

View session detail

Author Block: **M. N. Bainbridge**[1], A. Wenger[2], S. Batalov[3], J. Stone[2], P. Baybayan[2], C. Lambert[2]; [1]Rady Children's Inst. for Genomic Med., San Diego, CA, [2]Pacific BioSci.s, Menlo Park, CA, [3]Rady Childrens Inst., Genomic Med., San Diego, CA
Disclosure Block: **M.N. Bainbridge:** None.
Despite advances in sequencing and analytics, diagnostic rates for critically ill children remain in the 30-40% range. We selected a cohort of 22 patients, who remained undiagnosed after analysis both clinically and through a research pipeline of their 40x WGS short read sequenced genomes. Phenotypes of patients ranged from epilepsy, syndromic autism, complex undetermined syndromes and sudden infant death. We also selected three patients with known genetic diagnosis that were difficult to identify with short reads. We sequenced this cohort of patients to 10-30X depth of coverage using Pacific Biosciences HiFi long-read technology to assess whether there was an increase in diagnostic rate.

Of the three controls, long read successfully identified a pathogenic, hemizygous frameshift mutation in IKBKG. Due to high sequence homology this variant was not callable with short reads and patient was only diagnosed from a gene specific assay. Long reads were also able to detect a 60Mbp inversion which disrupted EYA1, the cause of autosomal dominant Branchiootic syndrome 1 [MIM:602588]. Finally, long reads identified a 70Kbp contig that established an apparent translocation of between chromosomes 22 and 11. This patient was diagnosed with a derivative, supernumerary chromosome of 22 and 11 (Emanuel syndrome).

Of the undiagnosed patients, long reads identified an average of 52 structural variants that occurred in known disease genes per patient; this included a large deletion of FBN2. Intriguingly, long reads were also able to detect an average of 2,184 small (Long read sequencing can identify numerous variants, both small and structural that are not readily detectable by short reads. The number of small, coding variants in disease genes missed by short reads is of particular concern and may impact the overall diagnostic rate for critically ill children.

PrgmNr 1029 - Establishing nonhuman primate models of human disease using a publicly available rhesus macaque genomic variant database

Author Block: **S. Peterson**[1], A. Lewis[1], E. Vallender[2], A. Ericsen[3], K. Ray[1], B. N. Bimber[1], B. Ferguson[1]; [1]Oregon Hlth.& Sci. Univ., Portland, OR, [2]Univ Mississippi Med Ctr, Jackson, MS, [3]Emory Univ., Atlanta, GA

Disclosure Block: **S. Peterson:** None.

Rhesus macaques serve a vital role as preclinical models of disease due to their high level of genetic and physiological homology with humans. The discovery of new genetic models has been greatly assisted by publically available genomic data. The Macaque Genotype And Phenotype Resource (mGAP; https://mgap.ohsu.edu/) catalogs whole genome and whole exome sequence data from rhesus macaques from the Oregon National Primate Research Center (ONPRC) as well as other National Primate Research Centers and external collaborators. The current release (mGAP 2.1) includes genetic data from 2,329 rhesus macaques mapped onto the latest macaque genome (Mmul10) along with a LiftOver track to visualize the data on the human genome. Variants are extensively annotated with relevant information including the location relative to genes, population frequency, sequence conservation, and scores from various variant effect prediction tools (CADD, SnpEff, PolyPhen2) or those variants which identically match pathogenic or suspected pathogenic human ClinVar variants. Variants predicted to be damaging to over 2,700 OMIM disease/phenotypes have been identified to date. Critically, the variant information in this database includes subject-level genotype data allowing the resource to be leveraged along with extensive health information records and pedigree information for each monkey. This has allowed for the identification of spontaneous non-human primate models of disease either through the matching of observed disease phenotypes with a causative genetic variant or by facilitating pedigree screens of individuals who carry specific alleles of interest for specific signs of disease. These approaches have been successful in establishing numerous models of human disease, including epidermolysis bullosa, Bardet-Biedl Syndrome, oculocutaneous albinism, hemochromatosis, cobblestone lissencephaly, osteochondrodysplasia and dyshormonogenetic goiter. As we rapidly expand this list, these verified models are being used to further disease investigation through biomarker discovery, gene therapy approaches and the study of alternative metabolic pathways. Funded by NIH R24 OD021324

PrgmNr 1030 - Utilization of Dual-Label Optical Genome Mapping for genetic/epigenetic diagnosis

View session detail

Author Block: **S. Bhattacharya**[1], H. Sharim[2], Y. Ebenstein[2], Y-W. Chen[1], S. I. Berger[3], E. J. Vilain[3], H. Barseghyan[4]; [1]Children's Natl. Hosp., Washington, DC, [2]Tel Aviv Univ., Tel Aviv, Israel, [3]Children's Natl. Med. Ctr., Washington, DC, [4]Childrens Natl. Hosp., Washington, DC
Disclosure Block: **S. Bhattacharya:** None.
Short-read exome/genome sequencing (SRS) and chromosomal microarrays (CMA) have helped increase diagnostic rates across many genetic disorders. However, despite this success, about half of the cases remain undiagnosed. Due to the methodological limitations of both technologies (SRS, CMA) they fail to sensitively identify structural variants or balanced rearrangements, respectively. Additionally, both technologies have limitations in assessment of epigenetic changes. Short-read based bisulfite sequencing or methylation arrays do not provide long-range haplotype specific methylation states, rather the detected signals are averaged for individual genomic positions. These limitations can be alleviated with a novel dual-label optical genome mapping (DL-OGM) technology for detection of both genetic and epigenetic changes in one assay over long stretches of single DNA molecules and phased haplotypes. The method relies on differential labeling of high molecular weight DNA. First, long DNA molecules are nicked with BspQI endonuclease and labeled with red fluorescent nucleotides. Second, the same DNA molecules undergo treatment with M.TaqI methyltransferase that attaches green fluorescent cofactor onto non-methylated CpGs in ATCG sequences throughout the genome. Third, the pattern of fluorescent labels is captured in nanochannel arrays for de novo genome assembly, variant calling and quantification of epigenetic marks. Additionally, separate bioinformatics pipelines have been developed to annotate and filter the variants and quantify the methylation marks, producing robust genomic and epigenomic results. Here, we show the ability of DL-OGM to detect large copy number variants and methylation levels for Facioscapulohumeral muscular dystrophy (FSHD) and Beckwith-Wiedemann syndrome (BWS). We successfully identified the molecular diagnosis (constriction of D4Z4 array and associated hypomethylation) in FSHD case/control samples in the sub-telomeric region of chromosome 4q35. Additionally, we tested the method for a case diagnosed with BWS, where DL-OGM identified a duplication in the paternally inherited allele carrying epigenetic states resulting in the syndrome. DL-OGM technology offers substantial advantages over the current clinical diagnostic practices for specific disorders tested here (FSHD, BWS) and can be applied to other types of disorders such as CHARGE syndrome.

PrgmNr 1031 - 2D and 3D human neuronal cell models of *CHD2*-associated epilepsy

View session detail

Author Block: **K-M. J. Lamar**[1], J. Gunti[1], A. Tidball[2], J. Z. Cheng[1], J. Parent[2], G. L. Carvill[1];

Disclosure Block: **K.J. Lamar:** None.
Pathogenic variants in *CHD2* are associated with developmental epileptic encephalopathy (DEE) in humans. The majority of these variants are frameshifts or deletions and all are heterozygous, having arisen *de novo*, indicating that haploinsufficiency is the mode of pathogenesis.
Chromodomain helicase DNA binding protein 2 (CHD2) is a chromatin remodeler that is associated with sites of active transcription.To better understand the role of CHD2 in human DEE, we utilized the CRIPSR/Cas9 system to create heterozygous disruptions of *CHD2* in human induced pluripotent stem cells (iPSCs). To examine the effect of *CHD2* disruption in neuronal development, we differentiated these iPSC lines into neuronal progenitor cells (NPCs) and cerebral organoids (COs). We performed RNA sequencing on $CHD2^{+/-}$ NPCs and isogenic wild-type (WT) controls and found that $CHD2^{+/-}$ NPCs exhibited an upregulation of genes involved in neuronal differentiation and a downregulation of genes involved in proliferation. CHD2 disruption in NPCs also lead to misregulation of other epilepsy genes. We performed single cell RNA sequencing (scRNAseq) in Day 48 COs from two WT lines and two $CHD2^{+/-}$ lines to determine whether *CHD2* disruption in distinct neuronal subtypes causes misregulation of genes important for human neurogenesis. Analysis of scRNAseq from COs revealed that the organoids form distinct neuronal subtypes, including radial glia, outer radial glia, intermediate progenitor cells, excitatory neurons, and interneuron progenitors. Differential expression analyses are ongoing to determine in which neuronal cell types *CHD2* loss has the biggest effects on gene regulation.
Overall, our results suggest that *CHD2* haploinsufficiency results in a cell proliferation defect which likely contributes to premature neuronal differentiation. In the future we aim to identify CHD2 targets and epigenetic changes during development. Ultimately, we seek to understand the mechanisms leading to gene expression changes when *CHD2* is disrupted and the role of CHD2 in regulating other epilepsy genes. The role of chromatin remodeling and control of gene expression is largely unexplored in epilepsy, but it is a dynamic process with many therapeutic targets and presents a novel opportunity to develop new treatments for patients.

PrgmNr 1032 - Long-read Sequencing Identifies Missing Disease-Causing Variants and Resolves Complex Structural Variants

View session detail

Author Block: **D. Miller**[1], M. Galey[1], E. E. Eichler[2]; [1]Univ. of Washington, Seattle, WA, [2]Univ of Washington, Seattle, WA
Disclosure Block: **D. Miller:** None.
Despite the widespread use of clinical genetic testing, a substantial fraction of patients with suspected genetic diseases remain undiagnosed. In some cases, clinical testing reveals structural differences that are challenging to fully evaluate, while in other cases, a suspected gene cannot be adequately evaluated due to technical limitations of short reads. Long-read sequencing of native DNA overcomes many of the limitations of existing clinical testing, but is expensive to implement, it has not yet been evaluated for clinical use. We performed targeted long-read sequencing (T-LRS) on an Oxford Nanopore platform using Adaptive Sampling, which allowed us to computationally select specific regions of the genome for sequencing in real-time. We targeted up to 150 Mbp of sequence per experiment, resulting in an average of 20-50 fold sequence coverageÂ¬â□□a significant increase above background. After base calling and alignment, we identified single nucleotide variants and structural variants and found that our method had 100% concordance with variants identified on clinical testing. For cases in which T-LRS could not resolve complex structural variants that lie within highly repetitive regions we performed whole-genome long-read sequencing (WG-LRS) on the Nanopore platform. Pathogenic and likely pathogenic missing disease-causing variants were identified in individuals for whom traditional genetic testing revealed only a single pathogenic variant for a known autosomal recessive disorder or was nondiagnostic for a suspected autosomal dominant or X-linked disorder. For example, T-LRS of an individual with biochemically confirmed Lesch-Nyhan syndrome revealed a 17-Mb inversion of the X chromosome that bisects HPRT1 within an intron that was not identified by targeted clinical sequencing. T-LRS was also used to phase known variants, fully sequence resolve triplet repeat expansions as well as their methylation state and resolve complex copy number changes discovering novel rearrangement breakpoints of functional and clinical relevance. Assembly and analysis of WG-LRS data resolved complex structural changes and demonstrates limitation of T-LRS in large repetitive regions of the genome. We show that T-LRS can be used as a single, cost-effective genetic test to accurately resolve pathogenic structural variants, methylation status and identify single-nucleotide variants not identified by other technologies. Overall, long-read sequencing will facilitate gene discovery, discover missing genetic variants and provide clarity in difficult-to-access regions of the human genome, improving the rate of clinical diagnosis.

PrgmNr 1033 - Using CRISPR-based saturation genome editing to improve the diagnosis of neuro-developmental disorders

View session detail

Author Block: **E. Radford**[1,2], H. Tan[2], M. Andersson[2], H. Ironfield[2], J. Stephenson[3], S. Gerety[2], M. E. Hurles[2]; [1]Univ. of Cambridge, Cambridge, United Kingdom, [2]Wellcome Sanger Inst., Cambridge, United Kingdom, [3]EMBL-EBI, Cambridge, United Kingdom
Disclosure Block: **E. Radford:** None.
Genetic sequencing is a powerful and widely used diagnostic tool. However, correctly interpreting candidate genetic variants remains a major challenge, and the number of variants of uncertain significance (VUS) is growing exponentially. Predictive testing and some targeted therapies cannot be offered where VUS are identified. Conventional strategies to resolve VUS rely on the accumulation of clinical data and variant effect prediction algorithms. Clinical data accumulate too slowly to be useful to families with rare neurodevelopmental disorders. Variant effect prediction algorithms are confounded by circularity and error propagation and are often discordant. New approaches are urgently needed.
Saturation genome editing (SGE) utilises CRISPR-Cas9 technologies to specifically engineer thousands of genetic variants into the endogenous genetic locus of a pool of cells and directly test their functional impact *in vitro*. The use of a haploid human cell line (HAP1) simplifies the design and interpretation of genetic screens. As proof-of-principle we have applied SGE to *DDX3X*, an X-linked RNA helicase of the DEAD-box protein family which is essential in HAP1. Heterozygous *DDX3X* loss-of-function mutations are one of the commonest genetic causes of female intellectual disability (Snijders-Blok *et. al*, 2015). We have functionally characterised every possible *DDX3X* single nucleotide variant and codon deletion, the majority of which have not previously been observed in the human population. SGE correctly identifies synonymous variants as functional, while the majority of loss-of-function variants are non-functional - these variants abrogate the expression or function of *DDX3X*. SGE is therefore a sensitive and specific test of loss of *DDX3X* function. Missense variants show a bimodal distribution, allowing us to categorise which variants render the protein non-functional. Missense variants within the helicase domain of *DDX3X* (exons 12-15), are more likely to render the protein non-functional. Strikingly, in the final and penultimate exons, many nonsense variants remain functional, consistent with these regions escaping nonsense-mediated decay. The majority of variants that have been reported as likely/pathogenic in a clinical context are identified as non-functional in our assay, while those variants observed in population studies of healthy individuals (UK Biobank and GnomAD) are identified as functional. Together these data suggest that SGE in HAP1 cells is a valuable approach to functionally assess developmental disorder genetic variants at scale. We are now scaling up this approach to assess many developmental disorder-associated genes.

PrgmNr 1036 - Single cell â□□whole embryoâ□□ phenotyping of developmental disorders

View session detail

Disclosure Block: **J. Henck:** None.
Mouse models represent a critical tool to study human diseases, particularly developmental disorders. A fundamental challenge to study pleiotropic developmental disorders *in vivo* is the lack of current technologies with sufficient throughput and resolution to obtain a global view of the molecular states and trajectories of a rapidly diversifying and expanding number of cell types during embryogenesis. We set out to establish single cell RNA sequencing at the â□□whole embryoâ□□ scale as a tool for unbiased phenotyping of mouse genetic models. In a single experiment, we applied combinatorial indexing based sc-RNA-seq to profile 103 embryos of 22 different mouse mutants and 4 different wildtype backgrounds at embryonic stage E13.5. Towards evaluating the sensitivity of this approach, the severity of the mouse mutants investigated range from established multisystem disorders to single enhancer knockouts. The resulting mouse mutant cell atlas (MMCA) consists of over 1.9 million single cell RNA-seq profiles. We developed an analytical framework for molecular phenotyping of cell type and trajectory composition changes, gene expression alterations and developmental phenotypes. We identify mutant and strain specific cell type changes, compare phenotyping of gain and loss of function mutants, and characterize deletions of topological associating domains boundaries. Intriguingly, even amongst these 22 mutants, some changes are shared by distinct models, suggesting that the molecular and cellular correlates of the recurring â□□componentsâ□□ of pleiotropic phenotypes might be recovered by further scaling of this approach. Overall, our findings show that â□□whole embryoâ□□ single cell profiling represents a powerful tool to systematically investigate developmental disorders at unprecedented resolution.

PrgmNr 1037 - Identifying systematic variation at the single-cell level by leveraging low-resolution population-level data

View session detail

Author Block: **E. Rahmani**[1], E. Halperin[2], M. I. Jordan[1], N. Yosef[1]; [1]UC Berkeley, Berkeley, CA, [2]Univ California los Angeles, Los Angeles, CA
Disclosure Block: **E. Rahmani:** None.
INTRODUCTION: Existing single-cell (SC) datasets are limited by their number of donors (individuals). As a result, most of the current research in SC genomics focuses on studying processes that are broadly conserved across individuals, such as differentiation and tissue development. While studying such biology from a limited number of donors is possible due to the expected high consistency across donors, advancing our understanding of heterogeneous conditions that demonstrate molecular variation and therefore inconsistencies across individuals requires population-level data.
OBJECTIVE: Our goal was to develop an approach to integrate information from low-resolution yet large bulk data into the analysis of small yet high-resolution SC data, and to demonstrate its promise by detecting systematic singe-cell variation in gene-gene interactions with a heterogeneous condition.
METHODS: We developed â□□kernel of integrated single cellsâ□□ (Keris). By inferring cell-type-specific moments (means, variances, and gene-gene interactions) and their variation with conditions in large tissue-level bulk data representing a population, Keris allows us to generate testable hypotheses at the SC level. Particularly, population-based hypotheses generated by Keris can be interpreted in terms of single-cell variation and hence can be casted as hypotheses on populations of cells; this enables validation and further exploration using SC data from just a handful of donors.
RESULTS: We applied Keris to bulk PBMC data from two age groups (n=745; all 70 y/o) for detecting systematic cell-type-specific variation in gene-gene interactions with cellular senescence; we verified that achieving this goal in SC data alone would require a large number of donors, given the heterogeneity in aging (even within the same age group). Using PBMC from 4 donors (38, 70, 84, and 90 y/o), we first verified concordance between the Keris-predicted up-regulated interactions and expression of *CDKN2A*, a marker of cellular senescence. Then, we composed a cell-level senescence score by integrating expression across the Keris-derived gene-gene interactions and successfully used it to detect variation in cell populations across the trajectory of the senescence score; for example, we identified clear stratification of sub-populations of CD16 monocytes and natural killer cells according to our cellular senescence scores in all 4 donors.
CONCLUSIONS: Applying Keris to large bulk data identifies consistent single-cell variation in gene-gene interactions, thus enabling effective downstream analysis of heterogenous conditions using SC data without the need for a large number of donors.

PrgmNr 1038 - Discovery of target genes and pathways of blood trait loci using pooled CRISPR screens and single cell RNA sequencing

The majority of variants associated with complex traits and common diseases identified by genome-wide association studies (GWAS) map to noncoding regions of the genome with unknown regulatory effects in *cis* and *trans*. To discover target genes of noncoding variants, we developed an approach by leveraging biobank-scale GWAS data, massively parallel CRISPR screens and single cell sequencing. To identify candidate cis-regulatory elements (CREs), we first performed statistical fine-mapping with FINEMAP to identify putative causal SNPs from 29 quantitative blood trait GWAS in the UK Biobank. We then selected a subset of 88 noncoding SNPs from 56 loci that overlap DNase, ATAC-seq and H3K27ac ChIP-seq peaks in human erythrocyte progenitor cells (K562) for targeting with multiple CRISPR guide RNAs (gRNAs). We silenced these loci in a pooled manner in K562 cells that constitutively express a second-generation CRISPR repressor (MeCP2-dCas9-KRAB). Single cell RNA sequencing of 9,343 single cells, with an average of 10 gRNAs per cell, allowed us to test for differential expression induced by each gRNA. We identified significant target genes in *cis* (5% FDR) for nearly half of the 88 SNPs. For example, gRNAs targeting *rs4526602*, a candidate causal GWAS SNP for a monocyte percentage locus, were significantly associated only with *CD52* expression and not to two closer genes *AIM1L* or *UBXN11*.

Next, we tested if any gRNAs with *cis* effects also had downstream effects on the transcriptome and identified three SNPs with significant target genes in *trans*. For example, another lead SNP in a monocyte GWAS (*rs524137*) that mapped to an intergenic CRE for transcription factor *GFI1B* (-25 kb from its TSS) was also associated with 568 other genes in trans (1% FDR). The TSSs of these target genes were enriched for having *GFI1B* ChIP-seq peaks in K562 cells (odds ratio = 2.4, $p = 7.4x10^{-23}$] and had a replication rate of 56% in an independent data set. We further showed that the target genes form a coexpression network with multiple modules reflecting both direct and indirect targets of *GFI1B* that are expressed in human bone marrow progenitor cell types.

In summary, we have developed a high-throughput approach integrating genome engineering, single cell sequencing and computational methods to identify causal GWAS SNPs and connect them to their target genes. We identified target genes for blood trait loci and identified *trans* target gene networks. This methodology will enable massively parallel assays to catalog the target genes of human noncoding variants in both *cis* and *trans*.

PrgmNr 1039 - SIMBA-single cell embedding along with features

View session detail

Author Block: **H. Chen**[1], J. Ryu[1], M. Vinyard[1], A. Lerer[2], L. Pinello[1]; [1]Massachusetts Gen. Hosp./ Harvard Med. Sch., Boston, MA, [2]Facebook AI Res., Boston, MA
Disclosure Block: **H. Chen:** None.
Recent advances in single cell omics technologies enable the individual or joint profiling of cellular measurements including gene expression, epigenetic features, chromatin structure and DNA sequences.
Currently, single-cell analysis pipelines are mostly cluster-centric, i.e., they first construct cellular states based on clustering approaches and then extract their defining features. This characterization discretizes the continuous nature of cellular heterogeneity, highlighting only those features important to non-overlapping cell groups.
To address this shortcoming, we developed SIMBA, a method to embed cells along with their defining features such as gene expression, transcription factor binding sequences and chromatin accessibility peaks into the same latent space. In SIMBA, cells and features from different modalities are encoded as nodes and relations between them as edges in a single graph. These relations encode our knowledge on the different aspects of gene regulation. For example, if a cell expresses a gene, an edge between the cell and gene nodes is created. Similarly, an edge can encode a chromatin accessible peak in a cell, a TF binding in a peak, the DNA sequence of a peak, etc.
Low-dimensional representations for each of the nodes in this graph are then computed using an unsupervised graph embedding method. The resulting joint embedding of cells and features in a common latent space provides a non-cluster-centric and clustering-free way to study intrinsic relations between biological entities. Moreover, our efficient graph embedding procedure makes SIMBA easily scalable to millions of cells. Importantly we show that in addition to single-modal analyses (e.g., scRNA-seq or scATAC-seq), several current single-cell analysis tasks including batch correction, data integration and multimodal analysis can be naturally incorporated in this general framework.
We have extensively tested SIMBA on seven scRNA-seq datasets, five scATAC-seq datasets, and three dual-omics datasets. In each analysis, SIMBA performs comparably to or better than current state-of-the-art methods specifically developed for each task.
In summary, our study proposes a novel single-cell embedding method SIMBA. Our joint embedding of cells and features provides a new non-cluster-centric and clustering-free framework to study single-cell heterogeneity and mechanisms of gene regulation. SIMBA is available as a comprehensive open-source Python package at https://github.com/pinellolab/simba.

PrgmNr 1040 - Deciphering the variation of gene regulation among individuals via integrative single cell multi-omics analysis

View session detail

Author Block: **J. Wang**[1], X. Cheng[1], Q. Liang[1], M. Wang[1], M. DeAngelis[2], Y. Li[1], R. Chen[1]; [1]Molecular and Human Genetics, Baylor Coll. of Med., Houston, TX, [2]Dept. of Ophthalmology, Univ. at Buffalo The State Univ. of New York, New York, NY
Disclosure Block: **J. Wang:** None.
Gene regulation variation between individuals is an essential molecular phenotype underpinning human traits and diseases, and genes are regulated in a cell type specific manner. The recent advances in single-cell omics technologies offer unprecedented opportunities to evaluate the effect of genetic variants on gene regulation within each cell type in vivo. To probe the underlying drivers of gene regulation variation, retinae from 20 human donors were profiled with single nucleus RNA-sequencing (snRNA-seq) and single nucleus ATAC-sequencing (snATAC-seq). The 191,818 nuclei from snRNA-seq and 245,835 nuclei from snATAC-seq were assigned to one of ten major retinal cell types. The genes with variable expression and genomic regions with variable chromatin accessibility among individuals are identified for each cell type. In addition, whole genome sequencing was performed to obtain the genotype for each donor. By systematically analyzing the association between genetic variants, gene expression, and chromatin accessibility in each cell type, a list of single-cell expression QTLs (sc-eQTLs), single-cell chromatin accessibility QTLs (sc-caQTLs), single-cell allelic specific expression (sc-ASE), and single-cell allelic specific chromatin accessibility (sc-ASCA) were identified. Strikingly, a significant proportion of these associations are cell type specific, highlighting the power of single cell analyses. By combining sc-eQTL, sc-caQTL, sc-ASE, sc-ASCA, snATAC-peaks, and single cell gene expression, we identified a set of cis-elements that are likely to directly contribute to cell-type specific variation in gene expression. Furthermore, we uncovered the genetic variants that are likely to affect the activity of gene cis regulatory elements with cell-type specific effects. Finally, by integration of results from the single-cell datasets and bulk eQTL and GWAS, we fine-mapped causal variants and targeted genes in cell type resolution.

PrgmNr 1041 - scATAC.Explorer: A Single-Cell ATAC-Seq Database and Search Tool

View session detail

Author Block: **A. Gibson-Khademi**[1], E. Christensen[2], P. Shooshtari[3]; [1]Pathology and Lab. Med., Univ. of Western Ontario, London, ON, Canada, [2]Computer Sci., Univ. of Western Ontario, London, ON, Canada, [3]Children Hlth.Res. Inst., London, ON, Canada
Disclosure Block: **A. Gibson-Khademi:** None.
Single Cell Assay for Transposase-Accessible Chromatin using Sequencing (scATAC-seq) is a relatively new technology that allows for identifying regions of accessible chromatin at a single cell resolution, giving insights to epigenetic differences in tissues, cell types, and diseases. Although several scATAC-seq datasets have been generated recently, we still lack a comprehensive database of scATAC-seq that contains a wide-range of datasets in a consistent format. We have addressed this problem by creating an R accessible database and search tool that can query a curated collection of currently available scATAC-seq datasets, and return all datasets and metadata in a consistent format.
We gathered scATAC-seq datasets and associated metadata from NCBIâ□□s Gene Expression Omnibus (GEO) and research lab websites. Several different data formats were found. Datasets were then formatted into a consistent peak-by-cell matrix format using R. Cell type annotations or cell clustering assignments were also collected if available. We then developed an R package named scATAC.Explorer that allows for users to query for relevant datasets using parameters such as cell type, disease, and other dataset metadata. Datasets retrieved from scATAC.Explorer are available as SingleCellExperiment R objects for ease of use with Bioconductor R packages.
We found 27 publicly available scATAC-seq datasets and included them within scATAC.Explorer. 14 of 27 datasets contain cells from neuronal samples, 8 from immune cell samples, 6 from hematopoietic, and an assortment of others such as kidney, lung, epithelial, and other tissue and organ samples. 15 of 27 datasets contain mice samples, 8 from human samples, 3 from human and mouse cell lines, and a single dataset each relating to common fruit fly and chicken samples. 8 of 27 datasets relate to diseases such as diabetes, acute myeloid leukemia, astrocytoma, glioma, basal cell carcinoma, and other cancers. The included datasets vary in size between 227 to 246,942 sequenced cells and 20,103 to 279,559 genomic regions per cell.
This study has created a comprehensive scATAC-seq database that can be queried by researchers interested in analyzing scATAC-seq datasets relating to a range of organisms, cell types, and diseases. scATAC.Explorer can easily be integrated into existing R and Python analysis pipelines, allowing researchers to quickly analyze scATAC-seq data from multiple sources. The diversity in available datasets can also be used to quickly test and validate new scATAC-seq analysis techniques and pipelines. As new datasets are published, they will be included through the use of a dataset submission process.

PrgmNr 1044 - A statistical framework to assess replicability of signals from trans-ethnic genome-wide association meta-analysis: Applications to smoking/drinking addiction traits using 3.4 million individuals

View session detail

Author Block: **C. Wang**, GSCAN - the GWAS and Sequencing Consortium of Alcohol and Nicotine Use; Penn State Univ., Hershey, PA
Disclosure Block: **C. Wang:** None.

Consortium studies often use genome-wide association meta-analysis (GWAMA) aggregate summary statistics from multiple studies to empower genetic discovery. It is a standard practice to replicate the association signals using an independent dataset. Yet, as discovery studies continue to grow larger and more diverse, it becomes difficult to identify a large enough replication sample, and more so for studies of non-European ancestry. Without replication, the identified association signals are much more likely to be spurious and confound downstream studies. To address this challenge, we propose a novel statistical framework RATES (Replicability Assessment in Trans-Ethnic Studies) to assess replicability without a replication sample. RATES first models genetic effect variations across studies using meta-regression with principal components of genome-wide allele frequencies as covariates and adjusts genetic effect heterogeneities due to ancestry. Next, RATES leverages the strength and consistency of residual association signals across variants and studies to calculate a â□□posterior probability of replicabilityâ□□, based on the rationale that replicable association signals tend to be significantly associated across multiple studies. A parametric bootstrap method was also developed to evaluate the p-values for PPR. We performed extensive simulations where 1) the genetic effects are homogeneous across ancestries, 2) the genetic effects are ancestry-specific, and 3) false-positive signals occur in some studies in the meta-analysis. We compared RATES with popular meta-analysis methods including the fixed effect (FE), random effects (RE and RE2) and binary effect (BE) meta-analysis, and meta-regression (MR-MEGA). We showed when outliers are present, only RATES yields correct type I error, while other methods (e.g., FE or RE2) can have > 4 folds inflated type I error. RATES also gives higher or comparable power in all scenarios, even for simulations that favor alternative methods. For variants with ancestry-specific effects, the power of RATES is 7% to over 400% higher compared to the 2nd best performing meta-analysis method. We further applied RATES to smoking/drinking addiction traits using 3.4 million individuals of different ethnic groups. As the first step, RATES confirmed that all sentinel variants reported have PPR>99%. When comparing the mean chi-square as converted from p-values, RATES yields chi-square values that are 9 % higher than the 2nd best method (RE2). Applying RATES to rare and low-frequency variants that are typically filtered out, we further identified novel signals of biological relevance in addition to GWAMA of common variants.

PrgmNr 1045 - Pleiotropic decomposition regression to characterize multi-trait genetic architecture

View session detail

Author Block: **J. Ballard**, L. O'Connor; Broad Inst. of MIT and Harvard, Cambridge, MA
Disclosure Block: **J. Ballard:** None.
Pleiotropy is pervasive and points to shared genetic architecture and associations as well as shared biology among many common diseases and complex traits. Approaches that begin to quantify pleiotropy include cross-trait LDSC to estimate genetic correlation (Bulik-Sullivan et al. 2015 Nat Genet), as well as an approach based on joint fine-mapping (Pickrell et al. 2016 Nat Genet). Applications of these methods include multi-trait meta-analysis for increased power (Turley et al. 2018 Nat Genet), causal inference, and clustering disease variants by their effect on related phenotypes (Udler et al. 2018 PLOS Medicine). However, these various methods exploit only partial knowledge of the effect size distribution. We developed pleiotropic decomposition regression (PDR), which partitions the heritability of multiple traits into components implying different types of pleiotropic relationships (e.g. correlated, uncorrelated, trait-specific). We fit our model using Fourier regression (Oâ□□Connor in press Nat Genet). In simulations, our method distinguished genetic architectures with different types of pleiotropy. We applied our model to pairs of 23 traits from the UK Biobank to quantify pleiotropy from three sources: correlation, shared heritability enrichments and LD enrichments (Gazal et al. 2017 Nat Genet), and uncorrelated pleiotropy. Many trait pairs had substantial pleiotropy even in the absence of genetic correlation; about half was explained by shared enrichments and half was not, pointing instead to shared pathways and cell types. We exploited these sources of pleiotropy to produce Bayesian effect size estimates that were better than the original GWAS data. By incorporating data from three additional traits, accuracy improved from r^2 = 0.097 to r^2 = 0.280 for T2D and r^2 = 0.088 to r^2 = 0.311 for asthma in held-out data. These improvements exceeded the performance of MTAG (r^2 = 0.177 and r^2 = 0.171) and the performance of bivariate analyses.

PrgmNr 1046 - DeepNull: Modeling non-linear covariate effects improves phenotype prediction and association power

View session detail

Author Block: **F. Hormozdiari**[1], Z. R. McCaw[2], T. Colthurst[1], T. Yun[1], N. Furlotte[2], A. Carroll[2], B. Alipanahi[3], C. Y. McLean[1]; [1]Google Hlth., Cambridge, MA, [2]Google Hlth., Palo Alto, CA, [3]Google, Inc., Palo Alto, CA

Disclosure Block: **F. Hormozdiari:** Major Stockholder/Ownership Interest; All authors have Google LLC stock as part of their compensation.. Salary/Employment; All authors are employees of Google LLC..

Genome-wide association studies (GWAS) are among the foundations of statistical genetics research, having detected thousands of variants associated with complex traits and diseases. A typical GWAS examines the association between genotypes and a phenotype of interest while adjusting for a set of covariates. Although recent work has recognized the importance of including covariate-interaction effects (e.g. age and sex interactions), no systematic approach has been described for detecting the appropriate non-linear functions to adjust for in GWAS. Identifying the appropriate transformations and interactions among a set of covariates is difficult due to the exponential number of possible interactions that can arise from a finite set of covariates and the infinite number of possible transformations of any given continuous covariate. In addition, the optimal number of covariate interactions is unknown a priori and requires evaluating many different possible covariate interactions.

We introduce DeepNull, a method that models non-linear covariate effects on phenotypes using a deep neural network and then includes the networkâ□□s prediction as a single additional covariate in GWAS. DeepNull can be applied in conjunction with any existing GWAS method. We investigate the potential of DeepNull for improving power in simulated and real data sets. First, using simulated data, we show that DeepNull increases statistical power by up to 20% while maintaining tight control of the type I error in the presence of interactions and non-linear covariate effects. Second, DeepNull obtains similar results to standard GWAS when the covariates have only linear effects on the phenotype. Third, DeepNull detects more genome-wide significant hits (i.e. independent lead variants) and loci (independent regions after merging hits within 250 Kbp together) than standard GWAS (i.e. BOLT-LMM) for ten phenotypes obtained from UK Biobank (n=370K). For glaucoma referral probability (GRP; Alipanahi et al. 2021 AJHG), DeepNull detects 46.1% more significant loci (38 vs. 26). For ApoB, DeepNull detects 8.5% more significant loci (217 vs. 200). The average improvement for significant loci across all ten phenotypes was 7.9%. Finally, we observed that for GRP, LDL, Calcium, and ApoB, DeepNull improves phenotype prediction accuracy (R2) by 83.4% (P-200), 40.3% (Pâ□□189), 23.9% (Pâ□□44), and 21.6% (Pâ□□75), respectively, suggesting DeepNull as an avenue for improving polygenic risk prediction. Overall, DeepNull improves phenotype prediction by 23.7% on average for the ten phenotypes analyzed. The preprint is available at *doi.org/10.1101/2021.05.26.445783*.

PrgmNr 1047 - SR-TWAS: Leveraging multiple reference panels to improve TWAS power by ensemble machine learning

View session detail

Author Block: **R. Parrish**[1], A. S. Buchman[2], P. L. De Jager[3], D. A. Bennett[2], M. P. Epstein[4], J. Yang[1]; [1]Dept. of Human Genetics, Emory Univ, Atlanta, GA, [2]Rush Alzheimerâ□□s Disease Ctr., Rush Univ. Med. Ctr., Chicago, IL, [3]Columbia Univ Med Ctr, New York, NY, [4]Emory Univ, Atlanta, GA
Disclosure Block: **R. Parrish:** None.

A transcriptome-wide association study (TWAS) is a popular technique for integrating reference transcriptomic data with GWAS data to conduct gene-based association studies. Existing methods often assume a single reference panel of transcriptomic and genetic data from a relevant tissue for model training and determination of expression weights to be integrated with GWAS data for TWAS. However, multiple reference panels of a given tissue often exist; the Religious Orders Study (ROS), Rush Memory and Aging Project (MAP), and Genotype-Tissue Expression project (GTEx) all profile transcriptomic data of prefrontal cortex tissue. We anticipate that leveraging multiple reference panels can improve the performance of existing TWAS tools such as TIGAR and PrediXcan compared to the standard use of a single reference panel.

Here, we develop a novel TWAS method to leverage multiple reference panels using an Ensemble Machine Learning technique of Stacked Regression to form optimal linear combinations of GReX prediction models trained from multiple reference panels of the same tissue type. We refer to this method as Stacked Regression based TWAS (SR-TWAS), which is expected to improve GReX prediction accuracy and TWAS power over existing methods by leveraging multiple reference panels with increased effective training sample sizes.

We validated our SR-TWAS method by simulation studies using real whole genome sequencing (WGS) genotype data from GTEx V8 and ROS/MAP, as well as real application studies leveraging reference panels of the GTEx V8 and ROS/MAP with transcriptomic data of brain frontal cortex tissue. Under simulation scenarios with various proportions of true causal eQTL SNPs per gene, p_{causal}=(0.001, 0.01, 0.05, 0.1), and simulated gene expression heritability, h_e^2=0.2, SR-TWAS had up to 29% higher average gene expression prediction accuracy and up to 76% higher TWAS power than TIGAR using a single reference cohort (either GTEx V8 or ROS/MAP).

In real application studies, SR-TWAS using both GTEx V8 and ROS reference panels outperformed TIGAR using either reference panel alone with the highest prediction accuracy in the MAP cohort. Increased power was demonstrated in an application TWAS of Alzheimer's disease using public GWAS summary statistics from the International Genomics of Alzheimer's Project, where SR-TWAS identified 11 independent risk genes compared to 2 identified by TIGAR using only the ROS/MAP reference panel.

Our SR-TWAS tool will be publicly available on Github, providing a useful resource for leveraging multiple public transcriptomic databases to increase GReX prediction accuracy and TWAS power for mapping risk genes of complex diseases.

PrgmNr 1048 - Genetic and environmental correlations between complex phenotypes differ by race/ethnicity and sex

View session detail

Author Block: **M. Elgart**[1], A. W. Manichaikul[2], X. Guo[3], N. Franceschini[4], B. M. Psaty[5], C. Isasi[6], S. S. Rich[2], J. I. Rotter[7], R. Kaplan[8], R. D. Hernandez[9], S. Redline[10], Trans-Omics for Precision Medicine (TOPMed) Consortium, T. Sofer[11]; [1]Brigham and Women's Hosp., Harvard Med. Chan Sch. of Publ. Hlth., Boston, MA, [11]Harvard Med. Sch., Boston, MA

Disclosure Block: **M. Elgart:** None.

Rationale

Phenotypic correlations have genetic and environmental components. Previous studies used data from large biobanks to estimate genetic correlations between various phenotypes yet were limited to single race/ethnicity and sex combined. The computational approaches used to estimate genetic correlations are either computationally challenging (e.g. genetic restricted maximum likelihood, which uses individual level-data) and inapplicable to large cohorts, or fast (e.g. linkage disequilibrium score regression), but prone to inaccuracies when there is genetic heterogeneity between the target sample, reference LD panel, and the population used to compute genome-wide summary statistics.

Methods

We derived a closed form, computationally efficient, solution to estimate genetic and environmental correlation coefficients within the Haseman-Elston framework using individual level-data. We systematically interrogated heritabilities and genetic correlations between all phenotype-pairs of 28 blood pressure, lipids, blood counts, inflammation, and anthropometrics phenotypes from individual-level TOPMed dataset totaling 33,959 individuals, stratified by race/ethnicity. In Hispanic/Latino participants from HCHS/SOL we estimated genetic and environmental correlations between 61 phenotypes from 11 domains (diabetes, cardiovascular, blood pressure, kidney, lipids, lung, sleep, anthropometrics, iron, RBC, and WBC), further stratified by sex. Finally, we performed domain-level enrichment analysis.

Results

We estimated over 2000 genetic and environmental correlations between phenotype-pairs in the multi-ethnic TOPMed and the Hispanic/Latino datasets. Stratifying by race/ethnicity, 2% (Blacks, ~8K participants), 22% (Hispanics/Latino, ~8K participants) and 16% (Whites, ~16K participants) of the total estimated genetic correlations and heritabilities were significant only in that group. In HCHS/SOL, the genetic and environmental components of the phenotypic correlations differed between phenotype domains. For example, the association between diabetes and anthropometric, sleep, and lung domains were driven by genetic correlations, while the association between diabetes and cardiovascular and blood pressure domains were driven by shared environment. Domain correlation enrichment also differed by sex. E.g., sleep and anthropometric domains were enriched in genetic correlations only in males, while diabetes and lipids genetic correlation enrichment was only observed in females. While additional independent validation is needed, these results can be useful in prioritizing precision medicine initiatives

PrgmNr 1049 - Enrichment for gene-by-environment candidate SNPs with variance locus analysis: Extension of vQTL to binary traits in the Pan-UK Biobank

View session detail

Author Block: **X. Tong**, A. A. Motsinger-reif; NIH, Durham, NC
Disclosure Block: **X. Tong:** None.
Despite increasing awareness that gene-by-environment (GxE) interactions explain a portion of the missing heritability in complex diseases, statistical power limitations and computational tractability have limited the identification of GxE effects on disease outcomes. Variance quantitative trait locus (vQTL) analysis based on double linear modeling (DLM) or double generalized linear modeling (DGLM) has recently been used to overcome genome and exposome dimensionality issues. vQTL analysis allows the identification of GxE loci without assessing environmental exposures, based on the rationale that GxE unaccounted for in a genome-wide association study (GWAS) can result in heterogeneous residual variance across allele dosages in quantitative phenotypes.
In this study, we propose variance loci analysis (VLA) based on DLM augmented by squared SNP dosage. Through simulations, we demonstrated that VLA exhibits increased power to detect GxE candidates when direct environmental effects on the phenotype are weak. Furthermore, we show that DGLM is overly generic with squared dosage and overly restrictive without it. More importantly, we demonstrate that by properly adjusting covariates, VLA expands the vQTL approach to non-quantitative traits such as binary disease outcomes. VLA also has computational tractability superior to DLM/DGLM-based vQTL.
This extension to non-quantitative traits enables the reevaluation of publicly available genome-wide data to identify candidate variants likely involved in GxE interactions. We performed VLA on ~7,000 health- and disease-related phenotypes derived from the UK Biobank and cataloged the results analogous to the GWAS catalog. We show that our method enriches for variants across functional categories (e.g., eQTL and intergenic variants) and known environmental interactions without the need for environmental exposure data.
We used our most significant variance loci in type 2 diabetes (T2D), cardiovascular disease (CVD), and body mass index (BMI) to perform GxE analysis in the Personalized Environmental and Genes Study (PEGS), a North Carolina-based cohort (n=19,672) with extensive exposome (n=9,414) and whole genome sequencing (n=4,737). Our results confirm that the top VLA-selected candidates for CVD, T2D and BMI from the UK Biobank enriched the detection of genome-exposome-wide significant GxE variants in PEGS and demonstrate that the approach can be applied for both quantitative and binary outcomes.

PrgmNr 1058 - Long-Term systemic expression and cross-correction ability of HMI-203: Investigational gene therapy candidate for mucopolysaccharidosis type II or Hunter Syndrome

View session detail

Author Block: **K. Patel**[1], L. Smith[1], J. Gingras[2], A. Tzianabos[1], L. A. Schuman[1], V. Zhivich[1], M. Kivaa[1], D. Faulkner[1], A. Sengooba[1], L. Behmorias[1], T. Seabrook[1], S. Dollive[1], N. Avila[1], J. Zhao[1], Y. White[1], J. Newman[1], S. Woodcock[1], S. Smith[1], O. Francone[1], A. Seymour[2]; [1]Homology Med.s, Inc., Bedford, MA, [2]Homology Med.s, Bedford, MA

Disclosure Block: **K. Patel:** Salary/Employment; Homology Medicines Inc..

Mucopolysaccharidosis type II (MPS II), or Hunter syndrome, is a rare X-linked lysosomal storage disorder caused by mutations in the iduronate-2-sulfatase (*IDS)* gene, resulting in loss of I2S activity leading to systemic (peripheral organs and central nervous system (CNS)) toxic lysosomal accumulation of glycosaminoglycans (GAGs). GAGs are large polysaccharides made of repeating disaccharide units responsible for providing structure and hydration to the cell. The disease results in skeletal dysplasia, joint stiffness, organomegaly, airway obstruction and, in severe cases, neurocognitive deficits. Hunter syndrome occurs in approximately 1 in 100,000 to 1 in 170,000 males, and causes significantly reduced lifespan, with the severe form leading to life expectancy of 10 to 20 years The proposed therapeutic mechanism of gene therapy candidate HMIâ□□203 is based on both intracellular expression and synthesis of active I2S, as well as high levels of expression and secretion of active I2S enzyme to support cross correction. Herein, we report preclinical data where a single intravenous dose of HMI-203 delivering human *IDS* via a rAAVHSC vector in the MPS II murine model resulted in dose-dependent and long-term transduction, *IDS* expression and I2S enzymatic activity in the evaluated tissues, e.g., liver, brain and serum through 52 weeks post-dose. A significant correlation was observed between liver and serum I2S activity, suggesting that the liver was likely the major contributor to the elevated levels of active I2S in the serum. The circulating I2S protein in the serum was functionally active (i.e., 90 kDa form) and cross-correction activity via a mannose-6-phosphate receptor dependent pathway was demonstrated using an *in vitro* competition assay. The robust and broad *IDS* tissue expression, along with demonstrated cross-correction significantly reduced GAG heparan sulfate (GAG-HS) to wild type (WT) levels in all evaluated organs associated with the disease, cerebrospinal fluid (CSF) and urine. In addition, lysosomal-associated membrane protein-1 (LAMP1) levels were significantly reduced to WT-like levels in the peripheral organs and CNS tissues. Of note, positive and significant correlations were observed between reduction in GAG-HS and LAMP1 levels in the CNS and brain and CSF GAG-HS levels, suggesting that CSF GAG-HS levels could be indicative of overall brain GAG and lysosomal burden levels in the clinic. Taken together, we have demonstrated that HMI-203 combines transduction and expression with the potential for cross-correction. These HMI-203 IND-enabling studies support HMI-203 as a gene therapy candidate for the treatment of MPS II.

PrgmNr 1059 - Tasimelteon Safely and Effectively Improves Sleep in Smith Magenis Syndrome: results from a Double-Blind Randomized Trial Followed by an Open-Label Extension

View session detail

Author Block: **C. Polymeropoulos**[1], J. Brooks[1], S. P. Smieszek[1], E. Czeisler[1], M. Fisher[1], M. Gibson[1], K. Kite[1], C. Xiao[1], S. H. Elsea[2], G. Birznieks[1], M. H. Polymeropoulos[1]; [1]Vanda Pharmaceuticals Inc., Washington, DC, [2]Baylor Coll. Med., Houston, TX
Disclosure Block: **C. Polymeropoulos:** Salary/Employment; Vanda Pharmaceuticals Inc..
Smith-Magenis Syndrome (SMS; OMIM #182290) is a rare genetic disorder that results from an interstitial deletion of 17p11.2 and, in rare cases, from a retinoic acid induced 1 (*RAI1*) gene variant (Slager et al 2003). Currently, the prevailing theory is that there is an underlying circadian pathophysiology causing sleep disturbances in these patients, as they exhibit low overall melatonin concentrations and abnormal timing of peak plasma melatonin concentrations. This abnormal inverted circadian rhythm is estimated to occur in 95% of individuals with SMS (Boone et al., 2011; Spruyt et al., 2016). To assess the efficacy of tasimelteon, a melatonin receptor agonist, to improve sleep in SMS, a 9-week, double-blind, randomized, two-period crossover study was conducted at four U.S. clinical centers. Genetically-confirmed SMS patients, aged 3 to 39, with sleep complaints participated in the study. Patients were assigned to treatment with tasimelteon or placebo in a 4-week crossover study with a one week washout between treatments. Eligible patients participated in an open label study and were followed for > 3 months. Improvement of sleep quality (DDSQ50) and total sleep time (DDTST50) on the worst 50% of nights were primary endpoints. Secondary measures included actigraphy and behavioral parameters. Over three years, fifty-two patients were screened and twenty-five patients completed the randomized portion of the study. DDSQ50 significantly improved over placebo (0.4, p=0.0139) and DDTST50 also improved (18.5 min, p=0.0556). Average sleep quality (0.3, p=0.0155) and actigraphy-based total sleep time (21.1 min, p=0.0134) improved significantly, consistent with the primary outcomes. Patients treated for â¥ 90 days in the open label study showed persistent efficacy. Adverse events were similar between placebo and tasimelteon. Tasimelteon safely and effectively improved sleep in SMS. The 17p11.2 deletion encompasses *RAI1*, leading to haploinsufficiency, which is considered the primary cause for most features of SMS, including dysregulation of the molecular clock via its effect on *CLOCK* expression. ChIP-Chip and reporter studies suggest that RAI1 binds, directly or in a complex, to the 1st intron of *CLOCK*, enhancing transcriptional activity, resulting in reduced *CLOCK* expression in SMS patient-derived cells (Williams et al 2012). The results of this study suggest that treatment with a the circadian regulator can, in part, ameliorate the circadian deficiencies caused by RAI1 haploinsufficiency, providing further evidence of a critical role for RAI1 in the regulation of circadian rhythms.

PrgmNr 1060 - Unravelling African genomes: Whole-genome sequencing of 1000 Nigerian samples spanning 50 tribal groups provides new insights into diversity and admixture

View session detail

Author Block: **C. O'Dushlaine**[1], B. Ballew[1], C. Palmer[1], 54gene Research Team, NCD-GHS Consortium, B. Salako[2], O. Nash[3], S. Fatumo[4], O. Salako[5], O. Osifo[1], Z. Moddibo[1], A. Univ. of Lagos, Lagos, Nigeria
Disclosure Block: **C. O'Dushlaine:** Salary/Employment; 54gene.
The lack of adequate representation of diverse genomes in human genomics research may limit insights that can be made about variants influencing disease susceptibility and trait variability across populations. We are helping to address this gap by performing germline whole genome sequencing of a Nigerian cohort. Nigeria represents one of the most diverse and populous regions on earth, with a population of over 200 million and over 250 unique tribal groups. We coordinate data generation in Lagos with analysis by staff around the world by leveraging cloud resources and deploying a scalable, robust, portable pipeline for alignment and variant calling. We present results from an initial round of whole-genome sequencing of ~1000 subjects from 50 tribal groups in Nigeria. We describe patterns of variation across tribes including variants of different functional classes and frequencies. We survey patterns of autozygosity across groups and compare these to 1000 Genomes samples. We highlight genetic distances between tribes and reveal evidence of admixture with European and northern African populations. We compare frequencies within our dataset to those reported in publicly available data (e.g. 1000 Genomes) for specific loci of clinical utility, e.g. those associated with drug response, highlighting noteworthy differences. Lastly, we find widespread, tribe-specific differences in allele frequency for medically-relevant variation, underscoring the importance of variant discovery and replication in non-European ancestry cohorts. Our results add to the growing body of genomic data from diverse populations, investigating understudied groups and the unique opportunities for discovery that they represent. We highlight opportunities for precision medicine, and reveal insights about variants of most clinical importance within and between human populations.

Disclosure Block: **J.L. Rodriguez-Flores:** Salary/Employment; Regeneron Genetics Center LLC.

Cerebral Autosomal Dominant Arteriopathy with Subcortical Infarcts and Leukoencephalopathy (CADASIL) is an autosomal dominant Mendelian disorder characterized by early onset of migraine with aura, recurrent stroke, and dementia. Pathogenic CADASIL variants either add or remove a cysteine (Cys+/-) residue in one of 34 epidermal growth factor like repeats (EGFR) in the extra-cellular domain (ECD) or *NOTCH3*. Exome-wide association analysis of 4,882 stroke cases and 6,094 controls recruited in the Pakistan Genomic Resource (PGR) from Pakistan identified one such variant, p.Arg1231Cys, associated with subcortical stroke; p value 2.18e-8, odds ratio (OR) 2.97, 95% confidence interval (CI) 2.03 to 4.35, minor allele frequency (MAF) 7.1e-3. Analyses of the larger PGR cohort comprising of 80,000 participants identified additional heterozygous and homozygous carriers of this variant; call back studies of the carriers and their family members identified a high mortality in family members and a high prevalence of stroke. The Cys allele was found to disrupt a highly conserved domain (91% overall sequence identity between human and mouse), was predicted deleterious by PolyPhen2 (score 0.843 of 1), and was risk-increasing (cases MAF 0.016, controls MAF 0.0053). The p.Arg1231Cys variant was observed at a similar MAF in other South Asian populations sequenced by Regeneron Genetics Center, and present but orders of magnitude rarer in European populations. Despite rare prevalence in Europe, p.Arg1231Cys was associated with ischemic stroke in 450 thousand UK Biobank (UKB) participants; p value 8.8e-4, OR 3.38, CI 1.65 to 6.94, MAF 2.0e-4. In addition, p.Arg1231Cys was associated with multiple brain MRI phenotypes relevant to CADASIL in a 40K subset of UKB, such as mean diffusivity in the external capsule; p value 5.41e-10, OR 1.4, CI 0.96 to 1.8, MAF 2.8e-4. Consistent with CADASIL pathogenicity, a burden test limited to Cys+/- variants in the NOTCH3 ECD (including p.Arg1231Cys) strengthened associations in both Pakistan (subcortical stroke p value 1.5e-10, OR 3.39, CI 2.32 to 4.91) and UKB (ischemic stroke p value 9.3e-8, OR 3.38, CI 1.74 to 2.98). In both cohorts, p.Arg1231Cys was the most common Cys+/- variant in the NOTCH3 ECD. Taken together, these findings have major implications for precision medicine in South Asia, given that an estimated 1 in 92 (over 20 million of 1.9 billion) individuals are carriers for this variant and are at approximately 3-fold elevated risk for stroke. Our estimates suggest that around 2% of strokes in Pakistan may be attributable to NOTCH3 p.Arg1231Cys.

PrgmNr 1062 - A high-resolution panel for uncovering repeat expansions that cause ataxias

View session detail

Author Block: **Y-C. Tsai**[1], Z. McEachin[2,3], M. van Blitterswijk[4], J. Ziegle[1]; [1]Pacific BioSci.s, Menlo Park, CA, [2]Dept. of Cell Biology, Emory Univ., Atlanta, GA, [3]Lab. for Translational Cell Biology, Emory Univ., Atlanta, GA, [4]Dept. of NeuroSci., Mayo Clinic, Jacksonville, FL
Disclosure Block: **Y. Tsai:** Salary/Employment; Pacific Biosciences.
The hereditary ataxias are a group of rare neurological diseases with similar symptoms. Many of these ataxic syndromes are caused by expansions of short tandem repeat (STR) in a number of different genes. Molecular genetic testing to accurately determine the genetic cause of known ataxias is often employed to support clinical diagnoses. Advances in therapeutic strategies (e.g., antisense oligonucleotides) to target repeat expansions underscore the importance of understanding the genetic context and sequence complexity of ataxic repeat expansions. Further highlighting the importance of molecular genetic testing, several studies have shown that repeat sequence interruptions in certain ataxia expansions play important roles in modifying the penetrance of the disease and age of onset. PCR and Southern blotting assays are currently the most employed methods in commercially available ataxia repeat expansion panels for clinical testing. Although these electrophoresis-based methods could detect repeat expansions above pathogenic threshold, accurate sizing of the repeat expansion is difficult to achieve when the length of repeat sequence is longer than a few hundred bases. Sequence interruption information is also not available with these approaches. We have recently developed an ataxia expansion panel using the PacBio No-Amp targeted sequencing approach to capture and sequence repeat expansion loci associated with fifteen ataxia diseases. The method utilizes CRISPR-Cas9 nuclease and pairs of guide RNAs to excise DNA fragments containing the repeat sequences within ataxia genes. This approach eliminates PCR amplification artifacts, amplification bias, and preserves native DNA for base modification detection. In this study, we sequenced samples with known or unknown diagnosis for ataxia with the No-Amp targeted sequencing panel utilizing PacBio highly accurate long reads - HiFi reads. The high accuracy of HiFi reads provides both certainty in sizing of the repeat expansion and repeat sequence interruption within the expansion sequences. Sequencing results demonstrate the potential of using this repeat expansion panel for eventual genetic testing. As additional ataxia, and related neurological diseases, caused by STR expansions are discovered and studied, the No-Amp targeted sequencing panel could be expanded to include additional targets. The ability to multiplex samples from different patients also makes the method a potentially cost-effective option for molecular genetic screening in the future.

Patients with a suspected genetic disease are often unable to obtain a timely molecular diagnosis, and those in resource-limited locations face even greater challenges. Clinical whole genome sequencing (cWGS) shows promise as a comprehensive test which may shorten the diagnostic odyssey regardless of setting. The iHope Program is a philanthropic effort to provide cWGS to patients who are unable to obtain precision testing due to resource-limitations.

From June 2016 through June 9, 2021, 1004 individuals pursued cWGS test through the iHope Program. Cases were received from 23 partner iHope clinical sites spanning seven countries. Forty percent of cases (n=403) were received from global partners in Mexico (n=205), Peru (n=93), Italy (n=50), Democratic Republic of Congo (n=40), New Zealand (n=10), and the United Arab Emirates (n=5). Most testing was performed on duos and trios. Proband phenotypes were complex, with nervous system, head and neck, skeletal, eye, and digestive the five most frequently identified Human Phenotype Ontology root ancestor terms.

Variants were reported in 67% (n=677) of cases, of which 40.5% (n=407) conferred a definitive molecular diagnosis. Reported variants per case ranged from 0 to 5, and in 33 cases (3.3%), multiple molecular diagnoses were observed. Variants spanned 468 unique single genes. Of 1020 reported variants, a majority were nuclear SNVs or MNVs (n=693, 67.9%), followed by CNVs (n=175,17.2%), small indels (n=127, 12.5%), short tandem repeats (n=12, 1.2%), mitochondrial SNVs (n=10, 1%) and uniparental disomy (n=2, 0.1%). Copy number variants ranged in size from 3 kb to full aneuploidies. In fifteen individuals from eleven families, findings were suggestive of a structural chromosomal rearrangement.

At least ninety days after cWGS report delivery, a clinical utility survey was requested of the ordering clinician to assess effects on care and management. To date, surveys have been obtained for 581 patients (58%), representing one of the largest cWGS clinical utility datasets in a pediatric outpatient population. Data collection is ongoing, but initial analysis indicates that cWGS results prompted follow-up such as imaging, laboratory or physiological testing, referral for specialty consultation or

other evaluations in 40% (233/581) of patients. In 56.6% (329/581), cWGS results contributed to counseling about prognosis, recurrence risks, reproductive screening/testing options and screening/testing recommendations or options for family members. These findings suggest that deployment of cWGS in support of resource-limited patients is tractable globally and can have a substantial impact on patient management.

Cell-free DNA (cfDNA) consists of a mixture of DNA fragments released from various dying cells of the organism, providing unique access to molecular information about the pathological process and tissue of origin. cfDNA analysis in cancer patients holds a great promise for non-invasive disease management. Existing analysis paradigms concentrate on detecting genomic alterations but have rarely been designed to integrate biological properties of cfDNA. Therefore, they lacked the generalized ability to explore a range of diseases. Here we developed a generic approach, coined GIPSeqcluster for unbiased identification of genome-wide signatures in shallow whole-genome sequencing (0.1x) cfDNA data. This approach enables detection of different physiological and pathological conditions and opens alternative avenues for cfDNA investigation. With enhanced detection of informative molecular signals in cfDNA, we uncovered cancer-specific patterns through unsupervised clustering that stimulated accurate cancer signal detection and cancer type mapping via supervised learning. We applied GIPSeqcluster on cfDNA samples from healthy controls (n=367) and patients with different types of hematological cancers (n=238) and solid tumors (n=517) of varying stages. Surveying the large volume of cfDNA profiles, we revealed malignancy type-specific clusters that empowered disease localization. Moreover, we identified intriguing common cfDNA patterns in patients with cancer. Classification yielded an overall accuracy of 80.11% in discriminating malignant from healthy samples, resulting in sensitivities ranging from 13.04% to 94.97% at 95% specificity across different cancer types and stages. Increased identification of cancer signals was obtained with the AUC of 0.988 and 0.804, compared to AUC of 0.926 and 0.717 using copy number alterations only analysis, from patients with hematological and solid cancer, respectively. Performing cancer type classification in samples with cancer-associated signal, the disease type could be mapped in 70% of cases. Our approach offers a widely applicable strategy for non-invasive cancer detection and highlights crucial properties of cfDNA in improving our understanding of tumor biology.

PrgmNr 1067 - A novel method identifies liquid biopsy markers based on relative chromatin accessibility

View session detail

Author Block: **M. Mehrmohamadi**, P. Taklifi, F. Palizban; Univ. of Tehran, Tehran, Iran, Islamic Republic of
Disclosure Block: **M. Mehrmohamadi:** None.
Liquid biopsy testing refers to minimally invasive cancer detection using markers in bodily fluids. Dying cells, including those originating from tumors, shed their DNA into the blood and contribute to a pool of circulating fragments called cell-free DNA (cfDNA). Tumor-originating fragments harbor genetic and epigenetic markers of cancer. However, the majority of cfDNA fragments originate from blood cells during normal turnover, leading to a high background of non-marker fragments that necessitate deep next-generation sequencing for cancer detection. Thus, targeted sequencing panels are designed to enrich and sequence only small portions of the genome harboring cancer markers. Most of the currently existing targeted sequencing panels cover recurrent genetic aberrations. To improve the utility and sensitivity of liquid biopsies, focus has shifted to epigenetic markers at tissue-specific regulatory regions. Here, we propose a novel strategy to select marker regions based on data of assay for transposase accessible chromatin followed by sequencing (ATAC-seq). Since accessible chromatin regions are tissue-specific and undergo higher degradation, they are manifested as local decrease in sequencing depth and fragment length in cfDNA. Our pipeline integrates ATAC-seq data from TCGA tumors and normal blood samples to measure a relative chromatin accessibility metric. In each cancer, regions with a high fold-change in relative accessibility between tumor and blood (log ATAC-seq normalized count in cancer/blood > 1.5) are selected since they are expected to show fragmentation differences in cfDNA of healthy individuals compared with cancer patients. We then use the selected regions as input features into our machine-learning pipeline and build a classifier distinguishing each cancer from other cancers in the TCGA ATAC-seq dataset. We applied this pipeline to 6 common cancers from the TCGA and obtained high specificity and sensitivity in held-out data (average AUC=0.99). Regions in promoters of many known tissue-specific genes were among our identified markers such as *KLK2* in prostate, *NOXO1* in colorectal, *TBC1D9* and *ERBB4* in breast, *CLD18* and *STK31* in gastric, *NR1H4N* in kidney, and *SFTPB* and *SFA3* in lung cancers. These observations confirm the biological relevance of our findings. We then directly validated our marker regions in publicly available deep whole-genome sequencing cfDNA data from cancer patients**.** Overall, we propose a novel marker selection strategy that can be used either alone or in integration with other genetic and epigenetic markers for efficient liquid biopsy panel design.

PrgmNr 1068 - Distinct intratumoral oncogenic mechanisms between single cells in primary Ductal Carcinoma In Situ exposed by Primary Template-directed Amplification

View session detail

Author Block: **J. Zawistowski**[1], R. A. Carter[1], J. R. Marks[2], L. Simpson[2], D. M. Arvapalli[1], T. V. Morozova[1], E. S. Hwang[2], J. A. West[1]; [1]BioSkryb, Inc., Durham, NC, [2]Duke Univ. Med. Ctr., Durham, NC
Disclosure Block: **J. Zawistowski:** Major Stockholder/Ownership Interest; BioSkryb, Inc.. Salary/Employment; BioSkryb, Inc..
Ductal Carcinoma In Situ (DCIS) is a neoplastic proliferation of the ductal epithelium that can transition to invasive ductal carcinoma (IDC) and ultimately lead to metastatic dissemination of tumor cells. To design therapeutic strategies targeting this exploitable DCIS-to-IDC junction in the progression of the disease it is of paramount importance to define the specific genomic lesions that are driving the transition. The complete complement of genomic changes within rare intratumoral clones that have gained capacity to invade and contribute to the progression of disease are not detectable by bulk sequencing. We have therefore employed Primary Template-Directed Amplification (PTA), a whole-genome amplification (WGA) technology, to ascertain the genome sequence of single cells dissociated from a surgical resection of a patient tumor comprised of both DCIS and IDC features. The core technology of PTA attenuates the size of daughter amplicons to limit subsequent amplification, thereby yielding high breadth of coverage and uniformity with significantly diminished allelic skewing to accurately call single nucleotide variation (SNV) and copy number variation (CNV). As initial genomic insight into the DCIS to IDC transition in this patient we performed PTA followed by whole genome sequencing on 31 single cells that were immunoenriched for EpCAM by FACS, including 5 single cells cells that were derived from an ipsilateral breast stromal control biopsy. As validation of our technology and experimental design we identified prototypical copy number alterations, including chromosomal loss at regions harboring *TP53*, *BRCA2*, and *RB1* tumor suppressors. We observed striking heterogeneity in single-cell CNV profiles, whereby multiple bins of EpCAM-enriched cells emerged: a bin with no apparent copy number alterations, those with different combinations of prototypical CNVs, as well as a class of cells harboring copy number losses at novel, non-prototypical loci. While cataloging SNV, we identified a common driver mutation in DCIS/IDC, *PIK3CA* H1047R. Intriguingly, the single cells harboring *PIK3CA* H1047R lacked copy number alterations. This suggests distinct mechanisms of oncogenesis: some cells within the tumor proliferate uncontrollably due to loss of key tumor suppressor regulation, while in other single cells a missense mutation in a key signal transduction node affecting downstream MAPK-mediated cell proliferation and AKT-mediated survival signaling is sufficient to drive unchecked growth. We are currently extending these findings to comprehensively define prototypical and novel SNV in these individual cells, in both genic and intergenic space.

PrgmNr 1069 - Full-length transcriptome analysis of liver cancer using a long-read sequencing technology

View session detail

Author Block: **H. Kiyose**; The Univ. of Tokyo, Hongo, Bunkyo Ku, Japan
Disclosure Block: **H. Kiyose:** None.
Background: Various transcripts can be generated from a single gene by alternative splicing. These transcripts lead to variants of proteins with diverse functions that can play an important role in carcinogenesis. Therefore, the analysis of full-length transcripts should be significant for cancer research. However, the majority of previous transcriptome studies have used microarrays or short-read sequencing technologies, and due to the difficulty of predicting full-length transcripts with these technologies, abnormalities at the transcript level have been overlooked. One promising approach is the direct observation of full-length transcripts using long read sequencing technology. However, due to the high error rate, the analysis method has not been established and its application to cancer research has been limited. **Results:** In this study, we developed an analysis pipeline named SPLICE to analyze full-length cDNA sequencing data. SPLICE removed possible errors around splicing junction sites and pseudo fusion transcripts by considering alignment and mapping errors. Validation with MCF-7 cell line and PCR showed the reliability of our analysis. Using this method, we analyzed cDNA sequences from 42 pairs of hepatocellular carcinoma (HCC) and matched non-cancerous liver with MinION (Oxford Nanopore technologies). Our analysis detected 46,663 transcripts from the protein-coding genes in the HCCs and the matched non-cancerous livers, of which 5,366 (11.5 %) were novel. We identified 767 and 531 novel exons from the novel transcripts in HCCs and matched-livers, respectively. Interestingly, about 40 % of the novel exons were derived from transposable elements (TEs), which was a significantly higher proportion than the TE-derived known exons. Comparison of expression levels identified 9,933 differentially expressed transcripts (DETs) in 4,744 genes. Importantly, 746 genes with DET were not found by the gene-level analysis. We also detected cancer-related genes with TE-derived exons. In the analysis of transcripts from hepatitis B virus (HBV), HBx-human TE fusions were found to be overexpressed in the HCCs. Furthermore, we found 6 novel recurrent fusion genes. By comparing HBV- with HCV-related livers, significant differentiations in immune-related genes were detected. **Conclusion:** These results suggest that long-reads sequencing technologies allow us to analyze full-length transcripts, and show the importance of splicing variants in carcinogenesis.

PrgmNr 1070 - Functional genomics uncover novel regulatory genomic regions associated with gene expression and survival in multiple myeloma

View session detail

Author Block: **L. Bui**, H. Natri, B. Argente, A. J. Gutierrez, M-I. Chung, L. Peter, J. Keats, N. E. Banovich; Translational Genomics Res. Inst., Phoenix, AZ
Disclosure Block: **L. Bui:** None.
Multiple Myeloma (MM), a malignancy of plasma cells, is the second most common hematological cancer and is associated with a poor prognosis. MM displays a sex disparity in incidence with men having a 1.5-fold higher risk in developing MM than women. Recent GWAS and meta-analyses have identified 176 risk loci associated with MM susceptibility; of these, many are located within or adjacent to the regulatory regions, indicating a role in transcriptional regulation. However, the regulatory mechanisms underlying how these risk loci contribute to tumor etiology, progression and outcome are poorly understood.
In this study, we investigate the role of genetic variation (somatic or germline) on gene expression changes in MM patients. First, we analyzed whole-genome sequencing (WGS) from peripheral blood and WGS and RNA-seq from baseline tumor specimens of 693 participants from the CoMMpass study, a longitudinal clinical trial of the Multiple Myeloma Research Foundation. We performed joint and sex-stratified analyses and detected 7,737 variants associated with changes in gene expression, i.e. expression quantitative trait loci (eQTLs). Among the identified eQTLs, 33.75% exhibit sex-specific effects and 1,034 variants are associated with survival in the CoMMpass cohort. Second, we selected 159 eQTLs, corresponding to 110 unique target genes (eGenes), and validated their functions in transcriptional activity in MM cell lines (2 females, 2 males) using CRISPR interference screens (CRISPRi) with a scRNA-seq readout. These variants include 60 male specific eQTLs, 27 female specific eQTLs and 43 eQTLs associated with survival from the CoMMpass cohort. We detected reduction in expression levels of 68 out of the 110 eGenes in the cells containing the gRNA targeting eQTLs, confirming the roles of these eQTLs in gene expression regulation. We analyzed global transcriptional changes and identified potential downstream targets that may play essential roles in tumor etiology and progression in MM. Among eQTL/eGene pairs with global transcriptional effects are PSAP (Prosaposin), encodes a protein that interacts with CD74 and may play a role in MM carcinogenesis and CCT8 (a subunit of Chaperonin-containing T-complex protein 1) that is known to promote the migration and invasion of squamous carcinoma. We identify differences of the sex specific variants on gene expression regulation in different sexes. In conclusion, we have performed computational analysis and functional validation to identify new regulatory regions associated with gene expression changes in MM, thus providing novel targets for the development of personalized medicine approaches for better treatments.

PrgmNr 1071 - Genetic map of human brain folding and links to developmental pathways and disease

The human brain is a complex organ underlying many cognitive and physiological processes as well as a wide range of diseases. Genetic associations with brain structure are emerging but studies looking at specific local brain folding remain under-explored. Here we carried out the first detailed large-scale genome-wide association studies (GWAS) of regional brain cortical folding (sulci and gyri) in UK Biobank. We discovered 272 brain folding region associations across 77 regions at *p*-8 in GWAS (discovery n=26,530) which replicated at *p*

PrgmNr 1074 - Trans-ancestry imputation and exome sequencing of more than 1 million individuals identifies genetic variation protecting against SARS-CoV-2 infection and predicts individuals at risk for severe COVID-19 outcomes

View session detail

Author Block: **J. Kosmicki**[1], J. Horowitz[2], A. Damask[1], J. Mbatchou[1], A. Marcketta[1], L. Dobbyn[1], D. Sun[1], J. D. Backman[1], N. Banerjee[1], A. Verma[3], A. Baras[1], E. Stahl[1], J. Ferreira[1]; [1]Regeneron Genetics Ctr., Tarrytown, NY, [2]Regeneron Pharmaceuticals, Tarrytown, NY, [3]Dept. of Genetics, Perelman Sch. of Med., Univ. of Pennsylvania, Philadelphia, PA
Disclosure Block: **J. Kosmicki:** Salary/Employment; Regeneron.
COVID-19 symptoms vary widely, ranging from asymptomatic in some patients to fatal in others. Elucidating the host genetics of COVID-19 holds the potential for understanding both susceptibility to SARS-CoV-2 infection as well as heterogeneity in patient presentation and outcome. Prior work focused on identifying common variants associated with COVID-19 susceptibility and severity, but little has been done to explore the entire allele frequency spectrum of genetic variation, from common to rare exonic variants. Here, we present the largest trans-ancestry exome sequencing study of COVID-19 to date in 586,713 individuals, with a larger set of 1,012,636 individuals with imputed data across 7 studies and 5 continental ancestries.

Through exome sequencing of 21,820 COVID-19 cases and 564,893 controls, we did not identify any rare variants after Bonferroni correction (PDISP3 (*P*=2e-8; OR=1.8Â±0.3), *MARK1* (*P*=3e-9; OR=38.4Â±16.9), and *TLR7* (*P*=4e-8; OR=4.5Â±2.2). Despite having a 100x larger sample size, we could not replicate a previous reported role for rare variants in the interferon pathway (*P*=0.59).

Our larger GWAS of 56,841 cases and 955,795 controls found 11 loci (PACE2, the primary cell receptor for the SARS-CoV-2 spike protein (*P*=4.5e-13; OR=0.6Â±0.08; EUR MAF=0.003). Using RNA-seq, rs190509934 reduced ACE2 expression by 39% (P=3e-8), supporting the hypothesis that reduced ACE2 expression protects against SARS-CoV-2 infection.

Lastly, we developed a polygenic risk score (PRS) to predict hospitalization and severity of COVID-19. Among those of European ancestry, individuals with the top 10% PRSs are 1.8-fold more likely to be hospitalized (*P*=6e-11) and 1.58-fold more likely to be placed on a ventilator or die from COVID-19 (*P*=7e-10). These associations hold in other non-European populations (albeit with decreased power) and after accounting for known clinical risk factors.

Our data represents the most comprehensive survey of common and rare exonic variation associated with COVID-19 identifying new loci and polygenic risk scores that predict severity of COVID-19.

PrgmNr 1075 - Rare variant analyses in 239,395 whole exome and whole genome sequenced participants of the UK Biobank reveals novel genetic associations with renal function and chronic kidney disease

View session detail

Disclosure Block: **S. Li:** Salary/Employment; Janssen.
Genome-wide association studies have identified common genetic variants associated with chronic kidney disease (CKD), but the burden of rare loss-of-function (LoF) or pathogenic/likely pathogenic (P/LP) variants has not been well characterized. We performed gene-/region-based and variant association analyses for 5 renal function biomarkers (eGFR estimated from serum creatinine and/or cystatin-C, BUN, UACR) and 5 CKD endpoints (ESRD and stage4/5 CKD, CKD defined by biomarkers and/or diagnoses from NHS data, Cystic) in 239,395 UKB participants of genetically-assessed European ancestry and with whole exome (WES, n=171,172) or whole genome sequencing (WGS, n=121,019). For each trait, we fit a genome-wide regression model and tested for association using REGENIE V2.0, adjusting for age, sex, 10 principal components of ancestry, assessment center and BMI, where appropriate. For gene-based analyses, we generated 15 models to collapse ClinVar-classified P/LP, VEP(LOFTEE)-predicted putative LoF and deleterious variants predicted by 16 *in silico* scores (SIFT, Polyphen, BayesDel, etc.) from dbNSFP 4.1c. The WGS data further enabled annotation of promoter/enhancer variants, which were incorporated into collapsing models for gene-based association. In participants with WES, we identified 30 and 11 genes associated with â¥2 biomarkers and â¥1 CKD endpoint across collapsing models (FDRPKD1/2, COL4A3/4, CUBN, IFT140 were associated with both biomarkers and CKD. Association analyses also highlighted other genes including: *COL4A1, CST3, LAMC1, LRP2, SLC22A2, SLC34A3, SH2B3*. Variant-level analyses further informed impact on protein, e.g. the *SLC22A2* association signal was mainly driven by a frameshift (rs8177505) with lowering effects on eGFR (p=1.2e-27, beta=-6.2, MAF=0.12%). Exome-wide variant analyses revealed 25 genes (eg. *PDILT-UMOD*) with variant associations (p3 biomarkers or â¥1 endpoint, including 2 that were also implicated from the gene-based analyses (*COL4A4* and *CUBN*). Analyses of WGS allowed for sequence level validation of exome derived findings and the identification of additional variants not captured in WES. This study provides a framework for the assessment of the genetic landscape of kidney disease. The results validated known genes and identified potential novel associations with renal function.

PrgmNr 1076 - Novel genetic associations for rare diseases with GWAS and trans-ethnic analysis of self-reported medical data

Nearly 7000 rare diseases are known, and though each disease affects a few people, the total population prevalence of rare diseases is estimated to be 3.5-5.9%. A key challenge in the study of rare disease genetics is assembling large case cohorts for well-powered studies. Here we demonstrate use of large-scale self-reported rare disease data, combined with genetic data collected through the 23andMe direct-to-consumer platform, to study 33 rare diseases and identify genetic associations through GWAS. We developed web-based questionnaires, and gathered self-reported data on rare diseases from a cohort of over 1.6 million genotyped research-consented individuals. To reduce mis-reporting and maximize coverage, we used an autocomplete mechanism including 7000 rare diseases. We validated the approach through simulations and replication of known rare disease associations. In simulations based on genotypes from 4,957,230 European individuals, we show that GWAS can recover genome-wide significant associations in monogenic rare diseases for a variety of architectures. In rare diseases with known genetic associations, we reidentified 29 associations at a genome-wide significance level (p-value

PrgmNr 1077 - Common and rare variant analysis of 21K psoriasis cases and 623K controls identifies novel, protective associations in several genes in the type 1 interferon pathway

View session detail

Author Block: **J. Horowitz**[1], L. Gurski[1], D. Sun[1], L. Khrimian[2], M. LeBlanc[1], M. Jones[1], N. Banerjee[1], A. Verma[3], Regeneron Genetics Center, Geisinger DiscovEHR Collaboration, D. J. Baras[1]; [1]Regeneron Genetics Ctr., Tarrytown, NY, [2]Regeneron, Tarrytown, NY, [3]Univ. of Pennsylvania, Philadelphia, PA, [4]Univ of Pennsylvania, Philadelphia, PA, [5]Univ MICHIGAN, Ann Arbor, MI, [6]Kiel Univ., Kiel, Germany
Disclosure Block: **J. Horowitz:** Salary/Employment; Regeneron Genetics Center.
Psoriasis is a complex autoimmune disease resulting in chronic inflammation and hyperproliferation of the skin. The aberrant immune response associated with psoriasis is mediated by pathogenic T cells, which are activated, in part, by type 1 interferons (IFNs). Prior large-scale analyses of psoriasis cases focusing on common genetic variants have implicated >63 loci, including genes in the IFN signaling pathway. However, large-scale analysis of rare exonic variation is lacking.

To study the contribution of both common and rare variants to psoriasis risk, we performed whole-exome sequencing and meta-analysis of 20,810 psoriasis cases and 623,159 controls of EUR and AFR ancestry across 6 cohorts. Common variant analysis replicated 44 significant and independent associations in known psoriasis loci, including *IL23R*, *TYK2*, *IL12B*, *HLA-C*, and *DDX58*, among others. Rare-variant gene-burden analysis of putative loss-of-function (pLoF) and/or predicted-deleterious missense variants (IFIH1 (OR=0.74 [0.68, 0.81], p=4.1E-12), which encodes a pathogen sensor that activates IFN production, and *TRIM65* (OR=0.63 [0.50, 0.79], p=4.8E-5), which encodes a ubiquitin ligase that binds and activates IFIH1. We find the protective *TRIM65* association is driven by a rare, predicted-deleterious missense variant (rs202175254, AAF=0.1%) in the IFIH1-TRIM65 binding domain. Further, we find a nominally significant, protective association for the burden of rare pLoFs in *DDX58* (OR=0.76 [0.49, 0.89], p=6.7E-3), which encodes a second pathogen sensor that activates IFNs. This *DDX58* protective pLoF association helps confirm direction of effect at this known psoriasis locus.

Consistent with inhibition of IFNs being protective in psoriasis, we also found a significant and novel gene-burden association between increased odds of psoriasis and pLoFs in *ADAR* (OR=2.29 [1.68, 3.12], p=1.4E-7), which encodes a protein that suppresses IFNs and in which partial LoFs have been associated with Aicardi-GoutiÃ¨res syndrome, an inherited disorder that features over-production of IFNs.

Collectively, these results represent the largest rare-variant exome-sequencing analysis of psoriasis, to date. Future experiments will characterize effects of these pLoFs on protein expression and/or function, and further analysis will determine whether an IFN gene signature can identify a clinically-relevant subset of psoriasis patients who would therapeutically benefit from IFN inhibition.

PrgmNr 1078 - Investigating genetic and phenotypic associations for 168 blood metabolites in 120K UK Biobank participants

View session detail

Author Block: **A. Nag**[1], Q. Wang[2], A. Harper[1], D. Paul[1], A. Reznichenko[3], B. Challis[3], K. Carss[1], S. Petrovski[1]; [1]Ctr. for Genomics Res., AstraZeneca, Cambridge, United Kingdom, [2]Ctr. for Genomics Res., AstraZeneca, Waltham, MA, [3]Translational Sci. and Experimental Med., AstraZeneca, Gothenburg, Sweden

Disclosure Block: **A. Nag:** Salary/Employment; AstraZeneca.

In this study, we accessed the large-scale metabolomics, exome sequencing and phenomics data from the UK Biobank (UKB) to investigate gene-metabolite and metabolite-phenotype relationships. Blood metabolites (N=168) were profiled by Nightingale Health in ~120,000 UKB participants, >90% of whom had exome sequences and all had data on ~16,000 clinical traits.

We explored genetic associations with blood metabolites by two complementary approaches: (i) single-variant analysis, and (ii) gene-level collapsing analysis, using a linear regression model, adjusted for age, sex and BMI. For the single-variant analysis, we tested ~3.2 million variants under dominant and recessive models. For the gene-level collapsing analysis, the aggregate effect of variants in each gene was tested using 11 different models, including ones that focused on rare (MAFOur analyses provide a rich catalogue of significant (p-8) associations: 10,461 variant-metabolite, 970 gene-metabolite, and 127,947 metabolite-phenotype relationships. This includes well-established, biologically plausible associations such as variants in *PAH* with phenylalanine levels [beta=1.2; p-300] and the concentration of intermediate-density lipoprotein particles with type 2 diabetes [beta=-1.5; p-300]. These data may also provide insights into underlying biological mechanisms: for instance, the observed metabolite signature for mutations in a gene that is a known drug target (e.g, *HSD17B13*) can indicate the metabolic profile expected with desirable therapeutic response.

The catalogue of genetic and phenotypic relationships for blood metabolites, which will expand further once metabolomics data becomes available in the entire UKB cohort of ~500,000 subjects, represents an excellent resource to better understand mechanisms underlying complex human diseases.

PrgmNr 1079 - Practical implementation of polygenic risk scores and absolute risk score estimation across diverse ancestry groups

View session detail

Author Block: **R. Moore**, M. Golden, D. Thompson, F. Riveros-Mckay, P. Donnelly, G. McVean, V. Plagnol, M. E. Weale; Genomics plc, Oxford, United Kingdom
Disclosure Block: **R. Moore:** Salary/Employment; Genomics plc.
Polygenic risk scores (PRS) have generated considerable translational interest. Yet, most validation efforts focus on assessing relative rather than absolute risk scores (ARS), even though ARS are required for clinical decision making. ARS validation experiments are typically based on a single large cohort split into training/testing and rarely incorporate PRS. While such approaches typically generate calibrated ARS within the testing dataset, they do not properly capture the complex biases inherent to each healthcare context or account for environmental differences between countries and ethnicities. Consequently, the robustness of the ARS across different contexts is largely unknown.
To address these gaps, we derived a framework to combine ethnicity-specific disease baselines from a range of country-specific surveys, which capture social determinants of health, with ancestry-adjusted PRS (European OR per 1SD 1.87, 2.10, 1.51 and 2.09 respectively) for breast cancer, prostate cancer (PC), cardiovascular disease (CVD) and type 2 diabetes (T2D). We validated these ARS in independent datasets, computing calibration summary statistics, including the standard incidence ratio (SIR), calibration slope and intercept, and the integrated calibration index.
We find that inclusion of an ethnic specific baseline captures substantial ARS variability not captured by the PRS, particularly for PC, where an UK African and Caribbean baseline results in calibration (0.99-1.34 95% CI SIR) whilst the UK average baseline results in strong miscalibration (2.24-3.02 95% CI SIR). The extent of the calibration varied, with challenges arising for T2D and CVD, whose incidence has fluctuated across time and location in the US over the last decades. For T2D, baselines date from 1997-2019 but prospective testing data date from 1987-1999, resulting in miscalibration for White males (1.35-1.62 95% CI SIR). For CVD, baselines for myocardial infarction and fatal heart disease date from 2004-2011 and ischemic stroke from 1999, but prospective testing data date from 1986-2000, resulting in miscalibration for White females and males (0.66-0.92 and 1.04-1.31 95% CI SIR respectively).
We demonstrate that with appropriate data it is possible to translate genetic risk into clinically meaningful ARS that robustly replicate in diverse contexts. Our results also demonstrate the challenges arising from variation across ethnicity, geography and time and the need for population-relevant information on which risk prediction tools are to be applied.

PrgmNr 1103 - Characterization of molecular and motor phenotypes in CGG knock-in mice with CRISPR mediated deletion of the trinucleotide repeat

View session detail

Author Block: **C. M. Yrigollen**[1], L. Ohl[1], E. Lim[1], S. Zheng[2], K. Brida[3], Y. Chen[1], B. Simpson[1], B. L. Davidson[4]; [1]Children's Hosp. of Philadelphia, Philadelphia, PA, [2]Temple Univ., Philadelphia, PA, [3]Univ. of Alabama at Birmingham, Birmingham, AL, [4]The Children's Hosp. of Philadelphia, Philadelphia, PA
Disclosure Block: **C.M. Yrigollen:** None.
Fragile X-associated Tremor/Ataxia Syndrome (FXTAS) is a late onset neurodegenerative disorder that is caused by a premutation allele (55-200 CGG repeats) in the 5â untranslated region of the *FMR1* gene. *Fmr1* CGG knock-in (KI) mice with approximately 130 CGG repeats exhibit motor and memory impairments and are used to model FXTAS. We evaluated a Clustered Regularly Interspaced Short Palindromic Repeats (CRISPR) Cas9 based therapy for its ability to correct *FMR1* trinucleotide repeats in the KI mouse *in vivo.*

Two guideRNAs (gRNAs) were used to target the CGG repeats for deletion upon Cas9 mediated cleavage. Dual AAV vectors containing Cas9 and the gRNAs were injected into neonatal mouse pups at P0 to P1 bilaterally into the cerebral ventricles. Motor performance was evaluated at 12-15 weeks, 28-30 weeks and 52-54 weeks of age by accelerating rotarod. Motor impairment occurs in KI mice by 28 weeks, and results in quicker falls from the apparatus than is observed in WT littermates. Mice that were treated with the CRISPR constructs performed better than untreated knock-in mice, $p = 0.0041$ and were not statistically different their WT littermates at 28-30 weeks of age. At the late stage rotarod the *Fmr1* treated mice continued to perform similarly to the WT animals, but statistical differences were no longer observed between treatment groups.

Robust expression of SpCas9 and GFP were observed in the cortex, hippocampus, striatum, and cerebellum, of treated knock-in animals by qRT-PCR, but no significant reduction in Fmr1 was observed. These results are consistent with only a subset of cells needing to be transduced and edited to achieve a phenotypic rescue. Long read sequencing was performed to characterize the on-target outcomes of this gene editing strategy. We identified both expected and unexpected editing events (i.e., deletion of CGG repeats and vector sequence integration, respectively), highlighting the importance of fine mapping editing outcomes of this nascent gene therapy technology.

Our study is the first to demonstrate *in vivo* editing of expanded CGG repeats in *Fmr1* using CRISPR. This results in a therapeutic benefit, rescuing motor deficits present in aged KI mice. Long read sequencing and qRT-PCR provide insights into the variation of edits being achieved and how often unexpected editing events occur at the target locus. These results are important indicators that CRISPR mediated gene-editing is worth further development for treatment of FXTAS and other Fragile X-associated disorders.

PrgmNr 1104 - Upregulation of disease compensatory gene via CRISPR activation in muscular dystrophy mice

View session detail

Merosin-deficient congenital muscular dystrophy type 1A (MDC1A) is caused by mutations in the *LAMA2* gene encoding laminin-Î±2, an extracellular protein that is essential for skeletal muscle and Schwann cell functions. MDC1A patients with complete loss of expression never achieve independent ambulation and often do not reach adolescence, whereas those with partial deficiency exhibit milder phenotypes. Furthermore, there is a heterogeneity in the mutations found in the MDC1A patient population, which hampers the translation of genome editing approaches. The objective of this project is to develop a mutation-independent approach to treat MDC1A by upregulating a compensatory gene called *LAMA1* using CRISPR activation. We packaged a catalytically inactive SaCas9, 2XVP64 transcriptional activators and guide RNAs targeting the *Lama1* promoter into two adeno-associated viruses 9 (AAV9). Subsequently, we injected the AAV9 into the temporal vein of neonatal dy2j/dy2j, a mouse model with slightly reduced Lama2 and moderate phenotypes, or dyW/dyW, which have very low Lama2 and limited lifespan. We assessed the neuromuscular functions and histopathology to evaluate the therapeutic efficacy. We showed robust LAMA1 upregulation in skeletal muscle and peripheral nerves, leading to improvement in the dystrophic histopathology and functions, suggesting the therapeutic potential of this strategy. Current work involves the generation of a â□□mini-and-mightyâ□□ system by incorporating miniaturized transcriptional activators and utilization of single-AAV9 delivery system. Subsequently, we will evaluate the efficacy and safety of this strategy in the severe dyW/dyW mice. Successful completion of this project will open up new therapeutic avenues based on upregulation of compensatory gene in many diseases.

PrgmNr 1105 - Neuronal gene interaction:*Scn8a*, *Kcna1* and *Kcnq2*

View session detail

Author Block: **S. Hill**[1], P. Jafar-Nejad[2], F. Rigo[2], M. Meisler[3]; [1]Univ. of Michigan, Ann Arbor, MI, [2]Ionis Pharmaceuticals, Carlsbad, CA, [3]Univ Michigan, Ann Arbor, MI
Disclosure Block: **S. Hill:** None.
Gain-of-function mutations in the neuronal voltage-gated sodium channel gene *SCN8A* are a cause of developmental and epileptic encephalopathy (DEE). Modification of *Scn8a*-DEE in the mouse by interaction with a mutation of *Gabra2* was recently described (Yu et al, *Epilepsia* 61:2847-2856, 2020). The severity of *Scn8a*-DEE can be ameliorated by administration of an antisense oligonucleotide (ASO) that reduces expression of *Scn8a* (Lenk et al*, Ann. Neurol.* 87:339-346, 2020). This ASO also rescues survival of mice with mutation of the sodium channel *Scn1a.* The proteins encoded by *SCN1A* and *SCN8A* are concentrated at the axon initial segment of the neuron, where they contribute to the generation of action potentials. To evaluate genetic interaction between *Scn8a* and other channels located at the axon initial segment, we examined mice with mutations in the potassium channel genes *Kcnq2* and *Kcna1*. Mice with homozygous mutations of *Kcna1* and *Kcnq2* were treated on postnatal day 2 by intracerebroventricular injection of a dose of ASO that reduces the level of *Scn8a* transcript by 50%. Treatment with the *Scn8a* ASO resulted in significant delay in the age of seizure onset, as well as increased length of survival. A small effect was observed in mice with mutation of the synaptic protein LGI1. The data demonstrate that the severity of genetically determined seizure disorders can be modified by compensatory changes among co-localized ion channels. An ASO targeting *SCN8A* may therefore have therapeutic value in multiple types of genetic epilepsy.

PrgmNr 1106 - Adjunct treatment with glycogen synthase (GYS1) antisense oligonucleotides: Reduce glycogen in the Pompe disease mouse model

View session detail

Author Block: **L. Weiss**[1], M. Carrer[2], J. Lee[1], A. Shmara[1], J. Vu[1], C. Cheng[1], N. Raben[3], T. R. Grossman[2], J-n. Paymaan[2], V. E. Kimonis[1]; [1]Univ. of California, Irvine, Irvine, CA, [2]Ionis Pharmaceuticals, Carlsbad, CA, [3]NIH, Bethesda, MD

Disclosure Block: **L. Weiss:** None.

Pompe disease is a progressive myopathy resulting from the deficiency of acid a glucosidase. Enzyme replacement therapy (ERT) with recombinant human GAA works well in alleviating the cardiomyopathy; however, many patients continue to have progressive muscle weakness from muscle glycogen accumulation. Previous studies have provided proof of principle that knockdown of GYS1 mRNA by phosphorodiamidate morpholino oligonucleotide reduced glycogen. The lead from the screening over 150 ASOs were validated in a dose response study and the top 10 ASOs were screened in vivo. Three GYS1 ASOs showed the best tolerability and efficacy profile leading to knock down of GYS1 mRNA by approximately 50% of control. We performed an in vivo study of the toxicity and efficacy of the three GYS1 ASOs in Gaa -/- Pompe mice as monotherapy. The results showed over 16 doses (25mg/kg, once a week) of the best candidate, ASO#3 was safe and well tolerated. It significantly reduced muscle GYS1 mRNA levels, autophagy pathology, to a lesser extent glycogen content in muscle of Gaa -/- mice compared to the control groups, PBS and mismatch ASO. We are currently treating mice with a combination treatment of ASO#3 and ERT to maximize the therapeutic effect. After four months of treatment, the combination treatment group showed an upward trend of improvement in motor tests compared with ERT or ASO#3 alone groups.

PrgmNr 1107 - Transethnic evaluation of copy number burden in epilepsies from a genome-wide study of 34,132 subjects

View session detail

Author Block: L-M. Niestroj[1,2], **C. Leu**[1,3,4], D. Lal[1,5,4,2], Epi25 Consortium; [1]Genomic Med. Inst., Lerner Res. Inst., Cleveland Clinic, Cleveland, OH, [2]Cologne Ctr. for Genomics, Univ. of Cologne, Cologne, Germany, [3]Dept. of Clinical and Experimental Epilepsy, UCL Inst. of Neurology, London, United Kingdom, [4]Stanley Ctr. for Psychiatric Res., Broad Inst. of Harvard and M.I.T, Cambridge, MA, [5]Epilepsy Ctr., Neurological Inst., Cleveland Clinic, Cleveland, OH
Disclosure Block: **C. Leu:** None.
Rationale: Rare copy number variants (CNVs) are strongly implicated in the etiology of epilepsy. We previously published an association study of CNVs with different types of epilepsy in ~10k European epilepsy cases and ~6k ancestry-matched controls (Niestroj et al., 2019, *Brain*). We observed large differences in the CNV burden across epilepsy types and different CNV categories. We found that the established epilepsy-associated 15q13.3 deletion represents the strongest risk CNV for genetic generalized epilepsy (GGE), with a 34-fold risk for developing GGE. However, similar to most previous epilepsy genetics studies, we focused only on individuals with European ancestry. The distribution of CNVs that confer risk towards epilepsy and their effect sizes are not well established in non-European populations.
Methods: Using genome-wide genotyping data generated with the Illumina Global Screening Array-24 v1.0, we reanalyzed the current cohort of the Epi25 Consortium together with new genetic data, totaling 21,706 individuals with epilepsy and 12,426 ancestry-matched controls for the burden of rare CNVs.
Results: We identified 25,172 European- (EUR), 4,087 African- (AFR), and 1,824 Asian-ancestry (ASN) individuals in our study available for CNV burden analyses after quality control. Across all ancestries, we identified 305 CNV carriers of seven established epilepsy-associated CNV hotspots in 19,079 individuals with epilepsy and 70 carriers among 12,004 controls. Among all tested epilepsy subsyndromes and in line with previous evidence, we observed the highest CNV burden in individuals with GGE. The two most common recurrent CNVs, deletions at 15q11.2 and 16p13.11, known to be associated with GGE in European individuals, were also enriched in African and Asian individuals with GGE, with effect sizes similar to those in European individuals (e.g., 15q11.2: $P_{EUR}=6.89x10^{-5}$, $OR_{EUR}=2.44$ vs. $P_{AFR}=9.49x10^{-3}$, $OR_{AFR}=3.96$; or 16p13.11: $P_{EUR}=9.26x10^{-12}$, $OR_{EUR}=25.9$ vs. $P_{ASN}=6.58x10^{-3}$, $OR_{ASN}=26.4$). At the time of the conference, we will present additional analyses of different classes of CNVs and genome-wide CNV breakpoint association analyses that explore the similarities and possible differences between CNV architectures of European, African, and Asian ancestries.
Conclusions: Our study represents the largest and the first transethnic evaluation of the CNV burden in epilepsy. Our preliminary results indicate that established recurrent CNVs have similar effect sizes in different ethnicities. As CNVs are part of clinical genetic testing, our results will likely help alleviate health care disparities.

PrgmNr 1108 - Variant-to-gene-mapping of insomnia GWAS loci followed by a neuron-specific RNAi screen in *Drosophila melanogaster* implicates *PIGQ* at the â□□*WDR90*â□□ locus as a novel regulator of sleep

View session detail

Author Block: **S. F. Grant**[1,2], J. Palermo[3], S. Sonti[1], C. Lasconi[1], A. Chesi[1,2], D. R. Mazzotti[4], P. R. Gehrman[2], A. C. Keene[3]; [1]Children's Hosp. of Philadelphia, Philadelphia, PA, [2]Perelman Sch. of Medcine, Univ. of Pennsylvania, Philadelphia, PA, [3]Florida Atlantic Univ., Jupiter, FL, [4]Univ. of Kansas Med. Ctr., Kansas City, KS

Disclosure Block: **S.F. Grant:** None.

Insomnia is the most common sleep disorder and increases risk for subsequent psychiatric sequelae. In recent years, GWAS efforts have identified >200 insomnia loci, but the underlying causal mechanisms remain elusive. We elected to conduct the first variant to gene mapping for insomnia by identifying putative causal variants and their associated effector genes followed by assessing functional effects on sleep/wake regulation in the fruit fly, *Drosophila melanogaster*. Genome-wide significant signals identified from published insomnia GWAS (n>200) were included in this study. We integrated proxy SNPs in high linkage disequilibrium to each sentinel signal with both genome wide ATAC-seq and high-resolution promoter-focused Capture C data in order to implicate effector genes contacted directly by regulatory regions coinciding with these variants in iPSC-derived neural progenitor cells. The resulting putative effector gene list was subjected to a neuron-specific RNAi screen in *Drosophila melanogaster* followed by in-depth sleep phenotyping in order to assess the impact of such genetic perturbation on sleep/wake regulation. As a consequence, a number of short- and long-sleeping lines were derived. Most notably, multiple lines of evidence converged on the *PIGQ* gene at the â□□*WDR90*â□□ locus, which encodes phosphatidylinositol N-acetylglucosaminyltransferase subunit Q, an enzyme involved in the first step of glycosylphosphatidylinositol anchor biosynthesis. Knockdown of PIGQ significantly increased both daytime and nighttime sleep. Restricting knockdown to cholinergic neurons phenocopied pan-neuronal knockdown, supporting the notion that PIGQ modulates the function of excitatory neurons. To examine how PIGQ impacts sleep, we used video tracking prior to and following exposure to mechanical shaking of sleeping flies and measured the effect on sleep. No differences in arousal threshold were observed, suggesting that PIGQ regulates sleep duration, but not arousability which is considered an indicator of sleep depth. Together, these findings suggest PIGQ is selectively a regulator of sleep duration, but not sleep quality. Our ongoing studies seek to localize PIGQ function to specific regions within the brain, and to identify its impact on sleep intensity and function more precisely. These analyses strongly support a role for *PIGQ* at the â□□*WDR90*â□□ locus as a gene encoding a novel regulator of sleep, and thus a key contributor to the pathogenesis of insomnia. These results highlight the strength of leveraging multiple, converging approaches to characterize the genetic basis of insomnia based on the findings resulting from GWAS efforts.

PrgmNr 1111 - Somatic Mosaicism and Cardiovascular Disease: Uncovering Hidden Genetic Etiology with Clinical Implications

Hlth., Univ. of Texas, Houston, TX, [3]Dept. of Med./Div. of Cardiology, Baylor Coll. of Med., Houston, TX
Disclosure Block: **V. Chander:** None.
Cardiovascular disease (CVD) is the leading cause of death globally and constitutes a significant health burden. The identification of numerous genes associated with CVD has led to their incorporation into clinical genetic testing panels and yet the molecular basis of almost half of CVD cases remains unknown. A growing number of genetic disorders have been associated with somatic mosaicism, however, the prevalence and impact of somatic mutations in CVD have not been well-explored. Recent identification of the association of Clonal Hematopoiesis of Indeterminate Potential (CHIP), driven by somatic mosaicism, with increased risk for atherosclerosis suggests a role in CVD. Deep DNA sequencing can enable sensitive detection of somatic mutations and elucidation of their role in CVD.

We determined the prevalence of somatic mutations within a heart disease-enriched cohort (HeartCare), a genetic screen of >700 individuals, in ambulatory cardiovascular care clinics, targeting 158 genes associated with Mendelian CVD conditions. Using deep NGS to detect low-frequency disease-associated variants, we detected exonic somatic mutations in more than 10% of individuals, including a subset recurring in the same locus. To identify pathogenic somatic mutations, we filtered out common polymorphisms using population-level databases and narrowed down the deleterious variants to those supported by *in silico* pathogenicity prediction evidence. Among them, 82% had CVD indications but were negative for a germline mutation or LPA finding, thus without a clear genetic diagnosis.

Interestingly, we found links between somatic mutations in implicated genes (*ABCC6, ABCC9, SDHA, CACNA1C, CACNB2, COL5A1, COL5A2, MYH7, MYH11, RYR2*) and CVD events (e.g arrhythmia, high calcium score, heart attack, A-Fib) with instances where the expected gene-specific phenotype was observed, supporting causality. The implicated genes encode key proteins involved in drug and lipid transport, ATP-dependent transport in mitochondria, calcium channels, collagen synthesis, and actin-based motors. These genes have moderate to high expression in the cardiac tissue, including a subset expressed in hematopoietic stem cells with a potential role in CHIP. These results support the hypothesis that somatic mosaicism in CVD impairs pathways involved in intracellular transport and calcium channeling and may underly the link between clonal expansions and CVD conditions. Collectively, these results demonstrate the power of targeted NGS studies to reveal the impact of somatic mosaicism and suggest that somatic mosaicism represents an important etiology of CVD.

PrgmNr 1112 - Identifying the role of alternative splicing during human heart organogenesis

View session detail

Author Block: **K. Child**, T. Yankee, A. Wilderman, J. Cotney; UConn Hlth., Farmington, CT
Disclosure Block: **K. Child:** None.
Congenital Heart Defects (CHD) are one the most frequent congenital abnormalities affecting births worldwide. Many groups investigating CHDs have been focused on heart gene expression during fetal development and later. However, recent evidence has suggested that gene expression dynamics principally occurs during organogenesis, which happens before the fetal stage. This period encompasses the first eight weeks of human development and has been classified into 23 Carnegie Stages (CS). Our lab has published extensive work detailing the nature of gene expression during these early stages focusing on CS12 to 23 (4 to 8 post-conception weeks). Examination of gene co-expression across this window of development revealed RNA processing and splicing as a major module in this network. Furthermore, recent work has shown that alternative isoform utilization is the most dynamic in the heart and brain during fetal development which were the earliest stages surveyed. These results suggest alternative splicing and existence of novel isoforms during heart organogenesis could be important for normal heart development during the embryonic period. To identify alternative splicing events across development we reanalyzed short-read bulk gene expression from embryonic human heart. Consistent with results from fetal data, we found many differential splicing events between individual Carnegie stages within this period. These differentially spliced genes were enriched for functions related to heart development and abnormalities, however few overlapped with our previous differential expression results calculated at the composite gene level. Generation of *de novo* transcriptome assembly using this data revealed numerous previously unannotated isoforms, even amongst well studied heart related genes, many of which were differentially spliced during this developmental period. To confirm the existence of these novel isoforms we subsequently profiled the transcriptome of these same samples using Nanopore long-read sequencing. We validated a substantial number of these novel isoforms including a novel *TBX5* transcript which utilizes several previously unannotated 5â□□ exons. These exons could be important for post-transcriptional regulation of TBX5 and be an additional region to screen for in Holt-Oram Syndrome patients. Overall, our analysis identifies previously unknown transcript diversity in the developing human heart which could help explain previously undiagnosed genetic causes of CHD.

PrgmNr 1113 - Genetic deficiency of the AIM2 inflammasome mitigates *JAK2*p.V617F clonal hematopoiesis associated cardiovascular diseases risk

View session detail

Author Block: **Z. Yu**[1], T. Nakao[1], M. Uddin[1], A. Niroula[1], T. P. Fidler[2], S. M. Zekavat[3], C. J. Gibson[4], G. K. Griffin[5], A. R. Tall[2], P. Libby[5], S. Jaiswal[6], B. L. Ebert[4], A. Bick[7], P. Natarajan[8]; [1]Broad Inst. of MIT and Harvard, Cambridge, MA, [2]Columbia Univ. Irving Med. Ctr., New York, NY, [3]Yale Sch. of Med.; Broad Inst., Natick, MA, [4]Dana-Farber Cancer Inst., Boston, MA, [5]Brigham and Women's Hosp., Boston, MA, [6]Stanford Univ. Sch. of Med., Stanford, CA, [7]Vanderbilt Univ. Med. Ctr., Nashville, TN, [8]Massachusetts Gen. Hosp., Boston, MA

Disclosure Block: **Z. Yu:** None.

Clonal hematopoiesis of indeterminate potential (CHIP), a common condition among elderly where clonal expansion of blood cells harboring somatic mutations, has been associated with the risk of hematologic malignancy and cardiovascular diseases (CVD). *JAK2*^{V617F} is the most commonly observed point mutation in CHIP and confers the strongest CVD risk. Murine studies implicate NLRP3 inflammasome activation for *Tet2* CHIP, but both NLRP3 and AIM2 inflammasome activation for *JAK2*^{V617F} CHIP and atherosclerosis. Whether AIM2 inflammasome inactivation mitigates *JAK2*^{V617F} CHIP-associated CVD in human is unknown. We used whole exome sequencing data of blood DNA analyzed from 184,887 genetically unrelated participants in the UK Biobank without prevalent CVD and hematological cancers to identify those with *JAK2*^{V617F} mutations. We generated an *AIM2* gene expression reducing eQTL score using eQTL summary statistics from the eQTLGen consortium, where each score represents a genetic proxy for gene expression. We also extracted *IL6R* p.Asp358Ala genotype status, which was previously linked to reduced primarily *DNMT3A* and *TET2* CHIP-associated CVD risk. We examined the association between the *JAK2*^{V617F} status and incident CVD (myocardial infarction, coronary revascularization, stroke, or death) risk, and whether the *AIM2* eQTL score or *IL6R* p.Asp358Ala modifies that association. In the analyzed dataset, the mean (SD) age was 56.3 (8.0) years and 103,958 (56.2%) were women. We identified 114 (0.06%) individuals with *JAK2*^{V617F} mutation, 112 of whom carried large clones (allele fraction > 10%). During 10.8-year median follow-up, 18,771 incident CVD events were observed. *JAK2*^{V617F} was associated with 2.8-fold increased incident CVD risk (P $6.6*10^{-11}$) independent of age, sex, self-reported race, genotyping array, and first 10 principal components of ancestry. Decreased genetic predisposition to *AIM2* expression attenuated the risk among *JAK2*^{V617F} carriers (HR 0.27; 95% CI 0.09-0.84; P 0.023) but not those without the *JAK2*^{V617F} mutation (HR 1.00; 95% CI 0.98-1.01; P 0.73; $P_{interaction}$ 0.024). Restriction to large *JAK2*^{V617F} clones did not alter the results. Nor did carrier status of the *IL6R* p.Asp358Ala coding mutation exhibit interaction with *JAK2*^{V617F} status on CVD risk. Leveraging human genetic instruments, we observed that the *JAK2*^{V617F} mutation enhances CVD risk, but that genetically reduced *AIM2* expression attenuates this risk. Our human genetic findings corroborate recent murine observations and suggests that *AIM2* inhibition could specifically mitigate *JAK2*^{V617F} CHIP associated CVD. This hypothesis merits testing assessed in prospective clinical trials.

PrgmNr 1114 - *FHL5*, a Novel Coronary Artery Disease Gene, Regulates Smooth Muscle Cell Contractility

Disclosure Block: **D. Wong:** None.

Coronary artery disease (CAD) is the leading cause of death worldwide. Genome-wide association studies (GWAS) have identified over 200 loci associated with CAD, many of which cluster into distinct functional pathways. For example, in the most recent meta-analysis of myocardial infarction (MI) and CAD, *UFL1-FHL5* (chr6q16.1) emerged as a novel CAD/MI locus. Despite additional genetic associations with multiple vascular pathologies, the underlying mechanism of this locus has not been elucidated. We first prioritized *FHL5* as the top candidate causal gene at *UFL1-FHL5* using two statistical fine-mapping approaches, Summary-level Mendelian Randomization and *coloc*. FHL5 expression is enriched in contractile mural cells (smooth muscle cells (SMCs) and pericytes) and potently downregulated in atherosclerotic arteries. Given its reported role as a cofactor, we hypothesized that FHL5 functions as a transcriptional regulator of SMC contractile pathways to impact vascular tone and disease risk. To test the functional effects of FHL5 overexpression in SMCs, we performed confocal-based calcium imaging and collagen gel contraction assays. FHL5 overexpression increased the basal calcium concentration 2.5x, which correlated with increased contractility. To interrogate the molecular mechanism of FHL5 function in SMCs, we mapped FHL5 binding sites using the Cleavage Under Targets and Release Using Nuclease (CUT&RUN) method. Genes harboring FHL5 binding sites were enriched for CAD relevant pathways, such extracellular matrix organization and TGF-beta signaling. Furthermore, FHL5 binding sites were also enriched for CAD/blood pressure (BP) risk variants, suggesting interactions between FHL5 and other CAD/BP loci. Finally, by performing weighted gene co-expression and key driver analyses in coronary arteries, we demonstrate that FHL5 possess regulatory potential *in vivo* and resides in a module enriched for contractile genes and CAD/BP GWAS hits. Our results provide evidence that *FHL5* is the most likely causal gene at the *UFL1-FHL5* locus and may impact CAD risk by regulating a network of downstream disease associated genes. These findings may contribute to our understanding of the heritable risk for multiple vascular diseases.

Disclosure Block: **G. Png:** None.

Every year, an estimated 17.9 million deaths are caused by cardiovascular diseases, while more than one million die from type 2 diabetes. Cardiometabolic diseases such as these are linked to dysregulated protein levels, and understanding the genomic influence on these proteins can help to dissect the complex biology underpinning them. Here, we perform a protein quantitative trait loci (pQTL) analysis (n=2,893) of 257 serum proteins relevant to cardiometabolic processes. Meta-analysing deep whole-genome sequencing data from two Greek isolated cohorts, MANOLIS (n=1,356; 22.5x WGS) and Pomak (n=1,537; 18.4x WGS), we detect 309 independently-associated pQTL variants for 176 proteins, including 12 rare variants (minor allele frequency [MAF] cis- and three *trans*-acting) for 13 proteins that pass study-wide significance in both cohorts. Using replicating variants as instrumental variables, we find evidence of causal relationships between 35 proteins and various cardiometabolic traits via two-sample Mendelian randomisation. These include LRIG1 for atrial fibrillation and type 2 diabetes, SUMF2 for cholesterol levels, and MEP1B for high density lipoprotein (HDL) levels. Specifically, decreased MEP1B was causal for increased HDL levels. We sought *in vivo* validation in *Mep1Î²* knockout (KO) mice, where we observe significantly increased body weight and fat/lean mass ratio in female KO mice compared to their wild-type counterparts. We therefore derive causal protein-cardiometabolic trait relationships from novel pQTL data, and present orthogonal evidence supporting our findings.

PrgmNr 1116 - Network medicine-based multimodal omics discovery and iPSC-based validation of metformin for potential treatment of atrial fibrillation

Introduction: Atrial Fibrillation (AF) is the most prevalent cardiac arrhythmia in the United States, affecting 1% to 2% of the general population, significantly contributing to cardiovascular morbidity and mortality. Effective, safe, and durable therapeutic interventions are lacking. Thus, it is imperative to improve clinical management by utilizing novel approaches for drug repurposing. To date, multimodal omics analysis of genomics, transcriptomics, and interactomics (protein-protein interactions [PPIs]) have not been fully exploited for AF drug repurposing.
Hypothesis: We hypothesize that using Network Medicine-based multimodal omics analysis for drug prioritization and functional observations using induced pluripotent stem cell (iPSC) models can help us identify effective therapeutic strategies and elucidate drugâ□□s mechanisms-of-action for restoring normal sinus rhythm.
Methods: Here, we used RNA-sequencing data from a biobank of left atrial tissues obtained from cardiac surgery patients with abnormal and normal sinus rhythm to identify testable AF disease modules under the human protein-protein interactome network model. We systematically prioritized repurposable drug candidates for AF using both network proximity and gene-set enrichment analysis approaches by leveraging AF disease module findings, drug-target network, and drug-induced gene signatures in human cell lines. RNAseq was used to assess the transcriptomic impact of a top drug candidate, metformin, on gene expression of atrial myocytes differentiated from human iPSCs (a-iCMs).
Results: Via network-based screening of 2,891 FDA-approved or clinical drugs, we found nine putative drug candidates (including Metformin, Furosemide, and Rofecoxib) using both network proximity z-score and GSEA-based enrichment scores. RNA-seq analysis of metformin-treated a-iCMs identified 238 differentially expressed genes following multiple test correction (P**Conclusions:** In summary, this study presented state-of-the-art network medicine methodologies for AF drug repurposing and identified metformin as a candidate treatment for AF patients.

PrgmNr 1119 - The impact of evolutionary processes in shaping the genetics of complex traits in East Asia: A specific contribution from Denisovan introgression

View session detail

Author Block: **D. Koller**, F. R. Wendt, G. A. Pathak, A. De Lillo, F. De Angelis, B. Cabrera-Mendoza, R. Polimanti; Yale Sch. of Med., West Haven, CT
Disclosure Block: **D. Koller:** None.
Consistent evidence of how human evolution shaped the polygenicity of human traits and diseases has been observed in populations of European descent. However, no information is currently available about its impact on other ancestry groups. Here, we investigated how different evolutionary processes affected the genetics of traits and diseases in individuals of East Asian descent by leveraging genome-wide association statistics from the Biobank Japan (up to 158,284 participants). We assessed natural selection, archaic hominin introgression (*Denisova hominins* and *Homo neanderthalensis*), and several genomic functional categories regarding the heritability of physiological and pathological conditions. Similar to findings in European descent populations, the heritability of several traits was significantly enriched for annotations related to negative selection (e.g., serum creatinine: 8.8-fold enrichment for B-statistics, p=5.68Ã□10$^{â□□4}$). Regarding Denisovan introgression, we identified enrichments for left ventricular mass index (2.9-fold enrichment, p = 3.03Ã□10$^{â□□4}$), atopic dermatitis (9.2-fold enrichment, p=3.03Ã□10$^{â□□4}$), and coronary artery disease (1.7-fold enrichment, p=0.003). Neanderthal local ancestry was depleted for monocyte count (9.7-fold depletion, p = 0.002) and platelet count (4.9-fold depletion, p=0.006). To follow up these archaic-introgression enrichments, we conducted a phenome-wide association study of Denisovan- and Neanderthal alleles in participants of East Asian descent and other ancestral backgrounds from the UK Biobank. Denisovan- and Neanderthal-introgressed alleles were associated with 13 and 10 phenotypes, including metabolic, dermatological, immunological, cardiovascular, and endocrine traits. The strongest association was observed for the Denisovan-inherited locus rs59185462 with rheumatoid arthritis (beta = 0.82, p = 1.91Ã□10^{-105}). In summary, our study provides the first evidence regarding the impact of evolutionary processes on the genetics of complex traits, highlighting the specific contribution of Denisovan introgression in East Asian populations.

PrgmNr 1120 - The influence of Neanderthal introgression on human circadian biology

View session detail

Author Block: **K. Velazquez-Arcelay**[1], L. L. Colbran[2], E. McArthur[1], D. C. Rinker[1], J. A. Capra[3]; [1]Vanderbilt Univ., Nashville, TN, [2]Philadelphia, PA, [3]Univ. of California San Francisco, San Francisco, CA
Disclosure Block: **K. Velazquez-Arcelay:** None.
As the ancestors of modern Eurasians migrated out of Africa, they encountered novel environmental pressures, such as differences in day length, temperature, and pathogen exposures. These anatomically modern humans (AMH) also encountered groups of archaic humans in Eurasia, namely Neanderthals and Denisovans. For more than 400,000 years, these Eurasian hominins evolved and adapted to the variety of environments outside Africa. There is evidence of interbreeding events between these groups, resulting in the inheritance of parts of archaic genomes remaining in modern humans. This process potentially accelerated the adaptation of AMH to new environmental factors including reduced yearly ultra-violet radiation exposure and changing seasons. However, whether these groups differed substantially in circadian biology and chronotype, and whether archaic introgression contributed to the biology of human chronotype adaptation remains unknown. To address this question, we traced the evolution of chronotype based on analysis of available ancient DNA (aDNA) data from ~2,000 ancient Eurasian humans, four archaic hominins, and also genomes from thousands of present-day humans. First, we contrast circadian gene regulation patterns between archaic hominins and modern humans and identify 32 circadian genes likely divergently regulated between present-day Africans and archaic hominins, including PER2 and CLOCK. This suggests the potential for introgression to modify circadian gene regulation. Testing this hypothesis, we find that introgressed Neanderthal variants are enriched among eQTLs for circadian genes. Supporting the relevance of these gene regulatory effects on circadian traits, we found that introgressed alleles are enriched for heritability of morningness in the UK Biobank and an independent GWAS of chronotype, using stratified LD score regression. Finally, analyzing modern and ancient human DNA, we identify 1,287 circadian gene variants with significant allele frequency divergence by latitude in ancient humans. In addition to the introgressed circadian eQTL identified, we found many variants with diverse evolutionary histories with associations with traits related to chronotype. These findings demonstrate differences in circadian regulation between modern humans and archaic hominins and establish the importance of adaptive introgression on chronotype, a trait highly dependent on environmental variation.

PrgmNr 1121 - Systematic genomic investigation finds evidence of germline and somatic roles of Neanderthal introgression in liver cancer

View session detail

Author Block: **A. M. Taravella Oill**[1,2], K. H. Buetow[1,2], M. A. Wilson[1,2]; [1]Sch. of Life Sci., Arizona State Univ., Tempe, AZ, [2]Ctr. for Evolution and Med., Arizona State Univ., Tempe, AZ
Disclosure Block: **A.M. Taravella Oill:** None.
European and East Asian populations retain genetic relics of ancient contact with Neanderthals. Regions of introgressed Neanderthal DNA are often depleted in functional regions of the genome, but occasionally haplotypes remain that are predicted to provide some benefits to modern humans. In particular, there is limited understanding of the relationship between Neanderthal introgression and cancer risk. To better understand this, we have undertaken a systematic study of introgression in cancer, with a focus on liver cancer. Using publicly available introgression maps generated from European and Asian populations from the 1000 Genomes resource, we first tested whether Neanderthal introgression is enhanced or depleted in different categories of genes etiologically important in cancer among the general population. Recognizing that different cancers have variations in their underlying genetic etiology, we also examined germline and somatic changes in a single cancer - hepatocellular carcinoma - using germline and somatic variant data from 177 individuals of European ancestry and 159 individuals of East Asian ancestry from The Cancer Genome Atlas and find evidence for both risk and protective Neanderthal alleles. Among the general population, we do not find evidence for an excess or depletion of Neanderthal introgression at cancer risk genes. In liver cancer samples, we find genes with Neanderthal introgression (*LARS1* in Europeans and East Asians, *APTX* and *MCMBP* in Europeans only) exhibit an excess of somatic mutations compared to non-introgressed regions, suggesting introgressed regions may be more permissive to mutation. Provocatively, in people of East Asian descent, we find two genes (*CYB561D2* and *CACNA2D2*) that are enriched for Neanderthal introgression in the general population but depleted for introgression in people with liver cancer, suggesting introgression in these regions may be protective. As liver cancer is the second leading cause of cancer death worldwide, understanding the landscape and effects of Neanderthal introgression may inform about future susceptibility, as well as potential biomarkers for risk and therapeutic targets.

PrgmNr 1122 - Biobank-scale inference of ancestral recombination graphs reveals association to rare and common variants in complex traits

View session detail

Author Block: **B. Zhang**[1], A. Biddanda[1], P. Palamara[1,2]; [1]Dept. of Statistics, Univ. of Oxford, Oxford, United Kingdom, [2]Wellcome Ctr. for Human Genetics, Oxford, United Kingdom

The genealogical history of a set of genomes can be compactly represented using an ancestral recombination graph (ARG). We developed ARG-Needle, a method for inferring the ARG of hundreds of thousands of samples from array data, along with a mixed-model framework that leverages the ARG to detect unobserved genomic variants linked with complex traits. In extensive simulations across a variety of accuracy metrics, ARG-Needle matches or outperforms Relate (Speidel et al. Nat Genet 2019) while scaling to substantially larger sample sizes. Compared to tsinfer (Kelleher et al. Nat Genet 2019), a scalable method that only outputs ARG topology, ARG-Needle performs better on all metrics and infers both branch lengths and topology.
Using ARG-Needle, we built the genome-wide ARG for 337K unrelated European UK Biobank individuals from SNP array data. We performed mixed-model association of inferred ARG variants (focusing at first on MAF > 1%) and standing height, and compared to association of imputed variants from 65K HRC sequences (MAF > 0.1%). ARG-based association (permutation p We then tested for association between ultra-rare variants (URV, MAF These results demonstrate the impact of genealogical inference in complementing reference-based imputation for the study of complex traits and diseases, opening new possibilities for the analysis of under-sequenced cohorts for which reference panels are not yet available.

PrgmNr 1123 - Local ancestry inference for ~7,000 genomes in the Genome Aggregation Database characterizes fine-scale allele frequencies within admixed American populations

View session detail

Author Block: **M. Wilson**[1,2], K. J. Karczewski[1,2], Z. Koenig[1,2], A. R. Martin[1,2], gnomAD Consortium, M. J. Daly[2,1,3], G. Tiao[1,2], E. G. Atkinson[4,1]; [1]Broad Inst. of MIT and Harvard, Cambridge, MA, [2]Massachusetts Gen. Hosp., Boston, MA, [3]Inst. for Molecular Med. Finland, Helsinki, Finland, [4]Baylor Coll. of Med., Houston, TX

Disclosure Block: **M. Wilson:** None.

Currently, there is not a comprehensive understanding of the allele frequency (AF) spectrum in Native American (NatAm) and African haplotype tracts in admixed American populations. Accurate AF estimates are critical for clinical variant interpretation. The absence of this information contributes to health disparities for admixed American populations, some of which are at greater risk for developing common diseases including cardiometabolic disorders.

Here we describe the creation of a refined population frequency reference for the Genome Aggregation Database (gnomAD) for NatAm haplotypes in 6,972 Latinx individuals. NatAm haplotypes make up a significant component (13-48%) of the complex, admixed genetic structure of Latinx individuals. To define NatAm ancestry-specific haplotypes, we constructed a continental reference panel from a tailored subset of populations within the 1000 Genomes Project and the Human Genome Diversity Project. We then used this reference panel for phasing and local ancestry inference to assign a genetic ancestry to each chromosomal segment in gnomAD Latinx individuals. Finally, we used the tool Tractor to generate local ancestry dosages at each site and compute ancestry-specific AFs. We tested multiple local ancestry inference methodologies, reference panel compositions, and phasing tools to optimize for maximal efficiency and accuracy. This unified computational pipeline was written using the Hail Batch Python module and is publicly available through GitHub [github.com/broadinstitute/gnomad_local_ancestry].

Preliminary analysis reveals a highly diverse set of samples. The average estimated proportions of global ancestry of gnomAD Latinx individuals are 30% NatAm, 12% African, and 58% European. 5% of these individuals are homogeneous, 60% are two-way admixed, and 35% are three-way admixed, with subsets of individuals most closely resembling several distinct reference populations.

This effort will result in the largest publicly available dataset for NatAm-specific AFs, refined population frequencies within the gnomAD browser, and a computational pipeline to readily resolve AFs within admixed populations. Finer AF resolution increases gnomADâ□□s clinical utility for individuals of admixed ancestry by enabling better interpretation of rare variation. The decomposition of ancestral alleles will also enable us to build a demographic model to date admixture events within these populations and determine allelesâ□□ ancestral origins. The AF spectrums and quality metrics are available for direct download and for interactive browsing on the gnomAD website, [gnomad.broadinstitute.org].

PrgmNr 1124 - Sex-specific effective population size inference in recent history

View session detail

Author Block: **R. Cai**[1], B. Browning[2], S. Browning[2]; [1]Dept Biostatistics, Univ. of Washington, Seattle, WA, [2]Univ of Washington, Seattle, WA

The study of sex-specific population history is crucial for understanding if the males and females in a population have experienced differing demographic processes in the past, such as sex-specific migration processes or sex-biased family structures. Sex-specific effective population size serves as an important characterization of sex-specific population history. An approach to estimating recent effective population size is to reconstruct coalescence history through identity-by-decent (IBD) segments. Since human X chromosome and autosomes have different meiosis and recombination processes, the effective population size estimated from X chromosomal IBD segments and that from autosomal IBD segments would reflect the difference in the coalescence history of these two types of chromosomes. Therefore, by understanding the specific contribution of each sex to the coalescence history of X chromosome and autosomes, we can estimate sex-specific effective population size from the overall effective population size of X chromosome and that of autosomes.
In this study, we proposed a method to estimate sex-specific effective population size and the effective proportion of females in the population, known as the effective sex ratio (ESR), based on the distribution of IBD segment lengths and the overall effective population size of X chromosome and that of autosomes. We applied the hap-ibd program [1] and the ibd-ends program [2] to obtain the length distribution of IBD segments and estimated the overall effective population size with the IBDNe program [3]. Our method is able to correctly recover the sex-specific population size and the ESR in simulated data. Our method not only provides visualization of the sex-specific population dynamics through sex-specific population size but also estimates the ESR that could be used to test hypotheses on the sex ratio in a population. It enables us to understand sex-specific demographic dynamics that may not be revealed by the analysis of autosomes alone.

Due to the paucity of methodological and computational approaches that account for their genomic complexity, admixed populations are systematically excluded from statistical genomic studies. Admixed populations make up more than a third of the US populace but are severely underrepresented in biomedical research which may contribute to health disparities. To reap the full benefits from the ongoing efforts to collect samples from underrepresented populations and from existing mixed ancestry cohorts, tools facilitating the well-calibrated research of admixed peoples are urgently needed.

We recently developed a local ancestry aware GWAS model, Tractor, which corrects for fine-scale population structure at the genotype level, often boosts locus discovery power, and produces ancestry-specific effect size estimates and p values. Using Tractor summary statistics from African ancestry (AFR) tracts in ~4500 admixed UK Biobank (UKB) individuals, we built polygenic risk scores (PRS) and predicted blood panel phenotypes on homogenous African ancestry UKB individuals. We benchmarked these PRS against scores created from traditional GWAS runs on 1) the same admixed cohort, 2) a large European UKB sample, and 3) a large multi-ancestry meta-analysis of continental ancestry groups from the pan-UKB project (https://pan.ukbb.broadinstitute.org/). We also tested the accuracy of several PRS models including pruning and thresholding and PRS-CSx. We find that incorporating diverse samples and ancestry-specific estimates from admixed populations results in higher prediction accuracy for homogeneous AFR individuals. The bulk of African-descent GWAS participants are currently admixed individuals of the Americas, and some underrepresented ancestries are rarely found outside of the admixed context. Thus, building models based on ancestry-specific estimates generated from the deconvolved local ancestry tracts of admixed genomes allows for better PRS performance on many diverse populations from making better use of existing collections.

We additionally highlight several loci which we find to have well-demonstrated effect size differences across ancestries, a phenomenon for which there are few prior examples in the literature. As our models are constructed off of local ancestry components from the same admixed individuals, these results hint at genetic differences rather than environmental factors, which are often tricky to disentangle. Ultimately, our work highlights how Tractor and local ancestry allow for improved population characterization and can be leveraged to advance the understanding of complex diseases across diverse cohorts.

PrgmNr 1128 - Polygenic risk prediction of obesity across the life course and in diverse populations

Polygenic risk scores (PRSs) for body mass index (BMI) that leverage the increasing genome-wide association study (GWAS) sample sizes may aid risk stratification and allow targeted prevention of obesity at an early age. We constructed ancestry-specific and trans-ancestral PRSs to predict obesity in adulthood, and examined their added value over and above easily measurable predictors of obesity during childhood and adolescence.

We calculated PRSs based on summary statistics of up to 1.2 million common variants [minor allele frequency (MAF)>1%] from the GIANT consortiumâ□□s BMI GWAS meta-analysis of up to 1.6 million individuals (72% European (EUR), 16% East Asian (EAS), 6% African (AA), 4% Hispanic (HA), 2% South Asian (SAS)). Explained variance for BMI and discrimination for obesity were examined in the UK Biobank (UKB, n=437k) and Million Veteran Program (MVP, n=101k). The best performing PRS in EUR was taken forward to the Avon Longitudinal Study of Parents and Children (ALSPAC, n=5.8k), for cross-sectional and longitudinal associations with BMI across 21 time-points from birth to age 22y. We compared the predictive performance of the PRS to that of clinically available factors (maternal education, pre-pregnancy maternal BMI, household social status).

The trans-ancestral PRS explained more of the variation in BMI than ancestry-specific PRSs in all but the EUR-populations (R^2 min-max for non-EUR; UKB: 7.5-12.4% (AA/EAS); MVP: 5.7-11.1% (AA/HA); UKB-EUR (EUR-PRS): 15.8%; MVP-EUR (EUR-PRS): 13.1%). For all ancestries, maximum explained variance was roughly double that of previously published obesity PRSs. The PRSs were better at discriminating between adults with or without obesity than age, sex, or scores of genome-wide significant variants only. EUR-PRS associations with BMI were weak at birth, but increased rapidly during childhood, and remained stable from adolescence onwards (e.g., BMI-SD per PRS-SD at 13y (95%CI): 0.39 (0.37,0.42)). Consistently, longitudinal modeling of BMI trajectories using the PRS showed increasing divergence until early adolescence. When added to other factors available at birth, the PRS helped predict substantially more of BMI from 5y onwards (e.g., R^2 at 5y: 13 to 18%; 11y: 11

to 21%).
The current PRSs, based on larger GWAS sample sizes, double the previously explained variance for BMI across multiple ancestries, thereby advancing the options for prognostication in populations traditionally underrepresented in genetic research. Moreover, we find that genetic predisposition to adult obesity affects childhood growth trajectories, and shows potential to improve risk stratification for obesity at an early age.

Polygenic risk scores (PRS) are less effective when ported across populations. While the scale of non-European genomic resources has been expanded in recent years, a clear attenuation of the predictive performance of PRS remains in individuals who are genetically distant from Europeans.

In order to include data from all ancestral groups to ensure more equitable delivery of genomic prediction to global populations, we developed the first principled Bayesian PRS construction method, termed PRS-CSx, that jointly models GWAS summary statistics from multiple populations to improve cross-ancestry polygenic prediction. PRS-CSx couples genetic effects across populations via a shared continuous shrinkage prior, enabling more accurate effect size estimation by sharing information between summary statistics and leveraging linkage disequilibrium (LD) diversity across discovery samples, while inheriting computational efficiency and robustness from PRS-CS.

PRS-CSx outperformed existing PRS methods across various simulations settings with different sample sizes, fractions of causal variants, and genetic correlations between populations. Using quantitative traits from biobanks, we showed that PRS-CSx substantially improved the prediction accuracy even if only a small non-European GWAS was included in the discovery data. For example, the median R2 increased by 76% for individuals of East Asian ancestry when the Biobank Japan samples (N=62K-159K) were added to the UK Biobank European samples (N=340K-360K) to train the PRS. Similarly, the median R2 increased by 22% for individuals of African ancestry when the PAGE study samples (N=20K-50K) were integrated with UK Biobank and Biobank Japan samples (400K-519K). Furthermore, by integrating GWAS summary statistics of schizophrenia from East Asian (14K-17K cases due to leave-one-out) and European (33K cases) populations, PRS-CSx more accurately predicted schizophrenia risk in individuals of East Asian ancestry, showing 52% and 97% improvement in the liability R2 relative to PRS constructed using East Asian or European summary statistics only, and approximately doubled the prediction accuracy when compared with alternative methods that can combine multiple GWAS to make prediction.

Our method represents a much needed and critical breakthrough in PRS construction. Through joint modeling of multi-ancestry data, PRS-CSx substantially improves polygenic prediction in non-European populations. With the rapid expansion of non-European genomic resources, our method will help accelerate the equitable deployment of PRS in clinical settings and maximize its healthcare potential.

Approximately 7% of adults have severe hypercholesterolemia (SH; untreated low density lipoprotein (LDL-C) â¥ 190 mg/dL). SH is associated with a 6-fold increased risk of cardiovascular disease, and up to 20-fold increased risk in individuals identified with monogenic Familial Hypercholesterolemia (FH)-associated variants. Despite high frequency of cholesterol screening and awareness, individuals with SH remain undertreated, with disparities in treatment and LDL-C control observed among African American (AA) populations. Only 2.5% of individuals with SH harbor a monogenic FH-associated variant, and polygenic SH accounts for 15%-30% of clinical FH, motivating the development of a polygenic test for predicting SH in diverse populations. We obtained summary statistics for validated trans-ancestry polygenic risk scores (PRS) to predict LDL-C from the Global Lipids Genetics Consortium pre-publication. The PRS were developed from a genome-wide association study of ~1.6M trans-ethnic participants, and validated in European (EU), AA, African, Hispanic or Latino (HL), South Asian and East Asian populations. We leveraged independent genotype and phenotype data from the diverse BioMe biobank in New York City. We extracted laboratory values and medications from electronic health records for adults with an age range of 18-95 from three population groups: AA, EU, and HL (other groups were excluded due to low sample size). SH cases were defined as participants with statin-adjusted maximum LDL-C â¥ 190 mg/dL and controls with statin-adjusted maximum LDL-C

PrgmNr 1131 - Phenome-wide association study of polygenic risk for asthma in the UK Biobank highlights traits with shared genetic architecture and sex specific effects

Disclosure Block: **Y. Lee:** None.
Polygenic risk scores (PRSs) aggregate additive effects of genetic variants to estimate individual risks for heritable diseases and can be used clinically to inform decisions on screening, therapeutic intervention, and lifestyle modification. The aim of this study was to develop a PRS for asthma using genetic information from a large, multiethnic (ME) cohort and investigate its association with 267 phenotypes in the UK Biobank (UKB). Two asthma PRS models were developed based on European (EU) (19,954 cases, 107,715 controls) and ME (23,948 cases, 118,538 controls) summary statistics from the Trans-National Asthma Genetic Consortium meta-analysis. Posterior SNP effect size estimates were generated using a Bayesian regression framework, implemented in PRS-CS. To evaluate PRS prediction for asthma, each model was applied to white British (36,065 cases, 314,781 controls) and ME (43,109 cases, 377,061 controls) subjects from UKB using logistic regressions adjusting for sex and ancestry. The EU PRS applied to the white British cohort had the strongest association with doctor-diagnosed asthma ($p=1.96x10^{-295}$, OR=1.34, 95% CI=1.32-1.35, AUC=0.582) and was most strongly associated with childhood onset asthma (COA; onset before age 12; $p=1.77x10^{-181}$, OR=1.59, 95% CI=1.54-1.64, AUC=0.624). There were significant sex-by-PRS interaction effects for COA (p=0.049) and adult onset asthma (AOA; onset after age 25; p=0.048). Given the same PRS, males had a higher risk than females for COA but females had a higher risk than males for AOA. The phenome-wide association study identified significant associations between the PRS and 27 binary and 69 quantitative traits (Bonferroni p-4). The most significant association was with percent eosinophils ($p=9.33x10^{-298}$, $\hat{I}^2=0.11$), a known asthma-associated trait. Other associated traits included asthma age of onset ($p=4.12x10^{-94}$) and measures of lung function (FEV_1) ($p=1.91x10^{-117}$). Some associations were less expected. For example, age at first live birth was negatively correlated with the PRS ($p=8.57x10^{-15}$, $\hat{I}^2=-0.095$) and HbA1c was positively correlated with the PRS ($p=4.83x10^{-33}$, $\hat{I}^2=0.13$). Sex-specific effects were observed for 5 binary and 15 quantitative traits, such as fat-free mass ($p=1.71x10^{-6}$, $\hat{I}^2=0.028$ in females; p=0.42, $\hat{I}^2=7.6x10^{-3}$ in males). Overall, our results suggest shared genetic architectures between asthma and a broad swath of pulmonary, cardiometabolic, anthropometric, and reproductive traits, many of which had not previously been linked to asthma and some with sex-specific effects. This research was conducted using the UK Biobank Resource under application number 44300.

PrgmNr 1132 - Modelling hidden genetic risk from family history for improved polygenic risk prediction

View session detail

Author Block: **T. Lu**[1], V. Forgetta[2], B. Richards[1], C. M. Greenwood[3]; [1]McGill Univ., Montreal, QC, Canada, [2]Lady Davis Inst., Montreal, QC, Canada, [3]Jewish Gen. Hosp., Montreal, QC, Canada

With many polygenic risk scores demonstrating research and clinical utility, it is worth questioning whether family history, a traditional genetic predictor, still provides valuable information.
Family history of complex traits may be influenced by transmitted rare pathogenic variants, intra-familial shared exposures to environmental factors, as well as a common genetic predisposition. Therefore, we propose and develop a latent factor model to quantify disease risk in excess of that captured by a common SNP-based polygenic risk score, but inferable from family history. This model enables calibration of polygenic risk scores with respect to family history without fitting regression models.
We applied our model to predict adult height for 941 children in the Avon Longitudinal Study of Parents and Children. Our predictor was able to explain ~55% of the total variance in adult height, close to the estimated heritability of height and substantially higher than ~40% captured by a polygenic risk score for height or mid-parental height alone. For nine complex diseases, including metabolic syndromes, cardiovascular diseases, neurological disorders and several types of cancer, we used our model to improve polygenic risk prediction for >400,000 White British participants in the UK Biobank. For all nine complex diseases investigated in the UK Biobank, parental disease history brought significant improvements in the discriminative power of polygenic risk prediction. For instance, combined with age and sex, our predictor achieved an area under the receiver operating characteristic curve (AUROC) of 0.734 and an area under the precision-recall curve (AUPRC) of 0.171 in identifying individuals with type 2 diabetes, exhibiting significantly stronger discriminative power than the polygenic risk score (AUROC = 0.712; AUPRC = 0.148) or the parental disease history (AUROC = 0.707; AUPRC = 0.148) alone. Comparing to using a type 2 diabetes polygenic risk score, our predictor had a net reclassification index of 3.72% in identifying 20% of the population at an elevated risk.
Taken together, our work showcases an innovative paradigm for risk calculation, and supports the utility of incorporating family history into polygenic risk score-based genetic risk prediction models.

PrgmNr 1135 - A genome-wide mutational constraint map quantified from variation in 76,156 human genomes

View session detail

Author Block: **S. Chen**[1], R. Collins[1], Q. Wang[2], D. G. MacArthur[3], M. E. Talkowski[1], gnomAD Project Consortium, M. J. Daly[1], B. M. Neale[1], K. J. Karczewski[4]; [1]Massachusetts Gen. Hosp., Boston, MA, [2]Harvard Med. Sch., Boston, MA, [3]Garvan Inst., Darlinghurst, Australia, [4]Broad Inst., Medford, MA
Disclosure Block: **S. Chen:** None.
Assigning function to non-coding variation is a significant challenge in human genomics. While intolerance to protein-coding variation is a powerful predictor of the phenotypic consequences of gene disruption, attempts to assess intolerance in non-coding regions have proven more difficult. This is largely due to the lack of genetic code in non-coding DNA for predictable variant effects and the relatively small sample sizes of WGS reference data. Earlier studies have assessed non-coding function through evolutionary conservation, but these do not necessarily capture human-specific constraint.

Here we leverage 76,156 human genomes from the Genome Aggregation Database (gnomAD), the largest public dataset of genomic variants, to build a map of mutational constraint for the whole genome. We present a refined mutational model, which incorporates trinucleotide sequence context, base-level methylation, and regional genomic features to predict expected levels of variation under neutrality. We trained our model on 450K *de novo* variants previously detected in 5.5K parent-child pairs and applied it to assess constraint across the entire genome. Specifically, we divided the genome into non-overlapping 1kb windows and quantified constraint for each window by comparing the expected variation and the observed variation in the gnomAD dataset (totaling 400M high-quality rare variants). As expected, protein-coding sequences were skewed towards the most constrained percentile (Z>4) of the spectrum (2.7-fold compared to unconstrained Z-200). We further computed constraint against structural variation and found a strong correlation (p-200), internally validating our approach.

Examining exclusively on non-coding regions revealed significant enrichment of constraint (p-30; odds ratios 1.7-6.1) for regulatory elements, evolutionarily conserved sequences, GWAS loci, and predicted deleterious variants. Remarkably, the 9p21 locus - a widely recognized and replicated risk factor for coronary artery disease - although devoid of genes, appeared to be more constrained than regions encompassing coding sequences (4-fold, p=0.07). Other examples include an intergenic variant associated with type I diabetes (T1D; rs11594656) found in the 5th most constrained per-mille of the genome, which has been shown to influence transcription at *IL2RA* involved in T1D susceptibility.

This genome-wide constraint map, quantified from the largest public WGS reference cohort, is an asset to facilitate identification and interpretation of the functional fraction of non-coding DNA in the human genome.

PrgmNr 1136 - Assessment of mitochondrial genome constraint in the gnomAD database of >50,000 individuals using a composite likelihood model

View session detail

Mitochondria carry a ~16kb genome (mtDNA) encoding proteins, transfer RNAs and ribosomal RNAs. Pathogenic variants in mtDNA cause a range of phenotypes collectively known as mitochondrial diseases. Mitochondrial variant interpretation is challenging, and most candidate variants in individuals with disease are of uncertain significance. Constraint models for the nuclear genome have been extremely useful for the analysis and interpretation of variants. By comparing observed and expected levels of variation in a population, these models identify which regions and genes are most likely to harbor disease-causing variants. However an equivalent model for the mtDNA had not been developed, in part due to the unique features of this genome.

Here we developed the first constraint model specifically for mtDNA and applied it to the new gnomAD mtDNA database which reports variation in 56,434 individuals. We used a composite likelihood model to quantify mutability in trinucleotide contexts, as it is suited for possible sparsity of counts per context in mtDNA, and leverage de novo mutation datasets to build the model. Given selection occurs against both the number and heteroplasmy of mtDNA variants (fraction of mtDNA copies with the mutation), we applied the model to determine the expected sum of the maximum heteroplasmy of variants in genes/regions in gnomAD. We assess constraint as observed:expected (obs:exp) ratios and provide 90% confidence intervals (CI).

The model accurately predicted the level of neutral variation in gnomAD, establishing its utility (correlation coefficient R=1). We calculated the obs:exp ratio of variant types across and within each gene, and showed that known pathogenic variation was substantially constrained (eg. ClinVar ratio=0.10, CI=0.07-0.14). The overall synonymous obs:exp ratio was 1.0 (CI=0.99-1.02) and consistent across genes (CI upper bounds 0.92-1.17), unlike missense variants which showed lower and variable constraint (ratio=0.25, CI upper bounds 0.15-0.97). For tRNAs, we utilized their common structure to also characterize site-level constraint. Notably, we identified constraint in regions typically overlooked in disease analyses, such as rRNA and non-coding elements (eg. L-strand origin ratio=0.25, CI=0.18-0.32). Lastly, we demonstrate the utility of this model for variant interpretation in patients, including by showing enrichment of pathogenic variants in the most constrained regions.

In sum, this model represents a new tool for mtDNA analysis and variant interpretation. It further provides novel insight into which mtDNA regions are most important to function.

PrgmNr 1137 - Quantifying negative selection on synonymous variants

View session detail

Author Block: **M. Gudkov**, E. Giannoulatou, L. Thibaut; Victor Chang Cardiac Res. Inst., Sydney, Australia
Disclosure Block: **M. Gudkov:** None.
Most disease sequencing studies tend to focus primarily on missense and potential loss-of-function variants, such as stop-gain and frameshift variants, at the expense of other classes of mutations. In particular, synonymous genetic variants, that is, those single-nucleotide variants (SNVs) that do not alter the produced amino acid sequence, are routinely considered to be non-deleterious. However, the role of these so-called â□□silent mutationsâ□□ is potentially more important than was previously thought. For instance, synonymous SNVs (sSNVs) may create nonoptimal codons, thus affecting the stability of the produced mRNA and the overall translational efficiency.
It has also been shown that optimality-reducing sSNVs undergo purifying selection, the extent of which, nonetheless, remains unknown. The latter presents a significant limitation for variant prioritisation and, consequently, for finding the true causes of genetic disorders. Indeed, SNVs with unknown, unquantified deleteriousness are generally more likely to be overlooked or even excluded from further analysis. To fully understand the role of sSNVs in human disease, a quantitative framework is needed to assess their potential effect in comparison with other, better studied classes of mutations.
Here we quantify the intensity of the negative selection acting on all possible sSNVs. We calculated the mutability-adjusted proportion of singletons (MAPS), a recently developed metric of deleteriousness, for a QC compliant subset of sSNVs from 125,748 gnomAD exome sequences (release 2.1.1). Using MAPS, we found that optimality-reducing sSNVs are subject to stronger selection than optimality-increasing ones, which was confirmed using conservation and site-frequency spectrum analyses. Furthermore, we found that purifying selection affects sSNVs in a gene- and amino acid-dependent manner, with glutamine being particularly intolerant to such mutations. We also propose an improved version of MAPS for sSNVs.

PrgmNr 1138 - Objective targeting of *de novo* loss of function variants in constrained genes improves diagnostic rates in the 100,000 Genomes Project

Large-scale sequencing programs are aiding in the affordability and accessibility of genome sequencing (GS) for diagnostic purposes. The 100,000 Genomes Project (100KGP) has led the way in integrating GS within a national health service; however, sequencing thousands of individuals necessitates time and resources to generate patient reports. Consequently, virtual gene panels have been applied for more efficient analysis, restricting the number of variants assessed for diagnostic reporting. Panels rely on clearly characterized phenotypes and accurate gene selection, yet risk missing pathogenic variants outside of the panel applied. We propose an approach targeted at large-scale sequencing projects that objectively filters for high-yield variants in constrained genes. The LOEUF score is a continuous metric of loss-of-function gene constraint, with low scores highly correlated with haploinsufficient genes. We filtered 25,050 rare disease trios in 100KGP for *de novo*, loss-of-function variants in genes with a LOEUF score

PrgmNr 1139 - Biallelic noncoding regulatory mutations in autism spectrum disorder

View session detail

Author Block: **R. N. Doan**, J. Scotellaro, L. Kelley, T. W. Yu, C. A. Walsh; Boston Children's Hosp., Boston, MA
Disclosure Block: **R.N. Doan:** None.
The phenotypic and genetic heterogeneity of autism spectrum disorder (ASD) in children has posed immense clinical and research challenges to understanding the underlying genetic determinants of risk. Despite the association of more than 1,000 genes with ASD, many families lack an identifiable *de novo* or inherited protein altering mutation, suggesting that much of the genetic etiology lies within noncoding portions of the genome. While recent studies have begun to shed light on the role of noncoding mutations (*e.g*., gene promoters and human-specific enhancers) on ASD risk, the ability to distinguish damaging regulatory mutations from the vast numbers of benign events remains challenging. To overcome this challenge, we developed a custom variant classification system for assessing the transcriptional and translational impacts of mutations from whole genome (WGS) and whole-exome (WES) sequencing data from more than 5,000 families with ASD. Furthermore, we developed a custom-curated database consisting of more than 26,000 conserved neurally active promoter elements (CNPs; core promoters, proximal promoters, and untranslated regions [UTRs]) and regulatory regions to identify alleles with the greatest likelihood of impacting neural development. Strikingly, we find that biallelic mutations within these elements contribute to risk in at least 3% of families with ASD. Predicted damaging promoter mutations were highly enriched for established associations to ASD and intellectual disability, including more than 20 known ASD genes from SFARI gene database. Surprisingly, we identified 3 promoter-altering mutations in the *FMR1* gene, the well-established cause of Fragile X, with 2 of the mutations impacting core promoter elements (*e.g*. GC-Box) and a third mutation affecting the Kozak sequence. Beyond well-recognized genes, we identify strong candidate mutations in lesser-established ASD genes, such as a promoter mutation within*TTI2*, a gene linked to ID and ASD features, that causes the loss of an essential TFIIB-recognition element (BRE). Collectively, our data provide the first evidence that biallelic mutations impacting neurally active gene promoters and UTRs contribute to ASD risk and give insight into one possible mechanism underlying the wide phenotypic spectrum observed amongst families.

PrgmNr 1140 - Estimating the clinical diagnostic yield of whole-genome sequencing in 825 orofacial cleft trios

Disclosure Block: **K.K. Diaz Perez:** None.
Orofacial clefts (OFCs) are among the most common craniofacial birth defects and require years of treatment, presenting a societal and personal burden. Most OFCs occur as isolated events (nonsyndromic) and are thought to be etiologically complex, with genetic and environmental risk factors. However, common variants only account for 25% of the estimated heritability of OFCs, while whole-exome and -genome sequencing (WGS) studies increasingly support a role for rare variants with rare mutational drivers acting in a Mendelian manner in ~10% of nonsyndromic OFC cases. In support of this, we previously found a significant enrichment of *de novo* mutations (DNMs) in genes associated with autosomal dominant OFC syndromes. This study aims to comprehensively interrogate DNMs and rare inherited single-nucleotide and structural variants in a collection of 825 OFC trios to estimate the clinical diagnostic yield for sequencing in OFCs. We constructed a gene list of 510 OFC-related genes from commercially available clinical gene panels, OMIM, and expert-curated gene lists to focus our analysis. After filtering for allele frequency and variant effect, we categorized variants into a ranked tier system based on *in silico* prediction scores, gene constraint, and ClinVar annotations to prioritize potential pathogenic variants. Variants in highly ranked tiers were reviewed for possible pathogenicity using American College of Medical Genetics & Genomics (ACMG) criteria. Among OFC cases, 82% had at least one variant qualifying for ACMG review, demonstrating the difficulty in assessing the impact of rare variants by bioinformatic tools alone. We further filtered these results by focusing on protein-altering (missense and loss-of-function (LoF)) DNMs and inherited LoF variants, which are easier to interpret. We identified 46 DNMs in 7.8% of genes (5.5% cases). These mutations were in several well-established OFC genes, including *TFAP2A and IRF6*, each with 3 DNMs. We further identified 99 inherited LoF variants for review in 64 genes, accounting for 95 cases (12%). Five LoF variants were inherited from an affected parent. Moreover, various genes associated with OFCs, including *ARHGAP29* and *COL2A1*, showed an enrichment of inherited LoF mutations in our sample, each containing â¥ 3 LoF variants across all cases, highlighting the genetic heterogeneity of OFCs. Overall, using DNMs and inherited LoF variants, we conservatively estimate the diagnostic yield of WGS in OFCs to be only 5-15%. Given the complexity of OFCs, this is likely to be an underestimate but suggests clinical genetic sequencing could effectively refine recurrence risk estimates and reduce the diagnostic gap in OFCs.

PrgmNr 1143 - Modeling tissue co-regulation to quantify tissue-specific contributions to disease heritability

View session detail

Author Block: **T. Amariuta**, K. M. Siewert-Rocks, A. L. Price; Harvard T.H. Chan Sch. of Publ. Hlth., Boston, MA
Disclosure Block: **T. Amariuta:** None.
Despite abundant evidence of disease etiologies that span multiple tissues, quantifying tissue-specific contributions to disease heritability remains challenging. Previous work emphasizes the potential of accounting for tissue co-regulation (Ongen et al. 2017 Nat Genet), but tissue-specific disease effects have not been formally modeled.
We introduce a new method, tissue co-regulation score regression (TCSC), that quantifies tissue-specific contributions to disease heritability by regressing transcriptome-wide association study (TWAS) gene-disease chi-square statistics on tissue co-regulation scores, across genes and tissues. TWAS statistics include direct effects of predicted cis-genetic components of gene expression on disease and tagging effects of co-regulated tissues (Wainberg et al. 2019 Nat Genet). TCSC distinguishes causal versus tagging gene-disease effects across tissues by modeling pairwise correlations of predicted gene expression between tissues (tissue co-regulation scores). TCSC also quantifies tissue-specific contributions to genetic correlations between diseases by regressing products of TWAS z-scores from two diseases on tissue co-regulation scores. In simulations, TCSC detects causal tissues with well-calibrated false positive rate across a broad range of parameter settings. At default settings, TCSC attained 60% power to detect causal tissues, which is substantially higher than the power of the Ongen et al. method. TCSC also estimates the proportion of SNP-heritability explained by each tissue; estimates are conservative, as they exclude effects of genes with non-significant gene expression heritability at finite sample size.
We applied TCSC to 23 independent diseases and complex traits from UK Biobank (average N = 396K), using gene expression prediction models constructed from GTEx data across 47 tissues to compute TWAS statistics and co-regulation scores. Below, we discuss results for three anthropometric traits: body mass index (BMI), height, and waist-hip-ratio adjusted for BMI (WHR). For BMI, brain cerebellum was the only significant tissue after correcting for the number of tissues tested (proportion of SNP-heritability explained: 0.096 Â± 0.021); this is consistent with the known role of the central nervous system in BMI (Locke et al. 2015 Nature). For height, brain cerebellum was the most significant tissue (0.091 Â± 0.023). For WHR, skin fibroblast was the only significant tissue (0.116 Â± 0.038), consistent with the known role of connective tissue (Finucane et al. 2018 Nat Genet). In conclusion, TCSC is a powerful method for quantifying tissue-specific contributions to disease heritability.

PrgmNr 1144 - Uncovering context-specific genetic regulation of gene expression from single-cell RNA-sequencing using latent-factor models

View session detail

Author Block: **B. J. Strober**[1], K. Tayeb[2], J. M. Popp[1], M. Gordon[3], R. Perez[3], C. Ye[3], A. Battle[1]; [1]Johns Hopkins Univ, Baltimore, MD, [2]Univ. of Chicago, Chicago, IL, [3]UCSF, San Francisco, CA
Disclosure Block: **B.J. Strober:** None.
Identification of genetic variants associated with gene expression, or expression quantitative trait loci (eQTLs), can be used to better understand the regulatory mechanisms linking genetic variation with disease. However, genetic regulation of gene expression is a complex process, with genetic effects known to vary across contexts such as developmental time points, cell types, and environmental conditions. It is therefore critical to identify eQTLs from diverse contexts in order to properly characterize the molecular mechanisms underlying disease associated loci. Indeed, eQTLs from adult bulk tissue samples fail to explain the majority of known disease loci. Recent work has shown single-cell RNA-sequencing (scRNA-seq) provides unique data to uncover context-specific eQTLs; such higher-resolution data will naturally span diverse cell types and cellular states, many of which would not be observable from bulk RNA-seq. However, the relevant factors, such as cell type or state, that actually modulate genetic effects may not be known a priori. Furthermore, an individual cell may be defined by multiple, overlapping contexts, such as a particular cell type and perturbation response affecting partially overlapping sets of cells. Therefore, we developed SURGE, a novel probabilistic model that uses matrix factorization to jointly learn a continuous representation of the cellular contexts defining each measurement, and the corresponding eQTL effect sizes specific to each learned context, allowing for discovery of context-specific eQTLs without pre-specifying subsets of cells or samples. In a proof of concept using bulk expression data over 49 tissues from the GTEx project, SURGE automatically learns factors capturing tissue and cell type composition differences, in addition to one factor reflecting individual ancestry. We applied SURGE to a single-cell eQTL data set consisting of multiplexed single-cell RNA-sequencing data from over 750,000 peripheral blood mononuclear cells from 119 individuals. SURGE automatically identifies cell-type specific eQTLs from this data, identifying factors capturing continuous representations of distinct blood cell types and grouping biologically related cell types into the same factor. In summary, we provide a novel approach to automatically uncover cell types and contexts that modulate genetic regulation of gene expression, enabling the unbiased discovery of diverse context-specific eQTLs from single cell, time course, and multi-condition data, and expanding our ability to explain mechanisms underlying disease-associated loci.

PrgmNr 1145 - Acetylated chromatin domains link chromosomal organization to cell and circuit level dysfunction in schizophrenia and bipolar disorder

Acetylated chromatin domains link chromosomal organization to cell and circuit level dysfunction in schizophrenia and bipolar disorder

The three-dimensional (3D) genome organization is crucial for the interplay between cell specific gene expression, chromatin structure, and other epigenetic factors that underlies our brain functions. Dysregulation of transcription and chromatin structure leads to debilitating disorders such as schizophrenia (SCZ). To explore the dysgreulation in chromatin structure in SCZ and bipolar disorder (BD), we capitalized on histone modification landscapes as they are tightly linked to chromatin structures. We mapped **739 libraries** of active promoter and enhancer-associated histone methylation (H3K4me3) and acetylation (H3K27ac) profiles in PFC from **564 brain donors**, providing to date the largest histone modification dataset for SCZ and BD. In the first part of the study, dysregulation of enhancer-associated histone peaks (H3K27ac) across SCZ (BD) cases and controls showed stronger enrichment of SCZ (BD) GWAS risk variants in enhancers than in promoters specific regions. Additionally, we noticed enrichment in SCZ variants was coming from hyperacetylated peaks but not from hypoacetylated peaks. In the second part of the study, we built chromatin structure by leveraging the inter-individual correlations between histone peaks to identify domains of physically interacting regulatory elements called cis-regulatory domains (CRDs). Our in-silico biological validation of CRDs showed tight link to the structures of self-interacting domains, with enrichments of CTCF structural proteins at CRD domain boundaries, which is in line with CTCF enrichment of PFC NeuN+ Hi-C defined TAD boundaries. Next, we investigated dysregulation in chromatin structure using CRDs expression as a metric. Interestingly, SCZ and BD sensitive CRDs which were hyperacetylated were strongly enriched for SCZ (BD) GWAS risk variants than hypoacetylated CRDs. To further explore the role of disease sensitive CRDs, we created another layer of chromatin structure that manifested A/B compartments by taking the inter-individual correlation of diseased CRDs. K-means clustering of correlation of disease-sensitive H3K27ac CRDs revealed 3 Clusters. Out of which cluster 3 with majority of hyperacetylated CRDs were strongly enriched for glutamatergic specific H3K27ac peaks and chromHMM active chromatin states from fetal brain linking the connection of SCZ and BD with neurodevelopmental mechanism.In summary, our analysis strongly hint at a chromatin structure brain pathology representative of the broader population of subjects diagnosed with SCZ and BD.

PrgmNr 1146 - Genetic determinants of alternative splicing in stimulated iPSC-derived macrophages enhance the understanding of immune-mediated disease risk

View session detail

Author Block: **O. El Garwany**, N. I. Panousis, A. Knights, N. Kumasaka, M. Imaz, A. Barnett, L. B. Vilarino, A. Tsingene, C. Gomez, D. Gaffney, C. Anderson; Wellcome Sanger Inst., Hinxton, United Kingdom

Macrophages represent the first line of defence against numerous pathogens due to their ability to respond to environmental cues. Genetic variation can lead to substantial alterations of this response, increasing susceptibility to immune-mediated diseases (IMD). Thus, understanding how macrophage cellular phenotypes such as gene expression are genetically controlled, particularly in response to environmental stimuli, can provide much needed insight into IMD biology and risk.
Since modelling environmental contexts in primary cells at scale is not practically feasible, induced Pluripotent Stem Cells (iPSC) offer an alternative *in vitro* system to model environmental contexts, whilst providing enough cells to study the genetic determinants of gene expression and its different layers of control. Alternative splicing (AS) is one of the major post-transcriptional layers of gene expression control that results in remarkable diversification of the transcriptome. Mapping so-called splicing quantitative trait loci (sQTLs) can improve the understanding of how genetic variation affects AS and predisposes to IMDs. However, the extent to which sQTLs affect AS in stimulated versus naive macrophages, and how they can affect IMD risk, has not yet been systematically studied.
Here, we map sQTLs in iPSC-derived macrophages obtained from 200 individuals, and exposed to a panel of 12 different stimulants. Gene expression was measured at two timepoints for each condition after stimulation, resulting in 1,953 RNA-seq samples. We identify 5,300 genes that have an sQTL in at least one condition, with a median number of 1,300 such genes per condition. Colocalization analysis of sQTLs and inflammatory bowel disease (IBD) association signals revealed more than 40 loci across all stimulation conditions with posterior probability of sharing a single causal variant > 90%. Most of these high-confidence colocalization events can only be detected in stimulated conditions compared to naive state, and cannot be detected when only eQTL and GWAS signals are colocalized.
Our work highlights the added value of mapping context-aware sQTLs. We show that they provide independent high-confidence colocalizations with IBD risk loci, and that they can enhance the understanding of IMD risk loci as we extend our colocalization analysis to other IMDs.

PrgmNr 1147 - Leveraging single-cell ATAC-seq to identify disease-critical fetal and adult brain cell types

Identifying disease-critical cell types is a fundamental biological goal (Hekselman et al. 2020 Nat Rev Genet). Single-cell chromatin accessibility (scATAC-seq) and gene expression (scRNA-seq) have characterized cell types at high resolution, and early research on integrating GWAS with scRNA-seq has shown promise, but research on integrating GWAS with scATAC-seq has been limited. In addition, the impact on disease risk of cell types across developmental stages of the brain has not been widely explored.

Here, we integrate GWAS summary statistics from 28 brain-related diseases and traits (avg N=298K) with 3.2 million scATAC-seq and scRNA-seq profiles from 83 cell types spanning fetal and adult brain. We constructed cell-type annotations from scATAC-seq data by annotating SNPs in open chromatin regions, and from scRNA-seq data by annotating SNPs linked to specifically expressed genes using brain-specific enhancer-gene links. We identified disease-critical cell types using stratified LD score regression, assessing statistical significance using FDRIn analyses of fetal brain, we identified disease-critical cell types for 22 traits using scATAC-seq and 8 traits using scRNA-seq, recapitulating known biology. Notable findings using scATAC-seq included significant enrichments of fetal photoreceptor cells for major depressive disorder, fetal ganglion cells for BMI, and fetal astrocytes for ADHD, all of which are supported by known biology but have not previously been identified using genetic data.

In analyses of adult brain, we identified disease-critical cell types for 23 traits using sc-ATAC-seq and 17 traits using scRNA-seq. Notable findings using scATAC-seq included significant enrichments of adult VGLUT2 excitatory neurons for schizophrenia and BDNF excitatory neurons for major depressive disorder. Although fetal brain and adult brain scATAC-seq annotations for the 3 matched cell types were uncorrelated (r=0.00-0.01), the corresponding disease signals were strongly correlated (r=0.52 for -log(P-values)), reflecting partially shared biology. Interestingly, the enrichment of fetal astrocytes for ADHD was not observed in adult astrocytes, consistent with the lower efficiency of adult astrocytes in removing synaptosomes (Sloan et al. 2017 Neuron).

In conclusion, the disease-cell type associations that we identified improve our understanding of the biological mechanisms of complex disease. Cell-type annotations derived from scATAC-seq were particularly powerful in the data that we analyzed, with results only partially shared across fetal vs. adult brain.

PrgmNr 1148 - Computational and functional characterization of the hs737 enhancer in autism

Autism is a complex disorder with a high heritability and currently, based on whole-exome sequencing and array studies, ~10-30% of cases can be explained by variation in protein coding regions. This leaves an appreciable gap in the remaining contribution of genetics to autism. We and others have previously discovered a role for *de novo* variants in noncoding regulatory regions of the genome and predict that they explain 2-5% of individuals with autism. While these noncoding elements (e.g., enhancers) have been implicated in autism and other neurodevelopmental disorders (NDD), there have been few studies identifying specific elements reaching statistical significance and even fewer following up on these elements. Previously, we demonstrated the impact of noncoding variation in hs737 and its link to the critical neurodevelopmental transcription factor, *EBF3*, by analyzing whole-genome sequencing of 10,000 genomes (2,500 families) from the Simons Simplex Collection. Here, we perform deep characterization of hs737 and *EBF3* using computational, functional, and phenotypic analyses. First, to further elucidate the regulatory relationship between hs737 and *EBF3*, we analyzed Hi-C data from human fetal corticogenesis and demonstrate significant interactions between the two elements during neuronal migration. Second, we show by analyzing RNA-seq data from the BrainSpan atlas that *EBF3* expression peaks prenatally and is significantly correlated with many high confidence autism genes. Of these genes, there is a significant enrichment for those involved in chromatin and nucleosome organization, which have been recurrently implicated in NDDs. Finally, we performed phenotypic analyses of 20 probands (7 newly reported here) to demonstrate the consequences of coding and noncoding mutations affecting *EBF3* and find that noncoding mutations are significantly associated with autism while those in *EBF3* are significantly associated with intellectual disability. Currently, we are performing experiments to identify the key regulatory sites within hs737. To do so, we are performing a saturation mutagenesis massively parallel reporter assay for hs737 to gain understand the impact of every possible mutation in hs737. Second, using data from the Vertebrate Genome Project and ENSEMBL, we are performing an evolutionary analysis of hs737 to identify highly conserved nucleotides sites across ~500 species. Comprehensively characterizing noncoding elements involved in autism is an essential next step to understanding its genetics, as doing so will reveal novel regulatory relationships between genes that are not apparent by studying protein-coding regions of the genome.

Cell cycle Associated PRoteIN 1 (CAPRIN1) is a cytoplasmic ubiquitous phosphoprotein tightly correlated with cellular proliferation. In neurons, CAPRIN1 regulates the transport and translation of mRNAs of proteins involved in synaptic plasticity and interacts with many proteins involved in neurodevelopment, including Fragile-X Mental Retardation Protein (FMRP). Caprin1$^{+/-}$ mice show reduced social interactions and lower response to novelty and, interestingly, *CAPRIN1* has recently emerged as a possible candidate gene for autism spectrum disorders (ASD). We report nine cases carrying loss-of-function (LoF) variants in *CAPRIN1* (one genomic deletion, five nonsense, two invariant-site splicing, one frameshift variant) showing a spectrum of neurodevelopmental phenotypes. All variants were *de novo* except one maternally inherited (maternal phenotype unknown). Overall, language impairment (100%), speech delay (89%), intellectual disability (88%), ADHD (86%), ASD (68%), developmental delay (33%) and seizures (22%) were the main clinical features, together with breathing problems (56%), skeletal malformations (44%), infancy feeding difficulties (33%) and ocular issues (22%). No dysmorphic features were apparent. Expression analysis showed a half dose of the transcript and protein in patients-derived lymphoblasts or fibroblast cells. To further explore the effect of CAPRIN1 haploinsufficiency, we derived cortical neurons from *CAPRIN1*$^{+/-}$ hiPSCs generated by CRISPR/Cas9 mutagenesis. We studied CAPRIN1 temporal expression and localization during neuronal maturation, and found an overall disruption of the neuronal organization, and an increased neuronal death. Global and local alteration of translation in neurons were not observed. Some key proteins of the synaptic plasticity, including FMRP, AMPAR and NMDAR subunits, were down- or upregulated during a time course analysis of neuronal maturation, suggesting a dysregulation of some CAPRIN1-binding partners. Micro-Electrode Arrays (MEAs) measurements of electrical neuronal activity showed lower spike rates and bursts, with an overall

reduced activity. In conclusion, we provide evidence that *CAPRIN1* causes a novel neurodevelopmental disorder with language delay variably associated with ADHD, ASD and intellectual disability. Moreover, we demonstrated that CAPRIN1 half-dose causes morphologic, growth and functional alterations in neuronal cells *in vitro*, supporting haploinsufficiency as pathogenic mechanism.

Autophagy is an essential developmental and homeostatic process, driving the endolysosomal degradation of protein aggregates, organelles and pathogens. Ablation of autophagy in mouse causes embryonic or perinatal lethality. In humans, dysfunctional autophagy has been implicated in complex diseases including neurodegeneration and cancer, yet congenital autophagy disorders remain exceedingly rare. Using whole exome sequencing we identified pathogenic, biallelic variants in *ATG7*, encoding the principal driver of autophagy, in twelve patients from five families. These patients display complex neurodevelopmental disorders distinguished by selective neurological, neuromuscular and endocrine dysfunction. Notably, cerebellar hypoplasia and a thin posterior corpus callosum were identified in all affected patients who were assessed by neuroimaging. Contrasting conditional *Atg7* deletion in mouse which causes perinatal lethality, patients survive into adult life despite loss of ATG7 protein. Fibroblasts from affected individuals from each family displayed diminished autophagy, and expression of mutated *ATG7* failed to rescue autophagy-deficient model systems, supporting the pathogenicity of these variants. ATG7-deficient patient muscle revealed myopathic and inflammatory changes, together with subsarcolemmal p62/SQSTM1 accumulation. Despite loss of ATG7, autophagic structures were readily detected in patient fibroblasts and muscle, suggesting that ATG7-independent autophagosome biogenesis pathways may support basal autophagic degradation in human cells. Our study provides the first clinical, genetic and mechanistic demonstration that mutated *ATG7* leads to neurodevelopmental disease in humans, who can survive for decades with defective canonical autophagy. Importantly, two patients with undetectable ATG7 protein display a relatively mild phenotype, revealing that human life is compatible with the absence of a nonredundant core autophagy gene, thereby challenging current perceptions regarding the relationship between autophagy and human health and disease.

PrgmNr 1153 - ÂÂBi-allelic variants in the autophagy gene *ATG4D* are associated with a pediatric neurological disorder characterized by hypotonia, joint laxity, and delayed speech and motor development

Introduction: Macroautophagy is a dynamic and highly conserved process that regulates the degradation and recycling of cellular components. Autophagosomes are double-membraned organelles that deliver cellular components to the lysosomes for degradation. Defective autophagy has been shown to contribute to the pathogenesis of various human diseases. We describe three individuals from two unrelated families with a pediatric neurological disorder with bi-allelic variants in *ATG4D* that encodes one of the four ATG4 isoforms that process the LC3 and GABARAP protein subfamilies required for autophagosome biogenesis. Notably, a homozygous *ATG4D* missense variant is associated with a canine neurodegenerative disease. **Methods:** A detailed clinical evaluation was performed on each affected individual. Whole exome sequencing and family-based genomics were performed to identify candidate variants; variants were prioritized based on their frequency in population databases, level of conservation, and predicted deleteriousness. Expression analyses and functional assays to assess autophagosome biogenesis and autophagic flux were performed on patient cells and ATG4D-deficient HeLa cells generated by CRISPR-Cas9. Further, an *in vitro* assay using purified recombinant proteins was performed to evaluate the processing efficiency of each individual ATG4D variant on a known target of ATG4D, GABARAPL1. **Results:** Three individuals presented with a pediatric neurological disorder characterized by hypotonia, joint laxity, and delayed speech and motor development. Rare, conserved, and likely deleterious bi-allelic missense or frameshift variants were identified in *ATG4D* segregating with the disease. *ATG4D* mRNA expression and ATG4D protein levels in patient cells were comparable to controls. Autophagosome biogenesis and autophagic flux in patient cells and ATG4D-deficient HeLa cells were similar to controls, suggesting functional redundancy due to the other ATG4 isoforms. In order to functionally assess ATG4D activity in the absence of the other ATG4 isoforms, an *in vitro* priming assay was performed and demonstrated diminished GABARAPL1 processing efficiency for three of the four *ATG4D* variants. **Conclusion:** The clinical, bioinformatic, and functional data, together with the previously described role of ATG4D in autophagy and its association with neurodegenerative disease in other organisms, provide evidence that bi-allelic loss-of-function variants in *ATG4D* likely underlie the pathogenesis of this novel neurological disorder.

PrgmNr 1154 - Large-scale, multi-ethnic resource of gene, isoform, and splicing regulation in the developing human brain

Genome-wide associations (GWAS) for neuropsychiatric disorders including schizophrenia (SZ) and autism show strong enrichment among fetal brain regulatory elements. This has prompted several recent efforts to systematically characterize the impact of genetic variation on gene regulation in the developing human brain through expression, isoform, and splicing quantitative trait loci (eQTL, isoQTL, sQTL) mapping. However, to date, the scale of individual fetal brain studies has been relatively small, and lack of consistent processing has limited the ability to compare results across studies or with larger adult brain xQTL datasets. Moreover, there has been no systematic comparison of xQTL results across trimesters or ancestries.

Here we uniformly processed and mega-analyzed 5 fetal brain genomic datasets, 682 subjects in total, across European (N=292), African-American (N=164), and Admixed American ancestries (N=145), spanning all three developmental trimesters. Gene and isoform expression levels were quantified from raw RNAseq reads using Salmon and splicing levels were quantified using Leafcutter. SNP genotypes were imputed into the TOPMed reference panel. xQTL was comprehensively analyzed via FastQTL with adaptive permutations and multiple testing corrections, followed by fine mapping with SuSiE. Cell type-deconvolution with expression-based Swcam and chromatin accessibility-based CellWalker enabled the detection of cell type-specific and interacting genetic regulation. We identified 10094 genes, 22891 isoforms, and 37706 introns--many specific to fetal brain--showing significant cis-regulation. Compared with adult brain datasets from GTEx and PsychENCODE, we identified 5487 and 6325 new eGenes, respectively. cis-eQTL effect sizes are highly concordant between ancestries, with all pair-wise Spearman Ï greater than 0.83. We found substantial enrichment of psychiatric GWAS signals among all fetal brain xQTL annotations. Integration of fetal brain xQTL with GWAS via transcriptome-wide association study (TWAS) prioritized 96 candidate risk genes for SZ, 34 more than the previously largest fetal brain dataset.

By harmonizing and analyzing fetal brain datasets, we characterized xQTL and discovered that fetal brain regulatory elements are associated with neuropsychiatric disorders and other brain-related traits.

CELSR3 encodes the adhesion G protein-coupled receptor (aGPCR) ADGRC3 of the cadherin superfamily. It plays an important role in neuronal migration and planar cell polarity signaling. All known Cadherin EGF LAG seven-pass G-type receptors (CELSR1-3) are predicted to have various functions in epithelial cells and in the central nervous system (CNS). *Celsr1-3* mRNA patterns in mouse embryo revealed distinct expression in the developing CNS and during ureteric budding**.** Here we describe 14 families with congenital anomalies of the kidney and urinary tract (CAKUT), anorectal and CNS anomalies. These phenotypes either occurred in combination with each other or isolated among the affected. Assembly of these families was facilitated by GeneMatcher. The spectrum of kidney anomalies among the patients comprised anatomical and functional aberrations. In all patients, biallelic variants in *CELSR3* were found. Protein modelling of selected missense variants implicated the disruption of the normal protein structure, hinting towards a malfunction of the altered protein. To examine the function of ADGRC3 during early development and to gain insights into the embryonic architecture of aberrant kidney formations, we established a zebrafish larvae (zfl) knockdown model. Transient knockdown of *celsr3* in fluorescent reporter lines specific to the neuronal and urinary systems in zfl showed a disturbed embryonic development of the urinary tract and the CNS. Our molecular studies in humans and functional analysis of Celsr3 in zfl provide insights into *CELSR3* as a potential human disease gene for a novel syndrome comprising CAKUT, anorectal and CNS anomalies of variable expression. Non-coding splice-altering variants are thought to be implicated in over 15% of rare genetic disorders and are hypothesized to be particularly relevant in cases where targeted or whole exome sequencing failed to reveal disease causative variants. However, identifying deeply intronic variants that create pathogenic, cryptic splice site gains still represents a formidable challenge, especially in cases where obtaining RNA-seq data from relevant tissue types (e.g., brain) is impossible. Existing methods to predict the splice-altering impact of DNA variants directly from whole genome sequencing are plagued by a high rate of false positives as well as a nontrivial rate of false negatives, reducing their immediate utility in diagnostic workflows. Here, we develop a precise statistical model that incorporates intronic SpliceAI scores, coding region pathogenicity predictions, as well as likelihoods of specific, rare variants based on parental variant occurrence and an underlying mutational model in order to assess the significance of compound heterozygous variant pairs observed in recessive cases. When applied to a harmonized dataset of over 800 patients with suspected Mendelian conditions from the Undiagnosed Diseases Network, our approach recapitulates known diagnoses with high precision as well as significantly ranks previously uninvestigated splice-altering variants that perturb clinically relevant genes in undiagnosed cases. Our process includes a systematic clinical evaluation of top candidates, a high-throughput massively parallel splicing assay (MPSA) to verify the impact of intronic variants across a wide range of SpliceAI scores, as well as RNA-guided base alterations in cell line models to measure phenotypes of potentially diagnostic variants. Our results demonstrate that our statistical framework can accurately and rapidly detect clinically viable and verifiable cryptic splice site gains with etiological roles across cohorts of chronically undiagnosed cases.

Copy number variations (CNVs) are potent phenotypic modifiers associated with several rare genomic syndromes but their impact on complex traits remains understudied. To fill this gap, we called CNVs in 331â□□522 white, unrelated UK Biobank participants and performed genome-wide association studies (GWASs) between the copy-number of CNV-proxy probes and 57 continuous traits, revealing 131 independent signals across 47 phenotypes. Besides recapitulating well-known associations (e.g. 16p11.2 and weight), our analysis revealed the pleiotropic impact of recurrent CNVs, with 26 and 16 traits associated with 16p11.2-BP4-BP5 and 22q11.21, respectively. Forty CNV signals (31%) overlapped with previously identified GWAS signals for the same trait. For instance, deletion of urate transporter scaffold protein-encoding *PDZK1* decreased urate levels ($\hat{I}^2_{del}$ = -48.3 Î¼mol/L, p = 5.8e-13), with a 2.6-fold stronger effect in males (p_{diff} = 2.1e-3). Many associations mapped to rare disease regions, suggesting variable expressivity and a broad impact of these loci in the general population. For example, heterozygous deletion of the region encoding the hepatic transporters OATP1B1/3 associated with increased total bilirubin ($\hat{I}^2_{del}$ = 3.1 Î¼mol/L, p = 2.2e-13), whereas homozygous carriers affected with Rotor syndrome present with severe hyperbilirubinemia. Our approach also highlighted new gene functionalities: The copy-number of the region encompassing *MARF1*, a gene essential to murine oogenesis, correlated negatively with age at menarche ($\hat{I}^2_{mirror}$ = -0.6 years, p = 8.5e-15) and menopause ($\hat{I}^2_{dup}$ = -1.8 years, p = 1.7e-6), suggesting a conserved role in female reproductive timing. Moving beyond single CNVs, we found that an individualâ□□s CNV burden negatively impacted 35 of the 57 assessed traits, leading among others to increased adiposity and liver/kidney damage biomarkers, and decreased intelligence and physical capacity. Thirty traits remained burden-associated after correcting for the impact of significantly associated CNV regions, pointing to a polygenic CNV-architecture underlying complex traits and suggesting the presence of additional associations, which we currently lack the power to detect. Finally, we showed that an individualâ□□s CNV burden was negatively associated with both parental lifespan ($\hat{I}^2_{burden}$ = -0.18 years/Mb, p = 1.1e-7) and age (proxy for survivorship; $\hat{I}^2_{burden}$ = -0.21 years/Mb, p = 1.4e-5), suggesting that the deleterious impact of CNVs contributes to decreased longevity. Together, the numerous identified associations suggest that CNVs play an important role in shaping complex traits and that their study can reveal new biological insights.

PrgmNr 1160 - PAV: An assembly-based approach for discovering structural variants, indels, and point mutations in long-read phased genomes

View session detail

Author Block: **P. Audano**[1], P. Ebert[2], W. Harvey[3], Q. Zhu[1], Y. Mao[3], The Human Genome Structural Variant Consortium, C. Lee[1], T. Marschall[2], C. R. Beck[1,4,5], E. E. Eichler[3]; [1]The Jackson Lab. Inst. for Genomic Med., Farmington, CT, [2]Heinrich Heine Inst., DÃ¼sseldorf, Germany, [3]Univ. of Washington, Seattle, WA, [4]Dept. of Genetics and Genome Sci., Univ. of Connecticut Hlth.Ctr., Farmington, CT, [5]Inst. for Systems Genomics, Univ. of Connecticut Hlth.Ctr., Farmington, CT
Disclosure Block: **P. Audano:** None.
While variant discovery has been dominated by read alignments, phased genome assemblies offer greater contiguity across large repeats and structural variants (SVs) making them ideal for identifying a wider range of variant sizes over a larger proportion of the genome. Recent advances have increased the fidelity and contiguity of long-read assemblies, improved methods are phasing them into distinct haplotypes, and new tools are required to leverage these advances for characterizing human genetic variation more completely. We developed the phased assembly variant (PAV) pipeline designed for fast and accurate discovery of SVs, indels, and point mutations using assembled contigs from human genomes instead of read-based discovery. To control for false calls and to refine breakpoints for large SVs, we have introduced an alignment trimming step which eliminates 11.5 Mbp of redundantly mapped bases per assembled haplotype on average. By implementing a novel inversion detection algorithm that does not rely exclusively on split alignments, we can now resolve small inversions that are difficult to detect with current approaches while eliminating erroneous SVs and dense clusters of false indels and SNVs over these inverted sites. Per sample, we now routinely discover more than 24,000 structural variants per human genome including 55 inversions between 300 bp and 80 kbp more than doubling inversion calls from previous assembly-based methods. PAV was the foundation of a recently published callset constructed from 35 phased samples (70 haplotypes) using Strand-seq phased HiFi and CLR long-read assemblies. We are currently applying PAV to additional human genomes from the Human Pan Genome Reference Consortium as well as mouse and nonhuman primate genomes producing the most comprehensive set of sequence-resolved structural variants to date. Due to the reliability of the alignment and trimming steps, PAV accurately places SV junctions, which can be used to probe for mechanistic signatures such as breakpoint homology. PAV (v.1.1) has been further optimized to improve characterization of larger events and to more accurately delineate breakpoints to better understand mechanisms of origin. When paired with improved assembly methods, PAV has further increased sensitivity for inversions, and is now detecting up to 86 events per sample with new calls concentrated in larger sizes up to hundreds of kbp. The results of this work will serve as the basis for a new database of human structural variation critical for the discovery of pathogenic genetic variants as long-read sequence datasets begin to be more routinely applied to unsolved disease samples.

PrgmNr 1161 - Classes of rare and common variants differentially contribute to variably expressive phenotypes in complex disorders

View session detail

Girirajan[1]; [1]Pennsylvania State Univ., University Park, PA, [2]Geisinger Hlth.System, Lewisburg, PA, [3]Aarhus Univ, Aarhus, Denmark
Disclosure Block: **M.C. Jensen:** None.
Copy-number variants associated with complex disorders, such as autism and intellectual disability, are often characterized by extensive phenotypic variability. For example, the 520-kbp deletion on chromosome 16p12.1 contributes to schizophrenia risk and decreased intelligence among adults in the general population, and is also enriched among children with severe developmental delay, autism, and congenital features. As >90% of severely affected children inherit the deletion from a mildly affected parent, we hypothesized that the deletion sensitizes the genome for neuropsychiatric traits, while variants elsewhere in the genome, or â□□second-hitsâ□□, determine the ultimate phenotypic outcome. We therefore developed a framework to systematically quantify the roles of rare and common â□□second-hitâ□□ variants towards variable phenotypes of complex disorders, and used this framework to perform whole-genome sequencing and deep clinical phenotyping on 410 individuals in 131 families with the 16p12.1 deletion. We found that carrier children were enriched for rare variants, including short tandem repeats (STRs, p=0.047), loss-of-function (LOF) variants (p=0.041), and missense SNVs in genes intolerant to variation (p=0.030), compared to their carrier parents. Interestingly, carrier parents had higher polygenic risk for schizophrenia compared to their carrier children ($p=2.98Ã□10^{-3}$), suggesting differential contributions for rare and common variants towards early-onset and late-onset clinical features. Using mixed logistic models, we next assessed the effects of >25 rare variant classes towards six distinct developmental phenotypic domains in carrier children. For example, rare deletions (OR=15.45, p=0.011) and splice-site variants (OR=2.64, p=0.037), showed significant effects towards intellectual disability, while STRs were enriched in children with nervous system defects ($OR=3.20, p=8.73Ã□10^{-3}$) and LOF variants were enriched in children with congenital malformations (OR=2.01, p=0.014). We also observed correlations between rare deleterious coding variants and IQ (R=-0.326) and autism severity scores (R=0.283) among the deletion carriers. Finally, we identified enrichments for combinations of genes with â□□second-hitsâ□□ among carrier children with specific phenotypes, such as *ARHGEF19* and *ASPM* for psychiatric traits and *MYO7A* and *HYDIN* for musculoskeletal defects. Overall, we identified specific patterns of rare and common variants for distinct phenotypic domains among 16p12.1 deletion carriers, highlighting the utility of dissecting the genetic etiology of variable phenotypes to better understand complex disorders.

PrgmNr 1162 - Modeling haplotype sharing powers CNV detection and reveals large-effect phenotype associations

View session detail

Author Block: **M. Hujoel**[1], M. A. Sherman[2], A. Barton[3], P-R. Loh[1]; [1]Brigham and Women's Hosp. / Harvard Med. Sch., Boston, MA, [2]Massachusetts Inst. of Technology, Marblehead, MA, [3]Harvard Med. Sch., Boston, MA

Disclosure Block: **M. Hujoel:** None.

The effects of most copy number variants (CNVs) on human phenotypes are unknown. Existing methods for detecting CNVs from biobank-scale SNP-array data can only sensitively detect large CNVs (~50kb+). To address this challenge, we developed a new approach leveraging the idea that inherited, population-polymorphic CNVs are usually carried by multiple individuals within a large cohort, such that combining SNP-array data across multiple potential carriers of a CNV can greatly increase detection power.

-

Applying this approach to 452,520 UK Biobank participants detected an average of 31 CNVs per individual (~18 deletions and ~13 duplications), an order of magnitude more than previous analyses. Detected duplications were on average longer than deletions (84.7kb vs. 26.3kb), such that duplications tended to affect more total base pairs than deletions (900kb vs. 430kb). Validation using whole-genome sequencing of 48 participants indicated 80% sensitivity for detecting low-frequency CNVs >5kb that spanned at least 2 SNP-probes, with a false discovery rate -

Association and fine-mapping analyses of these CNVs with 58 quantitative traits identified 301 independent associations (*P* -8) - involving CNVs at 101 loci - that could not be explained by linkage disequilibrium with any nearby SNP. Most associated CNVs were very rare (MAFTFRC, which encodes the transferrin receptor, associated with a 2.24 (s.e. 0.22) SD decrease in mean corpuscular hemoglobin (P=3 x 10^{-22}) and increased anemia risk (OR = 5.2 (1.1-23.7)), and a very rare deletion of *DIS3L2* exon 9 (MAF=0.03%) previously implicated in autosomal recessive Perlman syndrome associated with a 1.1 inch (s.e. 0.1 inch) decrease in height in heterozygous carriers (P=4 x 10^{-22}). Rare CNVs also created extended allelic series at *JAK2* and *HBA* including deletions or duplications of distal enhancers that associated with much stronger phenotypic effects (>0.5 SD) than SNPs within these regulatory elements. Deletion and duplication burdens of non-syndromic CNVs each associated with decreased height and years of education (*P*

PrgmNr 1163 - Multi-tool discovery and joint genotyping of structural variations in 138,134 multi-ethnic TOPMed WGS samples

View session detail

Author Block: **G. Jun**[1], F. J. Sedlazeck[2], G. A. Metcalf[2], A. C. English[2], V. Menon[2], T. Blackwell[3], H. M. Kang[3], A. V. Smith[3], R. A. Gibbs[2], G. R. Abecasis[3], E. Boerwinkle[1]; [1]Univ. of Texas Hlth.Sci. Ctr. at Houston, Houston, TX, [2]Baylor Coll. of Med., Houston, TX, [3]Univ. of Michigan, Ann Arbor, MI
Disclosure Block: **G. Jun:** None.
Large-scale whole-genome sequencing (WGS) studies enable the evaluation of the functional impact of structural variations (SVs) on multiple human phenotypes and conditions. SVs are 50bp or larger genomic alterations and have been shown to be the main driver of genomic diversity with clear roles in human diseases or other phenotypes. There remains substantial technical challenges in discovery and genotyping of SVs from short-read sequence data, especially at-scale. A plethora of SV detection methods have been developed over the last decade and these methods have strengths identifying different SV types and sizes. We developed Parliament2, a SV discovery and merging pipeline that harmonizes calls from multiple SV detection software into a single SV callset that shows better specificity and sensitivity than any single method. We also developed an efficient joint-genotyping method, muCNV, that reduces false discoveries that accumulate across methods and large sample sizes. The Parliament2-muCNV pipeline has been employed to generate a comprehensive catalog of SVs for genetic association analyses across 138,134 multi-ethnic TOPMed WGS samples. We identified a total of 466,800 SVs, including 231,817 deletions, 197,412 duplications/CNVs, and 37,571 inversions. As expected, the majority of SVs were rare, with almost 46% being singletons. On average, an individual carries 3,303 deletions, 3,570 duplications, and 185 inversions. To estimate genotyping accuracy, we evaluated non-reference Mendelian inconsistency rates using 11,580 trios. The estimated error rates were 0.29% for deletions, 0.83% for biallelic duplications, and 3.1% for inversions. *De novo*heterozygote rates also showed similar numbers: 0.45%, 0.66%, and 4.2% for deletions, duplications, and inversions, respectively, demonstrating that the callset is suitable for genetic association analyses. The TOPMed program is ongoing and growing in sample size, and we expect an even larger and highly accurate SV callset at the time of presentation. These SV data are available for download from dbGaP to researchers with an approved TOPMed manuscript proposal and currently being analyzed for associations with a number of different traits. Assessing contributions of SVs to common and complex human traits and risk factors will further advance our understanding of genetics and biology of heart, lung, blood, and sleep disorders, especially when combined with transcriptomic, epigenetic, and metabolomic resources from the TOPMed program.

PrgmNr 1164 - Sequencing individual genomes with recurrent deletions reveals allelic architecture and disease loci for autosomal recessive traits

In medical genetics, discovery and characterization of new â□□disease genesâ□□ and disease associated rare variant alleles depends on genetic reasoning, study designs, and subsequently patient ascertainment that can reveal these novel findings and parsimoniously explain potential variant/gene contribution to the disease trait. Here, we present new insights to enhance discovery in the challenging context of recessive disease traits and bi-allelic disease. We demonstrate through computational analyses that a collection of 30 large recurrent genomic deletions scattered throughout the human genome likely contribute to more than 20% of disease load for over 2% of all known â□□recessive disease genesâ□□. Moreover, our modeling suggests that these deletion alleles are responsible for the majority of recessive disease burden in at least 70% of the segmental regions triggered by the recurrent rearrangement NAHR mechanism; which occurs *de novo* at such loci at a relatively high mutation rate (rates of 10^{-5} to 10^{-6}). We hypothesize that genetic sequencing of the hemizygous chromosomal regions in *trans* to these large deletions is an under-utilized approach for allele and gene discovery as well as an opportunity to improve clinical molecular diagnosis. To explore our hypothesis, we performed meta-analyses for all literature-reported affected patients with the 23 recessive disease genes whose carrier burden are predicted to be overwhelmingly from large recurrent genomic deletions. Our data and analyses support the contention that current diagnostic efforts for personal genomes with large recurrent deletions do not adequately exploit genome sequencing for its potential role in discovery and molecular diagnosis. Moreover, by reanalysis of previously undiagnostic exome sequencing (ES) data on 69 subjects harboring 26 distinct recurrent deletions, probable new diagnostic variants were uncovered in genes including *COX10*, *ERCC6, PRRT2* and *OTUD7A,* thereby demonstrating the potential clinical and discovery impact of our proposed approach. Finally, we suggest that analyses of population specific allele spectra may provide important insights for study design. Findings from this study support the contention that more whole genome sequencing (WGS) may further resolve molecular diagnoses and provide evidence for multi-locus pathogenic variation (MPV). Such analyses benefit all stakeholders in both research and patient clinical care.

PrgmNr 1167 - Web-based analysis and collaboration tool, seqr, for rare disease genomics

Disclosure Block: **L. Pais:** None.
The accelerated adoption and decreased costs of genomic sequencing have exponentially increased the amount of data available for rare disease analyses. To identify causal variants in these large datasets, powerful filtering and decision support tools are needed that can be easily used by researchers. While several tools for rare disease analysis exist, few are freely available. We have addressed this need through seqr - an open source, web-based tool for family-based monogenic disease analysis that allows researchers to work collaboratively to search and annotate genomic callsets. To enable more widespread access to this tool, seqr is also now available for any joint-called VCF files loaded on the AnVIL platform (anvilproject.org). To date, seqr has enabled analyses of over 10,000 unsolved cases in collaboration with the Broad Institute Center for Mendelian Genomics and facilitated the diagnosis of more than 3,800 cases and discovery of over 300 novel disease genes across our collaborative network of 45 research teams from 57 countries.
The user-friendly seqr interface allows researchers to filter a richly annotated variant call file using pre-defined default searches or their own customized search parameters. The platform supports efficient interrogation of candidate single nucleotide variants, small insertions and deletions, and copy number variants through integration of interactive read visualization, variant and gene-level annotations from multiple internal and external resources, and support for downstream data sharing. We will present examples of cases solved in seqr involving phenotype expansions, incomplete penetrance, genomic hotspots and deep intronic variants. We will also describe the seqr matchmaker interface that allows submission of candidates and metadata to Matchmaker Exchange for gene discovery, including tracking over 6,500 match communications to date. Finally, we will show how seqr can be used for project management and data sharing purposes. This presentation will demonstrate seqrâ□□s advanced capabilities and upcoming features for genomic analyses, and how researchers can utilize it in their respective rare disease research pipelines.

PrgmNr 1168 - Mendelian diseases and their role in a pediatric neurodegeneration cohort

View session detail

Author Block: **B. DiSanza**[1], R. Guo[1], F. D. Mentch[2], E. E. Will[1], E. J. Bhoj[1], R. C. Ahrens-Nicklas[1]; [1]Children's Hosp. of Philadelphia, Philadelphia, PA, [2]Childrens Hosp. of Philadelphia, Philadelphia, PA
Disclosure Block: **B. DiSanza:** None.
Pediatric neurodegenerative diseases are an uncommon and heterogeneous category of disorders that affect approximately 0.6 out of every 1,000 live births. Here, we further clarify the Mendelian etiology of neurodegenerative diseases observed in an unbiased cohort of pediatric patients, as well as the clinical implications of receiving the appropriate genetic diagnosis. Patients enrolled in the Center for Applied Genomics (CAG) Biobank at the Children's Hospital of Philadelphia were filtered through an algorithm to generate a cohort of pediatric patients with neurodegenerative phenotypes. We discovered 76 cases with a neurodegenerative phenotype out of ~100,000 pediatric patients enrolled. 7 patients were excluded after manual chart review due to secondary neurologic symptoms caused by other medical conditions or a total absence of neurologic symptoms. 42 patients (60.9%) had a genetic diagnosis, whereas 27 were undiagnosed (39.1%). We identified 32 distinct illnesses among those diagnosed. Rett syndrome, mitochondrial illnesses (Leigh syndrome), neuronal ceroid lipofuscinoses, X-linked adrenoleukodystrophy, and Aicardi Goutieres syndrome were among the most common monogenic diagnoses. In 39/42 (92.8%) of patients, obtaining a genetic diagnosis resulted in a change in clinical care, including the monitoring of known related problems, drug management, and/or enrollment in a clinical trial. We then performed genomic and metabolomic analysis to integrate in the undiagnosed cohort of pediatric neurodegeneration patients. These neurodegeneration cases differed significantly from healthy controls in several metabolites identified through untargeted metabolomics. In summary, the disorders uncovered in this cohort indicate the wide range of pathophysiology and diseases contributing to pediatric neurodegeneration. However, 39.1% of pediatric patients remained undiagnosed despite genetic testing for neurologic symptoms, thus emphasizing the importance of ongoing research in this field and the need for further studies. Techniques involving integrated genomic, transcriptomic, and metabolomic analysis should be utilized in gene discovery.

PrgmNr 1169 - A genome-first approach to rare variants in hypertrophic cardiomyopathy genes *MYBPC3* and *MYH7* in a medical biobank

View session detail

Author Block: **J. Park**, E. A. Packard, M. G. Levin, R. L. Judy, Regeneron Genetics Center, S. M. Damrauer, S. M. Day, M. D. Ritchie, D. J. Rader; Perelman Sch. of Med. at the Univ. of Pennsylvania, Philadelphia, PA

Disclosure Block: **J. Park:** None.

â□□Genome-firstâ□□ approaches to analyzing rare variants can reveal new insights into human biology and disease. Because pathogenic variants are often rare, new discovery requires aggregating rare coding variants into â□□gene burdensâ□□ for sufficient power. However, a major challenge is deciding which variants to include in gene burden tests. Pathogenic variants in *MYBPC3* and *MYH7* are well-known causes of hypertrophic cardiomyopathy (HCM), and focusing on these â□□positive controlâ□□ genes in a genome-first approach could help inform variant selection methods and gene burdening strategies for other genes and diseases. Integrating exome sequences with electronic health records among 41,759 participants in the Penn Medicine BioBank, we evaluated the performance of aggregating predicted loss-of-function (pLOF) and/or predicted deleterious missense (pDM) variants in *MYBPC3* and *MYH7* for gene burden phenome-wide association studies (PheWAS). The approach to grouping rare variants for these two genes produced very different results: pLOFs but not pDM variants in *MYBPC3* were strongly associated with HCM, whereas the opposite was true for *MYH7*. Detailed review of clinical charts revealed that only 38.5% of patients with HCM diagnoses carrying an HCM-associated variant in *MYBPC3* or *MYH7* had a clinical genetic test result. Additionally, 26.7% of *MYBPC3* pLOF carriers without HCM diagnoses had clear evidence of left atrial enlargement and/or septal/LV hypertrophy on echocardiography. Our study shows the importance of evaluating both pLOF and pDM variants for gene burden testing in future studies to uncover novel gene-disease relationships and identify new pathogenic loss-of-function variants across the human genome through genome-first analyses of healthcare-based populations.

PrgmNr 1170 - Incomplete penetrance of disease variants in the UK Biobank

View session detail

Author Block: **A. Barton**[1,2,3], M. Hujoel[1,2], M. A. Sherman[4,1,2], R. E. Mukamel[1,2], P-R. Loh[1,2]; [1]Div. of Genetics, Dept. of Med., Brigham and Women's Hosp. and Harvard Med. Sch., Boston, MA, [2]Broad Inst. of MIT and Harvard, Cambridge, MA, [3]Bioinformatics and Integrative Genomics Program, Dept. of BioMed. Informatics, Harvard Med. Sch., Boston, MA, [4]Computer Sci. and Artificial Intelligence Lab., Massachusetts Inst. of Technology, Cambridge, MA

Disclosure Block: **A. Barton:** None.

Recent work has found increasing evidence of mitigated, incompletely penetrant phenotypes in heterozygous carriers of disease-causing recessive variants. We leveraged whole-exome imputation within the UK Biobank cohort (*N*~500K) to extend such analyses to 3,481 variants (mostly very rare; median MAF=3.3 x 10^{-5}) annotated as â□□pathogenicâ□□ or â□□likely-pathogenicâ□□ in ClinVar and as â□□autosomal recessiveâ□□ in OMIM.

Testing these variants for association with 54 quantitative traits yielded 98 significant (*p* -8) associations spanning 38 traits and involving variants previously implicated in 33 different diseases. Notable examples included a *POR* missense variant implicated in Antley-Bixler syndrome that associated with a 0.27 (s.e. 0.04) SD increase in height, and an *ABCA3* missense variant implicated in interstitial lung disease that associated with a -0.12 (0.01) SD change in FEV1/FVC ratio (a measure of lung function). Association analyses with 1,257 disease traits yielded 16 additional variant-disease associations (*p* -8). One such association, involving a splice donor variant in *IFT140* (which encodes a protein involved in ciliary function), appeared to be novel. This variant, which has been implicated in retinitis pigmentosa and short-rib thoracic dysplasia, associated with cystic kidney disease in heterozygous carriers (OR = 18.4 (8.5-40.0)).

To explore potential mechanisms that might underlie incomplete penetrance, we examined the â□□modified penetranceâ□□ model of Castel *et al*. (2018) proposing that phenotypic effects of loss-of-function (LoF) variants may be modulated by *cis*-eQTLs regulating the expression of the functional allele on the opposite haplotype. We were powered to explore this model at *FLG*, for which 10% of UK Biobank participants carry a LoF variant associated with asthma or atopic dermatitis. However, association analyses in heterozygous carriers (restricting to variants on the functional haplotypes) did not detect any Bonferroni-significant associations with risk of either disease. As an alternative way to investigate this hypothesis, we also analyzed quantitative traits for which we could identify both large-effect coding variants and cis-eQTLs strongly associated with the same trait (*p* -50), searching for differential phenotypic effects depending on the relative phase of such variant pairs. These analyses also did not find any significant interaction effects; however, power was limited due to small numbers of carriers.

Our results show that many disease-associated recessive variants can produce mitigated phenotypes in heterozygous carriers and motivate further work exploring penetrance mechanisms.

PrgmNr 1171 - Biased pathogenic assertions of loss of function variants challenge molecular diagnosis of admixed individuals

Disclosure Block: **M.S. Naslavsky:** None.

Genomic analyses for diagnostic purposes of individuals affected by monogenic disorders was significantly improved by next-generation sequencing targeting clinically relevant genes. Whole exomes yield a large number of variants that require several filtering steps, prioritization, and pathogenicity classification. Among the criteria recommended by the American College of Medical Genetics and Genomics (ACMG), those that rely on population databases critically affect analyses of individuals with underrepresented ancestries. Population-specific allelic frequencies need consideration when characterizing potential deleteriousness of variants. An orthogonal input for classification is annotation of variants previously classified as pathogenic as a criterion that provide supporting evidence widely sourced at ClinVar. We used a whole-genome dataset from a census-based cohort of 1,171 elderly individuals from SÃ£o Paulo, Brazil, highly admixed and unaffected by severe monogenic disorders, to investigate if pathogenic assertions in ClinVar are enriched with higher proportions of European ancestry, indicating bias. Potential loss of function (pLOF) variants were filtered from 4,250 genes associated with Mendelian disorders and annotated with ClinVar assertions. Over 1,800 single nucleotide pLOF variants were included, 381 had non-Benign assertions. Among carriers (N=463), average European ancestry was significantly higher than non-carriers (N=708; p=0.011). pLOFs in genomic contexts of non-European local ancestries were nearly three times less likely to have any ClinVar entry (OR=0.353;p

PrgmNr 1172 - Leveraging human phenotype ontology based similarity to further functional annotation of the human genome

Disclosure Block: **A. Jolly:** None.

Next generation sequencing has contributed to the functional annotation of ~6000 computationally annotated genes mapped on the haploid human genome reference. Exome sequencing (ES) studies within the Centers for Mendelian Genomics (CMG) have driven discovery at a continuous rate of 1 per 30 ES and revealed aspects of molecular pathobiology in human disease. The discovery of previously unpublished gene-disease associations has been shown to be the most contributory factor to an increased molecular diagnostic rate upon ES reanalysis (Liu, *et al*. 2019. *NEJM*. *380(*25*)*:2478-2480). Moreover, use of the American College of Medical Genetics and Genomics criteria to classify pathogenic variants has allowed for the definitive demonstration of multi-locus pathogenic variation (MPV), i.e., multiple molecular diagnoses, in ~5% of clinical ES cases. Despite these advances, there remains a large proportion of cases unsolved by ES or whole genome sequencing (WGS), a substantial fraction of which we hypothesize are due to as-yet unrecognized Mendelian disease genes. Previously published exome reanalysis pipelines leveraged the Human Phenotype Ontology (HPO) to match known disease associated genes with a proband phenotype. We sought to expand these approaches by using HPOFiller to annotate non-disease associated genes with HPO terms to inform novel gene-phenotype associations. HPO annotated disease associated genes and non-disease associated genes were used to query a phenotypic match to probands/cohorts within the Baylor Hopkins CMG (BHCMG) database. Proof of concept studies successfully allowed for i) determination of individual variant impact within a case of MPV; ii) dissection of allele specific phenotypic spectrum within a genetically heterogeneous skeletal dysplasia cohort (Robinow Syndrome); iii) identification of critical dosage sensitive genes driving phenotype manifestation in a case of multiple *de novo* CNV; and iv) elucidation of the phenotypic spectrum of a gene associated with a birth defect sequence affecting the genitourinary tract. We now apply this discovery approach to the OMIM disease HPO database in order to cluster disease diagnoses by their phenotypic features, i.e. clinical synopsis of associated trait, rather than subjective clinical categorization in order to achieve a molecularly based categorization of congenital disease. Furthermore, we apply these novel experimental genomics and computational analytic approaches to the whole BHCMG database (~12,000 exomes) to solve previously unsolved cases and elucidate the prevalence of MPV across multiple disease phenotypes in the research sequencing setting.

PrgmNr 1175 - Attitudes in four Latin American countries towards donation of personal genetic data for research

View session detail

Author Block: **G. Chavarria-Soley**[1], F. Francis-Cartin[1], G. Macaya[2], R. Alfaro-Redondo[1], L. Robarts[3], A. Middleton[3], H. Raventos[4]; [1]Univ. de Costa Rica, San JosÃ©, Costa Rica, [2]Univ. de Costa Rica, San Pedro de Montes de Oca, San Jose, Costa Rica, [3]Wellcome Genome Campus, Cambridge, United Kingdom, [4]Univ Costa Rica, San Pedro, Costa Rica
Disclosure Block: **G. Chavarria-Soley:** None.
Currently, large amounts of genetic and genomic information are being generated worldwide. Making this data available to the research community is an attractive concept with many potential benefits, but which also raises various concerns. Ultimately, it is the person whose genetic data is being generated who decides whether to share it. â□□Your DNA, Your Sayâ□□ is an anonymous online survey that covers attitudes of the public towards genomic and medical data donation, trust in research professionals, and concerns about consequences of reidentification. It has been translated into 15 languages and has been answered by individuals from more than 20 countries. We explore the results of the survey in four Latin American countries: Argentina (N=919), Costa Rica (N=224, a pilot sample), Mexico (N=1347), and Brazil (N=1349). When confronted with different potential uses of their data, the four countries show a similar response pattern. A high proportion of individuals (59.6%-81,7%) are willing to donate their genetic data to their medical doctors, and the numbers are similar (55.9%-86.2%) when the intended users of the data are non-profit researchers. Willingness to donate in these two scenarios is much higher in Costa Rica. This is probably because the pilot sample is small and skewed towards people with higher education. In all countries, however, participants are significantly less likely to donate data to for-profit researchers (33.9%-38.4% willingness to donate). The three most cited concerns regarding donation of their genetic data are the same in Mexico, Argentina and Brazil: â□□my DNA being copied and then planted at the scene of a crimeâ□□, â□□being clonedâ□□, and â□□upsetting my genetic relativesâ□□. Again, the ranking of concerns in Costa Rica differs from the other countries. Participants were asked whether they would trust different persons with their genetic information. The pattern is similar in the four countries, with the participantâ□□s own doctor as the most trusted person (over 68% for all countries), followed by a researcher at a university in the participantâ□□s own country (over 30% for all countries). The lowest trust values were found for researchers at a company worldwide and governments worldwide. The â□□Your DNA, Your Sayâ□□ survey provides a valuable opportunity to study and compare the views on genetic and genomic data sharing in different regions of the world. Our results suggest that Latin American countries share similar views on the subject.

PrgmNr 1176 - Patient completion of updated hereditary cancer genetic testing

View session detail

Author Block: K. Clift, **S. K. Macklin-Mantia**, S. L. Hines; Mayo Clinic, Jacksonville, FL
Disclosure Block: **S.K. Macklin-Mantia:** None.
For many years, hereditary cancer genetic testing was often limited to one or two genes (i.e. *BRCA1* and *BRCA2*). Identification of additional hereditary cancer genes and advancements in testing technology have led to panel testing becoming commonplace. Individuals with previous nondiagnostic results may have a pathogenic variant in a more newly characterized hereditary cancer gene, and they and their family members may benefit greatly from recontact and updated expanded panel testing. Our aim was to identify how well follow up for updated analysis had been completed and review results of such expanded testing. From 2003-2020, 708 patients were identified who had completed *BRCA1/2* only analysis. The majority had an initial nondiagnostic result (674). Only about 15% (109) had already completed additional, panel genetic testing; 15 (13.7%) were found to carry a pathogenic variant. This study identified 368 patients with a nondiagnostic result who had not completed additional testing, were not known to be deceased, lived within the U.S., and had an email address within the medical record system. A recruitment message was sent to patientsâ email addresses and through their patient portals. An at-home salvia kit for a multi-cancer panel of 84 genes was ordered for participants at no personal charge, and no in person visit was required for testing. Of the 80 preliminary results thus far, 6 patients carried a pathogenic variant (7.5%), specifically in *ATM*, *CHEK2*, *MUTYH* (x2), *PALB2*, and *RAD50*. Thirty-nine patients carried one or more variant(s) of uncertain significance; 35 patients received negative results. Almost 1/3 (N=100, 27%) were noted to have opened their portal communication and then not pursue the option for complimentary, updated testing. These results further underscore the need to recontact patients to identify families with previously undetectable genetic risk for hereditary cancers to allow for individualized management. Many patients who would benefit from updated hereditary cancer genetic testing have not completed and chose not to pursue testing even though many potential barriers, such as need for travel, access to a genetics provider, and cost, were removed. Further understanding into what drives these decisions is warranted.

PrgmNr 1177 - Awareness and Use of Genetic Testing: An Analysis of the Health Information Trends Survey 2020

View session detail

Author Block: **J. Tiner**, L. E. Mechanic, L. Gallicchio, E. M. Gillanders, K. Helzlsouer; DCCPS/EGRP, Natl. Cancer Inst., Rockville, MD
Disclosure Block: **J. Tiner:** None.
Background: The growing availability and commercialization of genetic tests has improved public knowledge and uptake. Genetic testing for clinical and recreational purposes (e.g. ancestry testing) has increased in recent years. However, not all groups have had equal access and opportunity to use the technology. Previous research suggests that there are disparities in awareness and implementation of genetic testing specifically for racial and ethnic minorities and those with low income or education. **Goals**: This project examined awareness and use of genetic testing and associations with demographic characteristics and cancer history. **Methods**: The Health Information National Trends Survey (HINTS) is a national survey that regularly collects information on public awareness and use of cancer- and health-related information. Using HINTS 5 Cycle 4 data, collected in 2020, we examined responses to questions asking participants if they had ever heard of or ever had genetic testing. We examined the associations between demographic characteristics and ever heard of or had genetic testing using chi square tests. **Results:** A total of 3,865 participants completed the HINTS questionnaire for a response rate of 38%. Of these, 3,767 responded to the genetics related questions and were included in this analysis. Overall, 75% of participants reported that they had heard of genetic testing and 19% of participants reported they had genetic testing. Ancestry testing was the most common type of genetic test either heard of or received. Fourteen percent of those with a history of cancer reported having cancer related genetic testing. Of those with a history of cancer, 18% reported a history of breast cancer and 5% reported a history of colon cancer. Ethnicity, education, income, marital status and having a family history of cancer were associated with both hearing of and having any type of genetic test (pConclusion: The results of this analysis align with previously published work showing racial, ethnic, income and education disparities in knowledge and use of genetic testing. While few respondents who had a history of cancer reported having had cancer-related genetic testing, more details are needed to determine the appropriateness or eligibility for testing. These differences in knowledge and use of genetic testing support the need for improved communication and increased engagement within these communities.

PrgmNr 1178 - Health Locus of Control, Belief in Genetic Transmission of COVID-19, and COVID-related Outcomes in a Global Sample

View session detail

Author Block: **T. D. Dye**, S. Siddiqi, E. Pressman; Univ. of Rochester Sch. of Med. and Dentistry, Rochester, NY
Disclosure Block: **T.D. Dye:** None.
Perception that a disease is transmitted through â□□geneticsâ□□ can result in inaction and unnecessary exposure if genetically-transmitted diseases are perceived (as they often are) as untreatable/not preventable. We sought to examine how health locus of control was associated with belief in genetic transmission of COVID-19 (a viral disease not transmitted genetically), and how belief in COVID-19 genetic transmission related to a range of social and health outcomes. **Methods**: We ascertained belief in COVID-19 transmission modalities in a global study of COVID-19-related experience in April/May 2020 (early in the pandemic). In total, 7,411 respondents from 175 countries were recruited through social media and Amazonâ□□s mTURK digital workforce. Multidimensional Health Locus of Control (MHLC â□□Powerful Others,â□□ â□□Chance,â□□ â□□Internalâ□□) reflected oneâ□□s belief in influences on their health. We used logistic regression to generate adjusted Odds Ratios (aOR) and 95% Confidence Intervals (95% CI) to ascertain magnitude and significance of the association (<.05 between mhlc and belief in genetic transmission subsequently on covid-19 social health outcomes.>Results: In total, 7.1% (n=525) of participants believed that COVID-19 was transmitted through genes, with another 12.2% (905) unsure. Adjusting for age and education, participants with higher levels on all three MHLC domains were significantly more likely to believe COVID-19 was transmitted through genes (or were unsure): (MHLC-Chance aOR: 2.47; 95% CI: 2.13, 2.87; MHLC-Internal aOR: 1.50; 95% CI: 1.30, 1.73; MHLC-Powerful Others aOR: 2.51; 95% CI: 2.17, 2.90). Controlling for age, education, and all three MHLC levels, belief that COVID-19 was transmitted by genes was significantly associated with self-reported COVID-19 infection (aOR: 1.57; 1.24, 1.98), greater COVID-19-related worry (aOR: 1.16; 1.00, 1.35), vaccine hesitancy (aOR: 1.57; 1.34, 1.83), and higher COVID-19 livelihood impact (aOR: 1.53; 1.32, 1.78). **Discussion**: Early in the COVID-19 pandemic, belief that the virus was genetically transmitted may have influenced behavior to place individuals at excess risk for infection and poor COVID-19 outcomes, especially among people with stronger beliefs in the effects of fate and â□□powerful othersâ□□ on their health. Misunderstanding genetic transmission of disease - as in the case of COVID-19 - could have adverse health consequences in clinical practice and public health. Better understanding perceptions of genetic transmission and of COVID-19 may help reduce misunderstanding, improve perceptions and knowledge of treating COVID-19, and promote preventive behaviors in a more timely manner.

PrgmNr 1179 - Identifying message design considerations to motivate cascade testing for familial hypercholesterolemia: Stakeholders' advice for healthcare providers

View session detail

Author Block: **G. Campbell-Salome**[1], W. L. Nicole[2], I. G. Ladd[2], A. Sheldon[3], C. Davis Ahmed[3], A. Brangan[2], M. N. McMinn[2], A. K. Rahm[2], M. L. Schwartz[2], E. Tricou[2], C. L. Fisher[1], A. C. Sturm[4]; [1]Univ. of Florida, Gainesville, FL, [2]Geisinger, Danville, PA, [3]The FH Fndn., Pasadena, CA, [4]Geisinger, Lewis Center, OH

Disclosure Block: **G. Campbell-Salome:** None.

Purpose: Motivating families with familial hypercholesterolemia (FH) to undergo cascade testing is critical for diagnosis and life-saving treatment. Healthcare providers (HCPs) can assist in family communication about FH and motivate cascade testing uptake as authoritative sources of information. Identifying how to strategically communicate about FH risks can guide HCPs on effectively motivating at-risk relative to pursue cascade testing. The Extended Parallel Process Model (EPPM) was used to identify message approaches that focus on four key factors (severity, susceptibility, response efficacy, self-efficacy) that predict motivation to engage in a health behavior. The EPPM is a well-supported, contemporary model for strategic risk communication and has been applied to create messages promoting health protective behaviors in areas of smoking cessation, heart disease, and cancer screening. This study gathered stakeholdersâ perspectives on how to craft messages from HCPs to promote cascade testing uptake, informed by the EPPM. Methods: Participants with FH were recruited from a healthcare system in Pennsylvania, USA, and The FH Foundation. Participants were asked to recruit a family member for a dyadic interview. Additional participants responded to a survey. Open-ended survey and interview data captured stakeholdersâ feedback on written and verbal messages that were used to facilitate family communication about FH and cascade testing. Data were thematically analyzed and triangulated. Results: Participants included 22 individuals in 11 dyadic interviews and 98 survey respondents. Message approaches that address EPPM factors were identified to motivate cascade testing. Recommendations highlight the importance of balancing relativesâ sense of threat (severity and susceptibility) with their ability to reduce risk (efficacy). For *severity*, HCPs should list health risks associated with untreated FH and emphasize FH as a genetic condition affecting generations. For *susceptibility*, HCPs should explain how FH is inherited and that young relatives are susceptible. To promote *response efficacy*, HCPs should describe testing as providing a definitive FH diagnosis, highlight FH as easily treatable, and stress the value of early FH intervention. To promote *self-efficacy*, HCPs should clarify testing options and costs, provide instructions on how to pursue testing, and offer support resources. Conclusions: Results highlight ways to design messages to motivate cascade testing for FH and other hereditary conditions. A prospective, pragmatic trial will test these approaches to examine the impact of HCPs messages on cascade testing uptake.

PrgmNr 1180 - Usual care genetic counseling vs. ARIA: An RCT of an Accessible, Relational, Inclusive and Actionable model for sequencing results disclosure to historically underrepresented populations in the CSER CHARM study

View session detail

Author Block: **G. Joseph**[1], M. C. Leo[2], B. B. Biesecker[3], L. Riddle[1], C. Guerra[1], L. Amendola[4], M. J. Gilmore[2], J. M. Zepp[2], B. Rolf[5], K. P. Anderson[6], S. Okuyama-Sasaki[6], M. Caruncho[1], J. E. Hunter[2], E. M. Keast[2], T. L. Kauffman[2], N. M. Lindberg[2], A. A. Reyes[2], G. P. Jarvik[7], B. S. Wilfond[8], K. A. Goddard[9]; [1]Univ California San Francisco, San Francisco, CA, [2]Kaiser Permanente Ctr. for Hlth.Res., Portland, OR, [3]RTI Intl., Washington, DC, [4]Univ. of Washington, Seattle, WA, [5]Univ Washington, Seattle, Seattle, WA, [6]Denver Hlth.Ambulatory Care Services, Denver, CO, [7]Univ Washington Med Ctr., Seattle, WA, [8]Seattle Children's Res. Inst., Seattle, WA, [9]Kaiser Permanente Northwest, Portland, OR
Disclosure Block: **G. Joseph:** None.
Background. Barriers to effective communication in genetic counseling include high oral literacy demand, dominance of informational vs. psychosocial counseling dialogue, and limited provision of valued information. Prior research with historically underserved patients found that ineffective communication contributed to poor understanding and limited engagement. Methods. Within the NIH CSER consortium CHARM study, which recruited historically underserved populations, we assessed ARIA (Accessible, Relational, Inclusive and Actionable), an evidence-based genetic counseling communication model. ARIA is designed to increase accessibility of genetic counseling (GC) for all patients regardless of prior genetics knowledge or literacy level, and requires in-depth training of GCs in specific communication skills. We conducted a pragmatic randomized controlled trial to compare usual care (UC) GC to ARIA for the return of exome sequencing results in participants ages 18-49. We hypothesized that ARIA would be more effective in achieving satisfaction with communication and increasing essential knowledge. Two GCs were assigned to each arm for the duration of the trial. Study participants were randomized 1:1 and were blinded to the type of counseling they received. Results. Participants (353 ARIA; 344 UC) had a mean age of 34.6 (SD=8.2); 71% were female, 44% were low income, and 15% preferred Spanish. Almost 20% had marginal or inadequate health literacy. Preliminary analyses indicate that participants in both arms were highly satisfied, with high agreement on being treated with sensitivity and respect (100% UC vs 99% ARIA), feeling listened to (99% UC vs 98% ARIA), getting clear, understandable information (98% UC vs ARIA 97%), and feeling comfortable asking questions and voicing concerns (96% in UC vs 98% in ARIA). 97% of participants with normal cancer results recalled their results correctly vs. 90% with VUS results vs. 89% with abnormal results. 90% with normal additional finding results were accurate while patients with abnormal additional findings were more likely to recall results correctly if the result was medically actionable (88%) than if not (17%). Mean cancer genetics knowledge for both groups was high at baseline (81% accuracy UC, 78% ARIA) and showed a small increase from baseline to follow-up for both groups (+3% UC, +4% ARIA). Conclusions. Communication satisfaction appears to be similar between arms; inferential testing of the outcomes is in progress. Although knowledge was high, participantsâ recall of their results appeared to be similar between arms but may have varied by type and actionability of the result.

PrgmNr 1183 - Identification of clinically relevant variants in homologous regions in 41,755 exomes

View session detail

Author Block: **W. Steyaert**[1], M. Steehouwer[1], L. Haer-Wigman[1], R. Pfundt[1], A. P. Stegmann[2], H. Yntema[1], H. Brunner[1], A. Hoischen[1], C. Gilissen[1]; [1]Radboud Univ. Nijmegen Med. Ctr., Nijmegen, Netherlands, [2]Univ Hosp Maastricht, Maastricht, Netherlands
Disclosure Block: **W. Steyaert:** None.
Despite routine clinical exome sequencing, the molecular cause of disease remains unknown in the majority of patients with a rare genetic disease. A possible contributor to this problem is the difficulty in analyzing genomic regions with a high sequence similarity to other regions in the genome, i.e. homologous regions. Altogether, these segments comprise about 3.5% of the exome and consist mainly of protein coding genes having one or multiple pseudogenes. Short-read sequencing reads originating from these regions will either align with very low quality or discordant to their biological origin causing most single nucleotide variants (SNVs) as well as copy number variants (CNVs) to be undetected.
To address this problem we devised an algorithm and implemented it in a software package called Cameleolyser. In addition to aligning sequencing reads to a classical reference genome, Cameleolyser also maps reads to a masked version of it. Gene conversions and deletions are identified by using sequence differences between the homologs. To determine SNVs not introduced by a conversion event, a sensitive variant calling is conducted onto the masked alignment.
The application of Cameleolyser to a cohort of 41,755 whole exome sequencing samples yielded 17,394 rare homozygous deletions and 314,131 rare SNVs in these challenging regions. By generating PacBio high-fidelity high coverage genomes for a subset of 20 samples we could confirm 77 out of the 83 SNVs (93%). The SNVs that are the consequence of a gene conversion event (n=8) could all be confirmed. Out of the 15 CNVs that were found by our method in this subset of samples, 11 (73%) corresponded to the PacBio data. Furthermore, 7 randomly chosen ultra-rare SNVs were selected for validation and confirmed by Sanger sequencing.
We then focused on variation that could potentially be disease-causing. In the cohort we found 1,145 ultra-rare homozygous deletions in OMIM genes, 1,011 heterozygous loss-of-function (LoF) variants, and 54 homozygous LoF variants of which 50 due to gene conversions. The top ranked gene is *STRC*, encoding for stereocilin and a known autosomal recessive disease gene for deafness. In *STRC*, we identified 25 homozygous LoF mutations due to gene conversions as well as 37 homozygous deletions. All of these events were exclusively found in patients with hearing impairment.
In conclusion, we developed a novel method that can accurately identify clinically relevant copy number and single nucleotide variations in homologous coding regions from diagnostic exome sequencing data. We demonstrate that disease causing LoF and other variation is often introduced in these regions by means of gene conversions.

PrgmNr 1184 - Analytical validation of clinical whole genome sequencing across a diverse mutation spectrum

View session detail

Author Block: **K. V. Schulze**[1], J. Sinson[1], B. Yuan[2,3,1], V. T. Nguyen[3], M. Santana[3], D. C. Chen[4], C. Qu[3], H. DAI[4,3], C. Shaw[1,3], C. M. Eng[1,3], P. Liu[1,3]; [1]Baylor Coll. of Med., Houston, TX, [2]Seattle Children's Hosp., Seattle, WA, [3]Baylor Genetics Lab., Houston, TX, [4]Baylor Coll. Med., Houston, TX
Disclosure Block: **K.V. Schulze:** None.
Clinical whole genome sequencing (WGS) offers the opportunity to not only end but also prevent many diagnostic odysseys. Our experience suggests that WGS is preferentially ordered for patients with a history of negative molecular or cytogenetic testing, and less frequently requested as a comprehensive first-tier test for patients with a broad differential diagnosis.
To evaluate how well WGS performs compared to other molecular or cytogenetic tests that are commonly used as first-tier diagnostic assays we applied WGS to >250 de-identified cases with a variety of known disease-causing genetic variants that were previously detected in clinical testing using traditional diagnostic methods. For this analytical validation all samples were processed and analyzed in a CLIA/CAP certified laboratory, sequenced with a minimum average coverage of 40X, and their data mapped to the GRCh38 human reference genome using Illuminaâ□□s DRAGEN pipeline. Our study cohort was carefully selected to largely consist of cases with genetic variants that could pose diagnostic challenges for WGS, such as copy number variants (CNVs), in particular those mediated by repetitive elements, structural variants (SVs), such as translocations and mobile element insertions, as well as trinucleotide repeat (TNR) expansions.
In addition to single nucleotide variants that were confirmed both in the nuclear as well as the mitochondrial genome, regions with absence of heterozygosity, and uniparental disomy, we detected 264/265 (99.6%) of reported CNVs from 174 individuals that ranged in size from 0.002-35.1 Mb using a read depth-based algorithm. Our WGS analysis of TNR expansions in 45 cases, of which 26 had repeat lengths in the normal range, showed a sensitivity of 73.7% and specificity of 100% when we labeled samples by mutation categories according to disease-specific thresholds of repeat lengths. However, we noticed that the degree of deviation between repeat lengths found with WGS and those clinically reported drastically grew with increasing TNR sizes; repeat lengths found by WGS did not exceed 150, even for a TNR expansion in the *FXN* gene with a reported approximate size of 1,400. At this stage of our analysis we conclude that WGS can detect many, but not all, TNR expansions. Nonetheless, compared to traditional tests, WGS can reliably identify a diverse spectrum of genetic and genomic variants making it a robust assay suitable for both first- and last-tier diagnostic testing.

In SouthSeq, we conducted genome sequencing (GS) as a first-line test for infants with symptoms suggestive of a genetic disorder being cared for in a neonatal intensive care unit (NICU) and other pediatric units. Study recruitment targeted diverse populations representing racial/ethnic minorities and rural medically underserved areas that are historically under-represented in genomic medicine research. Genome sequencing and analysis were performed concurrent with standard clinical care for 367 affected newborns to detect disease-causal genetic variation. Definitive diagnostic (DD) and likely diagnostic (LD) findings were identified in 109 newborns (30%) with an additional 51 (14%) found to harbor an uncertain result. Thirty-nine percent of GS-detected DD/LD findings were identified via standard, concurrent clinical genetic testing, whereas 53.2% were not (7.3% of GS-detected DD/LD findings did not receive any clinical genetic testing), suggesting that GS testing is better for obtaining early genetic diagnosis in newborns. In most cases, GS detected a SNV/indel when only clinical CNV testing was ordered. We also identify phenotypes that correlate with the chances of receiving a DD/LD finding, such as an enrichment for craniofacial, ophthalmologic and auditory abnormalities. We did not observe any differences in diagnostic rates between racial/ethnic minority groups. SouthSeq has provided an early genetic diagnosis and has demonstrated the utility of using GS as a comprehensive first-line genetic test.

Disclosure Block: **S.F. Kingsmore:** None.

Many rare genetic diseases have effective treatments. Without immediate implementation many progress rapidly to severe morbidity or mortality. Front-line physicians are often unfamiliar with these diseases or treatments. Hence, timely molecular diagnosis may not always improve outcomes. We describe Genome-to-Treatment (GTRx), an automated, virtual system for genetic disease diagnosis and acute management guidance for ill children in intensive care units (ICU). Diagnosis was achieved in 13.5 hours by sequencing library preparation directly from blood, faster whole genome sequencing (WGS) and informatic analysis, natural language processing of electronic health records and automated interpretation. 563 severe genetic diseases with effective treatments were identified by literature review, clinician nomination and WGS experience. Specific treatments - drugs, devices, diets, and surgeries - were identified for each by automated internet and literature searches, and manually curated. Five clinical geneticists adjudicated the indications, contraindications, efficacy, and evidence-of-efficacy of each treatment in each disorder in this clinical context. After discussion, they agreed upon 189 of the first 190 treatments. We integrated 10 genetic disease information resources, and electronically linked them and the adjudicated treatments to each automated diagnostic result (http://gtrx.rbsapp.net/). This system had superior analytic performance for single nucleotide, insertion-deletion, structural and copy number variants. It provided correct diagnoses and acute management guidance in four retrospective patients. Prospectively, an infant with encephalopathy was diagnosed in 13.5 hours, received effective treatment immediately, and had a good outcome. GTRx will facilitate broad implementation of optimal acute treatment for children with rapidly progressive genetic diseases by front-line ICU physicians.

PrgmNr 1187 - Large scale Cas9 mediated depletion of highly abundant transcripts to expand the interpretable genome and improve the diagnostic yield of clinical RNA Seq

Whole genome sequencing (WGS) provides about a 100-fold increase in rare variants identified per human compared to whole exome sequencing (WES). However, recent analyses demonstrate this increased coverage of the genome provides only a modest improvement in diagnosis for rare genetic disorders. This is largely because the functional consequence for most of the non-coding variants identified by WGS remains unknown. To address this, several groups have performed whole-transcriptome sequencing (RNA-Seq) with WGS to improve clinical interpretation of these many variants. Using this combined approach, a 15-30% improvement in overall diagnostic yield has been reported, largely through the identification of rare DNA variants which are demonstrated to cause aberrant mRNA splicing. However, the utility of RNA-Seq is limited to genes that are well-expressed in tissues that are possible to access from patients. Although about 80% of all known disease-associated genes (OMIM) are observed in RNA-Seq from fibroblasts or blood, the vast majority of these are expressed at levels too low for comprehensive analysis of rare splicing variation, and only about 20% of all genes are robustly observed. To address this issue, we have developed a novel method to improve coverage of low-expressed genes through large-scale, selective depletion of the most abundant transcripts (TPM > 30). The CRISPRclean method utilizes Cas9 nuclease and 360,000 guide RNAs to specifically remove RNA-Seq library fragments from over 4,000 targeted genes, which are the well observed genes from non-depleted RNA-Seq, and results in an average six-fold increase in coverage of untargeted genes compared to untreated RNA-Seq libraries. We demonstrate expansion of the number of genes that can be assessed for rare splicing aberrations, or allelic alterations in expression, and thus greatly expand the proportion of the genome interpretable by RNA-Seq. The method can be applied to any cell type of RNA, and can be customized for maximal effect. This depletion method occurs post-library generation, and thus may be applied to already sequenced samples or added to existing clinical RNA-Seq workflows and effectively increases the dynamic range of gene expression observation and alternative splicing from various tissues. We demonstrate diagnostic efficacy by applying CRISPRclean to a large cohort of rare Mendelian disease samples from within the Undiagnosed Disease Network.

PrgmNr 1188 - Integration of proteomics with genomics, transcriptomics and phenomics increases the diagnostic rate of Mendelian disorders

Due to the lack of functional evidence, the diagnostic rate of whole exome and genome sequencing (WES/WGS) in Mendelian disorders plateaus at ~50%, increasing by 10-15% when complemented by transcriptomic data (RNA-seq). Here, we demonstrate the diagnostic power of integrating proteomics into a systematic multi-omic approach and provide a blueprint for its implementation in routine clinical practice.

Quantitative tandem mass tag (TMT) labelled proteomics was applied to fibroblasts from 145 individuals, detecting ~8,000 proteins per sample, spanning over half of all Mendelian-disease genes. To detect protein expression levels significantly outside of the physiological range, as evidence of underlying variant pathogenicity, we developed PROTRIDER, a denoising-autoencoder based algorithm controlling for known and unknown sources of proteome-wide variation. This approach was first validated in 22 samples with confirmed pathogenic variants, by protein underexpression in 64%, while the corresponding transcript was reduced only in 18%. We then applied the approach to 21 unsolved cases with prioritised variants of uncertain significance (VUS), validating 14 diagnoses, 67% by aberrant protein- and 24% (5/21) by aberrant RNA-expression.

In search of the diagnosis in the remaining unsolved cases, we called genome-wide significant RNA and protein expression outliers of three classes (RNA-only, protein-only, and RNA-and-protein) across the entire dataset. Outliers were enriched for splice, stop, and frameshift variants, in addition to missense and in-frame indel variants in protein-only outliers. Integrating these outlier calls with rare variant allelic data from WES/WGS and phenotype similarity scores for known disease-gene associations led to the diagnosis of 12 further unsolved cases and identified a novel mitochondrial disease gene, MRPL38.

Overall, our integrative multi-omic approach led to genetic resolution for 21% (26/121) of all unsolved WES/WGS cases and demonstrated the added value of proteomics both in detecting the functional consequence of missense variants, the most frequent VUS, and in delineating the downstream functional consequence of pathogenic variants on the protein complex level (39% of all diagnosed cases). The multi-omics pipeline is available at https://github.com/prokischlab/omicsDiagnostics/ .

PrgmNr 1191 - Integrative analysis of human genetic association studies, single cell transcriptomics, and knockout mouse models identifies cell types and genes involved in skeletal disease

Motivation: Genome-wide association studies (GWAS) have identified hundreds of genomic regions associated with skeletal disease traits. However, few of the causal genes underlying these associations have been identified and functionally validated *in vivo.*
Objective: We hypothesised that integration of human genetic association studies and single cell RNA sequencing (scRNA-seq) with phenotype data from knockout (KO) mouse models would identify disease-causing genes and identify the cellular context through which they function.
Methods: scRNA-seq was used to map the transcriptome of cells isolated from the endosteal and marrow compartments of mouse femurs. Hypergeometric tests were used to identify cell types enriched for expression of genes involved in monogenetic skeletal disorders. GWAS, and MAGMA gene-set analysis of 448,010 participants in the UK-Biobank Study was used to identify cell types enriched for bone mineral density (BMD) and height-associated genes. Skeletal phenotyping of >1000 unselected KO mouse lines was used to validate the functional roles of BMD and height-associated genes.
Results: scRNA-seq analysis of 133,942 bone and marrow cells identified 34 distinct cell types including multiple clusters of myeloid, lymphoid, and non-haematopoietic cells, each with distinct transcriptional profiles. Hypergeometric tests showed that osteoblasts and osteoclasts were enriched for human orthologues involved in monogenetic low and high bone mass disorders, respectively (P-7), whereas chondrocytes were enriched for orthologues involved in bone growth (P-9). GWAS of BMD and height, identified 90 novel loci including one intersecting *PLS3*, a known cause of juvenile X-linked osteoporosis (P-9). MAGMA gene set analysis involving GWAS and scRNA-seq results showed that osteoblasts, endothelial and vascular smooth muscle (VSM) cells were enriched for BMD-associated genes (P-4), whereas chondrocytes and B-cells were enriched for height-associated genes (P-3). Eight osteoblast, 7 endothelial and 5 VSM-specific genes associated with BMD were present in a cohort of 1000 unselected KO mouse lines. Deletion of 5, 5 and 4 of the corresponding genes in mice resulted in abnormal skeletal phenotypes. These included novel BMD-associated genes with previously unappreciated roles in the skeleton, including endothelial-specific gene *Slc9a3r2*, which when deleted, resulted in reduced trabecular bone mass.
Conclusions: Our multiscale approach identified novel candidate skeletal disease genes and provides insight into the cellular context through which they may contribute to the development of skeletal disease.

PrgmNr 1192 - A modular massively parallel reporter assay uncovers context-specific allelic activity of GWAS variants

Genome-wide association studies have nominated hundreds of genetic signals associated with the prevalent metabolic disease type 2 diabetes (T2D) and related traits. A majority (~90%) of these signals lie in noncoding regions of the genome, suggesting that dysregulated transcriptional circuitry is a primary mechanism contributing to T2D etiology. Predicting functional consequences of noncoding variants remains non-trivial; thus, specific insights about the relationship of these variants to effector transcripts and associated regulatory activity remains limited. To address this outstanding priority, we devised a modified STARR-seq (self-transcribing active regulatory region sequencing) strategy to systematically interrogate enhancer activity of the elements in which these variants reside, and how variants modulate this activity. We constructed a library of 79,380 oligonucleotides spanning the genomic context of 13,230 allelic pairs which we cloned into a vector with a series of configurations to assess position- and promoter-specific regulatory activity. Specifically, we placed inserts both up- and downstream of either a synthetic core promoter (*SCP1*) or a biologically relevant promoter for the human insulin gene (*INS*), then transfected the final library into the 832/13 rat insulinoma cell line to examine effects in pancreatic Î² cells. Overall, around 56% of inserts (n = 44,355/79,380) exhibited significant enhancer activity (FDR INS promoter (n = 370 upstream, 1,251 downstream, 16 common), while only two inserts displayed significant allelic effects across all four configurations. Together, these results indicate that reporter construct design clearly influences assayed reporter activity and hence, use of tissue-relevant promoters involved in disease pathophysiology will be key for comprehensively characterizing the allelic effects of disease-associated variants. Future work will integrate these results with existing genetic and genomic datasets from pancreatic islets and/or Î² cells to explore the regulatory features modified by these variants and prioritize specific elements for follow-up studies.

PrgmNr 1193 - Understanding cell-type-specific drug effects while controlling for genotype

View session detail

Author Block: **F. Wessely**[1], Z. Cader[2], C. Webber[1], StemBANCC consortium; [1]Cardiff Univ., Cardiff, United Kingdom, [2]Univ. of Oxford, Oxford, United Kingdom

Cells derived from human induced pluripotent stem cells (iPSCs) offer the possibility to study cell-type-specific drug effects within a controlled in vitro system. An unbiased and informative approach is to measure and compare the cellular transcriptomic response induced upon exposure to the compound. While there are large-scale drug perturbation databases available offering an important resource for drug discovery and repurposing, response profiles across different cell types are usually confounded by differing genotypes. To control for genotype while varying cell type, 12 different cell types were generated from three iPSC-lines derived from healthy and unrelated donors. Differentiated and undifferentiated cells were exposed for seven hours to a selected panel of 12 small molecule compounds with a broad range of mechanisms of action. Transcriptomic responses after compound or control vehicle exposure was measured by 3â mRNA-sequencing yielding approximately 1,700 gene expression profiles. Overall, we observed a highly variable transcriptional response between different cell types treated with the same compound. However, for the majority of compounds a small core set of common response genes shared between eight or more cell types was found, which also contributed to a common early response on the pathway level. This core set can be as specific as a single response gene, highlighting the power for high-resolution platforms to detect very subtle perturbations. Remarkably, even undifferentiated cells often share a common drug response with differentiated cells. And while in most cases variability of the proposed target gene expression was only moderately correlated with the response signal, we identified cases where other modulators such as specific transporters have a large impact on drug response.

PrgmNr 1194 - Modeling eQTLs at single-cell resolution identifies >2000 eQTLs with differential effects across continuous T cell states

View session detail

Author Block: **A. Nathan**[1,2], S. Asgari[1,2], K. Ishigaki[1,2], T. Amariuta[3], Y. Luo[1], J. I. Beynor[1], L. Lecca[4], M. B. Murray[1], D. Moody[1], S. Raychaudhuri[1,2,5]; [1]Harvard Med. T cells have fluid functional cell states (e.g., cytotoxicity, activation) that we have previously captured at high resolution with canonical correlation analysis (CCA) of single-cell mRNA and protein data (Nathan et al. *Nat Immunol* 2021). These states can trigger autoimmunity or infection response, but to understand genetic effects on such traits, it is essential to define the influence of cell states on gene regulatory variation. However, eQTL studies often obscure high-resolution states by reshaping single-cell data into discrete pseudobulk states. Here, we developed a powerful strategy to define state-dependent eQTLs by modeling the relationship between single-cell gene expression and genetic variants and their interactions with continuous T cell states using a Poisson mixed effects model.We conducted single-cell eQTL analysis of a CITE-seq dataset of over 500,000 memory T cells from an admixed Peruvian cohort to identify 6,511 pan-memory-T cell eQTLs, including previously undescribed eQTLs specific to Peruvian ancestry (e.g., rs9927852 regulating *MAF*). Using CCA-defined T cell states, we modeled eQTL interactions with the linear combination of the top seven continuous axes and found significant state-dependence of over one-third (2,237) of memory-T-cell eQTLs. This enabled us to better identify eQTLs interacting with potentially disease-relevant states like regulatory function: the continuous model not only recapitulated 74% of eGenes with regulatory T cell cluster-dependent effects, but also identified 744 other eGenes associated with continuous degree of regulatory function. Notably, independent eQTLs for the same eGene may have opposing correlations with T cell states, such as for *MDGA1*. After fine-mapping the effect at each locus, state-dependent eQTLs were more enriched in cell-state-specific regulatory regions compared to state-independent eQTLs. We identified many disease-associated variants with state-dependent effects, including autoimmune-associated rs3087243 and *CTLA4*.Our findings show that a single-cell eQTL model is essential to fully leverage single-cell data to study state-specific gene regulation. The regulatory specificity and disease association of these state-dependent eQTLs underscore their biological importance for expanding our understanding of T cell states in health and disease.

PrgmNr 1195 - Sex differences in the expression and genetic regulation of drug metabolism and transporter genes in human liver

Disclosure Block: **Y. Huang:** None.
Human metabolic activity and the elimination of xenobiotics exhibit sex differences. However, little is known about the underlying biology of the sex differences. Understanding the underlying cause of these sex differences can provide critical information in improving human health. Here, we characterized the sex differences in the expression level and genetic regulation of drug metabolism and transporter (DMET) genes, which have been well recognized in transforming both endogenous and exogenous compounds and are critical for human health. We first examine the differential gene expression in human liver using transcriptome data in the Genotype-Tissue Expression (GTEx) project. Among 372 DMET genes evaluated, 20 exhibit differences between the two sexes (FDR CYP3A4, *CYP2C19*, *CYP1A2* exhibit sex-biased expression, which cautions the use of medication between males and females. To identify sex-specific genetic effects on the human liver transcriptome, we then conducted the sex-stratified cis-expression quantitative trait loci (cis-eQTLs) analysis. We identified 71 single nucleotide variants (SNPs) that exhibit sex-specific genetic effects on these DMET genes from 1.5 million associations. To elucidate the phenotypic impact of sex-specific cis-eQTLs, we examined the sex-stratified genome-wide association studies (GWAS) in the UK Biobank. We found, for example, a SNP (rs34109652), associated with high cholesterol in male, also is a male-specific eQTL with *UGT2B17*, a gene that functionally annotated to metabolize testosterone. In contrast, these relationships were not observed in females. These findings allow us to construct a male-specific network of genetic regulation in *UGT2B17*, testosterone, and cholesterol. Lastly, we test sex heterogeneity of cis-DMET variants in 452 drug side-effect and human metabolic-related traits. We detected 40 traits that have at least one SNP shows sex heterogeneity. The most significant different loci are mapped to *ABCG2* associated with a greater risk to gout in males ($\hat{I}^2$-male = 0.028, $\hat{I}^2$-female = 0.0009, p-difference = 2.1e-183). Taken together, our work shows evidence of sex-specific variability in liver gene expression, genetic regulation, and phenotypic impact. Further elucidating the sex different interplay between genetic variants and gene expression of these DMET genes can enable precision medicine both in the identification of different disease etiology and in medication usage among sexes.

PrgmNr 1196 - Identifying disease-critical cell types and cellular processes across the human body by integration of single-cell profiles and human genetics

Disclosure Block: **A.L. Price:** None.

Cellular dysfunction is a hallmark of disease. Genome-wide association studies (GWAS) provide a powerful means to identify loci and genes contributing to disease risk, but in many cases the related cell types/states through which genes confer disease risk remain unknown. Deciphering such relationships is important both for our understanding of disease, and for developing therapeutic interventions.

Here, we introduce a framework for integrating single-cell RNA-seq (scRNA-seq), tissue-specific epigenomic maps and GWAS summary statistics to infer the underlying cell types and processes by which genetic variants influence disease. We analyzed 1.6 million scRNA-seq profiles from 209 individuals spanning 11 tissue types and 6 disease conditions, and constructed three types of gene programs: (i) cell type programs reflecting specific expression in the focal cell type; (ii) disease progression programs reflecting disease-specific differences in gene expression within the same cell type; and (iii) cellular process programs reflecting gene co-expression patterns within and across cell types. We evaluated these gene programs for relevance to disease by transforming them to SNP annotations with tissue-specific epigenomic maps and assessing disease heritability enrichment across 60 diseases and complex traits (average N=297K). We benchmarked our approach using blood cell traits, correctly recovering known cell type-trait pairs such as lymphocytes for WBC count (2.3x excess enrichment, $p = 3x10^{-5}$) and erythrocytes for RBC count (2.2x, $p = 2x10^{-7}$) while producing stronger signals than other approaches.

Results across a broader set of diseases and traits recapitulated known biology and produced novel findings. We highlight three examples. First, the GABAergic neuron cell type program was enriched for major depressive disorder (MDD) (4.0x, $p=1x10^{-4}$). GABAergic neurons regulate the brainâ□□s ability to control stress levels, which is the most prominent vulnerability factor in MDD. Second, the M cell disease progression program was enriched for ulcerative colitis (UC) (2.2x, $p=1.07x10^{-4}$). M cells surveil the lumen for pathogens and play a key role in immune-microbiome homeostasis. As a validation of this result, we determined that M cells expand dramatically in UC colon. Third, a disease-specific complement cascade cellular process program was enriched for multiple sclerosis (MS) (4.9x, $p=5.5x10^{-11}$), consistent with studies showing that complement activity is a marker for MS progression. In conclusion, our framework provides a powerful approach for identifying the cell types and cellular processes by which genetic variants influence disease.

PrgmNr 1240 - Interpreting Genome-Wide Association Studies of Inflammatory Bowel Disease Through the Lens of Single-Cell Sequencing

View session detail

Author Block: **M. Krzak**[1], D. L. Taylor[1], T. Alegbe[1], M. Ghouraba[1], M. Przybilla[1], R. McIntyre[1], T. Raine[2], C. Anderson[1]; [1]Wellcome Sanger Inst., Hinxton, United Kingdom, [2]Addenbrooke's NHS Hosptials, Cambridge, United Kingdom
Disclosure Block: **M. Krzak:** None.
Inflammatory bowel disease (IBD) is a complex disease characterised by chronic inflammation of the digestive tract. Genome-wide association studies (GWAS) have identified 241 risk loci significantly associated with the two common forms of IBD, Crohnâ□□s disease and ulcerative colitis. The vast majority of these risk loci reside in non-coding regions of the genome, and we only know which gene is dysregulated to increase risk of disease for a minority. This knowledge gap makes it difficult to draw insights into disease pathology and identify new candidate drug targets. To improve biological insights from IBD GWAS, we generated single cell RNA-sequencing data from ileal biopsies ascertained from 25 CD patients with active ileal inflammation and 26 non-IBD controls. We identified 49 different cell-types among the ~140K sequenced cells, including all major immune, enterocyte, secretory and mesenchymal populations (excluding granulocytes). Our optimized single-cell dissociation protocol reduced the effects of anoikis, enabling transcriptomes to be accurately profiled and placed along the entire crypt-villus axis, for the first time. We identified 797 unique genes differentially expressed between CD patients and controls, with notable expression differences in stem cell, secretory and enterocyte populations. Genes involved in interferon gamma signalling were enriched among those most frequently dysregulated across cell types. In an attempt to identify which of these expression differences are likely causal of disease, rather than simply a consequence of it, we integrated results from the latest IBD GWAS to assess the extent to which genes captured disease heritability, and in which cell-types. Genes specifically expressed in Tregs, monocytes and IL10-negative monocyte-derived macrophages captured a significant fraction of disease heritability, strongly implicating these cell-types in disease pathogenesis. We investigated which genes were driving these enrichment signals and identified candidate effector genes at many IBD risk loci, with follow-up analyses ongoing. Reassuringly, many confirmed IBD effector genes known to have a role in the normal functioning of these cell-types were found, including *NOD2, IL18RAP, IL23R, NCF4,* and *IL2RA*.

PrgmNr 1241 - Identifying genetic determinants of transcriptional response dynamics at single cell resolution

View session detail

Pique-Regi[1]; [1]Ctr. for Molecular Med. and Genetics, Wayne State Univ., Detroit, MI, [2]Dept. of Biostatistics, Univ. of Michigan, Ann arbor, MI, [3]Dept. of Psychology, Univ. of Georgia, Athens, GA, [4]Dept. of Psychology, Wayne State Univ., Detroit, MI
Disclosure Block: **J. Wei:** None.
Single cell technologies enabled gene expression analysis at single cell resolution to study heterogeneous cell populations across conditions and individuals; yet few computational methods exist to profile response dynamics. Single cell data can capture more fine-grained details by analyzing trajectory dynamics, variance or other higher order moments which are crucial to gain a better understanding of the molecular underpinnings in inter-individual variation in drug response. Here we collected new data and developed a new supervised approach based on the diagonal linear discriminant analysis (DLDA), to construct a robust low dimensional representation of transcriptional response dynamics for each cell-type and treatment. The DLDA axis is then used to identify gene-by-environment interactions in the response dynamics. To evaluate the new method and to compare to other dynamic metrics, we activated peripheral blood mononuclear cells from 96 African American donors with phytohemagglutinin (PHA) or lipopolysaccharide (LPS), and treated with the glucocorticoid dexamethasone (DEX). We performed scRNA-seq for 292,394 cells and identified four major cell types: B-cell, Monocyte, NK-cell and T-cell. We employed negative binomial distribution to calculate RNA expression dispersion. We detected 1,409 genes with variable dispersion, most in monocytes. Effects on dispersion induced by PHA and LPS are negatively correlated with those induced by DEX, which implies that DEX suppresses the activated immune response through effects on both gene expression mean and dispersion. We discovered 504 genetic variants associated with gene expression dispersion, corresponding to 89 unique genes. Our new DLDA approach is able to capture gene expression dynamic changes in response to treatments, and identify different dynamic patterns for gene expression along the response pseudotime (DLDA axis). For example, in the T cells treated with DEX we identified four distinctive expression response patterns: low, decreasing, high and increasing, of which the first two are enriched in response to virus and the TNF pathways. To identify genetic variants that regulate the response to treatments we performed both response eQTL mapping and dynamic interaction eQTL mapping using the response pseudotime. We identified 79 and 59 Genes with response eQTLs for mean and dispersion and 841 genes with DLDA eQTLs, most in T cells. Our results shed light on the dynamics of gene expression in response to stimuli and across individuals. These dynamic processes fundamentally regulate the immune system and may contribute to inter-individual variation in immunological processes and diseases.

PrgmNr 1242 - Opposing evolutionary pressures drive clonal evolution and health outcomes in the aging blood system

The genetic architecture of blood is highly complex with germline polymorphisms, somatic point mutations, and larger chromosomal alterations playing a role in shaping the fitness of the immune cells. Many advances have been made in understanding how the age associated acquisition of point mutations and somatic structural variants (SSVs) in blood, termed Age Related Clonal Hematopoiesis (ARCH) predispose individuals to hematological cancer or cardiovascular disease. Yet, ARCH is commonly observed in healthy individuals and our ability to predict who is at risk of progressing to disease remains limited. Here, we interrogate the mutational and selective pressures within blood to better understand how the full spectrum of somatic changes within an individual impact clonal fitness and disease outcomes. We integrate deep learning and population genetics methods to evaluate the complex interplay of positive and negative selection in deeply sequenced blood samples from 92 individuals who subsequently progressed to blood cancer and 385 healthy controls. We are able to discriminate amongst evolutionary classes with high accuracy (86%) and capture signatures of purifying selection in the majority of individuals. The proportion of passenger to driver mutations appears to be critical in determining if the selective advantage conferred by a driver mutation is able to overwhelm purifying selection acting on passenger mutations thus allowing disease-predisposing clones to rise to dominance. Further, we evaluate how selection shapes the prevalence of large somatic structural variation in blood sampled from 10,000 individuals across over 20 different genetic ancestries. Using dense genotyping arrays, we capture SSVs among 20 populations and find that ARCH attributed to somatic structural variation is twice as frequent as previously reported with up to one in ten individuals harboring a large SSV. We estimate the rate at which SSVs accrue in blood cells and find that selection impacts the size and frequency of SSVs within individual blood populations. To determine the functional impact of clonal mutations on molecular phenotypes, we investigate the relationship between structural variation and the transcriptome. We show that gains, losses and copy number neutral variants impact gene expression distinctly, with stabilising selection shaping the penetrance of copy number alterations on gene expression. Through exploring a range of evolutionary models, our work shows how different classes of selection shape clonal dynamics in both healthy and pre-malignant blood thus enabling us to better understand why certain individuals are at a high risk of malignancy.

PrgmNr 1243 - Trans-ethnic meta-analysis and functional characterization highlights gene regulation underlying the genetic architecture of telomere length

View session detail

Disclosure Block: **R. Keener:** None.
Regulation of telomere length (TL) is critical for human health. Individuals with very short TL exhibit Short Telomere Syndromes, which present as organ failure of bone marrow, liver, or lungs, while individuals with very long TL are predisposed to cancer. Genome-wide association studies (GWAS) have yielded numerous TL-associated loci, but the mechanisms underlying most of these signals remain poorly characterized. Many are non-coding, and the genes and cell types mediating their effects have been unclear. We performed a trans-ethnic meta-analysis including TL GWAS results on a total of 215,273 individuals from European (1,4), Singaporean Chinese (2), South Asian (3,4), African (4), and Hispanic/Latino (4) ancestries and identified 56 genome-wide significant loci. To understand the mechanisms underlying these signals we performed fine-mapping, colocalization analysis with expression quantitative trait loci (eQTLs) from diverse tissues, and functional characterization. Using the European individuals from the meta-analysis, we conducted LD Score regression (LDSC) and identified blood/immune cells as key cell types for TL. One of our novel loci colocalizes with an eQTL for *TCL1A* in GTEx whole blood. TCL1A promotes cellular proliferation through the AKT pathway and overexpression of *TCL1A* is associated with T-cell leukemia and lymphoma. We detected a suggestive interaction between the putative causal SNP and age; stratified analysis by age groups demonstrated that the effect size for this SNP significantly increases with age. We have pursued functional characterization in human cell lines for several genes implicated by colocalization to examine their causal effect on telomere length. Among these, we have found evidence that proteins involved in RNA processing and cellular proliferation affect telomere length in cultured cells. Our results demonstrate mechanisms of novel genes associated with telomere length that will increase our understanding of human telomere length regulation mechanisms.1. Li et al. AJHG, 2020 2. PrgmNr 1244 - Genetic associations from the COVID-19 Host Genetics Initiative highlight biology behind severe symptoms and infection susceptibility

View session detail

Author Block: **J. Karjalainen**, The COVID-19 Host Genetics Initiative; Inst. for Molecular Med. Finland, Helsinki, Finland
Disclosure Block: **J. Karjalainen:** None.
The ongoing SARS-CoV-2 pandemic is a global health concern. Knowledge of human biology underlying susceptibility and severity of COVID-19 post-infection is needed to inform development of therapeutics and better understand individual risk.
The COVID-19 Host Genetics Initiative (HGI) brings together the international human genetics community to generate, share and analyze data to identify the genetic determinants of COVID-19 susceptibility, severity, and outcomes. The initiative repeatedly performs meta-analysis of participating studies.
The HGI's analyses have replicated previous findings and implicated new biologically relevant variants for COVID-19 severity. For example, a TYK2 missense variant associated with protection from autoimmune disease and known to reduce TYK2 activity increases risk of COVID-19 related illness. Variants in the FOXP4 region, more common in non-European populations and showcasing the power of global analysis, that were previously associated with lung adenocarcinoma and ILD also confer risk to severe COVID-19 outcomes.
The HGI's sixth data freeze (spring 2021) consists of 61 studies from 24 countries, including many countries and ancestries typically underrepresented in genetic studies. The meta-analysis includes 9,376 cases of critical illness (respiratory support or death), 25,027 cases with severe symptoms (hospitalization), and 125,548 cases with lab-confirmed or self-reported PCR-confirmed infection.
With the current data we find additional genetic variation associated with severe COVID-19 symptoms. Curiously, rs35705950 at MUC5B, an strong risk variant for idiopathic pulmonary fibrosis, confers protection from severe symptoms (p 5.5e-9, OR 0.89). Other novel associations to severe symptoms include a lead missense variant (rs721917) in surfactant protein SFTPD previously associated to COPD (p 1.9e-8, OR 1.06), and a lead missense variant (rs117169628) in the lung-expressed transporter SLC22A31 which is co-expressed with surfactant protein genes (p=2.5e-8, OR 1.09).
Interestingly, in the current analysis of infected cases, we find a strong protective effect for rs190509934 69 bases from the transcriptional start site of ACE2, a receptor for the spike protein of SARS-CoV-2 (p 3.6e-18, OR 0.69, AF SAS 0.03, AF EUR 0.002), suggesting genetic variation at ACE2 is associated with protection from SARS-CoV-2 infection.
The initiative shows the power of quickly translating genetic data worldwide to biologically relevant findings for follow-up studies and creates an example for future global genetics efforts. The HGI's results are immediately made available at covid19hg.org with no restriction of use.

PrgmNr 1245 - Whole Genome Sequencing (WGS) based Association Study of 21 Inflammation Biomarkers in up to 38,473 Multi-Ethnic Individuals Identifies Novel Signals

View session detail

Author Block: **M. Jiang**[1], S. Gaynor[2], Y. Li[3], L. M. Raffield[4], P. L. Auer[5]; [1]Univ. of North Carolina at Chapel Hill, Chapel Hill, NC, [2]Harvard Univ., Boston, MA, [3]Univ North Carolina, Chapel Hill, NC, [4]UNC - Chapel Hill, Chapel Hill, NC, [5]Univ. of Wisconsin Milwaukee, Milwaukee, WI
Disclosure Block: **M. Jiang:** None.
Chronic inflammation is associated with a variety of diseases and health conditions including diabetes, cardiovascular disease, cancer, and allergic or autoimmune disorders such as asthma and rheumatoid arthritis. Genome-wide association studies (GWAS) have been performed on some inflammation biomarkers, such as c-reactive protein (CRP). But many others remain under-studied and mostly assessed in individuals of European ancestry. The latest CRP GWAS from Raffield et al. examined a multi-ancestry population (n = 23,279) with WGS data from the Trans-Omics for Precision Medicine (TOPMed) program and found evidence for eight distinct associations at the *CRP* locus. Here, we present a larger scale (up to n = 38,473 multi-ancestry samples) WGS-based association study for 21 inflammation biomarkers - CD40, CRP, E-Selectin, ICAM1, IL10, IL18, IL1, IL6, IL8, 8-Epi-PGF2 alpha, Lp-PLA2 activity, Lp-PLA2 mass, MCP1, MMP1, MMP9, MPO, OPG, P-Selectin, TNFa-r1, TNFa, and TNF-r2. We performed linear mixed model based single variant association analysis on variants with a minor allele count >= 10, using the GENESIS tool on the BioData Catalyst platform, adjusting for age, sex, race, study, and 11 genotype principal components. Using a genome-wide significance threshold of $1x10^{-9}$, we identified 44 unique loci, corresponding to 50 locus-trait pairs, for these 21 biomarker traits, ranging from zero locus for CD40, IL10, IL1, IL8, 8-Epi-PGF2 alpha, MMP1, MPO, OPG, TNFa-r1, and TNFa, to 16 loci for CRP, where a locus is loosely defined by genomic location. Conditioning on known variants for each trait if available, we identified the *MMP9* gene locus for MMP9. Surprisingly this association has not been previously reported. We also performed sequential conditional analysis to detect distinct signals at each identified locus, revealing multiple new distinct signals at known loci. Specifically, we detected 34 new distinct signals across 14 loci for 7 biomarkers - 4 new signals for CRP, 4 for P-Selectin, 4 for E-Selectin, 1 for IL6, 10 for ICAM1, 7 for Lp-PLA2 activity, and 4 for Lp-PLA2 mass. For example, for the phenotype P-Selectin, our analyses revealed 3 new distinct signals at the *SELP* locus, in addition to the 2 distinct signals previously reported by Barbalic et al. and Suhrefound et al. (2017); similarly at the *ABO* locus, our P-Selectin analyses identified one new signal distinct from the one previously reported. These results demonstrate the power of increased sample size and increased genetic diversity to identify new associations with inflammatory traits.

PrgmNr 1248 - Potential regulatory effect of the type 2 diabetes associated *KCNQ1* locus on *CDKN1C* expression identified using induced pluripotent stem cell derived pancreatic islet-like cells

View session detail

Author Block: **A. K. Nair**[1], Y. L. Muller[2], M. Traurig[2], J. Sutherland[1], R. G. Nelson[1], C. Bogardus[2], L. Baier[2]; [1]Natl. Inst. of Diabetes and Digestive and Kidney Diseases, NIH, Phoenix, AZ, [2]Natl. Inst. of Diabetes Digestive and Kidney Diseases, NIH, Phoenix, AZ
Disclosure Block: **A.K. Nair:** None.
American Indians from Southwest Arizona have a high incidence rate of type 2 diabetes (T2D). In GWAS for T2D in this population, the top T2D signal maps to intron 15 of *KCNQ1* which resides in a gene-rich region on chromosome 11. This region is highly imprinted (genes expressed solely from maternal or paternal allele) and several genes show tissue and developmental stage-specific imprinting. A previous study found that this T2D signal has a parent-of-origin effect in American Indians, with increased T2D risk and, among normal glucose tolerant individuals, a lower insulin secretion when the risk allele is inherited maternally. The genes in this region include *KCNQ1*, *CDKN1C*, *TRPM5*, *IGF2*, *TH*, *H19*, *INS* and others known to be important for islet development and function and may contribute to T2D. To identify the effector gene and causal SNPs at this locus, we obtained induced pluripotent stem cells (iPSC) derived from blood cells of American Indians who were clinically characterized and their DNA genotyped, and optimized a seven-stage differentiation protocol to generate glucose-responsive pancreatic islet-like cells. Using these iPSCs, we analyzed imprinting for *KCNQ1*, *CDKN1C*, *TRPM5* and *TH* during different stages of differentiation. *KCNQ1* had monoallelic expression during the iPSC stage (day 0), pancreatic progenitor stage (PP, day 10) and endocrine progenitor stage (day 13-16) while there was a gradual loss of imprinting thereafter. *CDKN1C* had monoallelic expression during all stages of differentiation. In contrast, *TRPM5* started losing imprinting during the PP stage and we observed bi-allelic expression during later stages while *TH* had biallelic expression during all stages. RNA sequencing data from different stages of pancreatic islet development identified 20 genes in a 1.2MB region around the T2D signal that are expressed during various stages of islet development. We then used CRISPR/CAS9 to generate isogenic iPSCs with hemizygous deletion in a region predicted to have regulatory function and has 4 SNPs, including the GWAS index SNP, by in-vitro assays and bio-informatic analysis. Differentiating this iPSC identified increased expression of *CDKN1C* during islet development compared to the parental cell line where the biggest difference (~2 fold) was seen on Day 13 while no difference was seen for the other genes, suggestive of a potential regulatory effect. However, we cannot rule of the possibility that the effect on *CDKN1C* expression may be independent of the SNPs. To further validate this, our ongoing work includes generation and differentiation of isogenic iPSCs with targeted edits at multiple SNPs in this region to assess the effect on *CDKN1C* expression.

PrgmNr 1249 - Single-cell gene expression and chromatin accessibility profiling of human pancreatic islets at basal and stimulatory conditions nominates mechanisms of type 1 diabetes genetic risk

View session detail

Author Block: **R. D'Oliveira Albanus**[1], X. Tang[2], H. Taylor[3], M. Erdos[3], N. Narisu[3], F. S. Collins[3], S. Chen[2], S. Parker[1]; [1]Univ. of Michigan, Ann Arbor, MI, [2]Weil Cornell Med., New York, NY, [3]NIH, Bethesda, MD

Disclosure Block: **R. D'Oliveira Albanus:** None.

Type 1 diabetes (T1D) is an autoimmune disease arising from a complex interplay of genetics and environmental factors. The role of beta cells in the genetics of T1D predisposition is not yet fully understood. Here, we investigated how genetics and the pancreatic islet chromatin and transcriptome landscapes mediate T1D risk. We performed single-cell multi-omics (chromatin accessibility and gene expression) profiling of healthy (n=8), pre-T1D (n=2), and T1D (n=1) human islets. Healthy islets (n=3) were additionally profiled under cytokine stimulation (TNF-Î± and IL-1Î²) and CVB4 infection to mimic T1D environmental effects. Joint integration of all datasets (n=34) yielded ~121k cells (~50k snATAC, ~71k scRNA). We identified 10 different cell types, ranging from 1.4% (immune) to 35% (ductal) of all cells. Beta cells (13% of all cells) expression analyses identified sets of differentially expressed genes (DEGs) across healthy/disease/environmental conditions. Environmental DEGs shared pathway-level enrichments with T1D DEGs, indicating molecular concordance between *in vivo* disease state and *in vitro* disease models. Comparing T1D GWAS summary statistics to basal chromatin profiles identified immune cells with the highest enrichment (log enrichment = 2.78; fGWAS), and also identified enrichment in beta, alpha, acinar, ductal, and quiescent stellate cells (log enrichment range 1.53 to 2.12; fGWAS). Differentially accessible regions in pre-T1D beta cells were more enriched for T1D GWAS signals compared to non-differentially accessible regions in the same cell type (log enrichment = 3.43 and 1.75, respectively; fGWAS). A similar trend was observed in alpha and delta cells, indicating a role for non-immune islet cells mediating T1D risk at early disease stages. Functional fine-mapping using chromatin accessibility prioritized three T1D GWAS variants at the *DLK1/MEG3*, *TOX*, and *RASGRP1* loci overlapping beta- or islet-specific regulatory elements. Beta cell allelic effects in these loci were additionally supported by a predictive model, which was validated with allele-specific chromatin accessibility analyses. Condition-specific co-accessibility analyses nominated four effector transcripts at these three loci (gene-SNP distance 0-159 kb). We are currently generating human induced pluripotent stem cells knockout lines and differentiating them into beta cells to functionally validate the nominated genes and regulatory elements. We plan to present these validation results during the meeting. Together, our work reveals the environmental context specificity of T1D genetic risk mediated through endocrine islet cells.

PrgmNr 1250 - The Kidney genome atlas reveals a novel locus on chromosome 14 associated with adult proteinuric kidney diseases

Chronic Kidney disease (CKD) affects 1 in 9 people worldwide. There is a high unmet need for drugs that extend and restore kidney function, because dialysis and organ transplantation carry substantial economic and psychological burden. To foster drug development of genetically validated targets, we have created the Kidney Genome Atlas (KGA) by assembling ~23,000 whole genomes from 2,832 kidney disease cases including proteinuric kidney disease cases such as Focal segmental glomerulosclerosis (571 cases), minimal change disease (244 cases), nephrotic syndrome (196 cases) and idiopathic proteinuria (1,123 cases) and 19,804 controls. Following the gnomAD pipeline, we implemented a rigorous quality control procedure to obtain a high confidence dataset for downstream analyses of proteinuric kidney diseases. Ancestries were inferred genetically based on a k-NN model trained on 1,000 Genomes data which resulted in 597 cases and 10,127 controls of European (EUR) ancestry, 513 cases and 3,805 controls of African (AFR) ancestry, and 290 cases and 754 controls of Latino/Admixed American (AMR) ancestry for association testing. Meta-analysis of common variants across ancestries showed minimal impact of potential confounders, such as ancestry or sequencing center differences (lambda=1.03). We identified a novel locus on chromosome 14 (rs11160484; effect size = -0.42, P = $2.8*10^{-8}$) associated with proteinuric kidney disease. In addition, we confirmed the well-known association of APOL1 risk haplotypes (G1/G1, G2/G2 or G1/G2; effect size = 0.50, P = $2.4*10^{-9}$, under recessive model) in the AFR cohort. LD-score regression analysis revealed a trend towards a weak positive genetic correlation (rg = 0.097, 90% CI [0.010, 0.18]) between proteinuric kidney diseases and CKD defined by estimated glomerular filtration rate or eGFR (Wuttke et al, 2019). Using summary statistics from our EUR dataset, we estimated the SNP heritability of proteinuric kidney diseases at 0.15 (95% CI [0.095, 0.20]), suggesting that there may be many more genetic contributions that are yet to be discovered. These findings advance our understanding of the genetic architecture of proteinuric kidney diseases and highlight an opportunity for novel therapies and patient stratification.

PrgmNr 1251 - Computational and functional gene prioritization from a saturated GWAS of adult height in >5 million people

Adult height, the classical polygenic trait, is the result of childhood skeletal growth. A prior abstract described the GIANT consortium GWAS of height, now up to >5 million individuals including >1 million of non-European ancestry, that has identified >12,000 approximately independent signals of association. In European-ancestry individuals, these signals account for ~40% of variation in height, ~80% of the heritability attributable to common variation (h^2_{SNP}). Across multiple ancestries, >90% of h^2_{SNP} maps to the ~23% of the genome that lies within 35 kb of these signals. We have now taken computational and experimental approaches to prioritize genes likely underlying the height associations. We used DEPICT, PoPS, and MAGMA, separately and in combination, to prioritize genes from height GWAS. The combination of all 3 methods yielded a set of 356 genes; these scored better than genes prioritized by fewer methods, as assessed by multiple metrics. These include per-SNP heritability (LD score regression normalized Ï=4.38, 95% CI=2.35-6.41); in addition, 54% of the 356 genes were nearest to a GWAS signal and 16% were âOMIM genesâ that underlie monogenic skeletal growth disorders. We also analyzed expression data relevant to growth plate chondrocytes, a key cell type for skeletal growth. First, we compared gene expression for microdissected samples from the 3 main layers of the mouse growth plate: round, flat, and hypertrophic. For each gene, we computed specificity for each layer as (layer expression/total expression) and also MAGMA gene-based *p* values from height GWAS. Specificity in all 3 layers was significantly correlated with GWAS *p* values; this was driven by genes with specificity for the least differentiated layer (round cells, *p*-6 conditioned on other layers). We also generated expression data from an *in vitro* murine model of chondrocyte differentiation and showed that specificity for expression earlier in differentiation was correlated with GWAS *p* values (*p*-5, conditioned on late expression). Finally, we used this *in vitro* system to perform a pooled CRISPR screen to identify genes that, when perturbed, accelerate or delay differentiation (assayed by cell surface CD200, which appears late in differentiation). The 10 genes that most strongly accelerate maturation when perturbed include OMIM genes (*EED*, *EZH2*, *SUZ12*), known regulators of growth plate maturation (*PTCH1*, *SUFU*), and genes prioritized by all 3 computational methods (*SUFU*, *DOT1L*, *SMAD6*). In summary, a combination of GWAS, experimental data and computational approaches identifies genes with multiple lines of evidence for regulating skeletal biology and height.

PrgmNr 1252 - Genetic and functional characterisation of the Melanocortin 3 Receptor (*MC3R*) links nutritional state to growth, body composition and the onset of puberty

The state of somatic energy stores in metazoan organisms is communicated to the brain, which regulates key aspects of behaviour, growth, nutrient partitioning and development. The central melanocortin system is an important component of this, with the Melanocortin 4 Receptor (MC4R) controlling appetite, food intake and energy expenditure. Humans lacking *MC4R* are obese, hyperphagic and have reduced basal energy expenditure. Melanocortin 3 Receptor (MC3R) is the only other melanocortin receptor that is predominantly expressed in the brain. Rare functionally compromised heterozygous variants in *MC3R* have been reported in humans, however no clear consistent phenotype has been reported.

We aimed to establish the role of MC3R in human physiology using a reverse genetics approach. We identified naturally occurring coding mutations in *MC3R* in 3 population-based cohorts - Avon Longitudinal Study of Parents and Children (ALSPAC), UK Biobank and Genes & Health using exome sequencing and array-based genotyping. We functionally studied these mutations *in vitro* to identify those resulting in functional impairment of the receptor and subsequently studied the relationship of these variants with human phenotypes. We further characterised the population of *Mc3r* expressing neurons in the mouse hypothalamus using single cell RNA-sequencing (scRNA-seq) and RNA-scope.

We found that humans who carry characterised loss of function mutations in MC3R, including a single homozygote consanguineous individual, have a later onset of puberty. These individuals also had reduced linear growth, having reduced height in both childhood and adulthood. The carriers of these mutations had reduced lean mass and lower circulating IGF-1 levels, an indirect measure of growth hormone.

scRNA-seq of the mouse hypothalamus and RNA-scope show that within the hypothalamus *Mc3r* expression is enriched in sub-populations of neurons expressing either Growth hormone-releasing hormone (*Ghrh*) or Kisspeptin/Tachykinin B (*Kiss1*/*Tac2*) which regulate growth and reproductive function, respectively.

Across the animal kingdom, nutritional status is a critical determinant of linear growth and the timing of reproductive maturity. MC3R appears to play an important role in linking signals of caloric sufficiency that act through POMC expressing neurons to the central control of growth and reproduction.

PrgmNr 1253 - Causal signatures in skeletal muscle single nucleus multi-omics data across 287 individuals

View session detail

Skeletal muscle is the largest organ, by weight (>40%) and relevant for several polygenic traits including insulin resistance and type 2 diabetes (T2D). Identifying genetic mechanisms orchestrating these traits requires pinpointing the set of causal variants, the target genes these variants regulate, and the specific cell populations in which they function. Here, we generated single nucleus chromatin (snATAC) and transcription (snRNA) profiles across 287 frozen human skeletal muscle biopsies. We integrated 414,982 nuclei across the modalities with LIGER and identified 13 cell types, ranging in abundance from 38.1% (type 1 fiber) to 0.5). Using summary-based mendelian randomization (SMR) techniques, we inferred causality between chromatin accessibility and gene expression. We identified 6,190 caQTL peaks (caPeaks) that were causal on 1,299 eQTL genes (eGenes), and 1,277 eGenes that were causal on 6,236 caPeaks (SMR 5% FDR, pHEIDI > 0.05). caPeaks causal on eGenes are further from the gene TSS than target caPeaks (Wilcoxon rank sum test P=9e-4), suggesting that distal caPeaks are enhancers that causally affect gene expression whereas proximal caPeaks can be modulated by the transcription machinery near gene TSSs. We performed colocalization and chain-of-causality inferences of e/caQTL with various genome-wide association study (GWAS) signals across the five cell types. Of 100 T2D GWAS signals that colocalize with caQTL, 48 are cell type-specific, highlighting the importance of sn-caQTL maps for GWAS functional studies. We identified 287 caPeaks that mediated effects on 129 eGenes which then mediated effects on T2D. Studying COVID19 GWAS, we observed that the IFNAR2 signal colocalized with a caQTL in the region, and eQTLs for both IFNAR2 and the neighboring IL10RB cytokine receptor genes. The caQTLs are causal on both the eQTLs that are causal on COVID19. These results inform the causal chain of molecular events that influence the complex genetic regulatory architecture of skeletal muscle at high-resolution epigenomic, transcriptomic, and cell state scales.

Asthma is a complex and multifactorial disease that affects millions of people worldwide and varies in prevalence by an order of magnitude across geographic regions and diverse populations. However, the extent to which genetic variation contributes to these disparities is unclear, as studies probing the genetics of asthma have been primarily limited to populations of European descent. To expand our understanding of the genetic factors underlying asthma risk in different ancestral populations, we conducted the largest genome-wide association study of asthma to date (N cases=153,763 and N controls=1,647,022) via meta-analysis across 18 biobanks with harmonized phenotype definitions and spanning multiple countries and genetic ancestries, collectively called the Global Biobank Meta-analysis Initiative (GBMI). This meta-analysis discovered 180 independent genome-wide significant loci (p

Genome-wide polygenic risk scores (PRS) are reported to have higher performance than standard genome-wide significant PRS across numerous traits. We evaluated the ability of genome-wide PRS to evaluate prostate cancer risk compared to our recently developed and highly predictive multi-ancestry PRS of 269 established prostate cancer risk variants. Genome-wide PRS approaches included LDpred2, PRS-CSx, and EB-PRS. Models were trained using the largest and most diverse prostate cancer GWAS to date of 107,247 cases and 127,006 controls, which was previously used to develop the multi-ancestry PRS of 269 variants. Resulting models were tested in independent samples of 1,586 cases and 1,047 controls of African ancestry from the California Uganda Study and 8,045 cases and 191,835 controls of European ancestry from the UK Biobank. Among the genome-wide PRS approaches, LDpred2 had the best performance, with AUCs of 0.649 (95% CI=0.627-0.670) in African and 0.819 (95% CI=0.815-0.823) in European ancestry men. African and European ancestry men in the top PRS decile relative to men in the median 40-60% PRS category had odds of prostate cancer of 3.29 (95% CI=2.47-4.40) and 2.99 (95% CI=2.78-3.23), respectively. However, the PRS constructed using 269 variants had significantly larger AUCs in both African (0.679, 95% CI=0.659-0.700) and European ancestry men (0.845, 95% CI=0.841-0.849), with African and European ancestry men in the top PRS decile having larger odds of prostate cancer (3.53, 95% CI=2.66-4.69 and 4.20, 95% CI=3.89-4.53, respectively). We are currently further validating these findings in diverse men from Million Veteranâ□□s Program. This investigation suggests that genome-wide PRS may not improve the ability to distinguish prostate cancer compared to a genome-wide significant PRS.

PrgmNr 1258 - Genetic association of phenotypes derived by self-supervised deep learning of retina fundus images reveals new genes for eye development

Although genome-wide association studies (GWAS) have achieved great success and identified thousands of genetic associations, phenotypes of most existing GWAS studies are predefined. While these phenotypes encode valuable biomedical knowledge, they are also biased by current clinical practice and epidemiological studies. Also as phenotype code is greatly simplified, it is often not sufficient to capture the complexity of human physiology and pathology in their entirety. Fortunately, with the medical record becoming increasingly digitized, there are new opportunities to derive phenotypes beyond expert-curation, which would avoid human bias and discover new phenotypes that are previously missed. Here, leveraging breakthroughs in self-supervised deep representation learning, we propose a new approach for phenotype discovery from medical images. We use a contrastive loss function over an Inception V3 architecture to learn a representation that captures the inherent image features of individuals. Using vessel segmentation masks generated from retina fundus images as inputs, we designed a phenotyper neural network model that generates 128 phenotypes representing retinal vasculature. After training on 40,000 images from EyePACS, our model generated phenotypes from 130,967 images of 65,629 British White participants in the UK Biobank. A GWAS of these vasculature phenotypes identified 34 independent loci, at least 5 are associated with vessel features. Mouse knockout experiments verified the role of the WNT7B gene, a newly found locus, in retinal vessel development. Our results establish a new framework of unsupervised image based genome wide genotype phenotype association studies (iGWAS). Our framework would expand the repertoire of GWAS phenotypes and enable discovery of new biology.

PrgmNr 1259 - Fine-mapping across diverse ancestries drives the discovery of putative causal variants underlying human complex traits and diseases

Genome-wide association studies (GWAS) of human complex traits or diseases often implicate genetic loci that span hundreds of significant genetic variants. However, these loci may only contain one or a handful of causal variants. Statistical fine-mapping reï¬nes a GWAS locus to a smaller set of likely causal variants (credible set). Since non-causal variants have marginally different effects across populations where LD differs, capitalizing on the genomic diversity across ancestries holds the promise to further improve the resolution of fine-mapping. However, to date, cross-population fine-mapping efforts have been limited, partly due to the lack of statistical methods that can appropriately integrate data from multiple ancestries. Building on Sum of Single Effects (SuSiE), a single-population fine-mapping model, we have developed SuSiEx, an accurate and computationally efficient method for trans-ancestry fine-mapping. SuSiEx assumes that causal variants are largely shared across populations, while allowing for varying variant effect sizes across populations. Our model can integrate data from an arbitrary number of ancestries, explicitly models population-specific LD patterns, accounts for multiple causal variants in a genomic region, and can be applied to GWAS summary statistics without access to individual-level data. We showed, via simulation studies, that compared with fine-mapping 100K European samples, integrating 50K European and 50K African samples using SuSiEx enabled fine-mapping of more association signals, and dramatically increased the resolution of credible sets. Comparing with PAINTOR, SuSiEx had a 37% reduction in the median size of credible sets and a 54% increase in the number of high Posterior Inclusion Probability (PIP) variants. We applied SuSiEx to 25 quantitative traits that are available from both the Taiwan Biobank (TWB, n = 92,615) and UK Biobank (UKBB, n = 361,194) to fine-map genetic loci reaching genome-wide significance. Compared with single-population fine-mapping in UKBB, cross-ancestry fine-mapping significantly reduced the size of credible sets and increased the PIP of the most probable variant. We additionally applied our method to schizophrenia GWAS summary statistics of East Asian and European ancestries. Compared with the published fine-mapping results from PGC using FINEMAP on the same data, SuSiEx reduced the size of credible sets in 70% of the fine-mapped loci. Manual inspection confirmed that SuSiEx provided more sensible results in many loci. As the accumulation of GWAS results from different ancestries, the application of our method will be much promising.

PrgmNr 1260 - Analysis across Taiwan Biobank, Biobank Japan and UK Biobank identifies hundreds of novel loci for 36 quantitative traits

Disclosure Block: **Y. Lin:** None.
Genome-wide association studies (GWAS) have identified tens of thousands of genetic loci associated with human complex traits and diseases. However, the majority of GWAS were conducted in individuals of European (EUR) ancestry. Failure to capture global genetic diversity has limited biological discovery and impeded equitable delivery of genomic knowledge to diverse populations. Here we performed genome-wide analysis on 102,900 individuals across 36 human quantitative traits in the Taiwan Biobank (TWB), a major biobank effort that broadens the population diversity of genetic studies in East Asia (EAS). We identified 1,907 independent genome-wide significant loci (P-value -8) across the 36 traits, among which 1,287 loci survived Bonferroni correction for the number of traits tested (P-value -8/36). The number of genome-wide significant loci per trait ranged from 1 for forced expiratory volume in one second (FEV1) and FEV1 to forced vital capacity (FVC) ratio (FEV1R), to 211 for height (HT). We estimated the SNP-based heritability (h^2g) for each trait, which ranged from 0.009 (FEV1R) to 0.384 (HT), and pairwise genetic correlations between these traits, which identified clusters of highly genetically correlated traits. Of the 1,907 genome-wide significant loci, 1,615 were fine-mapped to a total of 1,972 credible sets, each representing an independent association signal. Out of the 1,972 credible sets, 232 were mapped to a single variant with posterior inclusion probability (PIP) > 95%, among which 24 were missense variants. Leveraging GWAS summary statistics from Biobank Japan (BBJ) and UK Biobank (UKBB), we found that the genetic architecture of the quantitative traits examined was largely consistent within EAS and between EAS and EUR populations. Integrating TWB and BBJ GWAS identified a total of 2,975 genetic loci, among which 979 had not been reported in previous biobank studies. We also examined whether polygenic risk scores (PRS) of biomarkers can be used to predict the risk of common complex disease, and demonstrated the potential utility of biomarker GWAS in predicting disease risk (e.g., type 2 diabetes) and the promise of multi-trait cross-population polygenic prediction. Our novel findings represent a major advance in diversifying GWAS samples and the characterization of the genetic architecture of human complex traits in EAS populations. Future endeavors on increasing the sample size and phenotype coverage in TWB, and improving cross-biobank data harmonization will further facilitate genomic discovery.

PrgmNr 1261 - The effects of demographic-based selection bias on GWAS results in the UK Biobank

Genome-wide association studies (GWASs) are almost always based on a non-random sample of the underlying population, as obtaining very large sample sizes, rather than ensuring such samples are representative, has been key to their success. Selection bias in estimated genetic associations, including how it varies across traits, is poorly understood. A sample of particular interest is the widely used UK Biobank (UKB). Because of the need for very large samples, the UKB is included in almost all large GWASs as one of the largest cohorts. In addition, UKB's subsample of genotyped siblings (UKBSIB) has become a crucial resource for estimating genetic effects free of environmental confounding. Using nationally representative UK Census microdata as a reference, we document substantial non-random selection into the UKB, and even stronger for UKBSIB: individuals in the UKB and UKBSIB are more likely to be female, higher educated, and older, compared to the underlying population that received an invitation. We also show that this non-random selection leads to significant selection bias in associations between various demographic and health-related traits estimated in the UKB. We then estimate probabilities of UKB participation for each UKB participant to estimate selection-corrected GWASs for multiple traits using inverse probability weighting. Based on preliminary analyses for the top 5,000 SNPs associated with BMI, education, and height, respectively, we show that the extent to which selection-corrected GWAS results differ from those of regular GWASs is trait-specific. Genetic associations for educational attainment and BMI are the most altered after correcting for volunteer bias, whereas associations for height remain relatively unaffected. For educational attainment, 12.6% of our estimated SNP effects flip sign after correcting for selection bias, suggesting that current GWAS methods are not sufficiently robust. We will extend these analyses by investigating more phenotypes, conducting regular and inverse probability weighted GWASs in the UKB that incorporate all available SNPs, and comparing results. Our findings will be useful for understanding the extent to which a particular phenotype is prone to selection bias in GWAS, and our correction method provides an alternative when population-representative cohorts are not available.

PrgmNr 1264 - *HDAC9* structural variants disrupting *TWIST1* transcriptional regulation lead to craniofacial and limb malformations

Structural variants (SVs) such as insertions, deletions duplications, translocations and inversions, are associated with human disorders. SVs can affect protein coding sequences as well as gene regulatory elements. However, SVs disrupting protein coding sequences that also function as cis regulatory elements remain largely uncharacterized. Here, we show that craniosynostosis patients with SVs containing the Histone deacetylase 9 (HDAC9) protein coding sequence are associated with disruption of *TWIST1* regulatory elements that reside within *HDAC9* sequence. Using epigenetic marks and *in vivo* enhancer assays, we characterized six craniofacial *TWIST1* enhancers located in the *TWIST1-HDAC9* locus. Based on SVs within the *HDAC9-TWIST1* locus, we defined the 3' *HDAC9* sequence (~500Kb) as a critical Twist1 regulatory region. By deleting Twist1 enhancers within the Hdac9 protein coding sequence in mice (eTw5-7$^{Del/Del}$), we showed that *Twist1* expression was decreased, resulting in smaller sized and asymmetric skull and polydactyly. Furthermore, deletion of a Ctcf site (Ctcf$^{Del/Del}$) within the *Hdac9* protein coding sequence, disrupted *Twist1* enhancer-promoter interactions and altered Twist1 expression which led to deformed skull and hindlimb polydactyly, resembling Twist1+/- mouse phenotype. Deletions of Twist1 regulatory elements altered the distinct anteriorposterior expression patterns of Shh pathway genes, including *Hand2* and *Alx4*. Using UMI-4C, we demonstrated that both enhancers and Ctcf site regions interact with *Twist1* promoter region. These interactions are depended on the presence of both regulatory regions, indicating a specific chromatin conformation of *Hdac9* in regulating *Twist1* expression. Finally, a large inversion of the entire *Hdac9* sequence (Hdac9$^{INV/+}$) that does not disrupt *Hdac9* expression but rather repositions *Twist1* regulatory elements showed a decrease in Twist1 expression that led to subtle craniofacial phenotype and hindlimb polydactyly. Thus, our study elucidated essential components of *TWIST1* transcriptional machinery that reside within the *HDAC9* sequence, suggesting that SVs, encompassing protein coding sequence, such as HDAC9, could lead to a phenotype that is not attributed to its protein function but rather to a disruption of the transcriptional regulation of a nearby gene, such as TWIST1.

Background: Despite successes in the investigation of *de novo* mutations (DNMs) in the etiology of some birth defects (autism, congenital heart defects), only a limited number have been reported for nonsyndromic cleft lip with or without cleft palate (NSCL/P), the most common craniofacial birth defect. To identify high impact DNMs controlling risk of NSCL/P, we conducted whole genome sequencing (WGS) analyses of case-parent trios from an understudied population.

Method: A total of 150 nsCL/P African case-parent trios were sequenced for this study. Each trio comprises an affected child (with nsCL/P) and unaffected parents and were recruited from Ghana and Nigeria. Saliva samples were collected from these individuals and their genomes were sequenced from extracted DNA. After quality control, we screened the genomes of the remaining 130 trios for high impact DNMs possibly contributing to risk of nsCL/P. We used bioinformatic prediction tools to identify those mutations predicted to damage and affect the protein structures and functions.

Results: We identified 110 potential pathogenic DNMs. These include novel loss of function (LOF) variants in *TTN, MINK1* and *ARHGAP10* genes; and missense variants in *DHRS3, TULP4, SHH, TP63, FKBP10, ACAN, RECQL4* and *KMT2D*. These variants are predicted to be damaging and are among the most deleterious (top 1%) mutations in the human genome. Experimental evidence in published works showed *TTN, SHH, TP63, FKBP10, ACAN, RECQL4* and *KMT2D* genes are involved in facial development and are involved in the etiology of syndromic CL/P. While *DHRS3, SHH* and *TP63* contribute to the risk of nsCL/P. Interestingly, our *SHH de novo* variant p.Ser362Leu has been reported to cause holoprosencephaly 3 (HPE3), a syndromic form of CL/P. Damaging mutations in the *DHRS3* gene affects retinoic acid signaling during embryogenesis which causes cleft palate. Association studies have identified *TULP4* as a potential cleft candidate gene, while *ARHGAP10* interacts with *CTNNB1* to control WNT signaling. *MINK1* plays a role in cell-cell adhesion and migration, and causes abnormal tooth morphogenesis in mice. Our gene-set enrichment analysis identified additional genes that are important in palatal development. These include *DLX6* and *EPHB2* and they both harbored novel damaging DNMs.

Conclusion: Our WGS adds to the available data on Africa population (a historically underrepresented

group in genetics study) and has identified novel pathogenic *de novo* variants that may contribute to the developmental pathogenesis of NSCL/P. These findings demonstrate the power of WGS analysis of trios for discovering potential pathogenic variants.

PrgmNr 1266 - Identification of novel molecular pathways in syndromic orofacial clefting

View session detail

Author Block: **K. Wilson**[1], D. Newbury[2], U. Kini[1,3]; [1]Oxford Ctr. for Genomic Med., Oxford Univ. Hosp. NHS Fndn. Trust, Oxford, United Kingdom, [2]Faculty of Hlth.and Life Sci., Oxford Brookes Univ., Oxford, United Kingdom, [3]Spires Cleft Ctr., John Radcliffe Hosp., Oxford, United Kingdom
Disclosure Block: **K. Wilson:** None.
Background: Syndromic orofacial clefting (OC) accounts for 30% of cleft lip and/or palate. An updated review of molecular pathways associated with syndromic OC is unavailable. The Deciphering Developmental Disorders (DDD) study provides a source of quality data to assemble this information. The Genomics England PanelApp is a publicly available database of curated virtual gene panels and is a valuable reference tool for genes associated with syndromic OC.
Aim: To investigate molecular pathways associated with syndromic OC by reviewing the results of exome sequencing (ES) and exon-arrayCGH in a large cohort of patients with syndromic OC.
Methods: Patients with the HPO terms â□□cleftâ□□ and â□□bifid uvulaâ□□ were identified through a Complementary Analysis Project within the DDD study. Possible diagnostic variants were identified by automated variant filtering and manual review. Single nucleotide variants (SNVs) within known disease-causing genes and copy number variants (CNVs) were classified according to the ACMG guidelines, the ACGS Best Practice Guidelines and consensus opinion. Functional analyses of identified genes were performed within STRING, Cytoscape and MCODE. Associated phenotypes were explored using the International Mouse Phenotyping Consortium. Gene expression analyses were performed within GENE2FUNC.
Results: 603/13612 (4.4%) patients were identified of whom 453/603 (75.1%) had trio ES. Pathogenic (P) or likely pathogenic (LP) variants were identified for 220/603 (36.5%) patients in 124 known disease-causing genes with *SATB2* the most common (16/220, 7.3%). 23/220 (10.5%) patients had a P or LP CNV of partial or full contribution to their phenotype. 35/124 genes fulfilled criteria to be added to the PanelApp â□□Cleftingâ□□ panel, increasing the size of the current panel by 23.8%. Gene ontology and pathway analyses identified novel molecular networks for syndromic OC which were distinct from those in non-syndromic OC. Gene expression analyses and investigation of knockout phenotypes also showed a distinction between syndromic and non-syndromic OC. Pathway and expression analyses showed an enrichment of genes associated with intellectual disability (FDR=2.8x10-33), RNA metabolism (FDRConclusion: This study demonstrates the utility of ES and CNV analysis for patients with syndromic OC and increases the diagnostic rate for this patient cohort. It also highlights novel molecular pathways specific to syndromic OC and enhances our understanding of lip and palate development.

PrgmNr 1267 - RERE deficiencycontributes to the development of orofacial clefts in humans and mice

View session detail

Author Block: **B-J. Kim**[1], H. Zaveri[1], V. K. Jordan[2], P. N. Kundert[1], T. M. Scott[3], J. Carmichael[4], D. A. Scott[5]; [1]Molecular & Human Genetics, Baylor Coll. Med., Houston, TX, [2]Baylor Coll. Med., Houston, TX, [3]Brigham Young Univ., Provo, UT, [4]Northampton Gen. Hosp., Cliftonvile, United Kingdom, [5]Baylor Coll. Med, Houston, TX
Disclosure Block: **B. Kim:** None.
Deletions of chromosome 1p36 are the most common telomeric deletions in humans and are associated with an increased risk of orofacial clefting. Deletion/phenotype mapping, combined with data from human and mouse studies, suggests the existence of multiple 1p36 genes associated with orofacial clefting including *SKI*, *PRDM16*, *PAX7*, and *GRHL3*. The arginine-glutamic acid dipeptide (RE) repeats gene (*RERE*) is located in the proximal critical region for 1p36 deletion syndrome and encodes a nuclear receptor co-regulator. Pathogenic *RERE* variants have been shown to cause neurodevelopmental disorder with or without anomalies of the brain, eye, or heart (NEDBEH), but have not been shown to cause orofacial clefting. Here we report the first individual with NEDBEH to have a cleft palate. We confirm that RERE is broadly expressed in the palate during mouse embryonic development, and we demonstrate that the majority of RERE-deficient mouse embryos on C57BL/6 background have cleft palate. We go on to show that ablation of *Rere* in cranial neural crest cells, mediated by a Wnt1-Cre, leads to delayed elevation of the palatal shelves and cleft palate, and that proliferation of mesenchymal cells in the palatal shelves is significantly reduced in $Rere^{flox/flox}$;Wnt1-Cre embryos. We conclude that loss of RERE function contributes to the development of cleft palate in individuals with proximal 1p36 deletions and NEDBEH, and that RERE expression in cranial neural crest cells and their derivatives is required for normal palatal development.

PrgmNr 1268 - Single cell transcriptomics-directed investigation of *de novo* mutations and rare inherited genetic variants in cleft lip and palate

View session detail

Disclosure Block: **K. Robinson:** None.
Cleft lip and palate (CL/P) is one of the most common congenital anomalies. The etiology of CL/P is complex with both environmental and genetic risk factors. While previous studies have identified several CL/P-associated genes or regions, only a fraction of all cases can be clearly attributed to specific genes. Additional genetic causes may be due to rare inherited variants (RIVs) or *de novo* mutations (DNMs) in simplex CL/P cases. To investigate this further, we performed single cell RNA sequencing on epithelial cells of the lambdoidal junction (Î») from gestational day (E)10.5 wildtype mouse embryos at the point of upper lip fusion. We identified six cell clusters, and using the top 150 differentially expressed genes from each, we carried out targeted evaluation of both DNMs and RIVs in whole genome sequences from 756 CL/P case-parent trios of Asian, Latino, and European ancestry. For each cluster we analyzed enrichment of nonsynonymous, loss-of-function (LOF), and protein altering (nonsynonymous + LOF) DNMs. Of these, the olfactory epithelium cluster was enriched for protein altering (p=0.005) and the periderm cluster was enriched for nonsynonymous variants (p=0.005). We then evaluated exonic RIVs as defined by a minor allele frequency of IRF6, *TFAP2A*, and *GRHL3*, all of which contained both DNMs and RIVs, suggesting other genes identified via this method may also be significant in risk for CL/P. Although all clusters were evaluated, the Î»-fusion effector cluster was of specific interest given its critical role in prominence fusion during normal craniofacial development. This cluster harbored variants of interest in 31 genes, a higher percentage than other clusters (23% vs. 9-19%). Further, gene ontology revealed a group of 14 genes enriched for terms related to transcription and, interestingly, both negative regulation of epithelial cell proliferation (FDR 0.015) and positive regulation of mesenchymal cell proliferation (FDR 0.049). Among this group was transcription factor *ZFHX3*, which contained the most variants including loss-of-function DNMs and RIVs; thus, it remains of high interest for novel CL/P risk association. This investigation illustrates the benefit of integrating genomic technologies to prioritize and identify novel genetic associations with risk to CL/P. Continued evaluation focused on gene interactions and pathways represented by these variants may further elucidate CL/P etiology.

PrgmNr 1269 - A novel 3 MB deletion on 6p24 removes distant neural-crest enhancers controlling *TFAP2A* resulting in mild Branchiooculofacial syndrome in a multiplex family with orofacial clefting

View session detail

Author Block: **T. Yankee**[1], C. Willett[2], K. Child[1], A. Petrin[3], A. Wilderman[4], T. Cox[5], T. Roscioli[6], L. Moreno-Uribe[3], E. J. Leslie[7], J. Cotney[8,9]; [1]Dept. of Genetics and Genome Sci., UConn Hlth.Graduate Program in Genetics and Dev.al Biology, Farmington, CT, [2]Emory Univ. Sch. of Med. Disclosure Block: **T. Yankee:** None.

In a previous effort to characterize large copy number variants as genetic risk factors for orofacial clefting (OFC) following a genome-wide association study, we identified a novel 3 Mb deletion on 6p24 in three affected members of the same family from Colombia. The reported pedigree had a dominant inheritance pattern and included 5 individuals with OFC. All affected family members carried the deletion, which was inherited from the probandâ□□s unaffected grandmother. Supporting the pathogenicity of this deletion, exome sequencing of this family found no segregating single nucleotide variants in OFC candidate genes. The 3Mb deleted region included 12 genes, none of which are strong OFC candidates and a 840 kb gene desert. We observed that the 3â□□ breakpoint of this deletion occurred within a large non-coding region directly adjacent to the important developmental transcription factor *TFAP2A*. *TFAP2A* loss of function is one of the primary genes associated with Branchiooculofacial syndrome (BFOS) that includes OFC in conjunction with branchial and ocular abnormalities. Affected members of this family display OFC, broad nasal root, and slight hypotelorism characteristic of BFOS. Cell type-specific enhancers in the genomic region directly flanking *TFAP2A* have been previously implicated in a subset of BOFS patients, however these enhancers remain intact in this family.We hypothesized that this deletion contains additional regulatory elements of *TFAP2A*, resulting in attenuated expression of this gene and a milder form of BOFS. To address this hypothesis and predict enhancer-gene interactions at this region, we used an activity by contact model (ABC-Enhancer) to integrate ChIP-seq based chromatin state annotations, chromosome conformation (Hi-C), and gene expression (RNA-Seq) from primary human craniofacial tissues and a culture model of cranial neural crest cells (CNCCs). We identified closely clustered, strong enhancer states that were predicted to have interactions with *TFAP2A* over a distance of greater than two megabases. To validate these predictions *in vivo*, we used CRISPR-Cas9 in human embryonic stem-cells to create homozyguous deletions of a 25kb region encompassing the strong enhancer segments. We differentiated these lines to CNCCs and compared gene expression and proliferative capacity to wildtype. We found this region is essential for cell viability during CNCC differentiation and differential gene expression analysis revealed substantial effects on *TFAP2A* expression. In summary, we identified a region within the inherited deletion that regulates *TFAP2A* gene expression and could contribute to the mild BOFS phenotype in this family.

PrgmNr 1272 - Increasingâ¯Detection ofâ¯Familial Hypercholesterolemiaâ¯in an Academic Medical Center:â¯Theâ¯Familial Hypercholesterolemia Identification Registryâ¯(FHIRE).â¯

View session detail

Author Block: **A. Miller**, S. Nigbur, I. J. Kullo; Mayo Clinic, Rochester, MN
Disclosure Block: **A. Miller:** None.
Background:â¯Familial Hypercholesterolemia (FH) is a common genetic disorder with a prevalence of 1:2201. FH is a Tier 1 genetic disorder, and early detection and treatment of FH has potential to positively impact public health2.â¯ There is no universal screening mechanism for FH in the United States, and it is estimated that 90% of people with FH are undiagnosed3.â¯ Methods:â¯â¯The Familial Hypercholesterolemia Identification Registry (FHIRE)â¯combines an automatedâ¯algorithm withâ¯manual review to identify patients with FHâ¯at Mayo Clinic Rochester. Daily lists of patients who have anâ¯LDL-cholesterol >190 mg/dL and an upcoming appointment areâ¯generatedâ¯in an automated fashionâ¯and sentâ¯to the study team. Theâ¯electronic health recordsâ¯of theseâ¯patients areâ¯manually reviewed to calculate a Dutch Lipid Clinic Network (DLCN) or MEDPED score. Patients with a DLCN scoreâ¯ofâ¯â¯â¥6 or who met MEDPED criteria for definite FH areâ¯offered enrollmentâ¯in theâ¯registry. Patients who consent undergo CLIA certified genetic sequencing ofâ¯LDLR,â¯APOB, andâ¯PCSK9.â¯ Results:â¯â¯Between 1/1/2019 and 6/8/2021,â¯95â¯participantsâ¯consentedâ¯andâ¯84â¯completedâ¯geneticâ¯testing. Of these,â¯38â¯(45.2%)â¯hadâ¯aâ¯pathogenic/likely pathogenicâ¯(P/LP)â¯variant consistent with a diagnosis ofâ¯monogenicâ¯FH;â¯9â¯carried the APOB founder variant c.10580G>A (p.Arg3527Gln)â¯andâ¯1 carriedâ¯theâ¯c.10579C>Tâ¯(p.Arg3527Trp)â¯P/LPâ¯APOB variant.â¯The remainingâ¯28â¯had P/LP variants in LDLR:â¯18â¯missenseâ¯(includingâ¯1â¯in-frame insertion/deletion),â¯1 duplication,â¯5â¯copy number variants, andâ¯5â¯splice site alterations.â¯8â¯participants (9.5%) hadâ¯aâ¯variant of uncertain significanceâ¯(VUS);â¯5â¯had both a P/LP and VUSâ¯(6%),â¯andâ¯38â¯(45.2%)â¯had negative findings.â¯The detection rateâ¯of monogenic FH inâ¯FHIREâ¯was 56%.â¯Participants with a P/LP and/or VUS finding were invited to discuss their results with a genetic counselor.â¯â¯ Conclusion:â¯We designedâ¯a novel, two-step protocol for identifying individuals with monogenic FHâ¯in an academic medical center. The protocol has a high detection rate and could be deployed across health care systems to increase the detection of FH.â¯

PrgmNr 1273 - Finding the Sweet Spot: Exploring patientsâ perspectives on the adoption of AI and Chatbots in genetic service delivery

Author Block: **Y. Bombard**[1,2], S. Luca[3], M. Clausen[2], A. Shaw[2], W. Lee[1,3], S. Krishnapillai[1,2], E. Adi-Wauran[1,2], H. Faghfoury[4], G. Costain[5], R. Jobling[5], M. Aronson[4,6], E. Liston[5,7], J. Silver[4,7], C. Shuman[7], L. Chad[5], R. Z. Hayeems[1,3]; [1]Inst. of Hlth.Policy, Management, and Evaluation, Univ. of Toronto, Toronto, ON, Canada, [2]Genomics Hlth.Services Res. Program, Li Ka Shing Knowledge Inst., St. Michaelâs Hosp., Unity Hlth.Toronto, Toronto, ON, Canada, [3]Program in Child Hlth.Evaluative Sci., The Hosp. for Sick Children, Toronto, ON, Canada, [4]Fred A. Litwin Family Ctr. in Genetic Med., Univ. Hlth.Network and Sinai Hlth.System, Toronto, ON, Canada, [5]Div. of Clinical and Metabolic Genetics, The Hosp. for Sick Children, Toronto, ON, Canada, [6]Zane Cohen Ctr. for Digestive Diseases, Sinai Hlth.System, Toronto, ON, Canada, [7]Dept. of Molecular Genetics, Univ. of Toronto, Toronto, ON, Canada
Disclosure Block: **Y. Bombard:** None.
Background: Innovative strategies are needed to increase the capacity and efficiency of genetic service delivery in light of workforce shortages. eHealth tools such as digital platforms, artificial intelligence (AI) and conversational agents, such as chatbots, are potential solutions. Digitizing components of care can increase the time available for in-person patient care, improve access and potentially decrease administrative burden on providers. However, research exploring patientsâ preferences and attitudes towards AI and chatbots in genetic service delivery is only emerging.
Aim: To understand patient perspectives on digitizing the genetic counseling and testing experience through a patient-facing genetics platform that integrates AI and a chatbot.
Methods: A qualitative study was conducted using semi-structured interviews to explore patient perspectives on a proposed genetics platform integrating AI and a chatbot. Thematic analysis employing interpretive description was used to analyze interview transcripts.
Results: We interviewed 30 participants (n= 20 female; age range= 30-79, n= 17 patients, n=13 parents of patients) who previously received genetic testing for themselves or their child. Participants perceived AI as an opportunity to provide them with âpersonalizedâ information. However, they expressed reservations about the use of chatbots. Specifically, they anticipated that chatbots would be âinefficientâ or lack the capabilities needed to manage complex interactions but said they may be helpful in providing some types of basic information. Participants expressed that the utility of a chatbot would be low if it were designed to assist with tasks that are either too simple (e.g., defining medical terminology) or too complex (e.g., responses incorporating personal health information). The highest level of acceptability was in the âsweet spotâ, where participants saw value in a chatbot that could assist with moderately complex tasks (e.g., providing a pros/cons list for a specific type of genetic testing). Irrespective of the chatbotâs complexity, participants needed a âsafety netâ in the form of access to a care provider throughout their use of the platform, in case the chatbot was unable to address their needs. Knowing that a care provider would be available to them as needed increased participantsâ comfort with using chatbots or AI as part of the platform.
Conclusion: Results provide timely insights into patientsâ comforts with and limits on integrating AI and chatbots into genomics platforms, which can optimize implementation of these tools in practice.

PrgmNr 1274 - A Step Towards Real-World Population Screening for Hereditary Cancer and Hypercholesterolemia

View session detail

Author Block: **B. H. Shirts**[1], N. Rao[2], J. Huey[1], S. Coe[1], D. Tsinajinnie[1], J. Kaganovsky[1], G. P. Jarvik[3], S. M. Fullerton[2], A. T. Chen[1]; [1]Univ of Washington, Seattle, WA, [2]Univ. of Washington, Seattle, WA, [3]Univ Washington Med Ctr., Seattle, WA

Disclosure Block: **B.H. Shirts:** None.

Timely identification of individuals carrying risk variants for Hereditary Breast and Ovarian Cancer Syndrome, Lynch Syndrome, and Hereditary Hypercholesterolemia is vital for treating, delaying or preventing disease onset. Population genetic screening is a proposed strategy to detect individuals who would benefit from medical intervention but who are currently missed under existing screening guidelines.

We sought to assess the feasibility of population screening by inviting adults who have received care at the University of Washington Medical Center to participate in a targeted hereditary disease screening. Unlike other population screening studies, our study does not focus on individuals who have previously enrolled in genetic research. We attempted to design a study that would be as similar as possible in approach to a member of the general public requesting a COVID-19 testing appointment online. The study started in June 2020. Adults were identified through the electronic health record regardless of family or personal history of disease, oversampling for racial and ethnic minorities as well as LGBTQ+ individuals (diverse participants). After they receive an email invitation to participate, invited individuals can learn more about the study by clicking a link in their email invitation to the study FAQ, which includes details about the studyâ□□s targeted testing, minimal health education about genetics, potential risks of genetic screening, and additional information about study participation.

Participants could request a DNA saliva kit be mailed to them for sample collection. Samples returned were screened for pathogenic or likely pathogenic variants in 25 genes associated with increased risk of cancer, including *BRCA1/2* and genes associated with Lynch, or familial hyperlipidemia using a custom capture panel and sequencing. Participants who tested positive for a pathogenic or likely pathogenic variant receive counseling about results from study genetic counselors and are advised to receive follow-up care with genetics providers. All other participants are able to access their results through a secure online portal.

Thus far, more than 38,000 people have been invited for genetic screening and >1,700 (77% racial, ethnic minorities, and/or LGBT+) have chosen to participate. We will reach our goal of 2,500 participants in summer 2021. Positive results were observed in 4.6% of participants tested to date; almost half were already aware of their genetic risk. Full results from this population screening study will help determine if broad implementation of genetic screening is an effective way to identify diverse at-risk individuals.

PrgmNr 1275 - Using Supervised Machine Learning to Accelerate Variant Curation and Genomic Diagnosis in Suspected Mendelian Disorders

View session detail

Author Block: **P. Dai**[1,2], R. Fieldhouse[3], A. Honda[4], J. Copty[4], A. Statham[4], M. Hobbs[4], T. Ohnesorg[4], G. Hollway[2,4], B. A. Lundie[4], E. Lee[4], K. Enthoven[1], S. Tangye[1], P. Gray[5], M. Wong[5], W. Kaplan[2,4], T. Phan[1,2], L. Burnett[2,4]; [1]Garvan Inst. of Med. Res., Sydney, Australia, [2]St Vincent's Clinical Sch., Faculty of Med., Univ. of New South Wales, Sydney, Australia, [3]Univ. of Sydney, Sydney, Australia, [4]Kinghorn Ctr. for Clinical Genomics, Sydney, Australia, [5]Sydney Children's Hosp. Network, Sydney, Australia
Disclosure Block: **P. Dai:** None.
Background: Massive parallel sequencing (MPS) has revolutionized the diagnosis of rare Mendelian disorders over the last decade. However, despite technological improvements in sequencing and bioinformatics, there still exist significant bottlenecks in variant curation due to the need for manual review of large number of potential variants against in silico annotations, the literature and clinical phenotype. **Aim:** We developed a parsimonious algorithm for rapid variant prioritization using supervised machine learning (ML) combined with an orthogonal phenotype-based variant prioritization tool. **Method:** We generated a data set of 158,626 genomic variants drawn from the genomes of 291 near-consecutive patients who underwent diagnostic whole genome sequencing (WGS) at the Kinghorn Centre for Clinical Genomics (KCCG) between 2015 and 2018. We subsequently extracted 121 American College of Medical Genetics and Genomics (ACMG) Class 4/5 (likely pathogenic/pathogenic) variants and an equal number of randomly selected variants that had been deemed as non-diagnostic by ACMG criteria. Using the â□□Wekaâ□□ ML environment (University of Waikato, New Zealand), we subsequently performed attribute reduction and developed a variant prioritization ML parsimonious algorithm based on in silico genomic annotations by training the J48 algorithm on this dataset with diagnostic performance assessed by 10-fold cross validation. We also separately evaluated a variant prioritization orthogonal algorithm based purely on patient phenotypes (AMELIE, Stanford University, CA USA) without inclusion of any genomic attributes. **Results:** The ML algorithm successfully captured 119/121 (98%) of ACMG Class 4/5 pathogenic variants with 15/121 (12%) of the non-pathogenic variants misclassified as pathogenic. Overall the ML algorithm reduced the number of variants requiring manual curation by approximately 2/3. We further applied the short-listed set of variants from the ML algorithm to AMELIE in 10 randomly selected cases and found the candidate pathogenic variant to be occurring within the top 10 short-listed variants in 100% of cases. **Conclusion**: A simple supervised machine learning algorithm trained on manually curated genomic variants in combination with an orthogonal phenotype-based variant prioritization tool can markedly reduce the workload of variant curation without significant sacrifices in sensitivity. This will allow both rapid semi-automated initial genome analysis and subsequent re-analysis of suspected Mendelian disorders. Further work will involve testing our pipeline on larger independent and prospective test data sets.

PrgmNr 1276 - Design and implementation of genome interpretation for coronary disease - including monogenic and polygenic risk assessment - in a Preventive Genomics Clinic

View session detail

Author Block: **D. Brockman**[1], D. Maamari[1], R. Pelletier[1], E. Folkerts[1], C. Leonard[1], L. Petronio[2], K. H. Huang[2], P. Natarajan[1], K. Aragam[1], H. L. Rehm[1], A. V. Khera[1]; [1]Massachusetts Gen. Hosp., Boston, MA, [2]Broad Inst. of MIT and Harvard, Cambridge, MA
Disclosure Block: **D. Brockman:** None.
Introduction: State-of-the-art genome interpretation for common diseases is now recognized as requiring assessment of both monogenic variants - single base pair changes that disrupt a specific pathway - and polygenic background, the cumulative impact of many common variants. Taking coronary artery disease (CAD) as an example, we and others have noted striking ability to stratify the population - from birth - into genetic subgroups with very different trajectories of disease onset. Alongside considerable (and warranted) enthusiasm for this new approach are several areas of uncertainty around optimal approach for implementation and disclosure.
Methods: First, we designed a web-based user educational tool focused on the scientific basis of polygenic scoring and a PDF report designed for inclusion in the medical record. Second, we partnered with Color Health to develop a clinical-grade test for both monogenic variants and polygenic score calculation. Third, we designed a prospective study to assess monogenic and polygenic drivers for CAD and evaluate impact of risk disclosure for patients seen in a new Preventive Genomics Clinic at Massachusetts General Hospital.
Results: A new educational tool created using â□□scrolly-tellingâ□□ principles (polygenicscores.org/explained/) was developed with a team of data visualization, clinical, and genetic experts - now viewed 7600 times across 19 countries. A static PDF report was drafted and refined based on formal user experience testing. We launched a clinical test - enabled by saliva collection kits sent directly to patientâ□□s homes - for CAD assessment in our clinic. Of the first 34 patients, median age was 50.5 years (range 27 to 77), 71% were male, and 74% were white. Primary rationale for obtaining the test included a strong family history (71%), a personal history of heart disease and interest in understanding any genetic contribution (32%), or concern in the absence of family or personal history (15%). The disclosed results led to a change in clinical management for 56% of patients studied to date - including informing decision to start new preventive medications, additional imaging scans or biomarkers, or stated intent to enhance adherence to a healthy lifestyle. 92% of participants reported learning valuable information related to their health and 83% reported the reporting tools were either â□□veryâ□□ or â□□extremelyâ□□ helpful.
Conclusions: We describe a generalizable approach to develop and test tools for sophisticated genetic prediction models understandable to both patient and clinical stakeholders. These results are likely to inform ongoing efforts related to genetic risk disclosure within clinical practice.

PrgmNr 1277 - Innovative approaches to optimizing the electronic health record for genomic medicine

Author Block: **K. Lau-Min**[1], S. Byers Asher[2], D. Mckenna[1], T. Bardakjian[3], J. Chen[4], S. M. Domchek[1], J. Landgraf[4], A. Schoenbaum[4], G. Hoffecker[2], S. Tuteja[2], L. Steinfeld[5], C. Vanzandbergen[4], M. D. Ritchie[6], K. L. Nathanson[2]; [1]Div. of Hematology/Oncology, Dept. of Med., Perelman Sch. of Med., Univ. of Pennsylvania, Philadelphia, PA, [2]Div. of Translational Med. and Human Genetics, Dept. of Med., Perelman Sch. of Med., Univ. of Pennsylvania, Philadelphia, PA, [3]Dept. of Neurology, Perelman Sch. of Med., Univ. of Pennsylvania, Philadelphia, PA, [4]Information Services Applications, Penn Med., Univ. of Pennsylvania, Philadelphia, PA, [5]Carey Law Sch., Univ. of Pennsylvania, Philadelphia, PA, [6]Dept. of Genetics, Perelman Sch. of Med., Univ. of Pennsylvania, Philadelphia, PA
Disclosure Block: **K. Lau-Min:** None.
The PennChart Genomics Initiative (PGI) at the University of Pennsylvania is a multidisciplinary collaborative that aims to optimize the electronic health record (EHR) for the delivery of genomic medicine. We leverage the collective expertise of clinicians, pathologists, researchers, legal staff, and information services throughout Penn Medicine and its partners to devise innovative EHR-based approaches. We previously described our initial efforts to link our EHR (PennChart) directly with clinical testing laboratories, integrate discrete genetic data, link to clinical decision support, and enhance patient access to their own genetic testing results. The PGI has since expanded to interface with three commercial genetic testing laboratories for computerized provider order entry (CPOE) and discrete result reporting, resulting in the creation of over 390 unique genetic testing orders. The CPOE interface has also been refined to include additional details such as test specimen source, as well as linkage to patient demographic information to facilitate insurance benefits investigations. To date, a total of 1,065 genetic testing orders have been placed as a part of clinical care, with a 31% increase over the last six months. Results from these tests filter discretely into the PennChart Precision Medicine Tab, a centralized location in the EHR that enables easy access to all genetic data, including over 17,500 legacy scans containing unstructured genetic data. The number of Genomic Indicators - tags that indicate potential disease risk or drug sensitivity based on a patientâ□□s discrete genetic testing results - has also expanded to include 21 disease-associated and 55 pharmacogenetic variants, enabling easier interpretability for non-genetics clinicians and patients while also facilitating the development of downstream clinical decision support. Finally, to mitigate the confusion or distress that may arise if patients receive their genetic testing results in isolation, a Genomics Release Portal has been built to retain genetic testing results from release to the EHR until after the ordering genetics provider has had the opportunity to review, disclose, and counsel patients on their clinical interpretation. All in all, the PGIâ□□s efforts have significantly streamlined what was previously a manual process of placing genetic testing orders, handling results, and interfacing with the EHR, resulting in substantial improvements in provider workflows and satisfaction. Future work will continue to broaden the programâ□□s scope of genetic variants and clinical decision support systems to further optimize the delivery of genomic medicine for our patients.

PrgmNr 1280 - Understanding clonal distributions during human cortical development deciphered through brain somatic mosaicism

View session detail

Author Block: **X. Yang**[1,2], M. W. Breuss[3,1,2], J. C. M. Schlachetzki[1], D. Antaki[1,2], J. G. Gleeson[1,2]; [1]Univ. of California, San Diego, La Jolla, CA, [2]Rady Children's Inst. for Genomic Med., San Diego, CA, [3]Univ. of Colorado, Sch. of Med., Aurora, CO
Disclosure Block: **X. Yang:** None.
The structure of the human neocortex underlies species-specific traits and is a reflection of intricate developmental programs. Yet, lineage tracing and clonal analysis in the human brain are challenging compared with other species. Somatic mosaic mutations across the genome have the potential to address this problem when employing them as neutral recorders for lineage history and early embryonic development of the human cortex. Thus, a thorough study of the distribution of mosaic clones in human cortical areas may help us to understand several unanswered questions about the normal and malformatted brain: 1] How are clones in the human brain distributed during early embryonic development? 2] What is the total committed progenitor population size for the early human cortex? 3] Why are brain disorders such as focal cortical dysplasias (FCD) in humans limited to a single hemisphere?We addressed these questions through the study of neurotypical postmortem human brains through a comprehensive assessment of brain somatic mosaicism, which deciphered neocortical cellular lineages. By combining a sampling of 50 distinct anatomic locations with 300x ultra-deep whole-genome sequencing from 4 neurotypical cadavers, we identified hundreds of *bona fide* mosaic variants, resolving major cortical cell types, and single-nuclei clade organizations across the brain and other organs.We found that clones derived after the accumulation of 90 to 200 progenitors in the cerebral cortex tended to respect the midline axis, well before clones respect anterior-posterior or ventral-dorsal axes, and that cell fate correlated better with location rather than early lineage. There was evidence for local clonal expansion as well as a broad range of stochastic distributions of somatic variants across the cortex. Similar to rodents, cortical cells originated from both dorsal and ventral cellular populations, whereas microglia lineages appeared as distinct from other resident brain cells.Our data provide a comprehensive analysis of brain somatic mosaicism across the cortex, demonstrate cellular origins and migration patterns within typically developed human brains, and reveal mechanisms how mosaic variants lead to focal brain disease. Future analysis can help to deconvolve cellular lineages.

PrgmNr 1281 - *MYCN* gain-of-function variants induce excess proliferation of neurons and cause a novel megalencephaly syndrome

View session detail

Author Block: **Y. Nishio**[1,2], K. Kato[1,2,3], T. M. Frederic[4], S. Otsuji[1], C. QuÃ©lin[5], H. Oishi[6], Y. Takahashi[2], S. Saitoh[1]; [1]Dept. of Pediatrics and Neonatology, Nagoya City Univ. Graduate Sch. of Med. Sci., Nagoya, Japan, [2]Dept. of Pediatrics, Nagoya Univ. Graduate Sch. of Med., Nagoya, Japan, [3]Dept. of Genetics, Res. Inst. of Environmental Med., Nagoya, Japan, [4]UnitÃ© Fonctionnelle 6254 dâInnovation en Diagnostique GÃ©nomique des Maladies Rares, PÃ´le de Biologie, CHU Dijon Bourgogne, Dijon, France, [5]Service de GÃ©nÃ©tique Clinique, CLAD Ouest, CHU Rennes, HÃ´pital Sud, Rennes, France, [6]Dept. of Comparative and Experimental Med., Nagoya City Univ. Graduate Sch. of Med. Sci. and Med. Sch., Nagoya, Japan

Disclosure Block: **Y. Nishio:** None.

Background: *MYCN,* a member of the *MYC* proto-oncogene family, encodes a transcription factor that regulates genes promoting cell growth and proliferation. Loss-of-function variants in *MYCN* are the causes of Feingold syndrome characterized by microcephaly, brachydactyly, and syndactyly. In contrast, we previously reported a patient with a novel megalencephaly syndrome with ventriculomegaly, neuroblastoma, and polydactyly, who carried a gain-of-function variant in *MYCN* (p.Thr58Met). Although it was likely that gain-of-function variants cause a mirror phenotype of Feingold syndrome, additional cases were needed to confirm it and elucidate the underlying molecular mechanism. **Methods:** Exome sequencing and cellular biological analyses were performed to identify and evaluate a pathogenic variant. We also generated knock-in mice ($Mycn^{WT/T58M}$) and knock-out mice ($Mycn^{WT/del}$) to delineate the pathophysiological significance of the gain-of-function or loss-of-function variants for fetal development. **Results:** We identified a *de novo MYCN* missense variant (p.Pro60Leu) in a fetus delivered under artificial abortion at the 32nd week of gestation. The patient exhibited megalencephaly, ventriculomegaly and postaxial polydactyly, that were similar phenotypes to the previous one. Immunoblot analyses of MYCN-P60L indicated a drastically decreased phosphorylation level at T58, whose phosphorylation lead to MYCN protein degradation. In fact, MYCN-P60L showed significantly increased stability and excess accumulation, indicating the gain-of-function properties as MYCN-T58M. The excess accumulation of Mycn protein was also confirmed in the E14.5 brain cortex of $Mycn^{WT/T58M}$ mice. In addition, as with the phenotypes of the patient, a postaxial polydactyly and macrocephaly with increased number of neuronal cells were observed in $Mycn^{WT/T58M}$ mice compared to littermate controls in P56, whereas $Mycn^{WT/del}$ showed microcephaly. **Conclusions:** These results confirm that *MYCN* gain-of-function variants cause a novel megalencephaly syndrome. Mirror phenotypes of Mycn gain-of-function and loss-of-function mice model suggest that MYCN plays a crucial proliferative role during neuronal development.

PrgmNr 1282 - Gain and loss of function variants in *EZH1* disrupt neuronal differentiation and lead to overlapping neurodevelopmental disorders

Disclosure Block: **N. Akizu:** None.

Enhancer of Zeste Homologue 1 (*EZH1*) encodes one of the two Histone H3 Lysine 27 (H3K27) methyltransferases of the Polycomb Repressive Complex 2 (PRC2). Its paralogue, EZH2, has been traditionally considered the major responsible of the H3K27 trimethylation (H3K27me3) involved in the PRC2 mediated transcriptional silencing. However, EZH2 is mostly expressed in dividing cells, while EZH1 is widely expressed in both dividing and postmitotic cells, including in the developing and adult nervous system where it also contributes to H3K27me3. Whereas the function of EZH2 has been extensively characterized and its dysregulation associated with cancer and development disorders (i.e. Weaver syndrome), reports implicating EZH1 in human disorders are scarce and its biological relevance poorly understood. Here we report heterozygous missense and biallelic truncating variants in *EZH1* in ten children with neurodevelopmental delay. Recurrent clinical features of these children include intellectual disability, delayed developmental milestones, and dysmorphic facial features. By western blot analysis of a lymphoblastoid cell line derived from one of five patients, we show that biallelic truncating mutations lead to loss of EZH1 expression. In contrast, *in vitro* methyltransferase assays with three of the five missense variants showed modified methyltransferase kinetics that led to increased H3K27me3 when the variants were expressed in neural stem cells. To test if mutations affect neural development, we generated human pluripotent stem cells (hPSCs) that carry EZH1 loss or gain of function variants ($EZH1^{LOF}$ and $EZH1^{GOF}$) and differentiated them to neurons. EZH^{LOF} hPSCs showed delayed neuronal differentiation and shorter neurites, while $EZH1^{GOF}$ hPSCs exhibited premature differentiation and longer neurites. Finally, we employed the chick embryo neural development model to test the effect of EZH1 loss or gain of function *in vivo*. Consistent with the hPSC results, knocking down EZH1 in the chick embryo neural tube led to a reduced number of postmitotic neurons while its overexpression induced a premature differentiation of neural progenitor cells. These results reveal a previously unreported function of EZH1 in neuronal differentiation and uncover overlapping neurodevelopmental disorders associated with gain and loss of function variants in EZH1.

PrgmNr 1283 - Genomic atlas of proteome from three tissues relevant to neurological disorders prioritizes proteins implicated in brain diseases

View session detail

Author Block: **C. Cruchaga**; Washington Univ. St. Louis, St. Louis, MO
Disclosure Block: **C. Cruchaga:** None.
Understanding the tissue-specific genetic architecture of protein levels is instrumental to understand the biology of health and disease. We generated a genomic atlas of protein levels in multiple neurologically relevant tissues (380 brain, 835 cerebrospinal fluid (CSF) and 529 plasma), by profiling thousands of proteins (713 CSF, 931 plasma and 1079 brain) in a large and well-characterized cohort. We identified 274, 127 and 32 protein quantitative loci (pQTL) for CSF, plasma and brain respectively. cis-pQTL were more likely to be shared across tissues but trans-pQTL tend to be tissue-specific. Between 44% to 68.2% of the pQTL do not colocalize with expression, splicing, methylation or histone QTLs, indicating that protein levels have a different genetic architecture to those that regulate gene expression. By combining our pQTL with Mendelian Randomization approaches we identified potential novel biomarkers and drug targets for neurodegenerative diseases including Alzheimer disease and frontotemporal dementia. We identified one CSF, 13 plasma, and six brain proteins were likely to be in the causal pathways for AD risk. Among these proteins, plasma CD33 was a risk factor towards AD and is a drug target for other diseases, such as prostate cancer. As for Parkinson disease risk, 13 CSF, 12 plasma, and 23 brain proteins were likely to be the cause. Among these proteins, plasma IDUA was prioritized as a risk locus encoded it for PD and as a drug target for chondroitin sulfate, reported to treat osteoarthritis. Here we present the first multi-tissue study yielding hundreds of novel pQTLs. These results highlight the need to implement additional functional genomic approaches beyond gene expression to understand the biology of complex traits.. This first multi-tissue study will be instrumental to map signals from genome-wide association studies (GWAS) onto functional genes, to discover pathways from different proteins associated with the same pleiotropic region, and to identify drug targets for neurological diseases.

PrgmNr 1284 - Single-cell RNA-sequencing of human brain regions identifies cell types and states relevant to disease

View session detail

Author Block: **S. Gerges**[1], M. Goldman[1], M. Daly[2], S. Berretta[1], S. A. McCarroll[3]; [1]Broad Inst., Cambridge, MA, [2]Harvard Med. Sch., [3]Harvard Med. Sch., Boston, MA
Disclosure Block: **S. Gerges:** None.
Genetic association studies have identified a plethora of loci associated with brain disorders. However, the biology that mediates how genetic etiology manifests into disease remains elusive. Here, we show that single-cell RNA-sequencing (scRNA-seq) allows for unprecedented resolution into the cell types most relevant to psychiatric and neurological disease etiology as well as complex traits more broadly. We combine single-cell RNA-seq of over 120,000 cells from human choroid plexus, subventricular zone, amygdala, caudate and temporal cortex from across multiple individuals with genome-wide association study (GWAS) summary statistics and rare-variants from over 25 brain-related traits. We show that loci and genes associated with brain traits map to distinct expression signatures within diverse cell populations within the brain. We use partitioned LD score regression (LDSC) to show that schizophrenia, bipolar disorder, educational attainment and IQ are most enriched within amygdala excitatory neurons, as well as a novel cell-type population known as â□□eccentricâ□□ spiny projection neurons (eSPN) (p=1.29e-15, p=9.83e-11, p=9.22e-10 and p=3.72e-10 respectively), as well as both â□□directâ□□ (dSPN) and â□□indirectâ□□ (iSPN) populations in the patch and matrix compartments of the striatum (p We contrast this with other traits such major depressive disorder which is exclusively enriched in GABAergic neurons from the amygdala (p To our knowledge, this is the most in depth scRNA-seq survey of the amygdala, subventricular zone, cortex, caudate nucleus and choroid plexus. All regions that are heavily implicated in brain disorders, and provide an atlas for understanding the etiology of complex brain phenotypes. Altogether, we show that combining genetics with human single-cell data allows for biologically interpreting how genetics manifests within cells that contribute to disease onset.

PrgmNr 1285 - Joint transcriptome and chromatin accessibility profiling of the developing human brain cortex at the single cell level

View session detail

Disclosure Block: **K. Zhu:** None.
We performed multimodal profiling for gene expression and chromatin accessibility in 45,549 single nuclei isolated from the human cortex, across a broad developmental period (fetus, infancy, childhood, adolescence and adulthood). Integrative analysis of both modalities improves the *de novo* taxonomy compared to analysis using either single modality. We identified cell-type specific domains in which chromatin accessibility is highly correlated with gene expression. To better understand the regulatory mechanisms driving expression of lineage-specific genes during neurogenesis, we performed pseudotime trajectory analysis. Differentiation trajectory of neuronal populations displayed a lineage-priming pattern, suggesting that chromatin accessibility at *cis*-regulatory elements precedes the onset of gene expression. Using lineage-specific genes and peaks, we evaluated whether the genetic loci implicated in a panel of neurodegenerative and neuropsychiatric disorders map to specific cell types. Besides replicating many known associations, we found that common variants of autism are most enriched in fetal inhibitory neurons. Our results collectively suggest that single cell-derived marker genes and peaks lead to an enhanced cell type resolution of heritability analysis.

PrgmNr 1335 - Genotype first: Clinical genomics research through a reverse phenotyping approach

View session detail

Author Block: **C. Wilczewski**, J. Obasohan, L. G. Biesecker, A. E. Katz; Natl. Human Genome Res. Inst., Bethesda, MD
Disclosure Block: **C. Wilczewski:** None.
Clinical genomics research has traditionally started with a group of phenotypically similar individuals and tested whether a common genetic cause can be found. Genomic ascertainment research utilizes a novel, reverse approach. In these â□□reverse phenotypingâ□□ studies, phenotypically unselected individuals with a common genetic variant are recruited for phenotypic assessment to test whether they have similar physical characteristics. This approach holds promise to expand our understanding of the relationships between genetic variation and phenotype. The utility of this approach requires evaluation. To characterize and quantify the utility of reverse phenotyping, we reviewed 13 studies that recontacted 190 genomically ascertained participants and performed phenotypic assessment for 60 conditions. We categorized the type of research question under investigation and evaluated what results would have been obtained if complementary research methods such as electronic health records review or phenotypic ascertainment of research subjects would have been utilized instead. We evaluated 13 studies. Six tested a hypothesized novel gene-disease association. Six evaluated the phenotypic spectrum of a known association. One study performed ex vivo reverse phenotyping using patient samples obtained as a result of genomic ascertainment. In 62% of studies, testing the gene-disease association hypothesis via electronic health record review would have resulted in the opposite conclusion compared to prospective reverse phenotyping. In 92% of these studies, the genotype-phenotype hypothesis would not have been testable without prospective reverse phenotyping studies. Our conclusion is that reverse phenotyping is a valuable and effective tool to test relationships between genetic variation and phenotypes. This is especially true where there may be a subclinical disease presentation or presentation of rare phenotypes that are not typically assessed as part of routine healthcare. This work will inform how reverse phenotyping research capabilities can be utilized more broadly and efficiently to bring the reality of precision medicine closer within reach.

PrgmNr 1336 - The knowledge gap between pharmacogenomics and medical genetics: Is there a bridge in between?

View session detail

Author Block: **B. Li**[1], M. Whirl-Carrillo[2], T. E. Klein[3]; [1]Stanford Univ., Stanford, CA, [2]Stanford Univ, Palo Alto, CA, [3]Stanford Univ, Stanford, CA
Disclosure Block: **B. Li:** None.
Precision medicine faces many challenges including the gap of knowledge between medical genetics and pharmacogenomics (PGx). Medical genetics interprets the pathogenicity of genetic variants for diagnostic purposes while PGx investigates the genetic influences on drug responses. Ideally, the quality of health care would be improved from the point of disease diagnosis to drug prescribing and adherence if PGx knowledge was included. However, PGx variants are usually not reported as a secondary finding even if they are included in a clinical genetic test for diagnostic purposes despite the fact that the detection of PGx variants can provide valuable drug prescribing recommendations. One underlying reason is the lack of systematic classification of the knowledge overlap between PGx and medical genetics. Here, we cross-referenced annotations of pharmacogenes and pathogenic genes from multiple expert-curated knowledge databases, including the ClinGen curation efforts (1889 variant pathogenicity, 1220 clinical validity, and 526 clinical actionability), 440 CPIC gene-drug pairs, and the PharmGKB (4559 curated clinical annotations and 798 drug labels). We classified pharmacogenes and pathogenic genes based on the abundance of evidence supporting a geneâ□□s role in target phenotypes and the level of clinical actionability. In total, 678 pathogenic genes and 102 pharmacogenes were classified as genes with abundant supporting evidence; 25 genes were shared between them. These 25 genes were classified into three categories based on the connection between their pathogenic role and pharmacogenetic effect. (1) Pathogenic roles of the genes are related to their pharmacogenetic effects. Carriers of specific pathogenic genotypes can live without a clinical phenotype unless exposed to certain drugs, e.g., *RYR1* and *CACNA1S*. (2) Certain medications are contraindicated in individuals with the specific genetic disorders or carriers of specific genotypes. One example is the contraindication of valproic acid in patients with ornithine carbamoyltransferase deficiency or carriers of specific pathogenic *OTC* genotypes. (3) Medications are indicated for individuals with certain genetic conditions. E.g., velaglucerase alfa is a long-term therapy for type 1 Gaucher disease patients deficient of *GBA* enzyme activity. Interestingly, phenotypic variability has been observed in some of this class of genes, suggesting genetic heterogeneity. Overall, we characterized 25 pathogenic genes that warranted further investigation of genetic influences on drug efficacy and toxicity, which would collectively improve clinical care from disease diagnoses to drug prescribing.

PrgmNr 1337 - Population-based penetrance of clinical variants in individuals of diverse ancestries and ages

View session detail

Author Block: **I. Forrest**[1], K. Chaudhary[1], H. T. Vy[1], S. Bafna[2], D. M. Jordan[3], G. Rocheleau[1], R. Loos[4], J. H. Cho[1], R. Do[5]; [1]Icahn Sch. of Med. at Mount Sinai, New York, NY, [2]Icahn Sch. of Med. at Mount Sinai, Jersey City, NJ, [3]Icahn Sch. of Med. at Mt Sinai, New York, NY, [4]The Icahn Sch. of Med. at Mount Sinai, New York, NY, [5]Icahn Sch. of Med., New York, NY

Disclosure Block: **I. Forrest:** None.

Introduction: A population-based assessment of disease risk associated with variants informs clinical decisions and risk stratification. We aimed to evaluate the population-based disease risk of clinical variants in known disease-predisposition genes. **Methods**: We performed a cross-sectional study of two population-based biobanks with linked exome and electronic health record data, the UK Biobank and Bio*Me* Biobank. Participants included 72,434 individuals carrying 37,772 clinical variants who were of a diverse range of ages and ancestries. The exposure was clinically impactful variants that were reported as pathogenic in ClinVar or predicted to cause a loss of protein function by bioinformatic algorithms in genes mediating disease via loss-of-function mechanism. The primary outcome was disease risk of impactful variants; risk difference (RD) between the proportion of affected carriers (penetrance) versus affected noncarriers was measured. **Results**: Among 72,434 study participants, 43,395 were from the UK Biobank (mean [SD] age, 57 [8.0] years; 45% male; 7% non-European) and 29,039 were from the Bio*Me* Biobank (mean [SD] age, 56 [16] years; 40% male; 68% non-European). Biomarker levels were significantly associated with variant penetrance, such as in *LDLR* (0.53 mg/dL increase in low-density lipoprotein cholesterol per 1% penetrance increase; $P=4x10^{-3}$), *HNF1A* (0.76 mg/dL increase in glucose per 1% penetrance increase; $P=8x10^{-3}$), and *UCP3* (0.24 kg/m^2 increase in body mass index per 1% penetrance increase; $P=6x10^{-4}$). Of 5,359 impactful variants, 4,794 (89%) conferred RD â¤0.05. Mean penetrance was 6.9% (SD=23%) for pathogenic variants and 0.85% (SD=6.4%) for benign variants reported in ClinVar. A subset of variants was ancestry-specific (460 [8.6%]), such as the *HBB* S10fs variant significantly associated with thalassemia in Asians (RD=0.99; $P=9x10^{-6}$). Variant penetrance for late onset diseases was modified by carrier age, with mean penetrance 1.8% higher in â¥70-year-old carriers compared to â¥20-year-old carriers. Penetrance of impactful variants was heterogeneous even in known disease-predisposition genes, including *BRCA1* (mean [SD] variant penetrance, 38% [45%]), *BRCA2* (38% [46%]), and *PALB2* (26% [42%]). **Conclusions**: In two populations of diverse ancestries and ages, most impactful variants were associated with a low risk of disease. Current variant interpretation categories are not concordant with disease risk. Further research of population-based penetrance is needed to refine variant interpretation and guide screening and management of individuals who carry these variants in the general population.

PrgmNr 1338 - Common-variant dysregulation of Mendelian disorder genes contributes to complex disease

View session detail

Author Block: **E. McArthur**[1], M. L. Benton[2], C. Tubbs[1], D. Ruderfer[1], N. J. Cox[3], J. A. Capra[4]; [1]Vanderbilt Univ., Nashville, TN, [2]Baylor Univ., Waco, TX, [3]Vanderbilt Univ Med Ctr., Nashville, TN, [4]Univ. of California San Francisco, San Francisco, CA

Disclosure Block: **E. McArthur:** None.

Introduction: Although Mendelian disorders and common complex traits are often framed as distinct, there is increasing evidence that they exist on a continuum. Quantifying the shared genetic underpinnings of Mendelian and complex diseases will enable translation of insights into biological mechanisms, diagnosis, and treatment for both rare and common disease. Yet, we lack a framework for evaluating how common variation near Mendelian genes contributes to related traits at a personalized level.

Hypothesis: We hypothesize that common-variant-based dysregulation of Mendelian genes will associate with risk for related complex traits in relevant tissues. For example, do individuals with common-variant-mediated downregulation of monogenic diabetes genes have an increased risk of adult-onset diabetes?

Methods: To evaluate the relationship between genetic regulation of Mendelian genes and their functional effects, we use Vanderbiltâ□□s electronic health record (EHR)-linked biobank of 90,000+ genotyped individuals (BioVU). For each individual, we predict tissue-specific regulation of Mendelian disorder genes across 49 tissues using a PrediXcan/Transcriptome-wide Association Study framework trained with transcriptome data (GTEx v8). For each Mendelian gene, we test if dysregulation is associated with clinical phenotypes in the EHR across 1865 phecodes.

Results: We comprehensively quantify how common-variant regulation of Mendelian genes influences the medical phenome. We identify specific Mendelian genes with phenotypes shared by both monogenic disruption and common-variant dysregulation. For example, disruption of *WFS1* by coding variants causes Wolfram syndrome, a form of monogenic diabetes mellitus. We find that downregulation of *WFS1* by common regulatory variants is strongly associated with risk for diabetes, demonstrating a mechanism for both complex and monogenic diabetes pathogenesis. Then, we assess which phenotypes have a shared genetic basis between common and rare variants by testing regulation-mediated associations for genes in different phenotype domains. Finally, we consider unresolved questions about rare disease. For example, we show that individuals with downregulation of genes that cause Hereditary Hemochromatosis have higher rates of thyroid disease and certain cancer subtypes in the EHR. Thus, this approach may help prioritize screening for individuals with Mendelian disease and provide new avenues for testing phenotype expansion hypotheses. Ultimately, investigation into common-variant dysregulation of Mendelian genes will further our understanding of both common complex and rare Mendelian disorders.

PrgmNr 1339 - Understanding the importance of racial diversity in the development and implementation of pharmacogenomic guidelines in kidney transplant patients receiving tacrolimus

View session detail

Author Block: **Y. Ko**[1], M. Roberts[1], A. A. Seyerle[2]; [1]Univ. of North Carolina, Chapel Hill, NC, [2]Univ. of North Carolina at Chapel Hill, Apex, NC
Disclosure Block: **Y. Ko:** None.
Tacrolimus is a commonly prescribed immunosuppressant used to prevent organ rejection. Multiple studies show *CYP3A5* genotype is associated with tacrolimus serum concentration. However, in clinical settings tacrolimus is still dosed using a trial and error method with frequent trough concentration monitoring. Our study investigated the projected clinical benefit of implementing pharmacogenomics guidelines in tacrolimus dosing among kidney transplant patients. The primary outcome was acute rejection at one month post kidney transplant. Variables impacting trough level were simulated (e.g. age, body mass index, steroid use, panel reactive antibody present, genotype, number of human leukocyte antibodies mismatch). Simulated populations were analyzed under three different dosing scenarios: weight based dosing, pharmacogenomics based dosing accounting for *CYP3A5 *1* and *3* alleles, and comprehensive pharmacogenomics based dosing accounting for *CYP3A5 *1, *3, *6,* and *7*. Under all scenarios, the percentage of populations experiencing acute rejection was slightly higher in European Americans (4.5-7.6%) compared to African Americans (3.3-6.3%), with acute rejection rates lowest under our pharmacogenomics dosing scenarios (African Americans: 3.3-5.9%, European Americans: 4.5-7.5%) compared to weight based dosing (African Americans: 5.1-6.3%, European Americans: 6.2-7.6%). African Americans achieved the highest percent of the population in the targeted trough level (8-12ng/ml) using a dose of 0.1 mg/kg/day (35.2-41.1% compared to 36.4-39.0%) whereas European Americans achieved the greatest proportion in the target range using a dose of 0.125 mg/kg/day (41.5-42.1% compared to 26.7-41.2%). Our study demonstrated that African and European Americans achieved a higher percentage of patients within target trough levels using different dosing algorithms, suggesting that maximizing the clinical benefit of precision medicine may require investigating ancestry specific dosing algorithms. Furthermore, we found African Americans had a reduced risk of acute rejection compared to European Americans, which contradicts current literature. Given that our study assigned a consistent dosing level to all participants at baseline, this suggests that the higher rates of rejection in African Americans may be explained by the higher levels of interindividual dose variability seen in African Americans based on current weight based dosing algorithms. This further emphasizes the need to achieve accurate dosing levels early in treatment, a goal which can be accomplished more effectively with the use of pharmacogenomics based dosing.

PrgmNr 1340 - Genome-wide association of structural variations with lipid metabolism traits in TOPMed GOLDN study

View session detail

Author Block: **Y. Chen**[1], M. Gao[2], H. K. Tiwari[3], D. K. Arnett[4], M. R. Irvin[1], Z. Chong[2]; [1]Univ. of Alabama at Birmingham, Birmingham, AL, [2]UAB, Birmingham, AL, [3]Univ Alabama at Birmingham, Birmingham, IN, [4]Univ Alabama Birmingham, Birmingham, IN
Disclosure Block: **Y. Chen:** None.
Structural variations (SVs) contribute substantially to the divergence between species and polymorphisms within species. However, how SVs associate with specific traits in humans is less studied. Previous genome-wide association studies (GWAS) mainly focused on smaller genetic variants, such as SNPs and indels. And the balanced accuracy and resolution of these variants were also limited due to old platforms, SNP array for example. It is very critical to understand the impact of all genetic factors on complex human diseases at the population level. The Genetics of Lipid Lowering Drugs and Diet Network (GOLDN) study from Trans-Omics for Precision Medicine (TOPMed) program has generated a wealth of genomics and clinical phenotype data to assess how genetic factors interact with environmental (diet and drug) interventions. Previous GOLDN GWAS has identified several SNPs or genes significantly associated with relevant traits such as fasting lipids, fenofibrate treatment, and so on. Here, we present a genome-wide SV association study on GOLDN dataset. SV discovery using existing genotyping is a challenging problem. We developed an SV discovery and genotyping pipeline that enables accurate downstream GWAS analysis. It includes initial SV detection by Manta and a customized SV filter based on the number of split reads and abnormal read pairs with different thresholds for different sizes of SV events. To evaluate the precision of the SV discovery pipeline, we applied the pipeline on a benchmark sample with both short-read and long-read data. With the long-read data as the ground truth, we assessed the performance of the SV discovery pipeline and validated a precision over 90% for both deletion and insertion calls. We then applied the pipeline to 959 participants in the GOLDN study to generate high-confidence SV callsets, and we merged and genotyped the SV calls using a customized script. A family-based quantitative trait association analysis with the 29,050 common (AF>0.01) SVs highlighted 39 SVs significantly (pEPS8L1 is significantly associated with several fasting lipids (Triglyceride (p=2.9E-7), VLDL (p=3.2E-7), large VLDL (p=2.5E-6), and Chylomicrons (p=3.0E-6)); a 72bp deletion on *SLC1A7* is significantly associated with Glucose level (p=1.3E-6); a 73bp deletion on *IL2RA* is significantly associated with IL-2 sR alpha, an inflammation marker (p=6.2E-7). These results suggest that these SVs may be functionally important for lipid metabolism in the Caucasian population. Future detailed functional assays of these genes by introducing SVs in vivo and/or in vitro may provide further clues.

PrgmNr 1343 - Genetic mapping across autoimmune diseases reveals shared associations and mechanisms

View session detail

Author Block: **M. R. Lincoln**[1], S. G. Chun[2,3], S. R. Sunyaev[2,3], C. Cotsapas[4]; [1]Yale Sch. of Med., New Haven, CT, [2]Harvard Med. Sch., Boston, MA, [3]Brigham & Women's Hosp., Boston, MA, [4]Yale Sch. Med., New Haven, CT

Disclosure Block: **M.R. Lincoln:** None.

Autoimmune and inflammatory diseases are heterogeneous disorders, where activation of innate and adaptive immunity, coupled with loss of self-tolerance leads to target tissue destruction. Genome-wide association studies (GWAS) have identified hundreds of susceptibility loci, including many loci that contain risk alleles for multiple diseases. It has been difficult to assign specific molecular mechanisms to individual risk loci, particularly as genetic resolution is limited by available cohort size. In this study, we show that many overlapping genetic associations in fact share common risk alleles. By jointly analyzing shared associations, we improve fine-mapping resolution and identify specific downstream mechanisms for multiple autoimmune diseases.

Applying LD score regression to 19 autoimmune disease GWAS, we first demonstrate substantial genome-wide shared heritability among autoimmune and inflammatory diseases. We observe a complex pattern of sharing, with strong correlations between individual pairs of diseases (e.g. among IBD subtypes, 0.63 â¤ r_g^2 â¤ 0.92) and weaker correlations among others (e.g. MS and RA, r_g^2 = 0.15). The pattern suggests multiple shared mechanisms that differ between pairs of diseases.

We then examine 224 instances where genetic associations to multiple diseases occur in the same region, using a collection of 129,058 cases and controls genotyped on the ImmunoChip. Using joint likelihoods, we show that 41.5% of these observed associations are due to pleiotropic variants, with the remainder being due to different alleles. We use meta-analysis to combine cases and controls across diseases, increasing fine-mapping resolution at shared loci two-fold on average. Mean 95% credible interval size decreases from 37.2 SNPs for individual diseases, to 17.3 SNPs upon meta-analysis across diseases.

With improved resolution, we identify new disease risk variants that alter gene expression in immune cell subtypes. Again using joint likelihoods, we identify 21 new disease:eQTL overlaps at shared loci (from 139 in individual diseases) in the BLUEPRINT dataset. Specificity is increased, with 11 prior disease:eQTL overlaps no longer significant in meta-analysis. Gains occur primarily in cases where meta-analysis reduces credible interval size, indicating that improved resolution drives these new associations.

Our results show that a large proportion of overlapping associations among autoimmune diseases are in fact shared, and that joint analysis of these uncovers shared mechanisms. Our approach can be applied to any set of traits, and is particularly valuable as existing sample collections become depleted.

PrgmNr 1344 - Systematic discovery of gene-environment interactions for metabolic serum biomarkers

View session detail

Author Block: **K. Westerman**[1], F. Giulianini[2], J. C. Florez[1], H. Chen[3], D. I. Chasman[4], M. S. Udler[5], A. K. Manning[1], J. B. Cole[6]; [1]Massachusetts Gen. Hosp., Boston, MA, [2]Brigham and Women's Hosp., Boston, MA, [3]The Univ. of Texas Hlth.Sci. Ctr. at Houston, Houston, TX, [4]Brigham & Women's Hosp, Boston, MA, [5]Broad Inst., Cambridge, MA, [6]The Broad Inst. of MIT and Harvard, Cambridge, MA
Disclosure Block: **K. Westerman:** None.

Gene-environment interactions (GEIs) inform precision genomic medicine by describing how environmental exposures modify the effects of genetic variants on disease risk. Comprehensive mapping of GEIs across all genetic variants, exposures, and outcomes is challenged by the massive search space and accompanying low statistical power. Variance-quantitative trait loci (vQTLs), or genetic variants that associate with differential variance (rather than mean) of an outcome, are enriched for underlying GEIs and can help prioritize variants for subsequent GEI testing. Here, we develop a catalog of GEIs affecting metabolic biomarkers using an initial genome-wide vQTL scan followed by systematic GEI testing across thousands of exposures.

A two-stage analysis was conducted in 355,790 unrelated participants in the UK Biobank, stratifying across four ancestries followed by meta-analysis. In stage one, genome-wide vQTL scans were performed using Leveneâ□□s test for differential phenotypic variance across genotypes for 20 serum metabolic biomarkers (e.g., lipids, lipoproteins, and glycemic measures) identifying 182 independent locus-biomarker relationships. While 90.5% of these variants were also known GWAS mean-effect loci, they represent only a small fraction (3%) of such loci, meaning that vQTL prioritization substantially reduced the GEI search space. 26 vQTLs (e.g., *APOE*) were shared across multiple biomarkers, and over 40% replicated nominally in the much smaller Womenâ□□s Genome Health Study (N=23,294), demonstrating robustness in our results.

In stage two, GEIs underlying these vQTLs were revealed by testing over 2300 socioeconomic, lifestyle, and clinical exposures. Across all pairwise combinations of exposures and vQTLs, 888 GEIs passed a stringent significance threshold. Many involved anthropometric exposures, where preliminary clustering analysis revealed distinct clusters of variants interacting with either fat-free mass- or adiposity-related traits. Other interactions had implications for lifestyle choices: alcohol intake was associated with an increase in ALT, a liver marker, specifically in carriers of two missense alleles at rs1229984 in the alcohol-processing *ADH1B* gene (p_{int}=8.310^{-13}).

Our vQTL scan prioritized a subset of well-known GWAS loci that affect metabolic biomarker variance, while the following systematic GEI analysis revealed hundreds of novel interactions and pinpointed specific participating exposures. Our catalog of vQTLs and GEIs, which is publicly available on the Common Metabolic Disease Knowledge Portal, provides a knowledge base for genome-centered precision approaches to metabolic health.

PrgmNr 1345 - Global Biobank Meta-analysis Initiative: power genetic discovery for human diseases with > 2.6 million samples across diverse ancestries

View session detail

Author Block: **W. Zhou**[1], M. Kanai[2], A. R. Martin[3], K-H. Wu[4], J. Karjalainen[5], M. Kurki[6], S. Chapman[2], C. J. Willer[4], B. M. Neale[3], M. J. Daly[3], Global Biobank Meta-analysis Initiative; [1]Massachusetts general Hosp., Broad Inst., Boston, MA, [2]Broad Inst. of MIT and Harvard, Cambridge, MA, [3]Massachusetts Gen. Hosp., Boston, MA, [4]Univ. of Michigan, Ann Arbor, MI, [5]Boston, MA, [6]

Disclosure Block: **W. Zhou:** None.

The Global Biobank Meta-analysis Initiative (GBMI) brings together large-scale genomic studies by biobanks to foster collaboration in understanding the genetic basis of human disease. 21 biobanks have joined the initiative, totaling more than 2.6 million individuals with matched genetic data and electronic health records. In the flagship project, we meta-analyzed up to 18 biobanks on 14 endpoints of common interest including common or well-studied diseases, such as asthma, less prevalent or understudied diseases, such as gout and acute appendicitis, and the relevant procedure endpoint, appendectomy. GBMI incorporates diverse ancestries in genetic studies by including biobank samples across 6 main populations: 341,000 East Asians, 31,000 South and Central Asians, 33,000 Africans, 18,000 Admixed Americans, 156,000 Finnish, and 1.2 million Non-Finnish Europeans. Analysis pipelines for conducting GWAS with harmonized phenotype definitions in individual biobanks and cloud-based infrastructure for sharing data and performing meta-analyses have been well established. All-biobank meta-analyses of 14 endpoints have successfully replicated 271 previously reported loci and identified 237 potentially novel loci. The effect sizes of 33 loci are heterogeneous across biobanks, 35 are heterogeneous across ancestry, and 47 are different in males and females. By evaluating the effect sizes and association p-values for index variants in previous studies and employing genetic correlation, we have validated the integration of genetic studies across biobanks despite the different underlying raw data, such as phenotype ascertainments (ICD vs. self-reported) and sample recruiting strategies (hospital vs. general population) and demonstrated the improved association power given the increased sample sizes. Out of the 10 loci identified for acute appendicitis by meta-analyzing 10 biobanks, 3 were also significant for appendectomy even though the sample size was 3 times lower, suggesting that the procedure endpoints can be useful in biobank-based genetic studies. Besides gleaning deeper biological implications for human diseases with extensive in-silico analyses, multiple groups within GBMI are working on demonstrating the value of such collaborative efforts, e.g. increased prediction accuracy of polygenic risk scores. GBMI is also addressing challenges commonly faced in biobank-based genetic studies such as establishing best practices to prioritize functional genes and variants which currently remains unclear. This flagship project provides considerations and guidelines for future work in biobank meta-analyses.

PrgmNr 1346 - Phenome-wide HLA association landscape of 235,000 Finnish biobank participants

View session detail

Author Block: **J. Partanen**, S. Koskela, K. Hyvarinen, FinnGen consortium, J. Ritari; FRC Blood Service, Helsinki, Finland
Disclosure Block: **J. Partanen:** None.
The human leukocyte antigen (HLA) system is the single most important genetic susceptibility factor for many autoimmune diseases and immunological traits. However, in a range of clinical phenotypes the impact of HLA alleles or their combinations on the disease risk are not comprehensively understood. For systematic population-level analysis of HLA-phenotype associations we imputed the alleles of classical HLA genes in a discovery cohort of 146,630 and replication cohort of 89,340 Finns of whom SNP genotype data and 3,355 disease phenotypes were available as part of the FinnGen project. In total, 3,649 statistically significant single HLA allele associations in 368 phenotypes were found in both cohorts. In addition to known susceptibility alleles, we discovered a number of previously poorly-established HLA associations. *DRB1*04:01-DQB1*03:02*, a frequent high-risk haplotype for many autoimmune diseases, was also independently associated with infectious diseases. Conditional analyses to distinguish protective effects from nonpredisposition showed that in 21 disease categories the effect of the high-risk allele was significantly modified by the other allele of the same gene. Furthermore, in many immunological diseases the strength of the top risk allele was significantly modified by an allele of another HLA gene. The results highlight the complex structure of HLA-disease associations and suggest that the entire HLA composition should be considered in genetic risk estimation and functional studies. Shared HLA alleles in autoimmune and infectious diseases support a link between environmental exposure and immunogenetics in these diseases.

PrgmNr 1347 - Global discovery of genetic risk variant allelic enhancer activity in allergic eosinophilic esophagitis and atopic dermatitis

View session detail

Author Block: **X. Lu**, X. Chen, Y. Huang, C. Forney, M. Granitto, A. Diouf, O. Donmez, S. Parameswaran, M. T. Weirauch, L. C. Kottyan; Cincinnati Children's Hosp. Med. Ctr., Cincinnati, OH
Disclosure Block: **X. Lu:** None.

Eosinophilic Esophagitis (EoE) is a chronic antigen-induced allergic inflammatory disease characterized by marked esophageal eosinophilia and esophageal dysfunction. While EoE is rare (1:1000), around 20% of patients with EoE will also develop atopic dermatitis (AD), which is one of the most prevalent inflammatory skin diseases. EoE and AD are characterized by Th2-associated inflammation marked by the production of Th2 cytokines, such as IL-4/IL-13, and the recruitment of Th2 cells into the inflamed tissues. IL-13 is involved in EoE and AD pathogenesis in *in vivo* models. Genome-wide association studies have identified disease-specific and common genetic predisposing factors to EoE and AD, with 531 genetic variants at 41 risk loci for EoE and 3,006 variants at 122 loci for AD. The vast majority of these variants are non-coding, suggested they likely act by impacting gene regulatory mechanisms. To systematically screen these variants for their effects on gene regulation, we constructed a massively parallel reporter assay (MPRA) library comprising 14,192 DNA oligonucleotides containing the genomic context around every allele of these 3,540 variants. Transfection into TE7 (esophagus) and HaCaT (keratinocyte) cells with or without IL13 stimulation revealed 577 variants with enhancer activity, with 138 variants showing genotype-dependent (allelic) enhancer activity. All 138 variants can be nominated as putative causal variants for these risk loci. Surprisingly, IL-13 stimulation doesnâ□□t have a significant effect on variants with enhancer activity, suggesting that IL-13 might not play an important role in gene regulatory mechanisms at EoE or AD risk loci in these cell types. These enhancer variants display strong disease specificity, with the predicted target genes for EoE and AD enriching for different disease-relevant pathways. We identified cell-type differences, with more than half of the variants not shared between two cells, indicating cell-type specific regulation of genetic variant activity. Transcription factor binding site motif enrichment analyses in the regions containing these variants with (allelic) enhancer activity reveals strong enrichment for a set of nuclear receptors in both diseases, including RARÎ³, RXRÎ± and LXRÎ². Collectively, these results reveal widespread, largely disparate allelic activity for these diseases, and reveal a potential common disease mechanism involving nuclear receptors regulating the activity of genetic variants for disease susceptibility.

PrgmNr 1348 - A genome-wide survey of recurrent repeat expansions in cancer genomes

View session detail

Author Block: **G. S. Erwin**; Stanford Univ., Palo Alto, CA
Disclosure Block: **G.S. Erwin:** None.
Expansion of a single repetitive DNA sequence, termed a tandem repeat (TR), is known to cause more than 30 rare but devastating diseases, including myotonic dystrophy and Fragile X syndrome. TR sequences can be short (150 bp), and indeed repeat expansions that create long TRs are the loci that are usually pathogenic. However, uniquely mapping repeat expansions with short-read DNA sequencing is difficult because TRs are ubiquitous in the genome. A failure to understand genetic variation in long TRs would make it impossible to capitalize on this information to develop new TR-targeting therapeutics, which I previously showed can rescue expression of genes dysregulated in disease (Erwin et al., Science 2017). Despite their importance to monogenic disease, the frequency and function of repeat expansions that create long TRs are unknown in complex genetic diseases such as cancer.We analyzed >2,500 cancer genomes from the PCAWG dataset with Expansion Hunter De Novo, a new bioinformatic tool that has been validated with both known and novel repeat expansions. We identified 79 recurrent repeat expansions (rREs) in 6 human cancers. Several repeat expansions were validated in an independent cohort of samples. In 5% of all cancers, expansions and contractions accumulate in short (UGT2B7, proximal to an enhancer. This expansion is correlated with a decrease in *UGT2B7* expression, and low expression of *UGT2B7* is associated with poor survival outcomes. Our data provide evidence that rREs are an important but overlooked source of genetic variation in human cancer.

PrgmNr 1351 - Brain-specific succinyl-CoA synthetase deficiency leads to increased protein succinylation, abnormal neuronal metabolism, and altered chromatin accessibility

View session detail

Author Block: **M. Anderson**[1], P. Gillespie[1], X. Chu[1], H. Gao[1], M. Marcus[1], Y. Liu[1,2], Y. Wang[1], B. H. Graham[1]; [1]Dept. of Med. and Molecular Genetics, Indiana Univ Sch. of Med., Indianapolis, IN, [2]Ctr. for Computational Biology & Bioinformatics, Indiana Univ Sch. of Med., Indianapolis, IN
Disclosure Block: **M. Anderson:** None.
Succinyl-CoA Synthetase (SCS) catalyzes the reversible conversion of succinyl-CoA to succinate in the Krebâ□□s cycle. In humans, pathogenic variants in SCS subunits are associated with mitochondrial encephalomyopathy with tissue-specific mitochondrial DNA (mtDNA) depletion. In eukaryotes, SCS is a heterodimer with a single catalytic alpha subunit, Suclg1, and two isoforms of its beta-subunit (Sucla2 or Suclg2). Using a CRISPR-Cas9 generated floxed allele of *Sucla2* and the forebrain-specific *CamKIIÎ±*-Cre, forebrain-specific knock-out of *Sucla2* has been achieved, resulting in the first *in vivo* adult model of homozygous SCS deficiency. Molecular validation via RT-qPCR demonstrates significant reduction of *Sucla2* gene expression in mutant cortex. However, western blot analysis indicates that forebrain-specific knockout of SUCLA2 results in reduced protein expression of both SUCLG1 and SUCLG2, suggesting significant post-transcriptional down-regulation of the entire SCS complex. Notably, this model does not exhibit mtDNA depletion, allowing investigation of brain-specific pathogenic mechanisms of SCS deficiency independent of metabolic defects caused by mtDNA depletion. Enzyme activity analysis revealed significantly reduced function of SCS, predicted to result in increased cellular succinyl-CoA. Accumulation of cellular succinyl-CoA is further corroborated by observed metabolic perturbations, including elevated C4-DC acyl-carnitines and methylmalonic acid (MMA). Succinyl-CoA is the substrate for protein lysine-succinylation, a post-translational modification shown to have impact on multiple biological processes, including many metabolic pathways and histone modification. Global protein succinylation is significantly increased in the cortex of the mutant model, and ATAC-seq results demonstrate significant alterations in chromatin accessibility. Ongoing studies include proteomics and transcriptomics to further elucidate the consequences of SCS deficiency in neurons. This unique model promises to provide new insight into the function of SCS and lysine succinylation on brain metabolism, which will have a significant impact on therapeutic research of metabolic and mitochondrial disorders.

PrgmNr 1352 - Aberrant posttranslational modifications contribute to MMA pathophysiology and identify new targets for therapy

View session detail

Author Block: **P. E. Head**[1], S. Myung[1], Y. Chen[1], D. Romero[1], J. Schneller[1], S. McCoy[1], I. Manoli[2], M. Gucek[1], C. P. Venditti[3]; [1]NIH, Bethesda, MD, [2]NIH, Bethesda, MD, [3]NHGRI (NIH), Bethesda, MD
Disclosure Block: **P.E. Head:** None.
Organic acidemias, such as methylmalonic acidemia (MMA), are a group of inborn errors of metabolism that typically arise from defects in the catabolism of amino- and fatty acids. The accretion of acylic acid species is postulated to cause intracellular toxicity and underlie the dysregulation of multiple intermediary pathways seen in the patients, such as the urea cycle and glycine cleavage system. Here, we explore an alternative pathophysiological consequence of impaired acyl-CoA metabolism: the accumulation of aberrant posttranslational modifications (PTMs) on enzymes in critical intracellular pathways. Using an MMA mouse model that recapitulates MMA hepatic mitochondriopathy (*Mmut*$^{-/-}$;*Tg*$^{INS\text{-}MCK\text{-}Mmut}$), we surveyed PTMs in hepatic extracts with acyl-lysine antibodies and discovered widespread hyper-acylation. Next, we performed mass spectrometry to characterize the PTM proteome. Excessive acylation of enzymes involved in glutathione, urea, arginine, tryptophan, valine, isoleucine, methionine, threonine, and fatty acid metabolism were detected in the MMA mice, and validated via immunoprecipitation analysis. We extended our analyses to other MMA perturbed pathways, including the glycine cleavage system, which we found to be aberrantly modified in liver extracts from MMA patients. These discoveries provide the mechanism underlying both hyperammonemia and ketotic hyperglycinemia, secondary perturbations of MMA. We have since identified the sirtuin deacylase capable of removing MMA-related PTMs and using rational mutagenesis, we created a â□□SuperSIRTâ□□ that was resistant to acylation-dependent inhibition, validated activity in vitro, cloned it behind a liver specific promoter (LSP), and packaged it within an AAV8 capsid. The resulting AAV8 LSP SuperSIRT or an AAV8 LSP EGFP control were then systemically delivered to *Mmut*$^{-/-}$;*Tg*$^{INS\text{-}MCK\text{-}Mmut}$ and *Mmut*$^{+/-}$;*Tg*$^{INS\text{-}MCK\text{-}Mmut}$ mice, at a dose of 1e13 GC/kg, and followed by biochemical and enzymatic analyses. Blood ammonia levels were significantly reduced in the treated mutant mice compared to the EGFP and untreated mutant control groups, while plasma methylmalonic acid levels remained unchanged. In hepatic extracts from the SuperSIRT treated *Mmut*$^{-/-}$;*Tg*$^{INS\text{-}MCK\text{-}Mmut}$ mice, aberrant acylation on key protein targets in the urea cycle and glycine cleavage system was reversed compared to GFP treated controls. In summary, our studies have identified a new PTM axis in patients and mice with MMA, which has allowed the development of a SuperSIRT gene therapy that could be used to treat all forms of MMA and might be extended to other disorders where aberrant acylation plays a role in disease pathophysiology.

PrgmNr 1353 - The gnomAD database of mitochondrial DNA variation across 56,434 individuals

View session detail

Disclosure Block: **S. Calvo:** None.
Databases of allele frequency are extremely helpful for evaluating clinical variants of uncertain significance, however until now genetic databases such as the Genome Aggregation Database (gnomAD) have ignored the mitochondrial genome (mtDNA). We have developed a pipeline to call mtDNA variants that addresses three technical challenges: (i) heteroplasmic variants present in any fraction of mtDNA molecules, (ii) a circular genome, and (iii) mis-alignment of nuclear sequences of mitochondrial origin (NUMTs). We apply this pipeline to 56,434 whole genome sequences in the gnomAD v3.1 database that includes individuals of European (58%), African (25%), Latino (10%), and Asian (5%) ancestry. We find that the number of mtDNA copies per cell varies across gnomAD cohorts and directly relates to accuracy in distinguishing heteroplasmic variants from NUMT-derived false positives, and thus we conservatively report only variants with heteroplasmy above 10%. Our gnomAD v3.1 release contains population frequencies for 10,850 unique mtDNA variants, and includes both homoplasmic (98%) and heteroplasmic (2%) variant calls. We observe that 1/250 individuals carry a pathogenic mtDNA variant with heteroplasmy >10%. The gnomAD database of population allele frequencies will be useful for evaluating clinical mtDNA variants of unknown significance, and will become increasingly useful as the database grows. The mtDNA variants are publicly available within gnomAD v3.1 (gnomad.broadinstitute.org).

PrgmNr 1354 - Clinician lead analysis of WGS data identifies missed diagnoses in suspected primary mitochondrial disease

View session detail

Author Block: **W. Macken**, C. McKittrick, C. Pizzamiglio, E. Bugiardini, M. Falabella, R. Quinlivan, H. Holden, M. Hanna, Genomics England Research Consortium, J. Vandrovcova, R. D. S. Pitceathly; UCL Inst. of Neurology, London, United Kingdom
Disclosure Block: **W. Macken:** Grant/Contracted Research Support (External); Medical Research Council.
Purpose: Clinical WGS promises improved diagnostic rates in rare disease, however, high-throughput approaches in clinical laboratories may overlook diagnoses with nuanced presentations. A broader approach is especially needed in conditions like Primary Mitochondrial Diseases (PMDs), where phenotypes are non-specific. We sought to assess whether a clinically focused review could increase the diagnostic rate of these complex patients. **Methods used:** One hundred and two probands attending a Specialised Service for PMDs underwent WGS (Illumina TruSeq, HiSeq 2500) via the 100,000 Genomes project following exclusion of common molecular causes of PMD. Standard virtual panel analysis was undertaken initially. The phenotype of undiagnosed patients was then scrutinised by a clinician, their data was re-annotated by a clinical bioinformation, and subsequently manually reviewed by a clinician on a clinical interpretation platform. Re-analysis of data included expansion of gene panels applied if appropriate, and analysis for cryptic in trans variants in strong candidate recessive genes, assessment for CNVs, and interrogation of mtDNA using a somatic variant caller. **Key Results:** The standard bioinformatic pipeline with clinical scientist-driven interpretation yielded diagnoses in 18/102 (17.6%). Expanded analysis resulted in a diagnostic uplift in 17/102 (16.7%) of cases; heteroplasmic mtDNA variants were identified in 3/102 patients; nDNA diagnoses were confirmed in 14/102 patients; separately, suspected pathogenic variants in novel genes were identified in 3 further patients. Reasons for missed diagnoses included limited use of virtual gene panels, interpretation problems with complex family histories, missed mosaic variants, missed heteroplasmic variants and missed variants in new morbid genes. Only 40% of all diagnoses were true PMDs, emphasising the need to include a broad differential when diagnosing these patients. Our approach close to doubled the diagnostic rate from 17.6% to 13.3%. To harness the full power of WGS in clinical services, high throughput analysis by clinical scientists should be include in depth phenotype-focused analysis by a genomic medicine clinician. This research was made possible through access to the data and findings generated by the 100,000 Genomes Project; http://www.genomicsengland.co.uk.

PrgmNr 1355 - Regulating *PCCA* gene expression by splice switching antisense oligonucleotide-mediated modulation of pseudoexon splicing to rescue propionyl CoA carboxylase enzyme activity in propionic acidemia

View session detail

Author Block: **U. Petersen**[1], M. Dembic[1], A. MartÃnez-Pizarro[2], L. R. Desviat[2], B. S. Andresen[1]; [1]Dept. of Biochemistry and Molecular Biology, Univ. of Southern Denmark, Odense M, Denmark, [2]Centro de BiologÃa Molecular Severo Ochoa, Departamento BiologÃa Molecular, Univ. AutÃ³noma de Madrid, Madrid, Spain
Disclosure Block: **U. Petersen:** None.
The deep intronic sequence variation, c.1285-1416A>G, activates an 84 bp pseudoexon from intron 14 in the *PCCA* gene by changing the activity of a splicing regulatory element within the pseudoexon sequence. The *PCCA* pseudoexon is activated for increased inclusion in mRNA, however, relatively high inclusion levels can be observed in normal cells as well. Inclusion of the pseudoexon introduces an in-frame premature termination codon, which targets the pseudoexon-containing mRNA for degradation by nonsense-mediated mRNA decay. Activation of the *PCCA* pseudoexon causes deficiency of propionyl-CoA carboxylase (PCC) and propionic acidemia, a rare autosomal recessive metabolic disorder with metabolic decompensation and multiorgan complications.
We and others have shown that splice-switching antisense oligonucleotides (SSO) can be employed to inhibit inclusion of the *PCCA* pseudoexon. We have used different minigenes to study the underlying molecular defect in detail and to identify efficient SSOs. We demonstrate that SSO-mediated skipping of the *PCCA* pseudoexon increases PCC enzyme activity in patient fibroblasts homozygous for *PCCA* c.1285-1416A>G, in patient fibroblasts with *PCCA* missense variations with residual PCC activity, and also in control fibroblasts with wildtype *PCCA*. We generated a HepG2 cell line with the *PCCA* c.1285-1416A>G variation, using the CRISPR/Cas12a system, providing us with a stable isogenic model of the pseudoexon activation event. SSO-mediated skipping of the *PCCA* pseudoexon restores normal splicing patterns and expression of wildtype *PCCA*. Interestingly, it increases both PCCA and PCCB protein levels and increases PCC activity in HepG2 *PCCA* c.1285-1416A>G and in HepG2 *PCCA* wildtype cell lines. This suggests that the *PCCA* pseudoexon can be exploited as a gene-regulatory switch and that SSO-mediated modulation of *PCCA* splicing patterns can be employed in treatment of propionic acidemia, both in patients with the *PCCA* pseudoexon activating variation and in patients with pathogenic missense variations with residual PCC activity. Moreover, we show that the SSO-mediated increase of PCCA protein amounts rescues unstable overproduction of PCCB from degradation, increasing the production of PCC heterododecamers and thereby increasing the PCC enzyme activity. This suggests that SSO-mediated skipping of the *PCCA* pseudoexon could potentially increase PCC activity also in cells with pathogenic *PCCB* missense variations with residual PCC activity.

PrgmNr 1356 - Multi-omics and functional studies in two cellular models of Barth Syndrome reveal novel mitochondrial defects and suggest new therapeutic approaches

View session detail

Author Block: **O. Sniezek**[1], A. Anzmann[2], N. Senoo[3], E. Tampakakis[4], S. Claypool[3], H. Vernon[1]; [1]Johns Hopkins Sch. of Med., Dept. of Genetic Med., Baltimore, MD, [2]Johns Hopkins Univ. Sch. of Med., Dept. of Genetic Med., Baltimore, MD, [3]Johns Hopkins Sch. of Med., Dept. of Physiology, Baltimore, MD, [4]Johns Hopkins Sch. of Med., Dept. of Med.: Cardiology, Baltimore, MD
Disclosure Block: **O. Sniezek:** None.
Barth Syndrome (BTHS) is a rare X-linked disorder caused by defects in the gene *TAFAZZIN*, resulting in defective cardiolipin synthesis. Clinically, BTHS is characterized by cardiomyopathy, neutropenia, skeletal myopathy, and growth defects, and has a high morbidity and mortality. Currently, there are no approved disease-specific treatments. In order to investigate the cellular pathology in BTHS, to understand tissue-specific disease effects, and to identify new areas of potential therapeutic intervention, we developed two CRISPR-edited cell lines: *TAFAZZIN*-null HEK293 cells, with which to perform broad-based discovery experiments, and *TAFAZZIN*-null iPSCs, which were differentiated into disease-relevant cell types to study tissue-specific disease effects. Proteomics, lipidomics, and metabolomics in *TAFAZZIN*-null HEK293 cells revealed diverse mitochondrial abnormalities, including abnormal mitochondrial complex I assembly, expression and function, and upregulation of PDK2, an inhibitor of pyruvate dehydrogenase. When we inhibited PDK2 function, we observed increased expression of proteins associated with mitochondrial stress. Thus, upregulated PDK2 expression may serve as a protective mechanism in *TAFAZZIN*-deficient cells and inhibition of PDK2, a therapeutic approach for other mitochondrial disorders, may be counterproductive in Barth Syndrome. When we targeted early steps in cardiolipin metabolism and cardiolipin stability with bromoenol lactone and elamipretide, respectively, we were able to remediate Complex I dysfunction. Thus, targeting cardiolipin metabolism, both proximally and distally to the primary molecular defect, are promising directions for therapeutic targeting. We next explored tissue-specific manifestations of Barth Syndrome via lipidomics and RNA-seq in iPSC-derived *TAFAZZIN*-deficient and wild-type cardiomyocytes and neurons. These studies revealed extensive disturbances in cellular lipid content and mitochondrial gene expression between both WT and *TAFAZZIN* null cells, and between *TAFAZZIN*-null cardiomyocytes and neurons. Oxygen consumption studies showed defective maximal respiratory capacity in both *TAFAZZIN*-null cardiomyocytes and neurons compared to WT. We are currently targeting specific fatty acid pools and early steps in cardiolipin metabolism in the differentiated *TAFAZZIN*-deficient cells with the goal of remediating cellular lipid, mitochondrial gene expression, and oxygen consumption abnormalities.

PrgmNr 1359 - Systematic functional interrogation of the Lynch Syndrome gene *MLH1* by deep mutational scanning

View session detail

Author Block: **X. Jia**[1], B. B. Burugula[1], S. Jayakody[1], S. L. Hemker[1], C. Smith[2], A. Scott[1], J. O. Kitzman[1,2]; [1]Dept. of Human Genetics, Univ. of Michigan, Ann Arbor, MI, [2]Dept. of Computational Med. and Bioinformatics, Univ. of Michigan, Ann Arbor, MI
Disclosure Block: **X. Jia:** None.
Variant interpretation poses a key barrier to the clinical utility of genetic testing. Even intensively studied genes, such as the DNA mismatch repair factors that underlie Lynch Syndrome, have a heavy burden of variants of uncertain significance (VUS). Missense variants are particularly challenging to interpret, and ~87% of the Lynch Syndrome gene missense variants listed in the ClinVar database remain unclassified. This VUS burden severely impedes diagnosis, prevention and intervention for this highly prevalent (~1:300) and actionable familial cancer syndrome. To systematically generate functional evidence that can assist clinical variant interpretation, we performed a deep mutational scan of *MLH1,* one of four key genes underlying Lynch Syndrome. We used saturation single-codon mutagenesis to generate libraries covering 99.6% of all *MLH1* missense mutations (N=14,364). These libraries were stably knocked in to *MLH1*-deficient human cell lines, and the resulting population of *MLH1* missense mutant cells was subjected to functional selection using 6-thioguanine treatment, an established assay for mismatch repair gene function. We deeply sequenced these *MLH1* libraries before and after selection, to generate loss-of-function (LoF) scores for >14,300 *MLH1* missense variants. These LoF scores were bimodally distributed, with 22% (n=3,139) of all missense variants having a damaging effect on MLH1 function. Overlaying these LoF scores onto MLH1 protein structural domains, we observe damaging variants are strongly enriched in the N-terminal ATPase domain (in which 26.8% of missense variants are LoF) and C-terminal dimerization domain (24.6%). By contrast, the internal, intrinsically disordered linker domain is highly tolerant to single missense mutations (only 7.9% of variants are LoF). These scores showed strong concordance (AUC ROC=0.995) with expert reviewed classifications from ClinVar (N=103 missense variants), suggesting that they are highly predictive of pathogenicity and can extrapolate to unclassified and newly observed variants. This map, together with a recent scan of another key Lynch gene *MSH2* from our group (Jia et al, *AJHG*, 2021), demonstrates the promise of systematic functional characterization for enabling prospective early detection and intervention in Lynch Syndrome.

PrgmNr 1360 - Comprehensive cell-type classification of tumor and normal cells from single cell RNA sequencing in pan cancer settings

View session detail

Author Block: **I. Nofech-Mozes**[1], S. Abelson[1], P. Awadalla[2]; [1]Ontario Inst. for Cancer Res., Toronto, ON, Canada, [2]Ontario Inst Cancer Res., Toronto, ON, Canada
Disclosure Block: **I. Nofech-Mozes:** None.
Single-cell RNA sequencing (scRNA-seq) has gained popularity due to its ability to study the transcriptome at a cellular level, where populations of cells are annotated based on the expression of marker genes. Thus, scRNA-seq provides a tool to gain cell-specific, subtle insights on cancer biology. However, precise annotation of cell type remains a challenge, hindering the efficiency and accuracy of data interpretation. A number of existing tools for cell-type annotation have been developed in an attempt to improve resolution and reproducibility, yet their performance is reduced when the reference dataset contains a large number of cell types from multiple tissue types, subclasses of similar cell types, or malignant cells. The large degree of interpatient malignant cell heterogeneity often leads to reduced accuracy when classifying cancer cells as most methods rely on correlations to a reference from a different source. Given the challenges in the annotation of scRNA-seq data of cancer and its high impact for elucidating mechanisms associated with tumor heterogeneity, pathogenesis, and treatment, we developed a comprehensive, hierarchically organized, multi-layered classifier spanning diverse malignant and normal cells of the tumor microenvironment. We found that performance improves when each layer focuses on a smaller number of classes and each cell sequentially moves down a series of classifiers with increased cell type resolution. When applied to 12 external validation datasets of solid tumor biopsies spanning diverse cancer types, the classifier accurately annotated the tissue of origin of malignant cells, and relevant subtypes of stromal and blood cells, with average specificity, sensitivity, and F1 scores of 0.99, 0.89 and 0.93 for cancer cells. Using confidence thresholds at each layer, the classifier abstains from classifying ambiguous cells. When applying CHETAH, an existing hierarchical classifier provided with the same reference, the majority of cancer cells are unclassified. Moreover, we validated our classifierâ□□s capability to correctly identify the tissue of origin in scRNA-seq data derived from brain metastasis of lung adenocarcinoma. This analysis demonstrates the classifierâ□□s power to uncover the tissue of origin in cancers of unknown primary. This study provides a flexible model for the annotation of cells comprising the tumor microenvironment in pan cancer settings, while existing methods require tissue-specific references for every cancer type. Our classifier provides a powerful method for investigating intercellular communication pathways between tumor cells and non-malignant cells of the tumor microenvironment.

PrgmNr 1361 - Deep transcriptomic profiling with quantitative measures identifies high-risk multiple myeloma

View session detail

Author Block: **R. Griffin Waller**[1], B. Avery[2], M. J. Madsen[2], H. A. Hanson[2], N. J. Camp[2]; [1]Mayo Clinic, Rochester, MN, [2]Huntsman Cancer Inst. and Univ. of Utah Sch. of Med., Salt Lake City, UT
Disclosure Block: **R. Griffin Waller:** None.

Transcriptomic studies can help decipher tumor heterogeneity and identify patient risk groups. SPECTRA is an approach to describe variation in bulk transcriptome with unsupervised quantitative variables. Spectra variables represent a deep dive into the transcriptome, including both large and small sources of variance, and can be used to model with any clinical, demographic, or biological endpoint. We applied the SPECTRA approach to multiple myeloma (MM), the second most common blood cancer. Using RNA sequencing from malignant cells, we derived 39 unsupervised spectra in 767 patients in the MMRF CoMMpass study. The 39 spectra capture 65% of the variation in patientsâ transcriptomes. In multivariate Cox regression for overall survival (OS, 179 events), 9 spectra were selected as predictor variables. Bootstrap internal validation was used to adjust for over fitting. The model attained an adjusted C-index (C_{adj}) = 0.66 (0.65-0.74). Gaussian mixture modeling was used to determine high and low-risk patients. High-risk patients (n = 88, 58 events) had median survival of 1.7 years. Low-risk patients (n = 679, 121 events) did not reach median survival after 6.5 years. The OS adjusted hazard ratio (HR_{adj}) = 4.27 (2.31-12.69) for spectra high/low risk patients. We compared this to the most widely adopted transcriptomic risk score for survival, UAMS, a score based on 70 differentially expressed genes (k-means defines high/low risk-groups). In the CoMMpass data, the OS HR_{adj} = 3.89 (2.53-5.45) for UAMS high/low risk patients. To understand the overlapping and distinct signals of the two scores and clinical risk factors we used added predictive value (APV). In multivariate Cox regression for OS, including revised internal staging system (R-ISS) and age at diagnosis, spectra risk-score was highly significant ($p = 2.36x10^{-20}$) with APV = 0.612. Spectra risk-score also added value in a model containing R-ISS, age at diagnosis and UAMS risk-score (APV = 0.109, $p = 7.4x10^{-5}$). In contrast, APV = 0.027 for UAMS in a model containing R-ISS, age at diagnosis and spectra risk-score. As our myeloma spectra are unsupervised, the same variable framework can be used to model any outcome or describe associations with clinical or demographic variables. For example, in multivariate Cox regression of time to treatment failure (TTF) 10 spectra were selected and predicted TTF with C_{adj} = 0.60 (0.59-0.66) and HR_{adj} = 3.10 (1.31-5.46) between high/low TTF risk-groups. In summary, the SPECTRA approach provides quantitative measures of transcriptome variation to deeply profile tumors. Application to MM outperformed UAMS and provides greater flexibility to describe tumors and model clinical outcomes.

PrgmNr 1362 - Integrated somatic and germline assessment of PROACTIVE genomic data

View session detail

Author Block: **A. Ghazani**[1], D. R. Koeller[2], A. Schwartz[2], D. K. Manning[3], H. Q. Rana[2], J. E. Garber[2]; [1]Brigham & Women's Hosp/Harvard Med. Sch., Boston, MA, [2]Dana Farber Cancer Inst, Boston, MA, [3]Brigham and Women's Hosp., Boston, MA

Disclosure Block: **A. Ghazani:** None.

Germline variants with low penetrance or in patients with non-syndromic phenotype present unique challenges in the interpretation of variant pathogenicity. In cancer, this challenge may be tempered by the presence of a second set of genomic information: the somatic genome. Here we present the results from genetic analysis of patients at Dana-Farber Cancer Institute and describe an integrated approach for the interpretation of somatic and germline findings. Germline results were obtained from DNA extracted from peripheral blood of patients enrolled in the PROACTIVE study, an institute-wide study that offers hereditary cancer testing of 133 genes for participants meeting disease-specific eligibility criteria. Somatic profiling of tumors was performed by OncoPanel at Brigham and Womenâ□□s Hospital to interrogate 447 cancer genes. To date, 913 patients have been enrolled in the PROACTIVE study; they are 43.9% male and 56.1% female aged between 6 months and 95 years old. Of those, 138 received reports that collectively contained deleterious germline variants in 45 genes; 24 genes (53%) are associated with high penetrance cancer syndromes and/or known clinical management guidelines. To date, 181 of patients have also had somatic sequencing obtained from the extracted DNA of the affected tumors. Reported somatic alterations include variants with well-established clinical utility (34), actionable gains (25) and losses (20), and structural rearrangements (25). Patients who were positive for germline deleterious variants in high penetrant genes but exhibited non-syndromic phenotypes or phenotypes discordant with the genotype were evaluated further using personal and family history of cancer as well as their somatic profiles in their component tumors when available. To date, we have identified ten probands and family members by this approach. Three germline *VHL* variants were found in those without a VHL syndromic phenotype; one germline *APC* variant was identified an individual without clinical suspicion of *APC* associated colon cancer or polyposis syndrome; one germline *MITF* variant was identified in an individual with vulvar mucosal melanoma. Concomitant evaluation of somatic and germline genome profiles, loss of function analysis, segregation, and detailed examination of phenotype and family history in these individuals suggested no evidence for penetrance in males or females in the germline *VHL* or *APC* families. The data also demonstrated new possible role of *MITF* beyond cutaneous melanoma. Our integrated approach of evaluation of both germline and somatic variants has led to the refined interpretation of germline variants and phenotypic implications.

PrgmNr 1363 - Germline HOXB13 variant contributes to risk of prostate cancer in men of African Ancestry

Introduction: The non-synonymous germline HOXB13 G84E mutation is rare (0.1-1.4% frequency) in men of European ancestry and accounts for ~5% of hereditary prostate cancer. Recently, an African ancestry-specific germline deletion variant in HOXB13 (rs77179853), which removes the stop-codon (X285K), was found in Martinican men with early-onset prostate cancer (frequency=3.2%). Given the role of HOXB13 germline variation in prostate cancer, we investigated the association between the HOXB13 X285K variant and prostate cancer risk in a large sample of African ancestry men. Methods: We used freeze 8 of the TOPMed reference panel to impute the HOXB13 X285K variant in 22,361 men of African ancestry, which included 11,681 prostate cancer cases from the African Ancestry Prostate Cancer (AAPC) GWAS Consortium, the ELLIPSE/PRACTICAL OncoArray Consortium, the California/Uganda Prostate Cancer Study, the Ghana Prostate Study, and the Men of African Descent and Carcinoma of the Prostate (MADCaP) Consortium. Logistic regression models were used to assess the association of X285K with prostate cancer risk and aggressive disease adjusting for age, study, and the first ten principal components of ancestry. Results: The risk allele was only present in men of West African ancestry, with allele frequencies of 0.40% in controls from Ghana, 0.31% in controls from Nigeria, and 0% in controls and cases from Uganda and South Africa. Allele frequencies ranged from 0% to 0.26% in African ancestry controls from North America, the UK, and France, likely due to admixture. Limiting to populations where the variant was observed (10,476 cases and 9,687 controls), the HOXB13 X285K variant was significantly associated with a 2.4-fold increased risk of prostate cancer (95% CI=1.5-3.9, P=2.0x10-4; allele frequency in cases=0.35% and controls=0.14%). The variant was more common in 3,092 cases with high- or very-high risk disease (defined as Gleason 8-10, stage T3/T4, PSAâ¥20 nm/ml, metastatic disease, or died due to prostate cancer), with an allele frequency of 0.53% (OR=3.3, 95% CI=1.9-5.6, P=1.6x10-5, compared to controls). Conclusion: The HOXB13 X285K variant is associated with increased risk of prostate cancer in men of African ancestry. The variant is only found in men with West African ancestry and arose on an ancestral haplotype, although studies in other populations are needed to understand the distribution of the variant in Africa. Further analysis is needed to understand how the HOXB13 X285K impacts the HOXB13 protein and the function of this homeobox transcription factor in the prostate. Men carrying this variant may benefit from earlier PSA screening.

PrgmNr 1364 - Identification of mitochondrial DNA variants associated with risk of neuroblastoma

View session detail

Author Block: **X. Chang**[1], H. Hakonarson[2]; [1]CHOP, Philadelphia, PA, [2]Children S Hosp. of Philadelphia, Philadelphia, PA

Neuroblastoma is a childhood cancer that originates in the developing sympathetic nervous system. Emerging evidence indicate an important role of mitochondrial DNA (mtDNA) in the pathobiology of neuroblastoma. In this study, we aimed at identifying mtDNA variants associated with neuroblastoma risk. We applied a mitochondrial genome imputation pipeline to the SNP array data of two pediatric cohorts containing a total of 2,404 Caucasian children diagnosed with neuroblastoma and 9,310 ancestry-matched controls recruited at The Childrenâ□□s Hospital of Philadelphia. We further conducted case-control studies to explore potential associations of mtDNA variants with the susceptibility of neuroblastoma using logistic regression. Our results indicate that the mtDNA variant rs2853493 is significantly associated with neuroblastoma risk in the discovery cohort (odds ratio 0.62, P = 3.06 â□□ 10^{-9}). This result was further confirmed in the replication cohort (odds ratio 0.75, P = 2.43 â□□ 10^{-3}). Meta-analysis of the discovery and replication data identified rs2853493 (odds ratio 0.67, P = 9.36 â□□ 10^{-11}) and rs2853499 (odds ratio 0.71, P = 2.57 â□□ 10^{-8}) reaching the genome-wide significance level. Further, eQTL analysis shows that genotypes of the rs2853493 variant are associated with expression levels of MT-ND4 and MT-ND5 in multiple human tissues, and associated with MT-CYB gene expression in neuroblastoma cells. In this study we uncovered two mtDNA variants associated with neuroblastoma risk and provide information on candidate genomic regions and genetic markers of biological interest we propose to target in future studies.

PrgmNr 1367 - The genomic landscape of mosaic Y chromosome loss in the VA Million Veteran Program

Background: Mosaic loss of the Y chromosome (mLOY) in peripheral blood cells is implicated in aging and mortality-related disease processes in men (Forsberg, *Hum. Genet.* 2017). The Million Veteran Program (MVP) is a large, ancestrally diverse cohort, and a majority of participants are older men, making it ideal for studying mLOY.

Methods: Following recent advances (Thompson et al, *Nature* 2019), we called mLOY events in MVP by detecting shifts in allelic ratio in the pseudoautosomal region 1 (PAR1) using MoChA. We found detectable levels of mLOY in 26% of European-ancestry men, and 13% of African-ancestry and Hispanic-ancestry men.

Results: Genome-wide association scans (GWAS) identified 330 independent signals associated with mLOY in European-ancestry men (N=401,035), more than double the number of previously discovered signals. A GWAS in African-ancestry men (N=99,103) yielded 51 independent significant loci, including novel African-specific signals at *MPL*, *BUB1B*, *ETV6*, *SRCAP*, *TNRC6C*, and *XPC*. Finally, a GWAS in Hispanic/Latino men (N=44,046) yielded 18 signals. We refined these associations through local ancestry deconvolution (Tractor), trans-ancestry fine-mapping, and colocalization analyses. We additionally found 18 novel rare variant associations with mLOY, including germline mutations in *CHEK2* and *ATM* and somatic mutations in *DNMT3A*, *IDH2*, and *JAK2*, all genotyped on the MVP array. Leveraging the VAâ□□s electronic health record, we replicated previously reported associations with mLOY and additionally observed a striking negative association between metabolic phenotypes and mLOY, which was robust to adjustment for blood cell counts. We subsequently demonstrated this relationship to be causal (metabolic syndrome -> reduced mLOY) using summary-based Mendelian randomization experiments.

Conclusions: We conducted the first trans-ancestry analysis of mLOY and discovered numerous novel variant associations in European and African ancestries. As MVP tends to be older and with more comorbidities than other similarly sized cohorts, we found novel associations with metabolic traits, highlighting connections between the immune and neuroendocrine systems.

Disclosure Block: **A. Mak:** None.

Background: Non-European populations are under-represented in both genome-wide association studies (GWAS) and expression quantitative trait loci (eQTLs) reference databases. The lack of adequate eQTL datasets limits fine mapping of GWAS results and the application of transcriptome-wide association studies (TWAS) in non-European ancestry populations. We leveraged whole genome and RNA sequencing data from 2,280 African American, Mexican American, and Puerto Rican children with and without asthma to investigate the relationship between genetic ancestry and heritability of gene expression. We quantified the prevalence of ancestry-specific eQTLs, developed gene expression models for TWAS, and demonstrated the gains in predictive power.

Results: Heritability (h^2) of gene expression in *cis* was highest in participants with the higher African (AFR) ancestry populations and lowest in participants with the higher Indigenous American ancestry (IAM). Participants with >50% AFR (AFR_{high}: h^2=0.17) had significantly higher h^2 compared to individuals with low: h^2=0.13, p=2.0Ã□10^{-147}). Among participants with >50% IAM, heritability was lower (h^2=0.12) compared to h^2=0.16, p=2.0Ã□10^{-147}). The results for higher heritability in AFR and lower for IAM were consistent when we used locus specific ancestry for heritability comparisons. We developed a framework to identify ancestry-specific eQTLs, accounting for linkage disequilibrium. We studied 9,635 heritable genes in the AFR_{high} individuals and found that over 25% had ancestry-specific eQTLs. We generated gene expression imputation models for 11,807 genes (mean cross-validation R^2=0.16) and compared these models with models based on GTEx and the Multi-Ethnic Study of Atherosclerosis (MESA) in a TWAS of 28 traits from the Population Architecture using Genomics and Epidemiology (PAGE) Consortium. The total number of genes examined in our models was 38% to 53% higher than GTEx and MESA, respectively. Applying our models to multi-ancestry GWAS results from PAGE identified 321 significantly associated genes (FDR-3) and in GTEx (in 83% of analyses, p=7.5Ã□10^{-3}).

Discussion: We found that *cis*-heritability of gene expression tracked with heterozygosity (highest in AFR and lowest in IAM). We also found that ancestry-specific eQTLs are common in a large fraction of genes, stressing the need for larger GWAS and RNA-seq sample size in AFR and IAM populations. Finally, we demonstrated the improved performance of ancestry-specific gene expression models for gene discovery in populations with mixed ancestry.

PrgmNr 1369 - Single-cell RNA-sequencing reveals pervasive but highly cell type-specific genetic ancestry effects on the response to viral infection

Humans vary in their susceptibility to infectious disease, partly due to variation in the immune response following infection. Genome-wide association studies and eQTL mapping studies in immune cells have shown that certain polymorphisms drive variation in the response to influenza, including expression patterns of key antiviral regulators. Influenza infection has also been shown to induce marked differences in response that are correlated with genetic ancestry in monocytes derived from African and European individuals. Yet, relatively little is known about the underlying genetic factors that contribute to heterogeneity in the influenza response across different immune cell types and subsets. Here, we used single-cell RNA-sequencing to quantify genetic contributions to this variation in peripheral blood mononuclear cells across 90 individuals, focusing specifically on the transcriptional response to influenza infection. We find that monocytes are the most responsive to infection, but that all cell types mount a conserved interferon response, which is stronger in individuals with increased European ancestry. By comparing expression patterns between European American (EA) and African American (AA) individuals, we show that genetic ancestry effects on expression are common, influencing 29% of genes, but highly cell type-specific, with over half detected in only one or two cell types. Further, we demonstrate that, on average, 53% of population-associated expression variation is explained by *cis*-expression quantitative trait loci. Finally, we provide evidence that genes associated with COVID-19 severity are strongly enriched for genes differentially expressed between African- and European-ancestry individuals, suggesting that immune response variation may compound some of the known health disparities that contribute to differences in COVID-19 susceptibility reported between AA and EA individuals. Our findings establish common *cis*-regulatory variantsâ□□including those that are differentiated by genetic ancestryâ□□as important determinants of the antiviral immune response.

PrgmNr 1370 - Chromatin accessibility differences between African and European Alzheimer Disease brains

Background: Local ancestry (LA) surrounding the APOE4 allele is associated with an increased risk for Alzheimer Disease (AD) in European (EU) LA compared to African (AF) LA. We recently demonstrated that APOE4 has significantly higher expression in astrocytes from EU compared to AF APOE4 LA carriers, but the specific molecular mechanism leading to this difference is not known. We investigated whether evaluating chromatin accessibility in the LA region in prefrontal cortex from both AF and EU LA could lead us to identify potential regulatory factors affecting chromatin remodeling and expression of APOE. **Method:** We performed single nuclei Assays for Transposase Accessible Chromatin sequencing (snATAC-seq) in five AF LA and six EU LA individuals with AD, all homozygous APOE4/4 carriers. We processed the snATAC-seq data using Archr. **Result:** In total, 46,454 nuclei were sequenced with an average of 11,698 median fragments per nuclei. Overall, 729,589 chromatin accessible peaks were identified. We detected 24 clusters using UMAPhCluster resolution 1.3. Most of the clusters showed no differential accessibility when comparing ancestry groups, however four clusters had increased accessibility in AF and two had decreased accessibility in AF. Within the two clusters with decrease accessibility in AF, the astrocytic cluster 11 had the most differentially chromatin accessible peaks between AF and EU (325 vs 7895 peaks respectively). Interestingly, 1,045 differentially accessible peaks were detected in chromosome 19, from which 56 peaks fall in the LA region. The APOE local ancestry region showed reduced accessibility in AF when compared to EU. Additionally, around 44% of the differentially accessible sites in cluster 11 are in promoter regions of genes. Further, enrichment analysis of genes with altered chromatin accessibility at their promoter regions showed enrichment for Alzheimer disease pathways. **Conclusion:** This study is one of the first studies to compare chromatin accessibility in AF and EU ancestry brains. It also represents initial efforts to investigate potential underlying mechanisms that contribute to the differential expression we have previously reported in APOE4 between AF and EU LA brains. Our data suggest that decreased chromatin accessibility around APOE in astrocytes correlate with the observed decreased expression of APOE4 from AF LA groups.

PrgmNr 1371 - Protein prediction for trait mapping in diverse populations

Author Block: **R. Schubert**[1], I. Gregga[1], E. Geoffroy[1], A. Mulford[1], A. W. Manichaikul[2], H. Im[3], H. E. Wheeler[4], NHLBI TOPMed Consortium; [1]Loyola Univ. Chicago, Chicago, IL, [2]Univ Virginia, Charlottesville, VA, [3]The Univ. of Chicago, Chicago, IL, [4]Loyola Univ Chicago, Chicago, IL
Disclosure Block: **R. Schubert:** None.
Genetically regulated gene expression has helped elucidate the biological mechanisms underlying complex traits and similar interrogation of the proteome is now possible. Here, we used the Trans-omics for Precision Medicine (TOPMed) Multi-omics pilot study, which comprises data from participants in the Multi-Ethnic Study of Atherosclerosis (MESA) cohort, to optimize genetic predictors of the plasma proteome for genetically regulated proteome association studies.
For 1305 proteins measured by a SOMAscan assay, we compared predictive models built via baseline elastic net regression to models integrating posterior inclusion probabilities estimated by fine-mapping SNPs prior to elastic net. In order to investigate the transferability of predictive models across ancestries, we built protein prediction models in five race/ethnic groups from MESA: African American (AFA, n = 183), Chinese (CHN, n = 71), European (EUR, n = 416), Hispanic/Latino (HIS, n = 301), and all populations combined (ALL, n=971).
We successfully built predictive models for 1187 unique proteins (R>0.1). As expected, fine-mapping produced more protein prediction models. Despite differences in sample size, EUR, HIS, and AFA training populations produced comparable numbers of predictive models. We used INTERVAL (n=3,301), a European ancestry study for out of sample estimation of model performance. For the proteins predicted by both the ALL and EUR training populations in INTERVAL, the ALL population predicted better than EUR with both the baseline (p=0.0012) and fine-mapped (p=0.0064) model building strategies. At current training population sample sizes, performance between baseline and fine-mapped protein prediction models was similar.
Using GWAS summary statistics from the Population Architecture using Genomics and Epidemiology (PAGE) study, which comprises â¼50,000 Hispanic/Latinos, African Americans, Asians, Native Hawaiians, and Native Americans, we applied S-PrediXcan to perform proteome association studies for 28 complex traits. The most protein-trait associations were discovered, colocalized, and replicated using proteome model training populations with similar ancestries to PAGE (i.e. predominantly African American and Hispanic). These 21 distinct associations provide more evidence that the SNPs at the locus are acting through protein abundance regulation to affect the associated phenotype and include: HP and Apo E associated with cholesterol traits and CRP, IL-1Ra, IL-6 sRa, and Apo E associated with C-reactive protein. More omics data in diverse populations are needed to better understand the mechanisms underlying complex traits in all populations.

Disclosure Block: **B.N. Wolford:** None.

Deep vein thrombosis and pulmonary embolism, collectively referred to as venous thromboembolism (VTE), are characterized by the formation of thrombi in large veins that may embolize to the pulmonary circulation. VTE is a common cause of morbidity and mortality, and while driven by environmental and lifestyle factors, is also estimated to be 40% heritable. After phenotype harmonization, genome wide association study (GWAS) results across 9 international cohorts of the Global Biobank Meta-analysis Initiative (GBMI), with representation across 6 super populations (NFE, AMR, AFR, EAS, FIN, SAS; cases=27,987, controls=1,035,290), were combined using inverse-variance weighted meta-analysis. This multi-ancestry GWAS resulted in 38 genome-wide significant loci, 22 of which were potentially novel. For each autosomal locus we performed gene prioritization using 6 independent, yet converging, lines of evidenceâ□□presence of an eQTL in relevant GTEx tissues, pathogenic variant in ClinVar, nonsynonymous variant in 95% credible set (calculated with sum of single effects [SuSiE]), the nearest gene, in genes with p-value

Brain development involves the organized differentiation of neural progenitors into neurons and glia, tightly orchestrated in both temporal and spatial domains. Alterations in embryonic brain development can manifest as altered postnatal brain structure and function, leading to neuropsychiatric illness. One such alteration is mutation in *Chromodomain helicase DNA binding protein 8 (ChD8)*; a gene that encodes an ATP-dependent chromatin remodeler. Heterozygous *Chd8* loss of function mutations result in ASD and macrocephaly in both humans and mouse models. However, how *Chd8* haploinsufficiency impacts brain structure across cortical development is unknown. Importantly, the increase in brain volume is localized in specific brain regions including the cortex, requiring a whole brain imaging approach to study the mutation effects. Here, we employ tissue clearing technology, light-sheet and confocal microscopy to acquire 3D cellular resolution images in intact whole brains derived from a mouse model with a single heterozygous point mutation in *ChD8*. Our goal is to quantify, using computational tools, neural progenitor and neuronal cell-types within annotated areas of the developing neocortex across critical time periods of neocortical neurogenesis in both WT and $Chd8^{+/-}$ mice. With this we will be able to determine the cell types that drive this ASD associated cortical hyper-expansion. At present, we have generated 3D cellular high resolution (0.75Âµmx0.75Âµmx4Âµm) images from a male $Chd8^{+/-}$ early postnatal time point (P4) labeled with upper layer neuronal marker (*Brn2*), lower layer neuronal marker (*Ctip2*), and a nuclear marker (YO-PRO). Using NuMorph, a suite of image analysis tools developed in our lab, we have registered the nuclei images to the Allen Developing Brain Atlas and quantified all the nuclei in the cortex. We detected about 13.8 million nuclei in the cortex which were YO-PRO positive. We also detected 2.94 million nuclei (21% of cortical nuclei) which were $Ctip2^{+}$/YO-PRO^{+} and additionally 2.94 million nuclei (21% of cortical nuclei) which were $Brn2^{+}$/YO-PRO^{+}. These results suggest that roughly about 42% of all cells in the cortex of P4 mouse brain may be excitatory neurons. Ongoing experiments will permit comparison to an age-matched WT littermate control. Moving forward, we aim to generate 9 biological replicates for each sex per genotype at this and other early developmental timepoints to elucidate the cellular basis and spatial localization of brain overgrowth in our mouse model, leading to a better understanding of how genetic variation can alter cortical development and alter risk for neurodevelopmental disorders.

Disclosure Block: **B. Trost:** None.

Background: Autism spectrum disorder (ASD) is extremely heterogeneous in both clinical presentation and genetic architecture. Fully understanding ASD genetics requires whole-genome sequencing (WGS), which theoretically allows the genome-wide detection of all sizes and types of variants. Our objective is to leverage the power of WGS to assess the contribution to ASD of a wide range of variation, including common and rare, sequence-level and structural, and coding and non-coding. **Results:** Using sequence-level variants from the largest ASD sequencing dataset assembled to date (>18,000 trios plus additional cases and controls with exome or genome sequencing data), we used the previously-described TADA+ method to generate a list of ~140 ASD genes with FDR n=11,312, including 5,102 with ASD), the Simons Simplex Collection (*n*=9,205, including 2,419 with ASD), and the 1000 Genomes Project (*n*=2,504 population controls). Frequently detected genomic disorder syndromes included 15q11-q13 duplications, 16p11.2 deletions, and 1q21.1 duplications. ASD-risk genes commonly affected by SVs included *AUTS2*, *MBD5*, *NRXN1*, *SHANK1*, and *PTCHD1-AS*. We identified several ASD-relevant SVs that could only have been characterized with WGS, including an inversion disrupting *SCN2A* and a complex rearrangement impacting *KCNQ2*. Calculating polygenic risk scores (PRSs) using a recent ASD GWAS, polygenic risk was significantly over-transmitted from parents to ASD-affected children (p -7) but not to unaffected siblings. No difference in mean PRS was observed between ASD-affected children in multiplex families (where ASD is more likely to be caused by inherited rather than *de novo* variation) versus simplex, suggesting that rare inherited variation may have a more prominent role in multiplex ASD. ASD-affected individuals without a known clinically significant rare variant had significantly higher PRS. Despite these aggregate trends, PRS was not predictive at the level of individuals or families. Transmission tests involving non-coding genomic features suggested a role for the disruption of boundaries of topologically associating domains containing ASD-risk genes. **Conclusion:** By analyzing many types of genetic variants (also including tandem repeat expansions from a recently-published study), we present what we believe to be the most comprehensive analysis of genetic variation in ASD thus far, providing new insights into the genetic heterogeneity of ASD.

PrgmNr 1377 - Genotype-phenotype analyses in 10,000 individuals with psychosis highlights complex role of ultra-rare coding variants and common polygenic risk in presentation and etiology

View session detail

Author Block: **T. Singh**[1], A. Palotie[2], B. M. Neale[2], M. Daly[3], on behalf of the SUPER psychosis study; [1]Massachussetts Gen. Hosp., Boston, MA, [2]Massachusetts Gen. Hosp., Boston, MA, [3]Harvard Med. Sch.
Disclosure Block: **T. Singh:** None.
Psychiatric disorders, particularly in psychotic disorders like schizophrenia, have seen significant progress in loci discovery, with common regulatory variants and ultra-rare coding variants in individual genes identified at genome-wide significance. Despite this success, the degree to which clinical presentation is influenced by different types of genetic risk has not been fully explored, with such efforts hampered by limited data in current studies and exacerbated by the imprecision of diagnostic criteria across disorders. Here, we present the SUPER psychosis study, a comprehensive nation-wide effort in Finland to recruit 10,417 individuals diagnosed with schizophrenia, bipolar disorder or major depressive disorder with psychotic features. All individuals underwent standardized psychiatric interviews and questionnaires with accessible electronic health record data from a national registry. Combined with imputed genotype and whole-exome sequence data, we explore how genetic risk from common and rare variants are associated with psychiatric symptomatology, severity and progression, cognition, and additional comorbidities. We replicated a significant excess of rare protein-truncating variants (PTVs) in schizophrenia-associated genes (P = 2.1 x 10-9) in psychosis cases compared to 11,367 matched controls, with these PTVs observed in 90 (~0.9% of) cases. Notably, this rare variant signal was observed not exclusively in diagnoses of schizophrenia (P = 7.5 x 10-10), but also across the broader psychosis spectrum that includes bipolar disorder (P = 6 x 10-5) and unspecified/other psychoses (P = 0.00275). We present additional associations between genetic risk, psychiatric symptomatology, and additional comorbidities, highlighting the dramatic concentration of rare variant carriers in individuals with additional cognitive impairment and learning difficulties compared to those without (2.5% compared to 0.86% of cases). We explore the phenotypic range of individuals carrying PTVs in the same genes (9 SETD1A, 7 AKAP11, and 6 SRRM2), and find that certain genes resemble more typical psychiatric presentation while all six SRRM2 carriers had additional intellectual disability. Combined, we show the immense value of standardized and comprehensive phenotyping when building new collections for advancing gene discovery, especially when studying highly heterogeneous syndromes and disorders.

PrgmNr 1378 - Genome-wide association study of over 40,000 cases of suicide attempts yields eight genome-wide significant loci

View session detail

Disclosure Block: **A. Ashley-Koch:** None.

Background Suicide accounts for >800,000 deaths per year worldwide and non-fatal suicide attempts occur over 20 times more frequently. Suicide attempt (SA) is heritable and only partially overlaps with the genetic etiology of related psychiatric disorders. The Million Veteran Program (MVP) and the International Suicide Genetics Consortium (ISGC) have conducted the two, independent largest genome-wide association studies (GWAS) of SA to date, identifying several genome-wide significant loci. Due to the polygenic etiology of SA, further increases in sample size should yield additional genetic loci. Here, we present a GWAS meta-analysis of SA between the MVP and ISGC cohorts, including >40,000 SA cases. **Methods** The MVP cohort included 14,089 veterans who made a SA and 395,359 controls. SA was defined from ICD codes, mental health surveys and data from the Suicide Prevention Application Network database. The ISGC cohort included 29,782 individuals who made a lifetime SA and 519,961 controls from 18 studies worldwide. SA was defined by psychiatric interviews for 10 studies, and self-report, hospital records, or coronersâ reports in remaining studies. GWAS of SA were conducted in each cohort and the genetic correlation between them was calculated using LD score regression (LDSC). A trans-ancestry fixed-effects meta-analysis was conducted between the cohorts, including 43,871 SA cases and 915,320 controls. Amongst SA cases, 81% were of European ancestry, with 11% African American, 5% Asian and 3% Latinx ancestry. LDSC was used to calculate the SNP-heritability of SA. Enrichment of SA-association signal in biological pathways and tissues was explored using FUMA. **Results** The genetic correlation of SA between the ISGC and MVP cohorts was 0.86 (se 0.09) and not significantly different from 1. Trans-ancestry meta-analysis found 8 loci reaching genome-wide significance for SA (PSLC6A9, NLGN1, ESR1, DRD2 and *FURIN* genes. The SNP-heritability of SA was 3.8% (se 0.003) on the liability scale. Genetic associations with SA were significantly enriched in genes expressed in brain tissues from the Genotype-Tissue Expression (GTEx) project. **Discussion** This meta-analysis is the largest GWAS of SA to date and implicates novel risk loci and biologically relevant pathways and tissues. Ongoing work includes ancestry-specific GWAS meta-analyses, integration of GWAS results with â omics data from brain tissues, and drug target enrichment analyses. These analyses will provide further novel insights into SA etiology and treatment.

PrgmNr 1379 - Chromatin accessibility mapping reveals compound genetic effects at a schizophrenia GWAS risk locus impairing neurodevelopment and synaptic function in human neurons

Genome-wide association studies (GWAS) of schizophrenia (SZ) and other neuropsychiatric disorders have identified hundreds of risk single nucleotide polymorphisms (SNPs). However, functional interpretation of these GWAS risk SNPs has been challenging. Recently, we described an approach to elucidate functional SNPs by their allele-specific open chromatin (ASoC) signatures (Zhang *et al.*, *Science* 2020). Here, using ASoC mapping and CRISPR/Cas9 genome editing in *NEUROG2* (*NGN2*)-induced excitatory neurons (NGN2-iNs), we aimed at making causal links between GWAS risk SNPs and SZ-relevant disease phenotypes. We initially identified thousands of ASoC SNPs in NGN2-iNs of 20 iPSC lines and found 31 credible functional SNP in 26 SZ risk loci (out of 108) that displayed ASoC. For the four SZ-associated ASoC SNPs (near *VPS45*, *BCL11B*, *PRBML1*/*GNL3*, and *BAG5*) that also replicated our previous ASoC results (Zhang *et al.*, *Science* 2020) in neural progenitor cells (NPCs)-derived glutamatergic neurons, we performed multiplex CRISPRi/single-cell RNA-seq (CROP-seq) in NGN2-iNs and found three SNP sites exhibited *cis*-regulatory effects on their flanking gene targets. Since the *VPS45* locus showed the strongest ASoC in ATAC-seq and transcriptional repression of *cis*-targets in CROP-seq, we further investigated the function of this ASoC SNP (rs2027349) by CRISPR/Cas9 editing. In NGN2-iNs derived from isogenic iPSC lines carrying the two different alleles of rs2027349, we found that risk allele A was associated with an increased expression of the bi-directionally transcribed genes *VPS45* and *AC244033.2* (the latter being a lncRNA), as well as a distal gene *C1orf54*. Notably, NGN2-iNs carrying risk allele A showed transcriptomic changes correlated with gene expression changes in post-mortem brains of SZ, bipolar disorder, and autism spectrum disorder. Phenotypically, NGN2-iNs with A allele exhibited increases in dendritic complexity, synaptic puncta density, neural firing rate, and the frequency of calcium transients. Moreover, RNA knockdown of each *cis*-regulated gene in risk allele-carrying neurons partially rescued the risk allele A-associated phenotypic changes, suggesting a phenotypic contribution from all three genes. The influence of rs2027349 was further corroborated by transcriptomic modelling, brain chromatin interaction (Hi-C) data, and the assay of local chromatin accessibility in isogenic NGN2-iNs. Our study thus reveals a complex gene regulation process at a single SZ GWAS locus that impairs neurodevelopment and synaptic function, providing a mechanistic link between a noncoding SZ risk variant and disease-related phenotypes.

PrgmNr 1380 - Lineage-specific analysis of epigenome and transcriptome changes in postmortem brains from Schizophrenia and Bipolar Disorder

View session detail

Author Block: **J. Bendl**[1], K. Girdhar[2], G. E. Hoffman[3], J. Fullard[1], P. Roussos[1]; [1]Icahn Sch. of Med. at Mount Sinai, New York City, NY, [2]Mount Sinai, New York, NY, [3]Icahn Sch. of Med. at Mount Sinai, New York, NY

Disclosure Block: **J. Bendl:** None.

Background: Regions of open chromatin house regulatory elements required to mediate cell-type and tissue-specific gene expression. Studies of human brain have shown that dysregulation of these regulatory mechanisms is associated with neuropsychiatric diseases. Here, we present the largest cell type and brain region-specific study of differential chromatin accessibility in SCZ and BD brains.

Methods: Using frozen postmortem tissue from 469 cases with SCZ, BD, and controls, we performed ATAC-seq to profile chromatin accessibility in neuronal and glial populations of cells, isolated by FACS from two different brain regions, i.e. dorsolateral prefrontal cortex and anterior cingulate cortex. We further performed phenotype-aware deconvolution of neuronal samples to glutamatergic and GABAergic neurons as well as glial samples to oligodendrocytes, astrocytes, and microglia. Then, we characterized epigenetics changes associated with SCZ and BD phenotypes. The availability of RNA-seq and whole-genome data for this cohort allowed us to measure the overlap between differentially regulated transcriptome and epigenome signatures and related pathways. Finally, we determined enhancer-promoter interactions, by utilizing additional omics in the brain tissue (Hi-C and H3K27ac ChIP-seq) and jointly analyzing with ATAC-seq based on the â□□activity-by-contactâ□□ (ABC) approach.

Results: We observed widespread differences in chromatin accessibility associated with SCZ and BD phenotypes, mostly in neuronal samples. While substantial changes between cases and controls can be seen in both assayed brain regions, dorsolateral prefrontal cortex is, in general, more affected than anterior cingulate cortex. The differentially accessible regions of open chromatin were enriched in disease-related pathways and regulated by distinct transcription factors. By integrating these results with SCZ and BD GWAS, we were able to shed light on the mechanisms of several risk loci.

Conclusions: This dataset provides a unique insight into molecular mechanisms underlying brain region and cell type-specific vulnerability to both SCZ and BD. Supported by NARSAD 27209, R01MH110921 and R01AG057440.

Disclosure Block: **I. Alim:** None.
Heritable mutations in the DNA mismatch repair (MMR) pathway cause Lynch syndrome (LS), a condition that significantly increases risk of colorectal and other cancers. LS mutations are commonly found in the *MLH1*, *MSH2*, *MSH6*, *PMS2* and *EPCAM* genes. Diagnosis of LS is reliant on gene panel sequencing. However, at least half have a variant of uncertain significance (VUS) that cannot be classified for pathogenicity or have no result that informs their diagnosis. Many LS patients are identified only after microsatellite instability testing of tumors is found to be high (MSI-H). We developed a diagnostic test, Cancer Risk C (CR-C), using flow-cytometry based functional variant assays (FVAs) to aid in the diagnosis of LS. Using patient-derived lymphoblastoid cell lines (LCLs) from the Colon Cancer Family Registry (CCFR) an initial cohort was established with either known pathogenic (n=20) or benign variants (n=20). FVAs were tested to identify the effects of pathogenic variants in MMR genes on the nuclear translocation of the MLH1 and MSH2 proteins and the nuclear phosphorylation of the ATM and ATR proteins in response to treatment with the alkylating agent, methylnitronitrosoguanidine. To differentiate pathogenic and benign variants, a risk classification score was developed based on a combination of MLH1, MSH2 and ATR assays. CR-C was 98% sensitive and 95% specific and could be completed within 48 hours. A second cohort of CCFR patient-derived cells with either pathogenic (n=40) or benign variants (n=40) was tested with CR-C and observed to have similar sensitivity and specificity, thus creating a new diagnostic for LS. Amongst those with VUS and MSI-H tumors (n=60), 72% were identified as having LS. This finding contrasted to the previously observed rate of 16% MMR pathogenic gene variants amongst patients with MSI-H tumors. Edited cells with pathogenic variants in MMR genes were rescued from pathogenic to benign when transfected with an expression plasmid containing wild-type cDNA and tested with CR-C. Direct comparison of matched whole blood samples and LCLs yielded comparable results with CR-C (r^2>0.9). Compared to cancer gene panel sequencing, CR-C is more accurate and rapid for diagnosing LS and can be performed on whole blood. When combined with gene rescue experiments in edited cells or LCLs, CR-C can be used to classify VUS as pathogenic or likely pathogenic.

PrgmNr 1408 - Does it make sense to report single pathogenic alleles in cancer susceptibility genes for childhood cancer patients? Results from the BASIC3 and Texas KidsCanSeq studies

Disclosure Block: **S.E. Plon:** Non-remunerative positions or influence such as officer, board member, trustee, or public spokesperson; Baylor Genetics.

Background: Multiple studies report that 8-13% of pediatric cancer patients have pathogenic or likely pathogenic variants (PV/LPV) in cancer susceptibility genes, although standards vary for reporting single PV/LPVs in genes associated with autosomal recessive (AR) syndromes. We report here results from two studies of pediatric cancer patients for the frequency of single AR variant results and relationship to the patientâ□□s presentation. **Methods:** The BASIC3 study included clinical germline and tumor exome sequencing in an ethnically diverse cohort of sequentially diagnosed children with CNS and non-CNS solid tumors. The Texas KidsCanSeq study included germline exome and panel sequencing for pediatric solid tumor patients across six sites in Texas. In both studies, other medical problems noted in the medical record were provided to the reporting laboratory. All result categories on the clinical exome and panel (when available) were returned to parents. **Results:** Among 278 enrolled patients in BASIC3 there was one patient with two PVs (a homozygous variant in *TJP2*) and 18 (6.5%) patients had a single PV/LPV in a wide spectrum of AR cancer genes. Only one patient had a tumor type (Wilms tumor) previously associated with the gene (*DIS3L2*). Patent foramen ovale in a patient with *FANCA* allele was the only syndromic feature. In the first 366 patients in KidsCanSeq there were no patients with biallelic PV/LPVs, 15 patients (4.1%) with one PV/LPV in AR genes of which 2 had the associated tumor type (*DIS3L2* with Wilms tumor and *SLC26A4* with thyroid cancer). Not included here are patients with PV/LPV in genes with both AR and dominant cancer phenotypes e.g., *ATM.* Germline results disclosure with parents discussed (1) their oncologist might request further targeted testing for a 2nd variant if there is concern that the patient has this rare disorder, (2) the patient (and often parent) are carriers of this rare disorder, (3) the lack of evidence relating the variant to the childâ□□s cancer diagnosis and (4) lack of any additional surveillance recommendations.**Conclusions:** There is increasing use of exome, genome or large hereditary cancer panels for genomic evaluation of cancer patients. Recessive diagnoses are very uncommon but about 5% of pediatric cancer patients have a single PV/LPV in rare AR cancer genes without other findings. These test results require substantial efforts for disclosure and family understanding. We suggest that limiting reporting to biallelic patients or those with features of the disorder including the specific cancer type would streamline the process at the cost of reproductive information. BASIC3 and Texas KidsCanSeq were supported by 1U01HG006485.

PrgmNr 1409 - Breast cancer polygenic risk scores and rare variants in Latinas

Disclosure Block: **J.L. Nierenberg:** None.

Introduction: Polygenic risk scores (PRS), assembled from common single nucleotide polymorphisms (SNPs), can be used to predict breast cancer risk. Individually, pathogenic variants (PVs) in high and intermediate penetrance breast cancer susceptibility genes are rare but have large effects on disease risk. Few studies have examined PRS and PVs in susceptibility genes together, and most previous breast cancer genetics studies have been conducted in European ancestry populations. Here, we report findings on the combined effects of PRS and PVs in Latinas.

Methods: We conducted a pooled case-control analysis of breast cancer in Latinas from the San Francisco Bay Area, Los Angeles, and Mexico (1,776 cases and 1,589 controls). Case ascertainment included 432 participants from high-risk studies (age below 50, family history, or bilateral breast cancer) and 1,344 from general population studies. We assembled a 180-SNP PRS from known breast cancer SNPs (P-8). We determined presence of a rare PV in 9 known breast cancer risk genes (*ATM*, *BARD1*, *BRCA1*, *BRCA2*, *CHEK2*, *PALB2*, *PTEN*, *RAD51C*, and *TP53*). We used multivariable logistic regression and area under the receiver operating characteristic curve (AUC) to examine the relationships between PRS, PV status, and breast cancer risk. All analyses were adjusted for age, study, and ancestry. Secondary analyses were stratified by age, family history, or indigenous ancestry above or below the median.

Results: Higher PRS was associated with higher risk of breast cancer, with an odds ratio of 1.6 (95% confidence interval [CI]: 1.5-1.7) per PRS standard deviation and an AUC of 0.61 (95% CI: 0.60-0.63). PVs were found in 125 case and 22 control participants. Having a PV was associated with a 5.9-fold (95% CI: 3.8-9.6) increased odds of breast cancer. The AUC for breast cancer improved to 0.64 (95% CI: 0.62-0.66) when PVs were added to the PRS model. Results were similar among 255 cases and 129 controls with family history of breast cancer and among those with indigenous ancestry above and below the median. Among 599 cases and 387 controls under age 50 years, the AUC for the PRS-rare variant model increased to 0.69 (95% CI: 0.65-0.72). Among all cases, those with a PRS below the median had a 1.9-fold (95% CI: 1.4-2.7) increased odds of having a PV.

Conclusion: We found that adding PV status to a PRS model improves prediction of breast cancer, indicating that there may be clinical utility in examining PRS and PVs together, especially among young women. The lower PRS among carriers of a PV is likely an effect of case ascertainment and could be useful in epidemiological design of new gene discovery efforts.

PrgmNr 1410 - Germline genetically predicted mammographic density is associated with breast tumor transcriptomic and proteomic features, CD8+ T cell infiltration, somatic mutational signatures, and tumor mutational burden in The Cancer Genome Atlas

View session detail

Author Block: **A. Francis**[1,2], T. Robinson[1,2], B. Lloyd-Lewis[3], Y. Liu[4], C. Peng[4,5], R. Tamimi[6], P. Kraft[4], P. Brennan[7], T. Gaunt[1,2], R. M. Martin[1,2,8], C. Relton[1,2], A. Gabriel[9], G. Gierach[10], J. McKay[9], S. Disclosure Block: **A. Francis:** None.

High mammographic density (MD) is one of the strongest risk factors for breast cancer, the most common cancer in women globally, but the molecular underpinnings of this association are poorly understood. Tumor cohorts with multi-omic phenotyping currently do not have linked MD data at scale, making it challenging to define the genomic landscape of breast tumors arising on a background of high MD. We took a new approach to address this challenge by integrating MD genome-wide association study (GWAS) data with The Cancer Genome Atlas (TCGA) breast tumor data. We built a polygenic score for MD using effect size estimates and allele information for the lead variants at 17 independent loci (P -8) from a GWAS of percent MD in 24,192 women of European ancestry. We performed sample and genotype quality control and imputation into the 1000 Genomes reference panel on germline genetic data from 721 female breast cancer cases of genetically inferred European ancestry from TCGA. We assigned each woman in this TCGA cohort, which lacks measured MD, her genetically predicted MD based on the MD polygenic score. We evaluated the association between germline genetically predicted MD and breast tumor genome-wide transcriptomic, proteomic, genomic, epigenomic, and immune traits in TCGA using linear (default) and quasi-Poisson (for overdispersed count data) regression models adjusted for age and stage at diagnosis, estrogen receptor status, and 10 genetic principal components, reporting associations at FDR DLL1, an estrogen-dependent Notch ligand previously implicated in breast oncogenesis ($P = 2 \times 10^{-6}$; top gene of 20,530 genes profiled by RNA-Seq). High genetically predicted MD was associated with increased breast tumor CD8+ T cell infiltration (P = 0.004) in our evaluation of 22 tumor immune infiltrates profiled by the CIBERSORT algorithm. Genetically predicted MD had positive and inverse associations with breast tumor MAPK ($P = 3 \times 10^{-4}$) and XRCC1 ($P = 4 \times 10^{-4}$) protein levels, respectively, of the 281 tumor proteins profiled by reverse-phase protein array, suggesting roles for mitogen-activated protein kinase signaling and DNA repair. High genetically predicted MD was associated with the mitotic clock-like, aging-related single base substitution mutational signatures 1 (P = 0.001) and 5 (P = 0.002) and with high tumor mutational load (P = 0.006 for association with non-silent mutations/Mb). Thus, we combined germline and somatic data to identify breast tumor molecular features associated with genetically predicted MD, with potential implications for breast cancer development and progression.

PrgmNr 1411 - Saturation Genome Editing of *PALB2* Reveals Functionally Abnormal Missense Variants

View session detail

Author Block: **I. Hill**[1,2], A. Patoski[1,2], K. de Leon[1,2], A. Mehrotra[1,2], N. Smith[1,2], J. Shendure[1,2,3], L. Starita[1,2]; [1]Department of Genome Sciences, University of Washington, Seattle, WA, [2]Brotman Baty Institute for Precision Medicine, Seattle, WA, [3]Howard Hughes Medical Institute, Seattle, WA
Disclosure Block: **I. Hill:** None.
Pathogenic variants in the *PALB2* gene are associated with an increased lifetime risk of developing breast, pancreatic, and ovarian cancer. However, the clinical utility of genetic testing for informing *PALB2*-associated cancer susceptibility is limited by a lack of evidence for interpreting individual variants. In fact, of the 3125 *PALB2* single nucleotide variants (SNVs) in ClinVar, 1850 (60%) are currently annotated as variants of uncertain significance (VUS). The situation is worse for missense variants, of which 1849 of 1874 (99%) are VUS. Multiplexed assays of variant effects can provide valuable evidence for reinterpreting VUS. For example, functional data from Saturation Genome Editing of *BRCA1* can be used as strong evidence that individual variants are pathogenic (PS3) or benign (BS3). Like *BRCA1*, *PALB2* - **P**artner and **L**ocalizer of **B**RCA**2** - which functions in the same double strand break repair pathway as *BRCA1*, is compatible with Saturation Genome Editing.
We performed Saturation Genome Editing on *PALB2* to generate functional data for all possible SNVs across the protein coding region and intron-exon junctions. Thus far, we have data for 2602 variants, spanning the coiled coil domain which is required for BRCA1 binding and the WD40 domain which is required for binding to BRCA2. Functional scores indicate that 176 of 1408 (12.5%) missense variants are indistinguishable from nonsense variants and are likely â□□functionally abnormalâ□□, loss-of-function variants. Our results are consistent with what is known about PALB2 function, with missense variants scoring as functionally abnormal falling in the coiled-coil (10.5%) or WD40 domain (15.6%), and 0% outside of those domains thus far (n.b. there is more missing data outside of the folded functional domains). Our results are also perfectly concordant for 26 variants with published orthogonal functional data. Nonetheless, it should be recognized that the relative lack of classified pathogenic or benign missense variants within *PALB2* presents a unique and challenging problem in validating these data for use in clinical variant interpretation. New strategies may be necessary before these data can be incorporated into variant interpretation frameworks. Finally, recent case-control studies suggest that *PALB2* missense variants do not appear to increase breast cancer risk, however, our data suggests grouping all missense variants for these studies, of which 87.5% are â□□functionally normalâ□□, may have obscured any signal.

Disclosure Block: **L. Wang:** None.
Background: A gene with an intact DNA sequence can compromise its function by epigenomic, transcriptomic, and proteomic level dysregulations. Such non-mutational inactivations are prevalent in cancers but, due to the heterogenetic causes, cannot be detected by the DNA-sequencing, immunohistochemical staining, or any other single assay alone. Therefore, they would become a significant impediment for molecular diagnostics, clinical management, and treatment selection for cancer patients. **Approach**: We hypothesized that when a transcription factor (TF) is functionally impaired, either due to genetic or non-genetic causes, the expression of downstream target genes would be significantly altered and that such expression alteration, in turn, can be used to predict the functional status of the TF. Here we used p53 as an example; we first define the p53 target genes through a comprehensive literature review and meta-analysis. Then, we build an SVM model using the composite expression scores of these target genes as features and using the â□□normal tissuesâ□□ (assuming p53â□□s tumor suppressor function is normal in this group) and â□□*TP53* truncating tumor samplesâ□□ (assuming p53â□□s tumor suppressor function is lost in this group) as training datasets. **Results**: Using 5-fold cross-validation, we demonstrated the superior performance of our SVM model (average AUC = 0.995, F1-score = 0.989, recall = 0.992) in TCGA LUNG and BRCA cohorts. When applying our SVM model to *TP53*^{WT} tumor samples, we found 87% of BRCA and 94% of LUNG samples were predicted to be LoF (termed as *TP53*^{WT}-LoF). These *TP53*^{WT}-LoF patients exhibited distinct genomic and clinical characteristics from the other *TP53*^{WT} patients. Specifically, *TP53*^{WT}-LoF patients have significantly higher tumor mutation burden, the fraction of genome with copy number variations, aneuploidy score, and hypoxia score, consistent with p53â□□s function as a central regulator of DNA damage repair and cellular stress response. In addition, *TP53*^{WT}-LoF patients with lung cancer have significantly shortened overall survival compared to those real *TP53*^{WT} patients. Further analyses revealed that *MDM2*/*MDM4* amplifications are significantly enriched in *TP53*^{WT}-LoF patients, partially and mechanistically explained the p53 loss-of-function.

PrgmNr 1413 - Multiple germline events lead to cancer development in patients with Li-Fraumeni syndrome

Li-Fraumeni syndrome (LFS) is an autosomal dominant cancer-predisposition syndrome associated with pathogenic germline variants in the *TP53* tumour suppressor gene, in approximately 70% of cases. The early identification of genetic susceptibility is especially important in these patients, as they are at markedly increased risk of developing a spectrum of early-onset malignancies. The impact of early identification of germline cancer-causing aberrations in these patients is substantial, as it informs the prospective management of patients and their families. As such, it is imperative to identify cancer-causing aberrations in the remaining ~30% of patients that fit the clinical definition of LFS, but lack a pathogenic germline variant in *TP53*. In addition, even among LFS patients that harbour a pathogenic germline *TP53* variant, the cumulative lifetime risk of developing cancer is approximately 68% in males and 93% in females. The incomplete/variable penetrance, suggests the presence of additional genetic and epigenetic driver events that contribute to increased or decreased cancer risk in certain individuals. Candidate gene approaches have been considered to evaluate other risk factors; however, few studies have utilized unbiased genome-wide DNA sequencing and epigenomic assays to explain this variability in cancer occurrence.

In this work, we leveraged family-based whole-genome sequencing and methylation of DNA procured from peripheral blood leukocytes to evaluate the germline genetic and/or epigenetic genomes of a large cohort of LFS patients (n=396) who harbour either pathogenic variant (n=374) or wildtype *TP53* (n=22). In patients lacking a pathogenic germline variant in *TP53*, we pinpointed the role of alternative cancer-causing genetic aberrations in 8/14 patients that developed cancer. Among *TP53* variant carriers, 19/49 individuals who developed cancer harboured an additional pathogenic variant in another cancer gene, while variants in the WNT signalling pathway were associated with decreased cancer incidence. In addition, we leveraged the non-coding genome and methylome to identify inherited epimutations that confer increased cancer risk. Overall, our study highlights the immense benefits of expanding genetic and epigenetic testing of LFS patients beyond *TP53*, as *TP53* status alone does not indicate whether an individual will develop cancer.

PrgmNr 1414 - Oncogenic mutations in the normal human brain

View session detail

Oncogenic mutations have been found in non-diseased, proliferative tissues such as skin, blood, and esophagus, showing an age-related increase in most cases. However, the prevalence of such mutations in the normal brain, a low-proliferating organ, is unknown and remains challenging due to the abundance of non-proliferating neurons concentrated in the grey matter. Thus, targeting the white matter for sequencing, which is rich in glial cells, and analyzing data from large cohorts would allow for enhanced power to detect oncogenic events in the non-diseased brain. We evaluated genes implicated in brain tumors by deep sequencing in over 418 normal brain samples derived from 110 individuals of varying ages, without tumor diagnosis, and separately analyzing white and grey matter and other brain regions. We detected predicted and reported pathogenic oncogenic variants in cancer driver genes such as *IDH1, PTPN11, NF1,* and *PTEN*. These mutations were predominantly present in the subcortical white matter (p=0.029) and, surprisingly, were less common in older individuals (p=0.025). In addition, we identified the recurrence of glioma driver variants and their enrichment in glial cells. These findings were replicated using 1,640 non-diseased bulk RNA-seq brain samples from the GTEx consortium, confirming the existence of oncogenic variants and depletion of protein disruptive variants with age. The normal brain exhibits enrichment of mutational signatures present in brain tumors (p=0.00018), suggesting that mutational processes of the normal brain drive early oncogenesis. Our study helps understand the origin and early evolution of brain tumors and opens avenues for early interventions and more accurate diagnosis baselines.

PrgmNr 1415 - A human importin-Ã-related disorder: Syndromic thoracic aortic aneurysm caused by bi-allelic loss-of-function variants in *IPO8*

Importin 8, encoded by *IPO8*, is an ubiquitously expressed member of the importin-Î² protein family that translocates cargo molecules such as proteins, RNAs and ribonucleoprotein complexes into the nucleus in a RanGTP-dependent manner. Current knowledge of the cargoes of importin 8 is limited, but TGF-Î² signaling components such as SMAD1-4 have been suggested to be amongst them. Here, we report that bi-allelic loss-of-function variants in *IPO8* cause a syndromic form of thoracic aortic aneurysm (TAA) with clinical overlap with Loeys-Dietz and Shprintzen-Goldberg syndrome. Seven individuals from six unrelated families showed a consistent phenotype with early-onset TAA, motor developmental delay, connective tissue findings and craniofacial dysmorphic features. A C57Bl/6N *Ipo8* knock-out mouse model recapitulates TAA development from 8-12 weeks onwards in both sexes, but most prominently shows ascending aorta dilatation with a propensity for dissection in males. Compliance assays suggest augmented passive stiffness of the ascending aorta in male *Ipo8*$^{-/-}$ mice throughout life. Immunohistological investigation of mutant aortic walls reveals elastic fiber disorganization and fragmentation along with a signature of increased TGF-Î² signaling, as evidenced by nuclear pSmad2 accumulation. RT-qPCR assays of the aortic wall in male *Ipo8*$^{-/-}$ mice demonstrate decreased *Smad6/7* and increased *Mmp2* and *Ccn2 (Ctgf)* expression, reinforcing a role for dysregulation of the TGF-Î² signaling pathway in TAA development. As importin 8 is the most downstream TGF-Î²-related effector implicated in TAA pathogenesis so far, it offers opportunities for future mechanistic studies and represents a candidate drug target for TAA.

PrgmNr 1416 - Genotype-phenotype correlations in *PIK3CA*-related overgrowth spectrum (PROS) and overlapping phenotypes: a systematic review of 1007 patients with *PIK3CA* pathogenic variants

Purpose: Post-zygotic activating *PIK3CA* variants are responsible for the several phenotypes under the *PIK3CA*-Related Overgrowth Spectrum (PROS). We describe 150 new patients referred for genetic testing, reporting data on their phenotype and underlined *PIK3CA* or *GNAQ, GNA11, RASA1*, and *TEK* variants. A detailed genotype-phenotype correlation in a literature-derived cohort of 1007 *PIK3CA*-mutated patients was also provided. **Methods:** We performed targeted NGS on DNA extracted from blood or buccal swab and tissue biopsy using a custom panel including genes involved in the PI3K/AKT/mTOR pathway and â□□vascularâ□□ genes (*RASA1, TEK, GNAQ,* and *GNA11*). Clinical and molecular data from literature were systematically reviewed and included in the search for correlations. **Results:** *PIK3CA* pathogenetic variants were identified in 93 of 150 unrelated patients. Fifty-seven had a wild type *PIK3CA* allele: pathogenetic variants in *GNA11*, *RASA1, GNAQ*, and *TEK* were found in 11 of them. Differences in the distribution of the variants across *PIK3CA* domains, in the Variant Allele Fraction (VAF) in different tissues, and in the degree of hyperactivation of the PI3K network related to the variant (variant strength) were found compared to current literature. Alone, 10 of the *PIK3CA* variants reported were responsible for more than 70% of cases, including the three

most common mutational hotspots usually reported in several cancers. Combining our cases with those from literature review we draw up a detailed list of all the 81 pathogenic variants described so far in PROS and related them to the respective phenotypes. Eight novel pathogenic variants were also reported. While some *PIK3CA* variants were exclusively associated with a specific PROS phenotype, some were scattered across all the phenotypes and others demonstrated enrichment in some specific phenotypes. Correlations between variant strength and absence of involvement of the central nervous system were also evident. VAF was not correlated with disease severity, and we report severe phenotypes with very low VAF. Patients with pathogenic variants in vascular genes clinically overlapped with PROS. **Conclusion:** Our findings combined with a review of the literature show novel genotype-phenotype correlations underlining the importance of performing a deep phenotyping, carry out a representative tissue sampling, and adopt a comprehensive molecular approach in PROS and overlapping phenotypes.

PrgmNr 1417 - Exome CNV calling and analysis in a large cohort of families with undiagnosed rare genetic disease

View session detail

Fu[1], Broad CMG Collaborators, M. Babadi[1], S. Lee[1], A. N. Smirnov[1], L. Gauthier[1], S. Baxter[1], D. MacArthur[3,1], H. Rehm[1], M. Talkowski[1], H. Brand[1], A. O'Donnell-Luria[1,2]; [1]Broad Institute of MIT and Harvard, Cambridge, MA, [2]Boston Childrenâ□□s Hospital, Boston, MA, [3]Murdoch Childrenâ□□s Research Institute, Melbourne, Australia
Disclosure Block: **G. Lemire:** None.
The Center for Mendelian Genomics (CMG) at the Broad Institute has sequenced 7,719 families with a suspected genetic disease since 2016. Many had a chromosomal microarray and gene panel sequencing for known causes of disease prior to exome sequencing through the CMG. For typical rare variant analysis, exome sequencing data can be used to call SNVs and indels smaller than 50 base pairs, and standard chromosomal microarrays will detect CNVs larger than 50 kilobases. However, mid-sized CNVs are not detected in routine exome analysis of SNVs and indels but molecular diagnostic laboratories are increasingly including CNV calling on exome data in analysis. Detecting CNVs from exome data has been notoriously difficult due in part to the non-uniform distribution of captured reads secondary to biases introduced by PCR and capture steps and many different algorithms have been developed for this purpose. The Genome Analysis Toolkitâ□□s (GATK) CNV tool, the Germline CNV (gCNV) caller, uses a probabilistic framework to infer rare CNVs from read depth data in the presence of systematic bias. We used the gCNV algorithm to call CNVs across the Broad CMG cohort. While analysis is ongoing, we have diagnosed 138 previously unsolved families to date. The identified CNVs consisted of 109 deletions, 20 duplications and 9 complex CNVs. A CNV in a known gene that is consistent with the phenotype was identified in 114 families and a CNV in a novel candidate gene was identified in 24 families. Supporting genetic and/or experimental evidence were required to consider a CNV in a novel gene as the diagnosis in a given family, most often by additional families identified through Matchmaker Exchange. The predominant phenotype present in these families were neurodevelopmental disorders (67%) followed by neuromuscular disorders (19%). We estimate that about 50% of the CNVs that solved CMG cases would not have been detected by standard chromosomal microarrays. Calling CNVs from existing exome data increases the diagnostic yield for individuals that remain undiagnosed after standard testing approaches, providing a higher resolution alternative to arrays at a fraction of the cost of genome sequencing.

PrgmNr 1418 - Brazil enters the genome sequencing era: The Rare Genomes Project - interim results

Rare diseases (RD) are estimated to affect between 3.2 and 13.2 million individuals in Brazil. The Rare Genomes Project (RGP) is a Brazilian initiative for whole genome sequencing (WGS) of patients with RD recruited from centers for rare diseases of the National Unified Health System (SUS). RGP initiated in 2020 and will sequence the genomes of 7755 patients with RD until the end of 2023, allowing the creation of the largest Brazilian genomic database of patients with RD and hereditary cancer. RGP also aims to study the clinical and social burden of RD in Brazil, provide valuable information for cost-effective national health policies for a population generally underrepresented in previous genomic studies and improve diagnosis, therapy, prevention, genetic counseling and the quality of life of patients. The ongoing project has recruited 1486 probands from nine centers of four out of five macroregions of the country. Among those, approximately 1300 have already had their genomes sequenced, and for 163 clinical reports were returned to attending physicians.The most prevalent disorders are neurological (n=402, average age:11.8 years), congenital malformations (n=376, average age:10.6 years), hereditary cancer (n=343; average age:45), inborn errors of immunity (n=145; average age:19.6 years) and clinical genetic syndromes (n=114; average age:10.9 years). Out of the 163 reports released, molecular diagnosis was established for 57 patients (34,9%). In 43 patients, no candidate variants were detected (26,38%). The remaining 63 (38,7%)patients presented variants of unknown significance (VUS) in heterozygous or homozygous state, heterozygous state for a recessive phenotype or pathogenic/likely pathogenic (P/LP) variants in heterozygous state and a VUS in the same gene for a recessive phenotype. Among the positive cases, the higher diagnostic rates were seen in the neurological (18 cases; 36%), clinical genetic syndromes (10 cases; 17.6%), inborn errors of metabolism (7; 12.3%), immunodeficiencies (5; 8.8%), and hereditary cancer syndromes (5;8.8%) cohorts. A total of 81 variants were detected in the 57 positive patients (67 SNVs and 14 large-scale CNVs/SVs), 69 (85.2%) being annotated as (P/LP) (57 SNVs and 12 CNVs/SVs). Interesting to mention that 112 positive cases (21.1%) had P/LP CNVs or SNVs in regulatory regions which would not be identified by whole exome sequencing (WES). In summary, the RGP is the largest rare disease sequencing effort in Brazil, and the preliminary results demonstrate a high diagnostic rate.

PrgmNr 1419 - Low-pass genome sequencing-based detection of absence of heterozygosity: validation in clinical cytogenetics

View session detail

Morton[4], K. choy; [1]The Chinese University of Hong Kong, Hong Kong, Hong Kong, [2]Hong Kong, China, [3]The Chinese University of Hong Kong, Hong Kong, China, [4]Brigham & Women's Hosp, Boston, MA
Disclosure Block: **Z. Dong:** None.
Introduction: Absence of heterozygosity (AOH) is a genetic characteristic known to cause human genetic disorders through autosomal recessive or imprinting mechanisms. However, the analysis of AOH via low-pass genome sequencing (GS) is not yet clinically available. **Materials and Methods:** Low-pass GS (fourfold) with different types of GS libraries was performed on 17 clinical samples with previously ascertained AOH by chromosomal microarray analysis (CMA). In addition, AOH detection was performed with low-pass GS data in 1,639 cases that had both GS and high-probe density CMA data available from the 1000 Genomes Project. Cases with multiple AOHs (coefficient of inbreeding F â¥ 1/32) or terminal AOHs â¥5 Mb (suspected uniparental disomy [UPD]) were reported based on the guidelines of the American College of Medical Genetics and Genomics. **Results: We first demonstrated the optimal read-depth for AOH analysis to be fourfold regardless of sequencing modes (paired-end or single-end) and library types (small-insert or large-insert). In addition,** low-pass GS revealed suspected segmental UPD and multiple AOHs (F â¥ 1/32) in nine and eight clinical cases, respectively, consistent with CMA. Lastly, among the 1,639 samples with CMA and GS available in the 1000 Genomes Project, low-pass GS not only consistently detected multiple AOHs (F â¥ 1/32) in 18 cases, but also reported 60 terminal AOHs in 44 cases including four mosaic AOHs at a level ranging from 50% to 75%. **Conclusion:** Overall, our study demonstrates the feasibility of AOH analysis (â¥5 Mb) with low-pass GS data and shows high concordance compared with CMA.

Background: 50-70% of inherited rare neuromuscular disease (NMD) patients remain undiagnosed even after DNA testing, a barrier for clinical trial enrolment. Recently, using a muscular-dystrophy next-generation-sequencing panel on 4656 congenital/limb-girdle muscular dystrophy (CMD/LGMD)-suspected patients across the US and using exome sequencing on 207 genetic myopathies across the Indian subcontinent, and investigating hereditary NMDs and peripheral neuropathies at CHOA, we identified the major hurdles were: a) lack of genotype-phenotype correlation, b) high prevalence (72%) of variants of uncertain significance (VUSs), c) >30% of all patients had pathogenic variant(s) or VUSs in â¥2 genes (multi-genic), and d) the lack of less-invasive biomarker-driven approaches. **Methods:** Here, we used high-throughput clinical-grade RNA-Seq with a proprietary tiered analytical pipeline, and co-immunoprecipitation combined with mass-spectrometry proteomics, and other targeted assays on muscle/skin/blood biopsy-tissues to resolve VUSs and multi-genic cases to enhance molecular diagnostics, and to resolve genotype-phenotype relationships. **Results:** Using targeted RNA-Seq analysis and other assays with genotype-clinical-data correlation on 548 cases, we achieved 64% diagnostic yield and 88% diagnostically informative results. Besides VUS reclassification, we identified variant mechanisms acting either by abnormal splicing/allele/gene-expression/protein-stability/function levels or causing defects in pathways. For example, an 8-year old child with proximal weakness, dystrophic changes on muscle biopsy with normal immunohistochemistry including alpha sarcoglycan stains harbored two variants (pathogenic: c.229C>T, likely pathogenic: c.957-11C>G) *in trans* in *SGCA*. This genotype-muscle biopsy discrepancy was resolved using above-mentioned technique by identifying normal mRNA and protein expression for all Sarcolgycans in muscle even with c.957-11C>G causing both exons 6-7 and 6-8 skips, and that the variantsâ pathogenicity acting at protein function level. Furthermore, the novel application helped discover a new gene, *DRGX*, associated with bilateral hand weakness, finger flexor contractures and sensory motor polyneuropathy in a teenager. Additionally, using enzyme assays and RNA-Seq, we reclassified 20 *GAA* (Î±-glucosidase) gene VUSs as pathogenic variants to resolve undiagnosed Pompe disease cases. **Conclusions:** Our results show the importance of using a multi-tiered approach that includes omics platforms, biomarkers and genotype-phenotype correlation not only for diagnostics but also for better trial-readiness.

PrgmNr 1421 - Functional characterization of haplotype surrounding *TOMM40*-523â repeat to assess differential risk effects on European ancestry *APOEÉ3* haplotypes

View session detail

Author Block: **M. Lipkin Vasquez**, P. Bussies, F. RAJABLI, K. L. Hamilton-Nelson, A. J. Griswold, M. A. Pericak-Vance, J. Young, J. M. Vance, K. Nuytemans; John P. Hussman Institute for Human Genomics, Miami, FL
Disclosure Block: **M. Lipkin Vasquez:** None.
Introduction: Reports on involvement of *TOMM40*, a gene neighboring *APOE*, in Alzheimer Disease (AD) risk have been inconsistent. Recently, we showed that the length of a poly-T repeat in *TOMM40* (*TOMM40*-523â) is associated with AD risk in individuals carrying *APOEÉ3*, the most common *APOE* haplotype in the general population, on European local ancestry (LA). âVery longâ repeat lengths (VL, >29T) have a protective effect compared to âshortâ repeat lengths (S, APOE*É3* or *APOEÉ4* haplotypes in either ancestral background. Therefore, we hypothesized that variants in linkage disequilibrium (LD) with *TOMM40*-523â on the European LA *APOEÉ3* haplotype can modify risk for AD, potentially through *APOE* regulation. Methods: We used the short tandem repeat detection bioinformatics algorithm HipSTR to type S and VL repeats in whole genome sequencing data of individuals homozygous for the *APOEÉ3* European LA haplotype from the Puerto Rico AD Initiative (PRADI) project. Frequency of variants on 16 S and 14 VL independent haplotypes were compared to determine variants in LD with the repeat. HaploView was used to determine the LD structure of the repeat and surrounding variants. Results: We identified a 16kb LD block surrounding *TOMM40*-523â harboring 21 variants in strong LD (r^2>0.9) with the repeat (hg19, chr19:45,395-45,411k). This region includes the putative *APOE* promoter (harboring LD variants rs405509, rs449446 and rs769450) and a *TOMM40* intronic region with previously reported enhancer activity (harboring LD variants rs157580, rs2075649 and rs157584). Assessment of combined regulatory function of variants in LD with the repeat on S or VL haplotypes in the *APOE* promoter and *TOMM40* enhancer region is currently ongoing using luciferase reporter assays in AD-relevant cell types (i.e. astrocytes, microglia and neurons). Discussion: The identification of clearly distinct S and VL haplotypes on *APOEÉ3* European LA background support importance of the surrounding variants in the risk effect observed in the association analyses. The LD analyses data suggest that *TOMM40*-523â LD variants could directly affect *APOE* expression through presence in the promoter itself and/or in an identified enhancer region in *TOMM40*. The follow-up functional data will pinpoint the driving regulatory element(s) and *TOMM40*-523â LD variants for the observed different AD risk effects in European ancestry *APOEÉ3* carriers. Long term, treatments targeting these regulatory regions may be relevant to a large amount of people given *APOEÉ3*âs frequency in the general population.

PrgmNr 1422 - Telomere length analysis in amyotrophic lateral sclerosis using large-scale whole genome sequence data

View session detail

Author Block: **A. Al Khleifat**, The Project MinE Consortium; Kingâ□□s College London, London, United Kingdom
Disclosure Block: **A. Al Khleifat:** None.
Background Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disease characterized by the loss of upper and lower motor neurons, leading to progressive weakness of voluntary muscles, with death following from neuromuscular respiratory failure, typically within 3 to 5 years. There is a strong genetic contribution to ALS risk. In 10% of cases or more, a family history of ALS or frontotemporal dementia is obtained, and the Mendelian genes responsible for ALS in such families have now been identified in about 80% of cases. Only about 14% of apparently sporadic ALS is explained by known genetic variation, suggesting that other forms of genetic variation are important. Telomeres maintain DNA integrity during cellular replication, differ between sexes, and shorten naturally with age. Gender and age are risk factors for ALS and we therefore investigated telomere length in ALS.
Methods: Samples were from Project MinE, an international ALS whole genome sequencing consortium that includes phenotype data. For validation we used donated brain samples from motor cortex from people with ALS and controls. Ancestry and relatedness were evaluated by principal components analysis and relationship matrices of DNA microarray data. Whole genome sequence data were from Illumina HiSeq platforms and aligned using the Isaac pipeline. We estimated telomere length by applying a bioinformatics analysis to the data. We tested the association of telomere length with ALS and ALS survival. **Findings**: There were 6,580 whole genome sequences, reducing to 6,195 samples (4,315 from people with ALS and 1,880 controls) after quality control, and 159 brain samples (106 ALS, 53 controls). Accounting for age and sex, there was a 20% (95% CI 14%, 25%) increase of telomere length in people with ALS compared to controls ($p = 1.1 \times 10^{-12}$), validated in the brain samples ($p = 0.03$). Those with shorter telomeres had a 10% increase in median survival ($p = 5.0 \times 10^{-7}$). Although there was no difference in telomere length between sporadic ALS and familial ALS ($p=0.64$), telomere length in 382 people with ALS due to expanded *C9orf72* repeats was less than in those without expanded *C9orf72* repeats ($p = 5.0 \times 10^{-4}$). **Interpretation:** Although telomeres shorten with age, longer telomeres are a risk factor for ALS and worsen prognosis.
Conclusions: It is likely that longer telomeres increase risk for ALS.

PrgmNr 1423 - Shared genetic aetiology of type 2 diabetes and knee osteoarthritis

View session detail

Author Block: **A. Arruda**[1], E. Zeggini[2,3]; [1]Institute of Translational Genomics, Helmholtz Association Munich, Neuherberg, Germany, [2]Helmholtz Association Munich, Neuherberg, Germany, [3]Technical University Munich and Klinikum Rechts der Isar, Munich, Germany
Disclosure Block: **A. Arruda:** None.
Type 2 diabetes (T2D) and knee osteoarthritis (OA) are two of the most prevalent chronic diseases worldwide. Both disorders share common risk factors, for instance, obesity and increasing age, and frequently coexist in older adults. Observational studies report a positive epidemiological association between the diseases beyond their common risk factors. Mendelian randomization has shown no causal relation between T2D and knee OA, whereas body-mass index (BMI) is a causal factor for both. Taking into consideration the increase of the worldâ□□s elderly population and the chronic nature of these comorbid diseases, understanding their shared aetiology is of utmost importance.
Using summary statistics of large-scale genome-wide association studies (GWAS) from T2D (n=898,130) and knee OA (n=490,345), we investigate the genetic intersection between the traits by performing statistical co-localization analysis of established association signals using *COLOC*. For co-localizing signals, we then perform a multi-trait co-localization analysis using *HyPrColoc* with eQTL information derived from four disease-specific human tissues: pancreatic islets, intact OA cartilage, degenerated OA cartilage and OA synovium. We further integrate eQTL information from GTEx.
We find robust evidence for co-localization of T2D and knee OA signals in multiple regions. For instance, a region around the *FTO* gene co-localizes with a posterior probability of a shared causal variant (PP4) of 0.9. The 95% credible set consists of six variants, with *rs1421085* as the lead SNP. *rs1421085* (C) is associated with increased BMI. Moreover, rs*1421085* is an eQTL for *IRX3* in the synovium tissue and pancreatic islets, and these eQTLs co-localize with the T2D and knee OA signals. The associated *FTO* variants are known to form a long-range functional connection to *IRX3*, interacting with its promoter and regulating its expression. Our results underline the shared epidemiological association of knee OA and T2D with obesity and BMI, by showing co-localization of both traits and an association to disease-relevant tissues in the *FTO* obesity-related region.

PrgmNr 1424 - Genetic control of mRNA splicing is affected by purifying selection and may be linked to incomplete penetrance

View session detail

Author Block: **J. Einson**[1,2], T. Lappalainen[2], D. A. Glinos[2]; [1]Columbia University, New York, NY, [2]New York Genome Center, New York, NY
Disclosure Block: **J. Einson:** None.
Common variants affecting mRNA splicing are typically identified by splicing quantitative trait locus (sQTL) mapping and have been shown to be enriched for GWAS signals by a similar degree to eQTLs. However, the specific splicing changes induced by these variants have been difficult to characterize, making it more complicated to analyze the effect size and direction of sQTLs.Furthermore, sQTLs may affect the dosage of LoF variants in their target exons. This scenario is a potential driver of incomplete penetrance. To test our model, we first catalogued sQTLs using RNA-seq and WGS data from GTEx v8, using each exonâ□□s percentage spliced in (PSI) metric as a quantitative phenotype. PSI is an interpretable way of assessing an sQTLâ□□s effect size and direction. In total, we identify 5,196 genes with at least one significant exon across at least 1 of 18 GTEx tissues. With this set of sQTLs, it is more common that the derived alleles decrease (n=2,744) rather than increase (n=2,185) the inclusion of their target exons, but have a lower allele frequency distribution compared to sQTLs that increase exon inclusion (K.S. test $p=1.998Ã□10^{-15}$). This suggests purifying selection is acting on sQTL variants based on their regulatory properties.We also performed colocalization analysis between sQTL and GWAS loci across 18 tissues and 114 GWAS studies. We found many examples of sQTL variants colocalizing with GWAS hits, and found some evidence that sQTL effect size, direction and other properties influence the likelihood of a significant colocalization event. Finally, we tested whether sQTLs modifying inclusion of their target exons may modify the penetrance of rare coding variants on the same haplotype. To this end, we analyzed signs of purifying selection by looking for depletion of high penetrance haplotype configurations in a general population. We tested for depletion of high penetrance haplotypes first using all 838 individuals in GTEx v8 with WGS, and then in the larger Trans-Omics for Precision Medicine (TOPMed) project, which includes whole genome sequencing from 63,420 individuals of European descent. The larger sample size allows us to probe penetrance patterns in ultra-rare variants, more common variants, and in genes with multiple rare variants across individuals. Ultimately, we provide insights into the multiple mechanisms how genetic effects on splicing contribute to patterns of genetic variation in human populations and genetic disease risk for common and rare diseases. This technique could improve our interpretation of the risks associated with genetic variation beyond the exome.

PrgmNr 1425 - Rare variants affecting multi-omic measurements of gene regulation implicated in EKG traits

View session detail

Author Block: **T. Li**[1], M. Arvanitis[1], B. J. Strober[1], B. Ni[1], V. Wang[1], J. K. Bonnie[1], R. Keener[1], H. J. Lin[2], J. I. Rotter[2], J. A. Brody[3], S. R. Heckbert[3], N. Sotoodehnia[3], D. E. Arking[4], A. Battle[1], NHLBI TOPMed consortium; [1]Johns Hopkins University, Baltimore, MD, [2]Lundquist Institute, Harbor-UCLA Med Ctr, Torrance, CA, [3]University of Washington, Seattle, WA, [4]Johns Hopkins School of Medicine, Baltimore, MD

Disclosure Block: **T. Li:** None.

Biobank-scale whole genome sequencing has identified molecular pathways relevant to disease that are disrupted by rare coding variants. However, interpretation of non-coding rare variants (RV) is still challenging. RVs have been implicated in complex diseases such as atrial fibrillation (AF). AF variants can be analyzed with electrocardiogram (EKG) traits, but mechanisms of associations remain elusive. Here, we leveraged transcriptomic, proteomic, and methylomic data from Multi-Ethnic Study of Atherosclerosis (MESA) in the TOPMed consortium, to evaluate functional RVs that affect EKG traits through expression of nearby genes in each omic signal. For a subset of 1816 European ancestry individuals, we calculated multi-omic z-scores after regressing out confounders. We observed enrichment of RVs near RNA, protein, and methylation signals with outlier z-scores. We used a hierarchical Bayesian model, Watershed, to prioritize functional RVs and assign posterior probabilities of functional effects for each triplet (gene, individual, RV; 104M analyzed). Compared to WGS annotations, our model significantly improved prediction of multi-omic outlier status for individuals with shared RVs (AUROC = 0.65). The model learned genomic features that predict outlier expression (e.g. TF binding for RNA, frameshift variants for protein). There was good correlation between z-scores of nearby genes and corresponding posteriors for RVs shared with GTEx. Watershed improved risk stratification for diverse polygenic traits over common variants. To study contributions of RVs to EKG traits, we built a framework to evaluate the excess of functional RV burden per gene on 5 EKG traits representing cardiac depolarization and conduction (PR, QRS); repolarization (QT, JT); and rate (RR interval). Multi-omic posteriors prioritized complementary genes associated with extreme EKG values. Extreme QRS intervals were associated with protein outliers of *CFC1*, a risk gene for congenital heart disease, and with mRNA outliers of *STUB1*, a ubiquitin ligase in the heart and striated muscle. A Cox proportional-hazards model showed that extreme values in all EKG traits, except JT, were significantly associated with poorer survival. In a mediation model, 40 genes had outlier protein levels potentially associated with poorer survival through extreme QRS values - for example *ARCN1*, part of the coatomer complex involved in developmental disorders. Our comprehensive survey of RVs and multi-omic outlier signals in a European cohort yields mechanistic insights into EKG traits. These methods are a framework for prioritizing functional RVs in precision medicine studies.

PrgmNr 1426 - Systematic evaluation and Improvements for trans-eQTL Detection Methods Allows Identification of Novel trans-eQTLs in the GTEx data

View session detail

Author Block: **C. Wu**, T. Xu, A. Goren, M. Gymrek; University of California, San Diego, San Diego, CA
Disclosure Block: **C. Wu:** None.
Studies of expression quantitative trait loci (eQTLs) have aimed to discover genetic variants that explain variation in gene expression levels due to associations with complex traits and human diseases. While thousands of cis-eQTLs have been reliably identified, consistently replicating trans-eQTL effects proved to be challenging due to insufficient statistical power, lack of comparable tissues and cohorts, and putative false positive associations. In particular, technical covariates lead to a substantial variation in expression datasets and result in multiple false positive eQTL calls. As a result, biological mechanisms and characteristics of trans-eQTLs remain largely unknown.
Here we present x-qtl â a novel trans-eQTL detection method. For a given trans-eQTL, we assume the distribution of association statistics to be a mixture of two distributions â for the target and non-target genes. x-qtl addresses two critical limitations of existing methods. First, the method allows downstream characterization of trans-eQTLs by predicting the number of target genes. Second, x-qtl applies principal component analysis to the expression matrix to account for gene correlations. Specifically, we represent the variables (genes) as the uncorrelated principal components which reduces noise from correlated genes that can obfuscate true trans-eQTL signals.
Next, we develop a simulation framework to evaluate trans-eQTL detection tools. Our framework enables for varied effect size distribution and number of target genes for each trans-eQTL, includes pairwise correlation between expression of different genes, and simulates effects of technical covariates. We use our framework to evaluate the power of x-qtl and two existing eQTL frameworks, MatrixeQTL and CPMA, to detect trans-eQTLs with a variety of characteristics. Our results indicate that only trans-eQTL with extremely large effect sizes, or affecting hundreds to thousands of target genes, can be reliably detected. Remarkably, x-qtl is more sensitive in detecting trans-eQTLs with a small number of targets than existing methods.
We benchmark x-qtl against existing tools using yeast expression data containing documented eQTLs. Then, we apply all methods to the recently released Genotype-Tissue Expression (GTEx) project v8 dataset with 838 human donors and 15,201 samples from 52 tissues. We observe a putative trans-eQTL in Nerve-Tibial involved in signal transduction pathways and another in Thyroid that is located in a thyroid-specific transcription factor. Additionally, we detect novel trans-eQTLs that are replicated among different tissues but were missed by traditional trans-eQTL analysis methods.

Previous studies integrating genome-wide association studies (GWAS) and brain expression quantitative trait loci (eQTL) data have discovered hundreds of risk genes associated with schizophrenia (SCZ). However, most studies focused on individuals of European Populations. Based on the differences in population structures such as linkage disequilibrium patterns and allele frequencies, we hypothesized that different populations had their own SNPs associated with brain gene expression; and population-relevant brain eQTL will improve interpretation of GWAS signals of the corresponding populations than the use of eQTL from other populations in SCZ.We first characterized the eQTL using RNA-seq and WGS data of brain samples from subjects of East Asian (EA, N = 228), Africa American (AFR, N = 175), and European (EU, N = 407) ancestries. Using FDR q-value Population shared (PS-), defined as the eQTL, of the identical SNP-gene pair, with the same effect in all three populations; or *Population-unique* (PU-), defined as the eQTL is only significant or has significantly different effect size in one population. Striking differences existed in eQTL across populations: only 3,999 genes were significantly associated with the same SNPs in three populations. We identified 1,308 and 333 PU-eQTL Genes in EA and AFR, respectively. Meanwhile, the SNP minor allele frequency and fixation index values of eQTLs are significantly higher in the PU-eQTL SNP than the PS-eQTL SNP (adjusted p

Capitalizing on linkage disequilibrium (LD) patterns to determine population substructure allows the discovery of additive association signals in genome-wide association studies (GWAS). As standard GWAS analyses are well-powered to interrogate additive models, investigating other plausible modes of inheritance such as dominance and epistasis may often require new approaches. Epistasis - interaction between genes, play an essential role in elucidating complex genetic networks that impact the human genome's structure and evolution. Given that evidence from model organism studies indicates long-range high LD regions to be under evolutionary selection, we hypothesized that these regions might play a key role in regulating disease mechanisms across various complex traits. Thus, we selected 20 diverse complex traits (neurological, ocular, cardiometabolic, immune) and created case/control cohorts of individuals in the eMERGE and UKBB datasets. We calculated Ohtaâ□□s D statistic on genome-wide pairs of variants to identify pairs in long-range (> 0.25cM) LD due to epistatic selection. On these resulting 136,019 SNPs culminating in a total of 5,625,845 SNP-SNP models, we used a penalized regression framework to determine the association of SNP-SNP pairs with a disease. Across 12 of the 20 phenotypes, we found 290 models (majority inter-chromosomal) that replicated in UKBB and eMERGE after multiple hypothesis testing correction. Characterization of replicating models indicate the genes they map to are 1) highly conserved gene families with complex roles in multiple pathways, 2) essential genes, and/or 3) already associated in the literature with complex traits that have diverse phenotypic presentations. Together, these results demonstrate the highly pleiotropic nature of variants under epistatic selection in conserved regions, supporting the hypothesis that epistatic interactions regulate diverse clinical mechanisms and can produce a range of phenotypic outcomes. A key example is the WFS1 gene, coding for the calcium-regulating wolframin protein. Over 200 mutations in WFS1 have been associated with Wolframin Syndrome, characterized by different combinations of diabetes, optic atrophy, urinary tract dysfunction, loss of hearing, and neurological symptoms. Our results support the conclusion that epistatic interactions between *WFS1* and other genes, including *VRK2, NT5C2, INA, and DIP2C*, regulate this syndrome and produce the range of phenotypes seen. This study examines numerous such cases and sheds light on the pleiotropic interactions underlying disease etiologies providing a more unified view of epistasis and pleiotropy in complex traits.

PrgmNr 1429 - Global Biobank Meta-Analysis Initiative: A genome-wide association meta-analysis identifies novel primary open-angle glaucoma loci and shared biology with vascular mechanisms

View session detail

Author Block: **V. Lo Faro**[1], J. Hirbo[2,3], A. Bhattacharya[4], W. Zhou[5,6,7], Global Biobank Meta-analysis Initiative, N. Jansonius[8], H. Snieder[9], K. Joos[10], N. Disclosure Block: **V. Lo Faro:** None.

Primary open-angle glaucoma (POAG) is a complex eye disease characterized by progressive loss of optic nerve function that if untreated ultimately leads to irreversible blindness. To date, the biological mechanisms causing POAG are still unclear. A vascular hypothesis of unstable ocular perfusion has been suggested to explain the process of optic nerve damage. However, no study has previously provided a detailed exploration of the biology underlying the potential vascular connection with POAG. The Global Biobank Meta-Initiative (GBMI), a collaboration of 20 global biobanks, provides an exceptional resource to examine potential shared vascular POAG biology. A large-scale Genome-wide association studies meta-analysis was conducted in subjects sourced from 15 global biobanks and from six ancestries (n=1,487,447). A total of 59 statistically significant loci-trait associations were identified, seven of which were novel. Four loci encompassing the genes *ZFP91-CNTF, GLYAT, KALRN, CCDC13, MIR2054* and *INTU* were tested and replicated in an independent POAG cohort (n=383,500). To add biological context to these variant-trait associations, we performed TWAS using JTI cis models in 24 GTEx tissues potentially relevant to ocular conditions. We then performed fine-mapping identifying 29 gene-trait associations, five of which have been implicated or have vascular related functions: *CDKN2B, SLC35E2A, ITGB5* and *MYL4*. Further, we performed a gene enrichment analysis in which morphology and development of blood vessels, and angiogenesis pathways were significantly enriched. A gene prioritization analysis found 60 co-regulated genes of which 39 were novel. In total, 15 of the 39 novel POAG genes identified were associated with blood regulation, cardiac disease and arterial stiffness measurement. We did extensive statistical validation analysis of genes in *SIX6* and *CDKN2B-AS1* loci, previously implicated in POAG, cardiovascular diseases and cancers across multiple ancestries. Results from this analysis confirmed that the TWAS association signals in these loci are attributed to the sentinel rs33912345 missense variant in the SIX6 gene and variants linked to the *CDKN2B-AS1* gene. We also found evidence of significant interaction between the rs33912345 and causal variants in chr9p21.3, with concomitant effect on expression of the genes *CDKN2A* and *CDKN2B*. We confirmed shared biology between cardiovascular diseases and POAG by performing meta-analysis cis model TWAS-PheWAS across the whole phenome in BioVU and UKbiobank data (n=456,423). Taken together, these findings enforce the contribution of genes involved in vascular mechanisms to POAG pathogenesis.

PrgmNr 1430 - Systematic comparison of family history and polygenic risk across 27 common diseases

View session detail

Author Block: **N. Mars**[1], J. V. Lindbohm[2,3], P. della Briotta Parolo[1], E. WidÃ©n[1], J. Kaprio[1,2], A. Palotie[1,4,5], FinnGen, S. Ripatti[1,6]; [1]Institute for Molecular Medicine Finland, HiLIFE, University of Helsinki, Helsinki, Finland, [2]Clinicum, Department of Public Health, University of Helsinki, Helsinki, Finland, [3]Department of Epidemiology and Public Health, University College London, London, United Kingdom, [4]Analytic and Translational Genetics Unit, Department of Medicine, Massachusetts General Hospital, Boston, MA, [5]Stanley Center for Psychiatric Research, Broad Institute of MIT and Harvard, Cambridge, MA, [6]Broad Institute of MIT and Harvard, Cambridge, MA
Disclosure Block: **N. Mars:** None.
Family history is the standard measure of inherited disease susceptibility in clinical practice, while polygenic risk scores (PRS) have recently been shown to capture efficiently personal genetic risks in many diseases. No studies have systematically compared how they overlap and complement each other in a wide range of common complex diseases.
Here we leverage family relationships, information about parental causes of death, and genome-wide genotyping of 306,418 individuals within the FinnGen study, to systematically examine the interplay of first and second-degree family history of diseases, parental causes of death, and genome-wide PRSs. With up to 50 years of follow-up within nationwide health registries, we study 27 diseases, covering a large proportion of the burden of non-communicable diseases in adults. The 27 genome-wide PRSs were constructed using PRS-CS.
The effects of PRS and family history were largely independent and provided complementary information for risk prediction. Both high PRS and family history were strongly associated with respective diseases, but a high PRS (>90th percentile) conferred larger risks than family history in cardiometabolic diseases and in the three common cancers studied. Among 39,444 individuals with a first-degree relative in the dataset, the impact of adjusting the PRS with first-degree family history was small (mean decrease in betas -3.4%, s.d. 1.8%). Similarly, the decrease was small adjusting the effect of first-degree family history with the PRS (-4.9%, s.d. 3.3%). The decreases were even smaller for second-degree family history (N=47,154), and for parental causes of death (N=227,982). In 23/27 diseases, PRS improved risk discrimination beyond first-degree family history, with largest increases in rheumatoid arthritis, asthma, and prostate and breast cancer.
PRSs were effective also for risk stratification among individuals with positive family history. In most diseases, a positive family history with a high PRS was associated with a considerably elevated risk, whereas a low PRS compensated completely for the risk implied by a positive family history. For instance, in type 2 diabetes, individuals with positive family history and high (>90th percentile), average (33-90th) or low (This study provides a catalogue of risk estimates and prediction accuracy for both family history of disease and PRSs. We demonstrate that these metrics are largely independent and complementary measures of familial susceptibility.

PrgmNr 1431 - Systematic comparison of performance of over 50 PRS across ancestries for 14 diseases

View session detail

Author Block: **V. Plagnol**, S. Selzam, W. Tarran, R. Moore, D. Wells, F. Riveros-Mckay, P. Donnelly, G. McVean, M. E. Weale; Genomics plc, Oxford, United Kingdom
Disclosure Block: **V. Plagnol:** Salary/Employment; Genomics plc.
There has been intense recent interest in the performance of PRSs across ancestry groups, in particular in the extent of performance deterioration in non-European individuals. This is particularly pressing as the technology moves closer to use in healthcare.
However, like-for-like comparison of reported performances is often difficult, for example because of differences in cohort recruitment, phenotype definition, population characteristics or use of covariates such as age/sex in reported metrics. Even if the same evaluation cohort was used, many of these interpretation issues remain. To overcome these issues we established a uniform PRS comparison pipeline. This leverages the UK Biobank and several ethnically diverse cohorts (Multi-Ethnic Cohort, BioMe, ARIC, MESA, PAGE) to enable direct comparison between over 50 published and internally developed PRS models for 14 complex diseases in four ancestry groups (European, South Asian, East Asian, African), where sufficient case numbers were available for analysis.
Maximum AUC values were observed for individuals of European ancestries, followed by East Asians (average AUC reduction 2.36%), South Asians (average AUC reduction 4.51%) and Africans (average AUC reduction 10.8%). A few publicly available PRS are optimised for a specific ancestry, but for these we did not observe a predictive boost in the target ancestry. Genome-wide PRS including millions of variants were systematically more effective than sparser models, even when European linkage disequilibrium (LD) was applied to non-European ancestries (e.g. cross ancestry AUC boost of 8.2% in breast cancer). Inclusion of functional annotations yielded slight improvements (average ÎAUC 0.005) across ancestries and diseases. Internal optimization using population specific LD maps and bespoke cross-ancestry methodologies generated a detectable increase in the target ancestries, provided that a training set with an effective sample size â¥20% of the European set was available. For example, type 2 diabetes prediction improved across all ancestries, for a minimum of 10% for African ancestries (ÎAUC 0.06) to a maximum of 16% for East Asian ancestries (ÎAUC 0.09).
Systematic comparisons of PRS models across ancestry groups shows that the expected deterioration of performance was relatively limited between European and East/South Asian ancestries, but much more marked in individuals with African ancestries. Choice of PRS methodology substantially impacted predictive performance, suggesting that methodological developments as well as increasing data availability from non-European studies, will improve PRS performance across ancestries.

PrgmNr 1432 - Power-improved meta-QTL analysis reveals the complex regulation of molecular QTL associated with brain diseases

View session detail

Author Block: **B. Zeng**, J. Bendl, G. E. Hoffman, R. Roussos; Icahn School of Medicine at Mount Sinai, New York, NY

Co-localization of risk variants for brain diseases with molecular quantitative trait loci (QTL) aims to refine the credible sets of causal variants and link them to specific genes. Increasing sample size and performing trans-ethnic analysis can increase fine-mapping resolution, and enlarge the power of colocalization analysis. We developed a statistical method, called multivariate multiple QTL (mmQTL), to perform multi-tissue and trans-ethnic large-scale QTL analysis. We first perform dense simulations to demonstrate that mmQTL increases power to detect QTLs, controls the false positive rate in trans-ethnic analysis, and reduces the credible sets of causal variants. We then applied mmQTL on brain bulk RNA-seq (n=3,956 libraries from 2,119 unique donors) and cell-type specific ATAC-seq samples (n=1995 libraries from 646 unique donors) from neuronal and glial cell types. We identify 10,769 eGenes (genes with at least a genome-wide significant eQTL), of which 5,336 eGenes have multiple eQTLs. We detect 17,425 significant caQTL in the neuronal cell, and 15,746 in the glial cell. Functional analysis based on evolutionary scores and rare-variant burden reveals eGenes are more likely to be mutant tolerant than no-eQTL genes, indicating evolutionary constraints on gene expression in the brain. Non-primary eQTLs capture regulatory elements defined by ATAC-seq peaks and are enriched for neuro-degenerative diseases. We found that caQTLs are largely shared among brain regions, but not in cell types. Fine-mapped variants from the power-improved caQTL are enriched to disrupt TF binding sites, and there are different sets of TF genes affected in neuronal and glial cells. Lastly, we integrated the detected eQTL and caQTL to conduct caQTL-eQTL-GWAS colocalization analysis, and revealed the regulation patterns for some disease-associated genes in the human brain. In this study, we have created the largest brain eQTL and caQTL resources to date, and they should be valuable to the community in exploring the underlying biological mechanism in brain diseases.

PrgmNr 1433 - Single-cell RNA sequencing of lung identifies disease-associated cell type-specific eQTLs

View session detail

Author Block: **H. M. Natri**[1], C. B. Azodi[2,3], A. J. Gutierrez[1], L. E. Bui[1], L. Peter[1], R. P. Kendle[1], D. J. McCarthy[2,3], N. E. Banovich[1]; [1]The Translational Genomics Research Institute, Phoenix, AZ, [2]University of Melbourne, Parkville, Victoria, Australia, [3]St. Vincentâ□□s Institute of Medical Research, Fitzroy, Victoria, Australia

Disclosure Block: **H.M. Natri:** None.

Genome-wide association studies and functional genomics approaches have identified regulatory loci that contribute to complex traits and disease. However, the effects of expression quantitative trait loci (eQTL) can be both cell-type and context-specific. Single-cell RNA-sequencing (sc-RNAseq) facilitates the mapping of eQTLs across different cell types, allowing the identification of cell type-specific eQTLs that would go undetected by bulk methods. Here we use sc-RNAseq to examine primary human tissue from the lungs of healthy individuals and those with interstitial lung disease (ILD). ILD is a chronic, progressive lung disease characterized by the scarring of lung tissue through epithelial remodeling and accumulation of extracellular matrix (ECM). Pulmonary Fibrosis (PF) is a clinical phenotype that exhibits the end stage of ILD. In general, progression of fibrosis occurs in a gradient resulting in some regions of extreme remodeling and some regions that appear largely normal. For the most common and severe form of ILD, idiopathic PF (IPF), lung transplantation is the only treatment option.

In the current study, we have used sc-RNAseq to generate expression profiles of 532,488 cells derived from 170 lung tissue samples from 52 healthy and 68 ILD donors, including 39 donors with IPF. To identify cell type-specific expression changes associated with genetic variation, we have used Whole Genome Sequencing (WGS) to genotype 97 individuals with available sc-RNAseq profiles. In an effort to map cis-eQTLs across lung cell types, we have used a pseudo-bulk approach aggregating the expression levels of cells for each of the study individuals. To identify shared and cell type-specific signatures, we have performed stratified analyses as well a joint analysis of all cell types to assess cis-eQTL effect size heterogeneity between cell types. Using this approach, we detect clear cell population, lineage, and cell type-specific signals Further integration with GWAS allows connecting PF risk variants to molecular functions in disease-relevant cell types.

These analyses aid in determining the cell types and states in which PF-associated genetic variants function, and highlight the importance of cellular context in gene regulation in health and disease.

PrgmNr 1434 - The Musculoskeletal 3D Epigenome Atlas

View session detail

Author Block: **M.-J. Tsai**[1], S. Reppe[2], T. Sato[3], R. Gill[4], M. Wein[3], K. Gautvik[2], NHLBI TOPMed Bone Mineralization workgroup, Y.-H. Hsu[1]; [1]Marcus Institute for Aging research and Harvard Medical School, Boston, MA, [2]Oslo University Hospital, Oslo, Norway, [3]Massachusetts General Hospital and Harvard Medical School, Boston, MA, [4]Genentech, San Mateo, CA
Disclosure Block: **M. Tsai:** None.
Musculoskeletal (MSK) disorders are a common and costly problem for elderly populations worldwide, most of which are polygenic disorders. Although an increasing number of human genome-wide association studies (GWAS) and population-based biobank studies identified sequence variants associated with risks of musculoskeletal diseases, there is a lack of information about the cell types in human bone and skeletal muscle tissues. Moreover, it is not a trivial task to understand specific genes regulating the landscape and understanding their functional involvement in musculoskeletal biology, especially for non-coding related variants.To address this issue, we generated HI-C seq, ATAC-seq, and RNA-seq in human primary mesenchymal stem cells, pre-mature osteoblasts, matured osteoblasts, osteocytes, skeletal myoblasts, and myotubes obtained from bone and skeletal muscle biopsies. These data were then combined with publicly available DNase-seq and ChIP-seq in a handful of relevant cell types from the ENCODE and Roadmap Epigenomics projects. We established global maps of regulatory elements and 3D chromatin looping structure with high-resolution (2kb) in human MSK relevant primary cell types. We identified (1) MSK-specific active enhancer-like regions; (2) MSK-specific active transcription factor binding sites and downstream-regulated genes in the open chromatin regions; (3) MSK-specific active promoter-like regions and transcription factors for protein-coding genes; (4) MSK specific proximal and distal enhancer-promoter interactions via the high-resolution 3D loop structure with ATAC-seq and RNA-seq data. The 3D MSK gene regulatory circuits and landscapes are implemented into an online searchable browser, which provides target gene prediction for all available (~700 million) non-coding variants for relevant diseases, visualization for MSK cell-type-specific gene regulatory circuits annotation for every sequence variant observed so far. We also integrated all update-to-date GWAS findings from GWAS Catalog to provide post-GWAS analyses for in-silico functional annotation of associated variants and underlying causal variants and genes prediction. We plan to extend our 3D Epigenome Atlas with additional human primary musculoskeletal cell types with single-cell RNA-seq and single-cell ATAC-seq.In summary, by integrating cell-type-specific multi-omics data, we have established MSK gene regulatory landscapes and developed an online searchable browser that provides comprehensive epigenome annotation and visualization of the 3D genome chromatin interactions. The browser is publicly available.

PrgmNr 1435 - Enhancer enhancer interaction networks involved in long-distance genome regulation link multiple non-coding variants to function

View session detail

Author Block: **X. Lin**; Stanford Univ., Belmont, CA
Disclosure Block: **X. Lin:** None.
Mammalian genomes often use multiple enhancers spanning an ultra long-distance (>Mb) to modulate genes, yet it is not clear how multiple enhancers may coordinate to achieve this task. In addition, Genome-Wide Association Studies (GWAS) reveal that variants in the non-coding regulatory elements, including enhancers, are estimated to account for >90% of the variants in disease. While individual enhancer variants mostly present small-to-modest clinical risks, a combination of multiple genetic variants among various enhancers can greatly amplify the effects of individual low-penetrance variants in complex diseases and traits, suggesting the importance of an enhancer-enhancer interaction network in controlling disease relevant genes and connecting multiple non-coding variants association to function. Recent progress in genomic mapping approaches and CRISPR perturbation technologies have accelerated the identification of enhancer and their roles in gene regulation. However, it remains unclear why multiple enhancers are needed, as well as a quantitative understanding of the underlying enhancer epistasis network, wherein the activity of an enhancer can functionally interact with others.
we used multiplexed CRISPR-based screening with a pooled library consisting of 87,025 sgRNA combinations to combinatorially probe enhancer-enhancer interactions. We discovered a previously uncharacterized two-layer enhancer-enhancer epistasis network across multiple oncogenes. In this network, we defined a class of synergistic regulatory elements (SREs) which are theorized to maintain both expression level and robustness of genes and provide buffering effects against genome instability over long distances. A suite of quantitative experimental and computational approaches, including chromatin interaction assays (Trac-looping), cellular imaging (multicolor 3-dimensional FISH), and machine learning (elastic-net regularized generalized linear model), unveiled mechanisms associated with this enhancer epistasis. We used this information to create a computational model to predict SREs and provided a strategy to link multiple non-coding variants to reveal their epistasis influence in clinical risk. In the genetic association analysis, we found that the SRE variants could cooperatively impact gene expression and alter clinical risk in cancer and autoimmune disorder. Our work unveiled new mechanisms underlying enhancer-mediated control of gene expression in ultra-long genomic distance, with implications for annotation of enhancer function within cells and interpretation of epistasis contribution of non-coding variants in human disease.

PrgmNr 1436 - Escape from X-inactivation in twins exhibits intra- and inter-individual variability across tissues

View session detail

Author Block: **A. Zito**[1,2], A. Visconti[1], N. Rossi[1], A. L. Roberts[1], R. Andres-Ejarque[3], S. Nardone[4], J. E. S. Moustafa[1], M. Falchi[1], K. S. Small[1]; [1]Twin Research & Genetic Epidemiology, King's College London, London, United Kingdom, [2]Present address: Massachusetts General Hospital, Boston, MA, [3]St Johnâ□□s Institute of Dermatology, Kingâ□□s College London, London, United Kingdom, [4]Department of Medicine, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA
Disclosure Block: **A. Zito:** None.

X-chromosome inactivation (XCI) silences one X in females to balance the unequal X-linked transcriptional dosage between the sexes. However, over 15% of X-genes escape XCI and is biallelically expressed. Our knowledge of XCI escape in humans largely rely on sex-differences, hybrid cell lines, and epigenetic marks, which are all indirect proxies of escape. Differently, tissue samples with skewed XCI enable the detection and measurement of escape directly in females. At present, the incidence and variability of escape across cells, tissues and individuals are not well known. The extent to which genetics and environment influence escape is also largely unknown. Using RNAseq and DNAseq data in a multi-tissue dataset sampled from 248 skewed female twins, we investigated escape prevalence and variability across fat and skin tissues, lymphoblastoid cell lines (LCLs), and purified immune cells (monocytes, B, T-CD4$^+$, T-CD8$^+$, NK), and individuals.
Solid tissues exhibit up to 13% higher incidence of escape than LCLs. 159 genes escaped XCI in least one tissue. This set includes 54 novel candidate escapees, of which 35% are long-non-coding RNAs. 24 genes constitutively escaped XCI across tissues, while a separate set of 51 genes exhibited tissue-restricted escape. Within an individual, there are both genes escaping XCI in all tissues, and genes showing tissue-restricted escape. Analysis of inter-individual variability revealed 40 genes (e.g. *BTK*, *CD99L2*) exhibiting consistent escape levels across females in at least one tissue, and 62 genes (e.g. *DDX3X*, *KDM6A*, *UBA1*) exhibiting inter-female variability in multiple tissues. Escape is heterogeneous across immune cell types, with higher incidence in lymphocytes than monocytes. There are both genes escaping XCI in multiple immune cell types, and immune cell type-specific escapees. Protein-protein network analysis highlighted that escapees interact with other proteins on a genome-wide scale, and are involved in varied processes and pathways such as epigenetic control of gene activity. Monozygotic (MZ) co-twins share significantly more similar escape levels than dizygotic (DZ) co-twins (corr.MZ=0.6; corr.DZ=0.46; P

PrgmNr 1437 - ChromBPNet: Deep learning models of base-resolution chromatin profiles reveal cis-regulatory syntax and regulatory variation

View session detail

Author Block: **A. Pampari**[1], A. Shcherbina[2], A. Kundaje[3]; [1]Computer Science, Stanford University, Stanford, CA, [2]Biomedical Data Sciences, Stanford University, Stanford, CA, [3]Stanford University, Stanford, CA

Disclosure Block: **A. Pampari:** None.

Chromatin profiling experiments such as DNase-seq, ATAC-seq, and histone ChIP-seq decorate cis-regulatory elements (cREs) with intricate read coverage profiles, whose magnitude, shape and span is regulated by cooperative binding of transcription factors (TFs). Here, we introduce ChromBPNet, the first end-to-end deep learning framework to map DNA sequence to base-resolution chromatin profiles, decipher predictive cis-regulatory sequence syntax of individual cREs and predict the impact of regulatory genetic variants on the strength and shape of different types of chromatin profiles across multiple cell types.

ChromBPNet is an optimized convolutional neural network architecture that models the influence of wide genomic sequence contexts (2-75 kbp) on quantitative base-resolution regulatory profiles from DNase-seq, ATAC-seq and histone ChIP-seq experiments. ChromBPNet trained on five ENCODE canonical cell lines achieved unprecedented predictive performance in held-out chromosomes, while automatically and optimally regressing out assay biases (DNase, Tn5 enzyme bias and input control for ChIP-seq). The models are highly performant over a range of sequencing depths and are able to de-noise and de-sparsify low coverage signal profiles at individual cREs.

We improved interpretation methods for de-novo inference of contribution of individual nucleotides across all putative cREs in the genome, thereby revealing predictive motif instances and their combinatorial interaction effects on base-resolution profiles. We deciphered syntactic sequence heterogeneity of all cREs in each cell-line and benchmarked these predictions against footprinting methods and TF ChIP-seq data. We found remarkable consistency between syntax derived from DNase-seq and ATAC-seq experiments. However, we also found intriguing differences in the influence of motif syntax and their associated cooperative TF complexes on different layers of regulatory activity (TF binding, chromatin accessibility, different types of histone marks) of individual cREs.

Finally, we developed a new variant effect score which predicts the impact of non-coding variants on the strength and shape of base-resolution chromatin profiles, thereby revealing a range of 'blast radii' of variants disrupting different types of TF motifs and syntax. Our models accurately predict quantitative trait loci associated with binding, accessibility and histone marks in lymphoblastoid cell-lines.

Our framework will enable high-resolution annotation of sequence syntax and regulatory variants in 100s of cell types that have been profiled with DNase-seq, ATAC-seq, and histone ChIP-seq experiments.

PrgmNr 1438 - NCBI ALFA Release 2for900 Million Variantsand Allele Frequencyfrom 200KdbGaPSubjects

Disclosure Block: **L. Phan:** None.
NCBI Allele Frequency Aggregator (ALFA) aims to provide the largest and most comprehensive aggregated variant datasets with allele frequency from dbGaP studies as open-access. dbGaP has over two million subjects and up to billions of variants along with thousands of phenotypes and molecular assay datasets. This unprecedented volume and the variety of data hold huge opportunities to exploring and studying genetic variations within human populations and identify genetic factors that influence health and diseases to improve diagnosis, treatment, and prevention.

ALFA Release 2 has over 900 million variants, including 300 million novel variants not in dbSNP Build 154. The data was generated from 79 dbGaP studies that included 192 thousand subjects and 5.8 trillion combined genotypes. Allele frequencies are available for 12 populations, including European, Hispanic, African, Asian, and other diverse population ancestries.

Allele frequencies are available for 86% of variants in dbSNP Build 155 (920M rs), 86% (334K rs) ClinVar small variants, and 99% (22K rs) of variants in the dbGaP GWAS catalog.

This massive amount of data is available as open-access from NCBI for variant interpretation and analysis. It is accessible by web search, FTP download, retrieval using API, and TrackHubs for genomic browsers. Please visit the ALFA homepage for more information about the project, releases, tutorials, and past presentations. ALFA website: https://www.ncbi.nlm.nih.gov/snp/docs/gsr/alfa/

PrgmNr 1439 - Phenome-wide association analysis of rare and common variation in 455,000 UK Biobank exome sequences accessible through public data portal

View session detail

Author Block: **Q. Wang**[1], K. Carss[2], R. S. Dhindsa[1], A. Harper[2], A. Nag[2], I. Tachmazidou[2], D. Vitsios[2], S. Deevi[2], J. Okae[2], S. Wasilewski[2], S. Katherine[2], S. Petrovski[2], AstraZeneca Genomics Initiative; [1]Centre for Genomics Research, AstraZeneca, Waltham, MA, [2]Centre for Genomics Research, AstraZeneca, Cambridge, United Kingdom
Disclosure Block: **Q. Wang:** Salary/Employment; AstraZeneca.
We adopted the exome sequences from ~455K UK Biobank participants to study the contribution of both rare and common protein-coding variation to thousands of phenotypic endpoints.
We performed a gene-based collapsing PheWAS and separately a variant-level PheWAS across ~17K binary/quantitative phenotypes, evaluating a range of genetic architectures. These analyses were conducted on our cloud-based platform. Overall, we identified 1,517 gene-phenotype relationships for binary phenotypes and 1,301 gene-phenotype relationships for quantitative phenotypes that were significantly associated (p-9), reflecting 125 and 378 distinct genes, respectively. On comparing with the OMIM database, among the significant findings for binary (clinical) phenotypes, 81% are previously known, 9% are known disease genes but represent novel phenotypic associations, and 10% are novel disease genes. The variant-level analysis yielded 5,178 significant (p-9) non-synonymous variant-phenotype relationships for binary phenotypes and 34,561 significant (p-9) non-synonymous variant-phenotype relationships for quantitative phenotypes, involving 586 and 3,860 distinct genes, respectively. Interestingly, 79% (1,197/1,517) and 46% (596/1,301) of the significant gene-phenotype relationships identified in the collapsing analysis for binary and quantitative phenotypes, respectively, were not detected in the corresponding single-variant analysis, demonstrating the complementarity of the two analytical approaches.
We will illustrate AstraZenecaâ□□s use of these data to rapidly validate and inform safety profiles of potential drug targets, identify novel targets, predict drug repositioning opportunities, and study prevalence of molecular endotypes. We also introduce a data portal to visually navigate this rich resource of PheWAS summary statistics for 19K genes and across 3.2M protein-coding variants. The portal supports the search of associations by gene, phenotype and variant, data visualisations to help interpret and explore the results, and ability to download focused results for further analysis.

PrgmNr 1440 - Integrated multi-omics analysis of thyroid cancer reveals key molecular pathways involved in tumor formation and metastasis

View session detail

Author Block: **S. Wu**[1], A. Sanghi[1], D. Ramazzotti[1], S. Chen[1], L. A. Orloff[1], M. M. Kasowski[1], M. P. Snyder[2]; [1]Stanford University, Palo Alto, CA, [2]Stanford Univ, Stanford, CA
Disclosure Block: **S. Wu:** None.
Thyroid cancer is one of the most common endocrine cancer with a continuously increasing incidence worldwide. Thyroid cancer has the lowest mutational burden among all cancers; however, it exhibits a high degree of heritability. The Cancer Genome Atlas (TCGA) study, one of the most comprehensive studies for thyroid cancer to date, profiled the mutations and transcriptome of 496 primary tumors, and identified two dominant molecular subtypes: BRAF-like and RAS-like. In this study, we performed deep multi-omics profiling (genomics, ATAC-seq, RNA-seq, proteomics, metabolomics, lipidomics) of 27 matched normal thyroid glands, 31 thyroid primary tumors, and 31 lymph node metastasis samples from 36 thyroid cancer patients. We observed dramatic molecular profiling differences between primary tumor/metastasis and normal samples, whereas not between primary tumor and metastasis samples. Transcriptomic, proteomic, metabolomic and lipidomic analyses revealed a dynamic choreography of molecular and cellular events that present three different changing patterns: cancer progression, tumor formation and tumor metastasis. These involve processes such as cell cycle and cell proliferation, cancer-related signaling pathways, immune response, metabolic reprogramming (including Warburg effects, dysregulated energy metabolism, carbohydrates, nucleotides, amino acids and lipids, etc), decreased thyroid hormone biosynthesis. Interestingly, activation of the AhR (aryl hydrocarbon receptor) signaling pathway was found to occur during tumor formation at transcript and protein levels, and we also detected the significant increase of tryptophan catabolite kynurenine, the endogenous tumor-promoting ligand of AhR, from our metabolomics data, indicating AhR signaling pathway and tryptophan catabolism may be the novel drug targets of thyroid cancer. Overall, our results reveal key genomic, molecular and cellular events during thyroid cancer formation and metastasis and its potential molecular mechanisms.

PrgmNr 1441 - Whole Blood RNA Sequencing in a Cohort of Undiagnosed Pediatric Patients

Marshall[2,8,9], A. Shlien[1,10], J. Dowling[1,3,11], M. D. Wilson[1,3]; [1]Genetics and Genome Biology, SickKids Research Institute, Toronto, ON, Canada, [2]Genome Diagnostics, Department of Paediatric Laboratory Medicine, The Hospital for Sick Children, Toronto, ON, Canada, [3]Department of Molecular Genetics, University of Toronto, Toronto, ON, Canada, [4]The Centre for Computational Medicine, SickKids Research Institute, Toronto, ON, Canada, [5]The Centre for Computational Medicine, The Hospital for Sick Children, Toronto, ON, Canada, [6]University of Wisconsin School of Medicine and Public Health, Madison, WI, [7]The Hospital for Sick Children, Toronto, ON, Canada, [8]The Centre for Applied Genomics, The Hospital for Sick Children, Toronto, ON, Canada, [9]Centre for Genetic Medicine, The Hospital for Sick Children, Toronto, ON, Canada, [10]Department of Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, Canada, [11]Department of Paediatrics, University of Toronto, Toronto, ON, Canada

Disclosure Block: **H. Hou:** None.

Background: RNA sequencing (RNA-seq) has the potential to improve our ability to interpret the functional and clinical significance of the genetic variants identified by Whole Exome Sequencing (WES) and Whole Genome Sequencing (WGS). A cohort of 134 pediatric patients with heterogeneous phenotypes collected through the SickKids Genome Clinic (Centre for Genomic Medicine) underwent testing by gene panels, microarray, and subsequently WGS. This resulted in the identification of pathogenic or plausibly causative variants in 44% of the samples. In this study, we set out to assess the utility of blood RNA-seq for the diagnosis of patients with diverse clinical indications and develop an interpretation schema to identify candidate genes.

Methods: We developed a clinical-grade, automated, scalable, and robust end-to-end RNA-seq library preparation platform capable of processing up to 96 samples at one time. We generated whole-blood RNA-seq from 134 individuals using this automated RNA-seq platform. Using a bioinformatics pipeline that incorporates various published tools and custom scripts, we identified expression outliers, aberrant splicing events, and allele-specific expression. We then took a disease gene-centric interpretation approach to identify clinically relevant transcriptional aberrations.

Results: Despite samples being archived for >3 years, we were able to generate good-quality RNA-seq data from all samples. With a median sequencing depth of 115M, we detected >70% of genes in curated genes panels related to phenotypes observed in our cohort. We identified expression outliers and/or aberrant splicing events in clinically relevant genes in 23.1% (31/134) blood RNA-seq data from our patient cohort. Specifically, we found RNA evidence supporting previously identified genetic variants in 30.5% (18/56) patients and proposed candidate genes in 16.6% (13/78) cases with negative WES/WGS findings. For example, we identified a known Joubert syndrome gene CEP120 as a decreasing expression outlier that contained a deep intronic splicing alteration in a patient with global developmental delay, abnormality of brain morphology, and dysmorphic facial features.

Conclusion: Our results support the use of clinical blood RNA-seq to facilitate genome diagnostics in pediatric patients with diverse phenotypes.

PrgmNr 1442 - Long read sequencing reveals extensive structural variation in diverse mouse genomes

View session detail

Author Block: **A. Ferraj**[1,2], P. A. Audano[2], P. Balachandran[2], I. A. Walawalkar[2], A. Czechanski[3], L. G. Reinholdt[3], C. R. Beck[1,2]; [1]University of Connecticut Health Center, Farmington, CT, [2]The Jackson Laboratory for Genomic Medicine, Farmington, CT, [3]The Jackson Laboratory, Bar Harbor, ME
Disclosure Block: **A. Ferraj:** None.
Structural variants (SVs) are genomic rearrangements that are larger than 50 bp in length. SVs consist of insertions, deletions, duplications, inversions, and complex combinations of these events; they collectively have implications in the pathology of cancer, Mendelian diseases, phenotypic variation, and evolution. Whole genome discovery and characterization of SVs has primarily utilized Illumina short-read sequencing, which can lack sensitivity in GC-rich regions and repetitive regions and can falter in the detection of some SVs, including inversions, complex SVs, and insertions. With mobile element polymorphisms, short reads cannot resolve the internal structure and sequence of these events when they are identified. Short reads have been used to study SVs in thousands of human and mouse genomes. In recent years, it has been shown that long-read sequencing excels at identifying many SVs, particularly insertions and duplications; these technologies can also resolve the nucleotide sequence of longer insertions. While the Human Genome Structural Variation Consortium (HGSVC) has released the most complete SV call sets to date, similar long-read efforts have not been applied to mouse strains, which leaves a gap in our understanding of a model organism critical to basic and clinical research. With Pacific Biosciences (PacBio) long-read sequencing, we are annotating and characterizing SVs in 13 widely-utilized inbred laboratory mouse strains. With an ensemble of long read SV calling algorithms, we have identified 495,452 SVs which occur at unique sites across the current mouse reference assembly, cumulatively affecting 10% (300Mb) of the mouse genome. We find that SVs account for over 5x the number of nucleotide changes between strains when compared to single nucleotide variants. Most of novel SVs found (90%) were specific to long-read detection. Furthermore, we have detected strain-specific as well as inter-strain SVs that exhibit high impact consequences, including over 2,300 coding sequence variants, 300 frameshift events, and insertion variants that dramatically affect the transcripts that they occur within. Our data comprehensively identify the extensive SVs present in diverse mouse genomes and strongly suggest that SVs contribute to inbred mouse genomic and phenotypic diversity.

PrgmNr 1443 - MERSCOPE™ reveals the transcriptional organization of the mouse brain

View session detail

Author Block: **G. Emanuel**, J. He, J. L. He; Vizgen, Cambridge, MA
Disclosure Block: **G. Emanuel:** Salary/Employment; Vizgen.
Biological systems are comprised of numerous cell types, intricately organized to form functional tissues and organs. Building molecular atlases to fully understand the structure and function of each cell within the brain is now a key aspect of neuroscience research. Atlas initiatives using single-cell RNA sequencing can characterize cell types based on their RNA expression profiles. However, the tissue organization is lost when cells are dissociated for single-cell sequencing, making it difficult to study how the cellular heterogeneity is contributing to the function of the tissue. Furthermore, accurately characterizing each cell within the brain is challenging due to the low expression of many functionally important genes such as nonsensory G-protein coupled receptors (GPCRs). A true spatial transcriptomics technology with high detection efficiency and single-molecule resolution is required to build accurate and complete molecular atlases. Vizgenâ□□s in situ genomics platform MERSCOPE™ enables the direct profiling of the spatial organization of intact tissue with subcellular resolution. MERSCOPE is built on multiplexed error robust in situ hybridization (MERFISH) technology that uses combinatorial labeling, sequential imaging, and error-robust barcoding to provide the highest detection efficiency and resolution available for spatial genomics. In a single experiment, hundreds of thousands of cells can be spatially profiled with high accuracy and reproducibility. To demonstrate the power of MERSCOPE, we mapped 483 genes across three full mouse brain coronal slices. We constructed a panel of canonical cell type markers and nonsensory GPCRs to spatially profile nonsensory GPCR expression across the brain with cellular context. Nonsensory GPCRs in the brain mediate signaling and may play vital roles behind brain ageing and neurodegenerative disorders but are difficult to analyze. Our experiment successfully detected multiple lowly expressed GPCRs including Oxtr, Tshr, and Insr. The mouse brain receptor map demonstrates MERSCOPE as a leading tool for molecular atlassing, enabling scientists to find greater insights into healthy versus diseased tissue.

PrgmNr 1444 - Identifying the genetic contributors of efficacy and adverse metabolic effects of thiazide diuretics in African Americans from the Genetics of Hypertension Associated Treatments (GenHAT) study

View session detail

Author Block: **N. M. Davis Armstrong**[1], V. Srinivasasainagendra[1], R. M. Tanner[1], B. A. Hidalgo[1], H. K. Tiwari[1], D. K. Arnett[2], M. R. Irvin[1]; [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Kentucky, Lexington, KY

Disclosure Block: **N.M. Davis Armstrong:** None.

African Americans (AAs) have a higher prevalence of hypertension (HTN) compared to whites, presenting with a more severe form due to earlier onset and more rapid vascular damage. AAs respond better to diuretics compared to beta blockers or ACE inhibitors, yet the reason is not well understood. While thiazide diuretics continue to be a first-line antihypertensive, there is clinical significance to adverse metabolic effects linked to thiazide use, including incident diabetes and hypokalemia. The GenHAT study is an ancillary study of the Antihypertensive and Lipid Lowering Treatment to Prevent Heart Attack Trial (ALLHAT). DNA from participants was extracted and hybridized to Illumina Multi-Ethnic AMR/AFR BeadChip arrays. Quality control was performed at the sample and variant level, resulting in the inclusion of 4,297 AAs taking chlorthalidone, a thiazide diuretic, and 969,031 genotyped variants. Upon imputation using the NHLBI TOPMed Freeze 8 reference panel, over 20 million variants with minor allele counts >20, imputation quality scores >0.3, and genotype probabilities >90% were retained for association analysis. Outcomes of interest included systolic (SBP) and diastolic (DBP) blood pressure response over 6 months, fasting glucose response (FG) over 24 months, and serum potassium response (K) over 2 months. Linear regression models for the response of all outcomes were performed in PLINK2 and adjusted for age, sex, baseline measure, and genetic ancestry. A total of 14 variants (3 SBP, 2 DBP, and 9 FG) exceeded statistical significance at pCDHR2 and *MINDY3-CUBN* gene regions for SBP, *LINC02211-CDH9* intergenic region for DBP, and *GIMAP1-GIMAP5* for FG analyses. While many of the variants identified had no previous association with HTN or drug response, variants located within *CDH9*, *MINDY3-CUBN*, and *GIMAP* gene regions were of particular interest. *CDH9* variants have been previously associated with coronary artery calcification in an AA meta-analysis, while variants in *CUBN* have been linked to albuminuria and coronary artery disease. The *GIMAP* GTPase family are potential modifiers in autoimmune diseases including diabetes, and have reported associations with triglycerides, von Willebrand factor, C-reactive protein, and fibrinogen levels. Replication for these variants is ongoing using data from the International Consortium for Antihypertensive Pharmacogenomics Studies (ICAPS) to determine whether these variants can help identify individuals at risk of poorer drug response or unfavorable metabolic changes.

PrgmNr 1445 - Paradigm Shift from Disease PRS to PGx PRS for Drug Response Prediction using PRS-PGx Methods

View session detail

Disclosure Block: **S. Zhai:** None.
Polygenic risk score (PRS), by combining many small prognostic genetic effects, has shown promise in predicting human diseases and complex traits. In efficacy-based pharmacogenomics (PGx) studies, the current practice is to apply such PRS built from disease GWAS directly to PGx data from randomized clinical trials for drug response prediction and patient stratification. However, this approach relies on the assumption that every variant selected for constructing PRS has a constant ratio between its genotype main and genotype-by-treatment interaction effects, which largely may not be true in real PGx data. A violation of such assumption will make disease PRS explain less heritability of drug responses and thus reduce power in predicting them. Here, we propose the paradigm shift from disease PRS to PGx PRS approaches by simultaneously modeling the prognostic and predictive effects and constructing both PRSs for drug response prediction in PGx. We make this paradigm shift possible by developing a series of novel PRS-PGx methods, including PRS-PGx-unadj (unadjusted), PRS-PGx-CT (Clumping + Thresholding), PRS-PGx-L, -GL, -SGL (Lasso-, Group Lasso-, Sparse Group Lasso-based penalized regression), and PRS-PGx-Bayes (Bayesian regression). In the framework of Bayesian regression, we propose a polygenic prediction method that infers posterior prognostic and predictive effect sizes of SNPs simultaneously using PGx genome-wide association summary statistics and an external linkage disequilibrium (LD) reference panel. By introducing global-local continuous shrinkage priors on SNP effect sizes, our proposed PRS-PGx-Bayes method is more robust to varying relationships between the genotype main and genotype-by-treatment interaction effects. Extensive simulation studies show that PRS-PGx methods generally outperform the current disease PRS (PRS-Dis) methods across a wide range of genetic architectures and PRS-PGx-Bayes is superior to all other PRS-PGx methods. We further apply the PRS-PGx methods to the IMPROVE-IT PGx GWAS data by constructing PGx PRSs via 5-fold cross-validation to predict low-density lipoprotein-cholesterol. The drug response prediction results demonstrate the great improvement of PRS-PGx-Bayes in both prediction accuracy and the capability of capturing the treatment-specific predictive effects over alternative methods.

PrgmNr 1446 - Utility of polygenic risk scores for colorectal cancer risk assessment across diverse populations

Colorectal cancer (CRC) is a leading cause of cancer-related mortality, yet many CRC are preventable by screening individuals at increased disease risk. Polygenic risk score (PRS) offer the prospect of precision prevention by defining individualâ□□s risk of CRC and tailoring screening. Genome-wide CRC-PRS built upon European (EUR) data (PMID: 32758450) have limited performance in non-EUR populations because of small number of non-EUR populations included in the training data set. To address this deficiency, we expanded our PRS development to include non-EUR populations.
We derived PRS by leveraging GWAS summary statistics and LD structure from EUR and East Asian (EAS) ancestry. Our training data contains 78,473 cases & 107,142 controls of EUR ancestry and 21,737 cases & 47,444 controls of EAS ancestry. We examined 3 approaches for PRS development, using 1) 180 CRC known loci, 2) genome-wide EAS and EUR summary statistics and LD matrices, 3) combined genome-wide EUR and EAS summary statistics and weighted LD matrices with weights defined as the proportion of subjects from each ancestry. For Approaches 2 and 3, we used LDpred2 to derive PRS including ~1M SNPs. For Approaches 1 and 3 we derived a single PRS across EAS and EUR populations, whereas for Approach 2 we first derived ancestry-specific PRSs (PRSEUR and PRSEAS) and then final PRS for each ancestry by leveraging PRS from other ancestry using a weighted sum of PRSEUR and PRSEAS where the weights were obtained from a multivariate regression model, using 2,627 cases & 3,797 controls for EAS and 29,864 cases & 31,629 controls for EUR ancestry. To evaluate the performance, we analyzed independent data from Genetic Epidemiology Research on Adult Health and Aging cohort of 101,987 individuals, which included 1,699 CRC cases.
The AUC of the best performing approach, which combined genome-wide EUR and EAS summary statistics and LD matrices (Approach 3), were 0.67, 0.65, 0.63 and 0.57 for European, East Asian, Latinx, and African American ancestry groups, respectively, with hazard ratios of top 30% vs.

remaining for corresponding groups of 2.52, 1.61, 2.15 and 1.37. Compared to EUR-based PRS (PMID: 32758450), the AUCs for Approach 3 are improved by 3%, 6%, 5% and 2% for European, East Asian, Latinx and African American ancestry groups, respectively.
A trans-ethnic PRS has the potential to reduce disparities in PRS performance between non-EUR and EUR which is critical if PRS is going to be implemented in clinical practice or populations screening programs. As the performance remains lower in non-EUR populations, larger and more racially and ethnically diverse study populations may further improve equitable risk prediction.

PrgmNr 1447 - Dissecting 90 percent of lipoprotein(a) heritability in 487,571 UK Biobank participants

View session detail

Author Block: **R. E. Mukamel**[1], R. E. Handsaker[2], M. A. Sherman[3], A. Barton[4], Y. Zheng[1], S. A. McCarroll[4], P.-R. Loh[5]; [1]Brigham and Women's Hospital/Harvard Medical School, Boston, MA, [2]Charlemont, MA, [3]Massachusetts Institute of Technology, Marblehead, MA, [4]Harvard Medical School, Boston, MA, [5]Brigham and Women's Hospital / Harvard Medical School, Boston, MA
Disclosure Block: **R.E. Mukamel:** None.
Lipoprotein(a) concentration [Lp(a)] is a highly heritable (h^2>90%), monogenic cardiovascular risk factor whose primary genetic determinant is the size of the *LPA* kringle IV-2 (KIV-2) repeat, which explains ~60% of Lp(a) heritability. However, the full spectrum of other functional sequence variants in *LPA* and the way in which they shape Lp(a) variation has been unclear due to the difficulty of genotyping KIV-2 variation from high-throughput genomic assays. We developed methods to accurately estimate haplotype-resolved KIV-2 allele lengths in N=49,959 exome-sequenced UK Biobank (UKB) participants (RMSE ~1 repeat unit), and to impute KIV-2 lengths into SNP haplotypes for the remaining N=437,612 UKB participants (imputation R^2=0.9).
To systematically identify and measure the effects of additional Lp(a)-altering variants, we isolated the contributions of individual *LPA* haplotypes by analyzing heterozygous carriers of two coding variants known to create nonfunctional alleles (rs41272114 and rs41259144, combined MAF=0.05). This approach created an effective haploid model for Lp(a). Stepwise conditional analyses controlling for KIV-2 length pointed to a series of 20 additional protein-altering and 5â UTR variants that appeared to further shape Lp(a). Together with KIV-2 length, these variants explained 90% of heritable Lp(a) variance in European-ancestry participants in a model that accounted for nonlinear and cis-epistatic effects. These variants also largely explained the ~4-fold variation in median Lp(a) across populations: the higher Lp(a) commonly observed in African populations appeared to result from a relative paucity of alleles carrying a large-effect Lp(a)-reducing coding or splice-altering SNP in LPA (affecting 13% vs. 43% for African vs. European alleles) and the high frequency of the Lp(a)-increasing 5â UTR variant rs1800769 (46% vs. 17% for African vs. European alleles).
The accuracy of genetically predicted Lp(a) also enabled insights into epidemiological associations with Lp(a). The myocardial infarction risk-increasing effect of higher Lp(a) extended to extreme Lp(a) levels in UKB (OR=3.1, 95% CI=1.9-5.2 for individuals with predicted Lp(a)>400 nmol/L). In contrast, lower genetically predicted Lp(a) did not associate with increased type-2 diabetes (T2D) risk, suggesting that the 17% (s.e. 1%) lower levels of measured Lp(a) observed in T2D patients represents reverse causation resulting from T2D itself, T2D-related liver comorbidities, or T2D medication.
These results demonstrate that complex genetics can underlie even monogenic traits and inform genetic approaches to cardiovascular risk stratification.

PrgmNr 1448 - Polygenic score from a large GWAS predicts cases of heart failure with reduced ejection fraction (HFrEF) but not preserved ejection fraction (HFpEF)

View session detail

Zhou[4], the Global Biobank Meta-analysis Initiative; [1]University of Michigan, Ann Arbor, MI, [2]Michigan Medicine, Ann Arbor, MI, [3]Massachusetts General Hospital, Boston, MA, [4]Massachusetts general hospital, Broad Institute, Boston, MA
Disclosure Block: **K. Wu:** None.
Introduction Heart failure (HF) is a complex disease with multiple subtypes that have distinct etiologies, pathophysiologies, and genetic risk. The performance of a heart failure polygenic score (PGS), derived from a new genome-wide association study (GWAS), was tested to predict cases of heart failure with reduced ejection fraction (HFrEF) and preserved ejection fraction (HFpEF). **Methods** GWAS was performed within the Global Biobank Meta-analysis Initiative (GBMI) â a global collaboration among 13 biobanks across the world with diverse ancestries. GWAS summary statistics were then used to generate a PGS in a combined cohort from the Michigan Genomics Initiative and Cardiovascular Health Improvement Project (MGI/CHIP). Heart failure cases in the GBMI training dataset were defined based upon ICD codes, which did not distinguish between HF subtypes. Electronic health record data available within MGI/CHIP enabled further classification of patients into HFrEF and HFpEF, using a previously validated methodology incorporating ICD diagnoses, free-text language processing, and left ventricular ejection fraction (LVEF). Twenty percent of the cases derived with this method were further adjudicated by clinicians to confirm the phenotype. To compare the predictive ability of PGS, we evaluated logistic regression models with PGS adjusted for age, sex, and principal components derived from genotype data separately for both HFrEF and HFpEF phenotypes. **Results** In the GBMI training dataset, genetic data was analyzed from a total of 67,049 HF patients from 1,305,592 samples from 6 ancestral populations: 25.4% of the samples were of non-European ancestry. The GWAS identified 22 index variants that reached genome-wide significance. The MGI/CHIP validation dataset contained: 360 HFrEF patients, 232 HFpEF patients, and 24,313 healthy controls. The genome-wide PGS is a significantly better predictor of HFrEF compared to HFpEF in the MGI/CHIP cohort. In the HFrEF model, the PGS had an adjusted odds ratio (aOR) of 1.40 (95% CI: 1.25-1.57; p-value: $1.25x10^{-8}$) compared to an aOR of 1.08 (95% CI: 0.93-1.24; p-value: 0.30) in the HFpEF model. **Conclusion** Our analyses showed that a PGS for heart failure derived from GBMI data is useful in predicting HFrEF in an independent dataset. The difficulty in predicting HFpEF could result from: (i) the GBMI HF phenotype preferencing HFrEF over HFpEF, (ii) increased diagnostic accuracy in HFrEF in the evaluation cohort (due to inclusion of decreased LVEF), or (iii) greater genetic heterogeneity in the HFpEF population. Future studies focused on a GWAS for HFpEF may create a more useful polygenic score, if the trait is sufficiently heritable.

PrgmNr 1449 - Rare variant carrier status on risk of coronary artery disease among individuals with high polygenic risk

View session detail

Author Block: **M. Shivakumar**[1], S.-H. JUNG[2], J.-S. Yun[3], M. D. Ritchie[2,4], D. Kim[2]; [1]Department of Biostatistics, Epidemiology and Informatics, University of Pennsylvania, Philadelphia, PA, USA, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA, [3]The Catholic University of Korea, Bryn Mawr, PA, [4]Institute for Biomedical Informatics, University of Pennsylvania, Philadelphia, PA
Disclosure Block: **M. Shivakumar:** None.

Polygenic risk scores (PRS) derived from large GWAS studies have been able to capture a large portion of genetic risk for coronary artery disease (CAD) risk. Previous studies have shown that the PRS for CAD (PRS_{CAD}) can be used to identify the subgroup from the population that is at greater than three-fold increased risk for CAD. However, in general, rare variants are known to have larger impacts than common variants, and complex diseases like CAD are influenced by both common and rare genetic variants. In this study, we examined the changes in the risk conferred by carriers of rare variants in known genes associated with CAD.

Among 154,799 unrelated individuals of European ancestry, we identified 2,553 CAD cases with both genotype and exome sequencing data available in UK Biobank (UKBB). PRS_{CAD} for all samples were calculated using genotype data using LDpred and summary statistics from the CARDIoGRAMplusC4D GWAS study. The rare variants were obtained from the exome sequencing data and were filtered to keep only predicted loss of function (LOF) variants, variants predicated with high impact by Variant Effect Predictor, and missense variants with REVEL score > 0.5. We split samples into 10 groups based on 5 PRS_{CAD} quantiles and rare variant carrier status. We calculated the risk of CAD between the first and last quantile combined with rare variant carrier status.

Of the 47 known replicated genes for CAD, we found 22 genes where the carriers of rare variants showed higher odds of CAD risk than non-carriers, and in the other 25 genes, the carriers of rare variants showed lower odds of CAD risk than the non-carriers in the high risk PRS group. The samples with LOF rare variants in genes such as *MIA3* (Lowest vs. highest PRS with non-carrier OR: 2.00, carrier OR: 4.13) and *TCF21* (non-carrier OR: 2.00, carrier OR: 3.09) showed higher OR. The high expression of MIA3 is expected to promote atheroprotective vascular smooth muscle cells and higher expression *TCF21* is known to inhibit risk for coronary artery disease. On the contrary, genes like *SMAD3* (non-carrier OR: 2.02, carrier OR: 1.25E-05) and HHIPL1 (non-carrier OR: 2.01, carrier OR: 1.29E-05) showed lower odds, and their expression is known to increase CAD progression.

We showed that the LOF rare variant carriers in the high risk PRS groups may increase or decrease the odds of CAD risk. This study also shows the need to take rare variants into consideration for risk stratification. Robust methods for integration of rare variants with PRS are greatly needed to further improve risk prediction for CAD and allow for the development of improved preventive measures and also novel therapeutic opportunities for CAD.

PrgmNr 1450 - Expanded Genetic Clustering of Type 2 Diabetes Loci Using a High-throughput Pipeline Reveals Mechanistic Pathways of Metabolic Diseases

Complex diseases such as type 2 diabetes (T2D) are highly polygenic and influenced by multiple biological pathways. Rapid expansion in the number of T2D loci can be leveraged to identify such pathways, which may facilitate improved patient management.

We developed a high-throughput pipeline to enable clustering of T2D loci based on variant-trait associations. Our pipeline extracted summary statistics from genome-wide association studies (GWAS) for T2D and related trait to generate a matrix of 336 variants x 64 trait associations and applied Bayesian Non-negative Factorization (bNMF) to identify genetic components of T2D.

We identified ten genetic clusters of T2D, which included five from our published prior analysis of 94 T2D loci. Four of the ten clusters related to mechanisms of insulin deficiency, five to insulin resistance, and one had an unclear mechanism. Novel clusters identified in this analysis related to beta-cell dysfunction, pronounced insulin secretion, and circulating levels of alkaline phosphatase, lipoprotein A, and sex hormone binding globulin.

The T2D genetic clusters displayed tissue-specific epigenomic enrichment, particularly in pancreatic islets, liver, and adipose tissue. Two of the clusters relating to insulin deficiency were differentially enriched in functional and stressed pancreatic beta-cell states. Additionally, cluster-specific polygenic scores were associated with distinct clinical outcomes across GWAS and confirmed in participants in the Mass General Brigham Biobank. Multiple observed T2D genetic pathways were shared across genetic clusters of coronary artery disease and chronic kidney disease.

Our approach stratifies T2D loci into physiologically meaningful clusters with distinct tissue specificity and association with metabolic conditions. The pipeline allows for efficient updating and refining of clusters as additional GWAS datasets become available, and can be readily applied to other conditions. This method supports translation of GWAS findings into a more granular understanding of disease mechanisms, with a view toward precision medicine.

PrgmNr 1451 - Mirror effects of *OPRD1* variants on diabetes and obesity

Opioid consumption leads to contradictory effects on metabolic homeostasis, by increasing hyperglycemia but improving lipid profile and adiposity. However, the mechanisms linking opioids and metabolism are unknown. RNA sequencing data showed that *OPRD1* encoding Î´ opioid receptor (DOP) is expressed in human islets, especially in Ã□ cells. DOP is an inhibitory G-protein coupled receptor. Based on *OPRD1* resequencing and functional experiments, we aimed to decipher the putative link between *OPRD1* mutations and metabolic disorders.

OPRD1 was sequenced in 6,971 individuals. The effect of each detected variant was assessed via luciferase experiments, in response to increasing concentrations of two DOP agonists (DII or DPDPE). We categorized these variants as gain-of-function (GoF) or loss-of-function (LoF). In parallel, expression and localization of each variant were assessed by western blotting and immunofluorescence assays. Association studies between GoF or LoF variants and various metabolic traits were assessed in our cohort, and in further 34,812 individuals from the T2D Knowledge Portal for the study of the frequent GoF variant encoding p.I52V. Finally, we performed glucose-stimulated insulin secretion (GSIS) in the human Ã□-cell model EndoCÃ□H1 overexpressing *OPRD1* and treated with DII DOP agonist.

In 6,971 individuals, we detected 31 rare variants and 3 frequent variants of *OPRD1*. Luciferase assays highlighted 7 GoF variants, including the frequent variant encoding p.I52V, and 12 LoF variants. Immunofluorescence assays showed that all the mutants were effectively expressed and localized at the plasma membrane, except for two LoF mutants (p.P14R and p.G36E). Western blots showed that these two mutants tended to have a lower expression than wild-type DOP. Association analyses revealed that rare LoF variants increased overweight and obesity risk (P=0.0054; OR=11) but decreased hyperglycemia risk (P=0.054; OR=0.23), while rare GoF variants significantly improved lipid profile. Besides, the frequent GoF p.I52V variant was associated with increased type 2 diabetes risk ($P=3.6 \times 10^{-6}$; OR=2) but decreased body mass index (P=0.0038; Ã□=-0.37) and improved lipid profile, confirming this mirror effect. Finally, we showed that DOP significantly inhibited insulin secretion from Ã□ cells.

This study highlights DOP as a major link between opioids and metabolic disorders. DOP agonists and/or antagonists should be considered as new tools to improve metabolic homeostasis.

PrgmNr 1452 - The effect of obesity-related traits on COVID-19 severe respiratory symptoms and hospitalization and its mediation by socioeconomic status: a multivariable Mendelian randomization study

View session detail

Author Block: **B. Cabrera Mendoza**[1,2], F. Wendt[1,2], G. Pathak[2,1], F. de Angelis[1,2], A. De Lillo[1], D. Koller[1,2], R. Polimanti[1,2]; [1]Yale University, New Haven, CT, [2]VA CT Health Care System, West Haven, CT
Disclosure Block: **B. Cabrera Mendoza:** None.
Obesity has been associated with a higher susceptibility to coronavirus disease 2019 (COVID-19), particularly with its more severe clinical manifestations. However, this association can be affected by many correlates of these traits. Due to its large impact on human health, socioeconomic status (SES) could influence at least partially the association between obesity and COVID-19 severity. To estimate the independent effect of traits related to body size and SES on the clinical manifestations of COVID-19, we conducted a Mendelian randomization (MR) study analyzing the effect of obesity-related anthropometric traits on COVID-19 outcomes. We evaluated the effects of body mass index (BMI), waist circumference (WC), hip circumference, (HIP) and waist-hip ratio (WHR) studied in up to 234,069 participants from the Genetic Investigation of ANthropometric Traits (GIANT) consortium with respect to three COVID-19 outcomes: severe respiratory COVID-19 (5,101 cases vs. 1,383,241 controls), hospitalized COVID-19 (9,986 cases vs. 1,877,672 controls), and COVID-19 infection (38,984 cases vs. 1,644,784 controls) obtained from the COVID-19 Host Genetics Initiative (HGI). Finally, to investigate the effect of SES, we analyzed genetic data related to self-reported household income (HI) information from 286,301 UK Biobank (UKB) participants. We found that BMI and WC were associated with severe respiratory COVID-19 (BMI: ORâ□□=â□□1.68 pâ□□=â□□0.0004; WC: ORâ□□=â□□1.72, pâ□□=â□□0.0072) and hospitalized COVID-19 (BMI: OR =â□□1.62, pâ□□=â□□1.35e-06; WC: ORâ□□=â□□1.62, pâ□□=â□□0.0001). Also, HIP showed to influence hospitalized COVID-19 (ORâ□□=â□□1.31, pâ□□=â□□0.012) and COVID-19 infection (ORâ□□=â□□1.18, pâ□□=â□□0.0016). Conversely, HI was associated with reduced severe respiratory COVID-19 (ORâ□□=â□□0.57, pâ□□=â□□0.011) and hospitalized COVID-19 (ORâ□□=â□□0.71, pâ□□=â□□0.045). Testing these effects in multivariable MR models, we observed that the effect of obesity-related anthropometric traits on COVID-19 outcomes is not independent of the SES effect assessed as HI.. In summary, our findings indicate that low SES is a contributor to the observed association between body size and COVID-19 outcomes. Thus, the association of obesity with COVID-19 outcomes may be due to the conditions related to low SES rather than pathogenic mechanisms linked to obesity. This result has major public health implications because it supports that preventive strategies targeting body size and composition to reduce COVID-19 morbidity and mortality may not be effective if they are not considered in the context of SES.

PrgmNr 1453 - Comparative genetic architecture of the inflammatory bowel disease across East Asian and European populations

View session detail

Author Block: **R. Liu**[1,2], H. Gao[3], M. Li[4], H. Huang[2,1], Z. Liu[3]; [1]Broad Institute of MIT and Harvard, Cambridge, MA, [2]Analytic and Translational Genetics Unit, Massachusetts General Hospital, Boston, MA, [3]Center for IBD Research, Department of Gastroenterology, Shanghai Tenth Peopleâ□□s Hospital of Tongji University, Shanghai, China, [4]Department of Gastroenterology, Third Affiliated Hospital of Guangzhou Medical University, Guangzhou, China
Disclosure Block: **R. Liu:** None.
The inflammatory bowel diseases (IBD) are a group of chronic autoimmune disorders including two major subtypes: Crohnâ□□s disease and ulcerative colitis. The prevalence and incidence of IBD are increasing worldwide, especially in East Asia and other developing countries. Genome-wide association studies have identified over 240 of risk loci for IBD. However, the majority of IBD genetic studies were conducted using subjects of European descent (EUR), limiting the discovery and application of IBD genetics to the rest of the world populations. To address this issue, we conducted a large-scale IBD genetic study in the East Asian populations (EAS) using subjects from China, Japan and Korea, for a total sample size close to 18,000 (CD: 4,323, UC: 3,648, and Control: 10,014). All subjects were genotyped on the Illumina Immunochip or the Asia Screening Array, and have undergone stringent quality controls and imputation. Using this cohort, we found 33 genetic loci associated with IBD beyond genome-wide significance, among which 17 had never been reported in IBD genetic studies in EAS. Two of these new IBD-associated loci in EAS are implicated by coding variants in *RUNX3* (P=2.9e-8) and *ADAP1* (P=2.8e-8). *RUNX3* is a transcription factor playing an important role during the development of T cells and regulating TGFÎ² signaling. Runx3 knockout mice spontaneously develop IBD. *ADAP1* is involved in the BCR Signaling Pathway. We also found a pleiotropic variant (P=1.1e-8), located in the intron of *GTF21*, associated with both IBD and systemic lupus erythematosus. Across the genome, we found common variants underlying IBD genetic risk have similar genetic effects between EAS and EUR ancestries, with a genetic correlation of 0.95. We also found the odds ratios of IBD putative causal variants highly consistent across ancestries (slope: 0.9). Despite the overall consistency and in line with previous reports, we found a few loci showing clearly different genetic effects in EAS vs EUR, including *TNFSF15* and *IL23R*, suggesting gene-environment interactions modifying the genetic risks across populations. Encouraged by the overall consistency of genetic effects across populations, we performed a fixed-effect meta-analysis with the latest European IBD GWAS and identified over 50 new loci associated with IBD. In summary, we have demonstrated the value of including diverse ancestries in IBD genetics research through building and leveraging the largest IBD genetics cohort of non-European ancestry. Through joint and comparative analyses with European IBD GWAS, we have identified over 50 new IBD genetic loci and revealed important insights into the genetic IBD epidemiology across populations.

PrgmNr 1454 - High-resolution genomic architecture of COVID-19 severe disease using multi-ethnic whole genome sequencing data

With the aim of exploring host genetic factors underlying COVID-19 severity, the Genetics Of Mortality In Critical Care consortium (GenOMICC) and Genomics England are recruiting participants with severe and mild COVID-19. Our previous work in the GenOMICC consortium revealed therapeutically-targetable variants underlying life threatening COVID-19 (Pairo-Castineira et al. 2020). Working with the global Host Genetics Initiative consortium (HGI), we have shown that the strongest genetic signals are present in the critically ill population. However, most previous work, including our own, has used genotyping arrays and largely focused on a subset of common genetic variation. In order to facilitate a high-resolution analysis of the genome and exploration of all types of genetic variation underlying disease risk, we are performing whole-genome sequencing (WGS) of up to 35,000 participants with severe and mild COVID-19. To increase statistical power, we are combining these data with WGS data generated through the 100,000 Genomes Project from a wide range of ancestral backgrounds. Recruitment is ongoing with successive rounds of analysis and data freezes being made available in a cloud-based research environment to facilitate international research efforts. Our latest data freeze consists of over 10,000 individuals with COVID-19, including the largest WGS cohort of critically ill COVID-19 patients assessed to-date. GWAS analysis of data on a freeze of 4,677 patients, replicated genetic associations previously identified by us, HGI and other groups on chromosomes 3,12,19, and 21. The WGS data enabled precise fine-mapping that narrowed down the 3p21.31 association cluster to two independent signals. Trans-ancestry GWAS analysis showed that one of the association signals on 3p21.31 can be independently replicated in multiple ethnicities but with significantly different effect sizes, underscoring the heterogenous impact of genetic ancestry on COVID-19. Rare variant burden analyses have yet to identify robustly any genes associated with severe COVID-19, which is consistent with other recent findings (Kosmicki et al. 2021). Our study provides the first comprehensive investigation of the contribution of rare and common genetic variation on COVID-19 disease outcomes using large scale WGS data, which will be instrumental in elucidating the genomic architecture of the disease and inform therapeutic interventions.

De novo mutations (DNMs) are known to play a prominent role in many sporadic disorders with reduced fitness and genetic heterogeneity. Due to this strong effect on fitness, we hypothesize that DNMs play a prominent role in male infertility and explain a significant proportion of the genetic causes in this understudied disorder, where large-scale studies have to yet been published. In our study, we performed trio-based exome sequencing in a unique cohort of 185 males with unexplained cases of azoospermia or oligozoospermia and their unaffected parents. In total, 145 rare protein-altering *de novo* SNVs and 2 *de novo* CNVs were identified in these patients. Following a systematic analysis assessing mutational impact and protein function, 29 DNMs were classified as possibly causative of the male infertility phenotype observed in the affected patients. Additionally, a significant enrichment was detected in the number of Loss-of-Function (LoF) DNMs in LoF-intolerant genes ($p=1.00x10^{-5}$) and in predicted pathogenic missense DNMs in missense-intolerant genes

($p=5.01x10^{-4}$). Overall, a significant increase was found in the number of protein-protein interactions amongst genes affected by these DNMs ($p=2.35x10^{-2}$). Among the new candidate genes identified was *RBM5*, an essential regulator of male germ cell pre-mRNA splicing. Besides the patient carrying the DNM in *RBM5*, 6 additional infertile men were found carrying a distinct rare pathogenic missense mutation in *RBM5* in an international cohort of patients (n=2,506), a significant enrichment when compared to the number of mutations found in *RBM5* in a cohort of confirmed fertile men (n=5,784; p=0.03).Taken together, our results provide strong evidence for the role of DNMs in severe male infertility and identify a number of new candidate genes affecting human male fertility.

PrgmNr 1456 - Genomic and Transcriptomic-wide Analysis Identifies Novel Genetic Risk Loci and Prioritization of Therapies for Myasthenia Gravis

Myasthenia gravis is a chronic autoimmune disorder caused by antibody-mediated destruction of receptors at the neuromuscular junction (NMJ) resulting in loss of communication between motor neuron and skeletal muscle. Genetics are likely to play a role as myasthenic patients have a higher risk of developing other autoimmune diseases. We performed a genome-wide association study (GWAS) and a transcriptome-wide association study (TWAS) to identify the genetic risks and candidate genes involved in disease etiology. The discovery cohort consists of 1,873 myasthenic patients with acetylcholine receptor antibodies and 36,370 healthy individuals, whereas 354 cases and 7,058 healthy individuals from the UK Biobank were included in the replication cohort. In addition to previous signals in *PTPN22*, *HLA-DQA1/HLA-B*, and *TNFRSF11A*, two novel signals in the acetylcholine receptor subunits genes, which are common antigenic target of the autoantibodies, were identified. From GWAS, the risk variant located in a promoter region of the cholinergic receptor nicotinic alpha 1 subunit (*CHRNA1*) gene on the forward strand increased risk by 1.57 ($p=3Â·07Ã10^{-8}$). TWAS identified two genes of which lower expression in skeletal muscle was predicted to increase disease risk: cholinergic receptor nicotinic beta 1 subunit (*CHRNB1,* $p=3Â·01x10^{-6}$, Z=-4Â·67*)* and epidermal growth factor receptor family of receptor tyrosine kinases (*ERBB2*, $p=5Â·63x10^{-7}$, Z=-5Â·00). Both *CHRNB1* and *ERBB2* are highly expressed at the NMJ and involved in the formation of functional acetylcholine complex. Thus, it is reasonable that lower expression of these proteins could impair neurotransmission. Onset-stratified analysis demonstrate that the genetic architecture is different between patients with early (CHRNA1, *CHRNB1* and *ERBB2* genes. In an unbiased approach, we identified several immunotherapies that may modify the disease progression based on their genetic profile. Our results demonstrate the power of genomics as a viable strategy for drug repurposing across diseases.

PrgmNr 1457 - Polygenic risk scores as a marker for lifetime epilepsy risk

View session detail

Author Block: **H. O. Heyne**[1,2], FinnGen, M. J. Daly[3,1], R. KÃ¤lviÃ¤inen[4]; [1]Institute for Molecular Medicine Finnland: FIMM, Helsinki, Finland, [2]Hasso Plattner Institute, Potsdam, Germany, [3]Massachusetts General Hospital, Boston, MA, [4]Kuopio University Hospital, Kuopio, Finland
Disclosure Block: **H.O. Heyne:** None.
Epilepsy affects approximately 1% of individuals worldwide. Making an epilepsy diagnosis is often difficult with estimates that up to 25% of epilepsy could initially be misdiagnosed. The SNP heritability of genetic generalized epilepsy is high (32%) and it has recently been shown that individuals with epilepsy also have elevated epilepsy polygenic risk scores (PRS). However, investigation how epilepsy PRS may predict epilepsy risk in an individual across lifetime or in individuals with unclear seizure events has so far been lacking.Here, we studied epilepsy PRS in detailed longitudinal electronic health records of > 269k Finns including ICD codes and drug purchases of over 50 years. Our dataset included 9660 individuals with epilepsy related diagnoses. We could confirm previous studies describing an elevated PRS for generalized epilepsy (PRS_{gen}) in individuals with generalized epilepsy. This was particularly high for juvenile myoclonic epilepsy, which could be because it represented the largest diagnosis group of the GWAS that was used to construct the PRS. Individuals with a top 10% PRS_{gen} in FinnGen had a more than doubled lifetime risk (p-value $1x10^{-11}$, hazard ratio 2.3) to develop generalized epilepsy compared to the bottom 90% PRS_{gen}. We further found that over half of individuals with specific diagnoses of generalized or focal epilepsy were initially diagnosed with unclear convulsions (R56.8) or unclear epilepsy (G40.9). Their PRS_{gen} was significantly higher than of those individuals who had only one unclear seizure event and did not later receive an epilepsy diagnosis. Specifically, individuals with a top 10% PRS_{gen} had a hazard ratio of 2.4 (p-value $1x10^{-4}$) to progress to generalized epilepsy after an unclear seizure event below the age of 40 compared to the bottom 90% PRS_{gen}. These results indicate a future potential for epilepsy PRS to help in predicting progression to epilepsy.

PrgmNr 1458 - Trans-ancestry GWAS meta-analysis of alcohol and tobacco addiction in 3.4 million individuals

The use and abuse of nicotine and alcohol accounts for >100 million disability-adjusted life years across the globe, constituting one of the worldâ□□s leading public health problems. Despite this, the vast majority of genome-wide association studies (GWAS) thus far have been restricted to individuals of European ancestry, representing

PrgmNr 1459 - A Genealogical Estimate of Genetic Relationships to Improve Detection of Population Structure Over Time

View session detail

Author Block: **C. W. Chiang**, C. Fan, N. Mancuso; University of Southern California, Los Angeles, CA
Disclosure Block: **C.W. Chiang:** None.
The application of genetic relationships among individuals, characterized by a genetic relationship matrix (GRM), has far-reaching effects in genetic epidemiology. However, the current standard to calculate the GRM does not take advantage of linkage information and does not reflect the underlying genealogical history of the study sample. Here, we propose a coalescent-informed framework to infer the expected relatedness between pairs of individuals given an ancestral recombination graph (ARG) of the sample. This expected GRM (eGRM) is an unbiased and highly correlated estimate ($r^2 > 0.97$) of the latent pairwise genome-wide relatedness and maintains the mathematical properties of canonical GRMs. Through extensive simulations we show that the eGRM is robust when using genealogies inferred from incomplete genetic data, and can reveal the time-varying nature of population structure in a spatial sample. When applied to genotyping data from a population sample from Northern and Eastern Finland (N=2,644), we found that clustering analysis using the eGRM more accurately delineates population structure than would be possible using the standard GRM, and the temporal pattern of population structure in this sample is consistent with that of a recently diverged and expanded population. Taken together, our proposed estimator drastically shifts the notion of genetic relatedness from a variant-centric to a tree-centric world view, and will be widely applicable to genetic studies in understudied human or ecological samples where whole genome sequencing data or references might not be readily available.

PrgmNr 1460 - DNA methylation patterns underlying lifespan differences in mammals

View session detail

Author Block: **A. Haghani**, S. Horvath; University of California Los Angeles, Los Angeles, CA
Disclosure Block: **A. Haghani:** None.
The comparative cross-species analysis is a powerful tool to resolve the mysteries of evolution and phenotypic disparities among animals. This study describes the largest multi-species DNAm dataset that was collected by over 100 collaborators from Mammalian Methylation Consortium. This dataset includes over 10,000 DNA methylome data from multiple tissues of different age ranges of over 190 mammalian species. The network analysis of this dataset allowed us to identify co-methylation modules that relate to the individual (age, sex, tissue type) and species characteristics (e.g., phylogenetic order, maximum lifespan, adult weight). The unexpected correlation between DNA methylation and species was sufficiently strong to construct *phyloepigenetic* trees that parallel the phylogenetic tree. The analysis identified the epigenetic marks and the associated genes that relate to the maximum lifespan of mammals. Moreover, we could define novel epigenetic biomarkers of longevity that responded to gold standard anti-aging interventions in mice such as caloric restriction or growth hormone receptor knock outs. Our novel cross-species epigenetic analysis is a rich source of targets for future experimental studies of aging and longevity.

PrgmNr 1461 - Guaranteeing unbiasedness in selection tests based on polygenic scores

View session detail

Author Block: **J. Blanc**, J. J. Berg; University of Chicago, Chicago, IL
Disclosure Block: **J. Blanc:** None.
Population stratification is a well-studied problem in genome-wide association studies, leading to biases in the estimated strength of phenotypic association for individual genetic variants. In short, if environmental effects on the phenotype are correlated with ancestry gradients within a GWAS panel, any variant that is stratified along this ancestry gradient will receive a biased effect size estimate. While state of the art methods to correct for stratification are generally effective in reducing the number of significant false positive associations, even subtle biases in effect size estimates can accumulate across loci, leading to systematic biases in polygenic scores. In turn, these biases in the distribution of polygenic scores can lead to false positives in downstream analyses, such as tests for polygenic adaptation or other analyses of among group genetic differences. One approach is to attempt to be overly aggressive in controlling for stratification. However, there is currently no way to tell conclusively if confounding effects have been removed. A second approach is to conduct the GWAS in an evolutionarily diverged sample that is less likely to share population genetic structure with the test panel. This renders potential biases in the effect sizes irrelevant to the test, but comes at the cost of significantly reduced statistical power due to the issue of poor portability of polygenic scores across samples of divergent ancestry. Here using theory from population and statistical genetics, together with simulations, we show how this second approach can be generalized to panels that do share genetic structure, and that it is possible to guarantee the unbiasedness of selection tests without needing to guarantee that the effect sizes are fully unbiased. Specifically, if the researchers performing the GWAS also have access to the panel of test individuals and have identified the specific test to be performed ahead of time, then it is possible to compute a covariate to include in the GWAS, which will guarantee that the test is unbiased. Further, even when the test is not known prior to conducting the GWAS, our theoretical results provide a way to put a lower bound on the amount of stratification that would be needed to generate a positive signal of polygenic adaptation, and to assess whether the set of principal components that were included in the GWAS are sufficient to render the polygenic adaptation test unbiased. More generally, our results have implications beyond tests for selection as any analysis that attempts to quantify the correlation between polygenic scores and demographic or environmental variables is subject to the same type of stratification biases.

PrgmNr 1462 - A cross-disorder and evidence-based tiered ranking of candidate genes for neuropsychiatric disorders

View session detail

Author Block: **H. Shimelis**[1], M. T. Oetjens[2], M. Znidarsic[1], K. E. Wain[2], S. Myers[1], D. Ledbetter[1], C. L. Martin[2]; [1]Autism & Developmental Medicine Institute, Geisinger, Lewisburg, PA, [2]Geisinger, Lewisburg, PA

Disclosure Block: **H. Shimelis:** None.

Sequencing studies of cohorts with neuropsychiatric disorders (NPD) continue to identify many new NPD genes. These studies have revealed that categorical disorders, including intellectual disability (ID), autism spectrum disorder (ASD), and schizophrenia (SCZ), share genetic etiologies. Several databases have been created to catalogue rare variants in NPD probands, serving as a resource for researchers studying NPD. However, these databases generally use a single categorical NPD diagnosis in their approach, which is inconsistent with the known genetic overlap of these conditions and may underrepresent evidence for a given gene. To address this gap, the Developmental Brain Disorder (DBD) Gene Database (https://dbd.geisingeradmi.org/) uses a cross-disorder and tiered genotype-phenotype data mining approach to identify novel candidate genes and provide further evidence to genes previously implicated in NPD. Here, we present an update of the DBD Gene Database which contains data from 1172 studies published 2003-2020 representing 6481 individuals with pathogenic loss-of-function (pLOF) variants in 649 genes. pLOF and single gene copy number variants are curated from published sequencing studies across six NPD phenotypes: ID, ASD, epilepsy, attention deficit hyperactivity disorder, SCZ, and bipolar disorder. All genes are ranked into four tiers based on the number of cases with *de novo* pLOF variants: Tier 1, the strongest level of evidence, includes genes with three or more *de novo* pLOF variants; Tier 2, genes with two *de novo* pLOF variants; Tier 3, genes with one *de novo* pLOF variant; and Tier 4, genes with only inherited (or unknown inheritance) pLOF variants. Autosomal recessive (AR) genes are curated separately from LOF tier rankings. In our latest update from May 2021, 177 were ranked as Tier 1, 79 as Tier 2, 114 as Tier 3, 147 as Tier 4, and 132 as AR genes. To examine whether genes ranked as Tier 1 were novel or previously recognized as high-confidence genes in other databases, we compared Tier 1 genes to two NPD-related databases: SFARI gene and DDG2P (accessed May 2021). Of the 177 Tier 1 genes, 145 were listed as genes with the highest confidence of being NPD-related in at least one of the two databases while 32 were ranked lower (n=30) or not yet included (n=2). When we evaluated phenotypes of individuals with pLOF variants in Tier 1 genes, 96% (170/177) of genes were associated with 2 or more disorders. These results show that using a cross-disorder approach to NPD gene discovery increases the yield of genes with strong evidence of being NPD-related. Furthermore, our results show evidence for phenotypic heterogeneity in individuals with a pLOF variant in the same gene.

Expansions of gene-specific CAG/CTG DNA repeats cause >15 neurodegenerative diseases, including Huntington Disease (HD) and spinocerebellar ataxia type 1 (SCA1). Inherited expansions continue to somatically expand as patients age, through a poorly understood mechanism. Larger expansions hasten disease onset and worsen severity and progression, so understanding the molecular processes of expansions is crucial to understanding pathogenesis. Somatic expansions may be regulated by tissue-specific expression of DNA repair proteins. Paradoxically, DNA repair proteins may exacerbate somatic expansions by incorrectly mediating repair of the expansion. We assessed the role of two single-strand DNA binding protein complexes in the expansion process. The canonical single-strand DNA binding complex in humans, replication protein A (RPA), composed of RPA1-RPA2-RPA3, is essential for DNA replication, repair, and recombination. Humans also express a poorly understood primate-specific alternative RPA complex (Alt-RPA) in which RPA4 replaces RPA2. Here we show RPA and Alt-RPA are differentially upregulated in HD and SCA1 patient brain regions, with Alt-RPA demonstrating up to 10-fold upregulation in the most affected brain tissues. In vitro repair of slipped-CAG structures, a DNA intermediate of expansions, shows that high concentrations of RPA enhance repair while high concentrations of Alt-RPA blocks repair. Coincidentally, while both Alt-RPA and RPA bind slipped-CAG structures, RPA efficiently melts slipped-DNAs while Alt-RPA does not. Conducting the first BioID interactomes for the RPA subunits we identified that RPA interacts with proteins known to protect against CAG-associated neurodegeneration, while Alt-RPA interacts with proteins which promote CAG-associated neurodegeneration and CAG expansions, including MSH3. We demonstrate that RPA overexpression completely inhibits somatic repeat expansions in vivo in the striatum of SCA1 mice, coinciding with reductions in biomarkers of CAG disease such as genome-wide DNA damage and mutant Ataxin-1 aggregation in striatal medium spiny neurons. Previously we demonstrated Rpa1 overexpression rescued motor phenotypes and ameliorated elevated DNA damage in cerebellar Purkinje neurons, in the same mice. Our new data demonstrate that somatic expansions in the striatum may contribute to SCA1 mouse phenotypes, and that RPA is an active player in suppressing CAG expansions and pathogenesis, effectively preventing somatic CAG expansions and molecular phenotypes through non-replication mechanisms. In contrast, Alt-RPA likely plays the opposite role by enhancing expansions and pathogenesis.

Introduction: Disorders with epilepsy are genetically and phenotypically heterogeneous. The rapid advancement of genetic testing has helped address these complexities and aided definitive diagnosis, precision medicine and genetic counseling in families with these disorders. **Methods:** We recruited 49 families (51 individuals) with neurodevelopmental disorder (NDDs) with epilepsy. Four individuals (four families) with clinically recognizable phenotypes underwent targeted genetic testing and 48 individuals (46 families) with clinically unrecognizable phenotypes and/or undiagnosed by targeted testing underwent genomic testing after detailed clinical evaluation. The implications on genetic counseling and therapy were evaluated in individuals with definitive diagnosis. **Results:** Our cohort comprises of 24 males (47%) and 27 females (53%) from 19 consanguineous (39%) and 30 non-consanguineous (61%) families. A definitive molecular diagnosis was achieved in 32 families with three being diagnosed by targeted testing and 29 by exome sequencing (ES). Twenty-nine monogenic disorders and one imprinting/microdeletion syndrome (Angelman syndrome) were identified. Of these, eight (25%) families had variants in seven genes causing developmental epileptic encephalopathies (*KCNQ2*, *STXBP1 UGDH*, *FGF13*, *AP3B2*, *FGF12*, *CYFIP2*). Seven (23%) families had variants in seven genes causing metabolic disorders (*HEXB, GCDH, GCSH, PNPT1, SHMT2, CARS2, SLC25A10*) of which six had variants in six nuclear encoded mitochondrial genes. Seven (23%) families had variants in 6 genes causing disorders with epilepsy as a core symptom (*SCN1A, KCTD7, NAXD, TRAPPC4, TPP1, KCNJ10*) and nine (29%) had variants in nine genes causing NDDs associated with epilepsy (*KMT2A, AP4S1, DYRK1A, RNASEH2C, DYNC1H1, GALNT2, ARID1B, ANKRD11, MECP2*). Biallelic variants were identified in 17 families (53%), *de novo* in 13 (41%), and heterozygous exonic deletion in one (3%) family. Seventeen (55%) of 31 disease-causing variants were novel. We also report variants in *SHMT2, SLC25A10*, and *FGF13* causing extremely rare disorders with less than 10 patients reported worldwide. Prenatal diagnosis was carried out in 19% (5/26) of families. Notably, ES had therapeutic implications in 50% of individuals (13/26) with a definitive diagnosis. **Conclusion:** The above-mentioned cohort is a part of an ongoing study of disorders with epilepsy. We herein describe the first cohort elucidating the genotypic spectrum and its clinical implications in disorders with epilepsies in Indian population.

PrgmNr 1465 - Identification of *NDEL1* as a novel gene for lissencephaly

View session detail

Author Block: **M.-H. TSAI**[1,2], H.-C. Ke[3], C.-Y. Fong[4], C.-C. Ng[4], K.-S. Lim[4], J.-W. Tsai[3]; [1]Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan, [2]Chang Gung University, Taoyuan, Taiwan, [3]National Yang-Ming Ciao-Tung Univeristy, Taipei, Taiwan, [4]University of Malaya, Kuala Lumpur, Malaysia

Disclosure Block: **M. Tsai:** None.

Background Lissencephaly (LIS) is a rare neurological disorder caused by abnormal neuronal migration. More than 20 LIS genes have been reported so far, most of them are functionally associated with the cytoskeleton. In a recent large study, more than 80% of patients with lissencephaly can have a pathogenic variant in reported genes. The genetics of lissencephaly in Asian patients is relatively under-explored. In addition, novel genes remain to be identified in unsolved cases. Method We recruited 33 lissencephaly patients and their family members. Candidate gene Sanger sequencing or whole exome sequencing (WES) was performed to search for known genetic causes. Trio WES study was used to study unsolved cases. In utero electrophoresis model was performed to investigate the effect of NDEL1 mutant on neuronal migration. Results In total, 33 patients with lissencephaly were enrolled in this study. 20/33 (60.6%) had a pathogenic variant in reported genes, including 7 DCX, 2 CEP85L, 2 DYNC1H1, 2 MAST1, 2 chromosome 17 deletion, 1 PAFAH1B1, 1 WDR62, 1 TUBA1A, 1 GRIN1, and 1 BICD2. WES Trio study was performed on the remaining 13/33 (39.3%) patients. One patient with a de novo NDEL1 missense variant was identified. NDEL1 is known to interact with LIS1 (PAFAH1B1) and required for microtubule organization and anchoring microtubule to the centrosome. Our preliminary functional study demonstrated that NDEL1 knock down and mutant both impaired neuronal migration. Conclusion The currently known lissencephaly genes are accounted for ~60% of our Asian cohort. We reported that NDEL1 is a novel gene for lissencephaly in human. NDEL1 dysfunction impaired neuronal migration during brain development.

PrgmNr 1466 - *EFEMP1* rare variants cause juvenile-onset open angle glaucoma in families from the Philippines

Glaucoma is the leading cause of irreversible blindness world-wide and exhibits both Mendelian (childhood onset) and complex (adult onset) inheritance. Ten genes are known to cause childhood glaucoma, but in total these only account for disease in approximately 20% of patients. Because most of the childhood glaucoma genes have been identified in European Caucasian populations, to facilitate novel gene discovery we have studied affected families from various geographic regions including the Philippines. As part of this effort, we used exome sequencing to evaluate 14 Filipino juvenile open-angle glaucoma (JOAG) families and identified 3 independent families (35, 2 and 27 members) with rare *EFEMP1* variants (p.N80Y, p.R477C and p.Ter494Glnext*29) co-segregating with disease. None of the rare variants are present in gnomAD and all modify highly conserved amino acids. Affected variant carriers (N= 34) exhibited severe disease with average age of disease onset of 16 years (range 3-43) and 76% developing blindness. Common SNPs near *EFEMP1* have been associated with adult-onset glaucoma (POAG) and a low frequency *EFEMP1* variant (p.R140W; MAF 0.0008%) may contribute to disease risk in one POAG family. Interestingly, a single *EFEMP1* missense allele (p.R345W) is known to cause Malattia Leventinese (ML), an inherited retinal degeneration. *EFEMP1* is an extracellular matrix protein with ocular expression similar to Myocilin, another extracellular matrix protein known to cause JOAG through a mechanism involving protein misfolding and endoplasmic reticulum aggregation. To determine if *EFEMP1* variants exhibit similar effects, we transfected COS7 cells with vectors expressing the three novel *EFEMP1* variants as well as variants associated with POAG and ML. We showed that all three variants found in JOAG patients caused significant intracellular protein aggregation compared to wild type and also the variants associated with the other phenotypes (p.R140W and p.R345W). These results suggest that rare coding *EFEMP1* variants can cause JOAG through a mechanism involving protein aggregation and that the extent of intracellular protein aggregation and retention appears to be the basis for the observed phenotype spectrum. This is the first report of *EFEMP1* variants causing early-onset glaucoma and we show that *EFEMP1* variation appears to be a relatively common cause of childhood glaucoma in these Filipino families. These results underscore the value of ethnically diverse populations for comprehensive detection of disease-causing mutations.

Background: Increasing demand for genomic testing coupled with existing workforce shortages in clinical genetics has placed unsustainable pressure on the standard models of care. Patient-facing digital health applications can empower patients and provide sustainable and scalable clinical solutions to address this gap. **Aim:** To transform our original Genomics ADvISER decision aid into a comprehensive patient-centered digital health application that will deliver education, counseling, and return of results for patients undergoing various form of genomic testing. **Methods:** Driven by user-centred design principles, we developed and conducted usability and acceptance testing of the application using an iterative, mixed-methods process consisting of: 1) consultations with an advisory board of providers and patients; 2) analysis of qualitative interviews with prior patients who used the original Genomics ADvISER decision aid; 3) creation of a digital wireframe prototype; 4) usability testing of the prototype; and 5) acceptability testing of the final digital application. ***Results:*** **Prototype development:** We created a new digital application, called the â□□Genetics Adviserâ□□, building on our original â□□Genomics ADvISERâ□□ that incorporated feedback from our advisory board, patients, genetics experts and the general public. The Genetics Adviser is designed to be easily adaptable to the needs of different types of patients, test modalities, and results. It consists of a pre-test module that focuses on: education, values, FAQs, patient stories/vignettes and the selection of results. It also includes a post-test check-in module to support users while they wait for results and a function that allows clinicians to upload results for patients to review before or after clinical consults. **Usability testing:** We conducted 25 usability tests with patients, the general public and genetics practitioners (15/25 female; mean age 41 years; 5/25 diagnosed with cancer). Participants were enthusiastic about the application, found it easy to navigate and comprehend. Participants recommended clarifying content and outlining the purpose of tasks. **Acceptance testing:** The application is currently undergoing qualitative and quantitative acceptability testing with a sample of patients and the general public (n=20). The final application will then be evaluated in a RCT with patients undergoing genomic testing. **Conclusions:** We created and tested an interactive, patient-centered application to optimize delivery, access and quality of care for pre- and post-test genomic testing, counselling, and return of results adaptable to any testing platform and setting.

PrgmNr 1470 - The cost of good health: Poverty association with differential gene expression

Luca[6]; [1]Morgan State University, Baltimore, MD, [2]Wayne State University, Detroit, MI, [3]John Hopkins University, Baltimore, MD, [4]National Institute on Aging, National Institutes of Health, Baltimore, MD, [5]National Institutes of Health, Silver Spring, MD, [6]Wayne State Univ, Detroit, MI

Disclosure Block: **N. Arnold:** None.

PURPOSE Psychosocial factors exert a powerful influence on health status and contribute to health disparities among marginalized populations. For example, overall life expectancy at birth throughout the United States tracks with poverty level, educational attainment, economic security and other upstream social determinants of health. Socioeconomic status (SES) and psychosocial factors are documented to affect gene expression in peripheral blood mononuclear cells, suggesting a molecular mechanism for some health disparities. Here we investigated the effects of poverty among Baltimore City residents participating in the Healthy Aging in Neighborhoods of Diversity across the Life Span (HANDLS). **METHODS** We examined 239 participants of the HANDLS cohort study in Baltimore whose reported household income was either above or below the 125% federal poverty line for 2004. This population sample was composed of 119 African Americans and 120 white, for a total of 119 men and 120 women. We performed RNA sequencing in peripheral blood mononuclear cells to assess differential gene expression patterns associated with poverty. **RESULTS** We identified 15 genes differentially expressed when testing for poverty while controlling for race, sex, and age. When focusing on women, we found that individuals living in poverty had increased expression for 9 genes and decreased expression for 11 genes compared to individuals living above the poverty line. GSEA identified an enrichment for Herpes simplex virus infection pathway and B cell mediated immunity in genes differentially expressed in women living in poverty. **CONCLUSIONS** Our study suggests that poverty status influences gene expression in the immune system. Improving health outcomes for at-risk populations is achievable by understanding the link between poverty and identifiable biological mechanisms that influence disease.

PrgmNr 1471 - The impact of clinically relevant CNVs in the general population - the health consequences and personalized management of undiagnosed adult CNV carriers in the Estonian biobank

View session detail

Author Block: **M. NÃµukas**[1], M. Palover[1], M. Lepamets[1], L. Pizzo[2], K. Lehto[1], A. Reigo[1], H. Alavere[1], L. Leitsalu[1], I. Xenarios[3,4], M. Metspalu[5], A. Reymond[6], S. Girirajan[2], N. TÃµnisson[1,7], K. MÃ¤nnik[3]; [1]Estonian Biobank, Institute of Genomics, University of Tartu, Tartu, Estonia, [2]Biochemistry & Molecular Biology, and Anthropology, Pennsylvania State University, University Park, PA, [3]Health2030 Genome Center, Geneva, Switzerland, [4]Lausanne University Hospital, Lausanne, Switzerland, [5]University of Tartu, Tartu, Estonia, [6]Univ Lausanne, Lausanne, Switzerland, [7]Department of Clinical Genetics in Tallinn, Tartu University Hospital, Tartu, Estonia
Disclosure Block: **M. NÃµukas:** None.
The role of CNVs is well established in children with neurodevelopmental disorders (NDDs). However, more research is needed towards systematic understanding on how: i) CNVs affect health in the adult population and ii) to responsibly disclose findings to CNV carriers at high genetic risk for complex disorders.
We screened the cohort of Estonian Biobank (EstBB; n=132,770) for 81 recurrent CNV regions associated with susceptibility to NDDs. In the first stage, we used the â□□genotype-firstâ□□ approach to fetch health data from the EstBB, linked electronic health registries (EHRs) and mapped each ND-CNV with their co-occurring disease traits. In the second stage, we selected 10 ND-CNVs as a paradigm to return of genetic risk data and analysis of at-risk individualsâ□□ experience and the impact of disclosed genetic finding on their health support.
Our results show that the prevalence of CNVs associated with susceptibility to NDDs in the EstBB is 2.6% (n=3,404). Further prioritization of CNVs listed in the DECIPHER database suggested a population prevalence of 0.5% (n=710) for clinically well-established CNV syndromes. According to EHRs, nearly half of them have previously documented neurological or mental and behavioural problems. Notably, only 4 out of 710 are aware of their genetic diagnosis.
Our results along with reports by others confirm that CNVs associated with NDDs are cumulatively common, but still understudied health problem in general population. This work was supported by the Jacobs Foundation Research Fellowship (Dr MÃ¤nnik), Swiss National Science Foundation grant (Dr A.R) and the Estonian Research Council grant (Dr TÃµnisson).

PrgmNr 1472 - Uptake of cancer risk management strategies among women who undergo cascade genetic testing for breast cancer susceptibility: How do they compare to non-cascade testers?

View session detail

Author Block: **S. Makhnoon**[1], L. Brooke[2], K. Mattie[2], R. Volk[1], G. Grana[3], B. Arun[1], S. K. Peterson[1]; [1]The University of Texas MD Anderson Cancer Center, Houston, TX, [2]MD Anderson Cancer Center at Cooper University Health Care, Camden, NJ, [3]Cooper Hlth System, Voorhees, NJ
Disclosure Block: **S. Makhnoon:** None.
Purpose: A primary rationale for cascade testing for hereditary breast and ovarian cancers (HBOC) is to offer cancer risk management options, including bilateral mastectomy (BLM), salpingo-oophorectomy (BSO), and intensified screening, to persons found to have an inherited predisposition to the disease. At-risk relatives of probands with a pathogenic variant have familial experiences with cancer genetic testing which may shape health beliefs and subsequent health behaviors. Yet, little is known about their genetically-informed cancer risk-reduction behaviors, and long-term outcome data among cascade testers are lacking. This study evaluated: (1) the uptake and timing of cancer preventive surgical and screening strategies between cascade and non-cascade testers, and (2) the association between uptake of cancer risk management strategies and proband characteristics. Methods: Medical records were abstracted for all unaffected women with pathogenic variants in HBOC-associated genes from two cancer hospitals with at least one year of follow-up to compare uptake of surgery and screening between cascade and non-cascade testers. Results: 341 women underwent post-test genetic counseling between 2013 and 2019, of whom 253 were included in the analytic sample. Cascade testers (79.8%) were younger than non-cascade testers (mean=37.6 vs. 43.5 years, p=0.002) and most commonly had a parent with a pathogenic variant (39.1%) followed by siblings (21.3%), and multiple other relatives (20.8%). Women were predominantly non-Hispanic White (81.0%) and underwent testing for *BRCA1* (42.0%) or *BRCA2* (47.2%) variants. Among women ageâ¥40 years, 43% underwent BLM and 71.6% underwent BSO with no significant difference in uptake between cascade and non-cascade testers. Mean time to BSO among cascade testers was shorter among women ageâ¥40 vs Conclusion: Management uptake among cascade testers is high with rates comparable to unaffected *BRCA* positive women. A large proportion of women act on cascade test results and this represents a novel report of utilization of cancer management strategies

PrgmNr 1473 - Haplotyping SNPs for allele-specific gene editing of the mutant huntingtin allele using long-read sequencing

View session detail

Author Block: **L. Fang**[1], A. M. Monteys[1], A. DÃ¼rr[2], M. Keiser[1], C. Cheng[1], A. Harapanahalli[1], P. Gonzalez-Alegre[1,3], B. L. Davidson[4], K. Wang[5]; [1]Children's Hospital of Philadelphia, PHILADELPHIA, PA, [2]Sorbonne UniversitÃ©, Paris, France, [3]University of Pennsylvania, Philadelphia, PA, [4]The Children's Hospital of Philadelphia, Philadelphia, PA, [5]Childrenâ□□s Hospital of Philadelphia, Philadelphia, PA
Disclosure Block: **L. Fang:** None.

Huntington's disease (HD) is an autosomal dominant neurodegenerative disease caused by CAG repeat expansions in the huntingtin (HTT) gene. Although trials of disease-modifying treatments are now on the horizon, the clinical care is focused on symptom management. We previously reported allele-specific deletion of the mutant HTT by CRISPR/Cas9 in a mouse model and human cell lines. Allele selectivity is achieved by targeting heterozygous SNPs that create or eliminate a Protospacer Adjacent Motif (PAM). However, given the lack of knowledge on haplotype structure in HD populations, a comprehensive analysis of all potential targeting sites is lacking and the optimal personalized editing strategy for HD individuals is unknown. To address this, we developed a multiplexed targeted long-read sequencing approach to sequence a 10.4 kb genomic region flanking exon-1 of HTT and created necessary computational tools (AmpBinner and AmpRepeat) to de-multiplex the data, detect repeats, and phase the reads. We applied this approach to two independent HD cohorts (974 individuals from the US and France), detected SNPs, analyzed haplotypes and potential editing sites for various enzymes. In the haplotype structure analysis, we showed potential founder effects in unrelated HD individuals from different continents. Based on the haplotype analysis, 23% of HD individuals of European ancestry can be edited by targeting one SNP (rs2857935). Up to 56% HD individuals of European ancestry can be potentially edited by combinatorial targeting of multiple SNPs. Our results provide the first haplotype map of the region surrounding exon-1 of HTT in HD cohorts. Our workflow can be applied to other repeat expansion diseases to facilitate allele-specific gene editing.

PrgmNr 1474 - A mouse model recapitulating Bruck Syndrome provides insight into the role of *Plod2* in bone and cartilage

View session detail

Author Block: **A. Kot**[1], I. Duran[1,2], J. H. Martin[1], D. Wachtell[1], M. Weis[3], D. R. Eyre[3], J. Zieba[1], D. Krakow[1]; [1]University of California, Los Angeles, Los Angeles, CA, [2]University of Malaga, Malaga, Spain, [3]University of Washington, Seattle, WA

Disclosure Block: **A. Kot:** None.

Bruck Syndrome is an autosomal recessive form of osteogenesis imperfecta characterized by bone fragility, short stature, and joint contractures resultant from biallelic mutations in either the genes encoding *PLOD2* or *FKBP10*. *PLOD2* encodes LH2 which is a component of an endoplasmic reticulum (ER) complex involved in type-I collagen telopeptide hydroxylation. Bruck Syndrome has features distinct from other forms of osteogenesis imperfecta, such as joint contractures, with pathophysiology that is not well understood. Studies on a previously published *Plod2* knockout mouse were limited due to early embryonic lethality. To study the pathophysiology of musculoskeletal development in Bruck Syndrome, we generated a mouse model with a homozygous mutation identified in two independent families with recurrent fractures, scoliosis, and congenital contractures. The mutation, *Plod2* c.1559dupC predicting the amino acid change p.Val523Cysfs*7, was introduced using targeted homologous recombination. *Plod2* is alternatively spliced and translated into short (LH2a) or long (LH2b) isoforms. The c.1559dupC mutation is in exon 13A, specific to LH2b, and is predicted to lead to loss of the long form of the protein. *Plod2*$^{V523fs/V523fs}$ mice did not survive past P0. At E18.5, *Plod2*$^{V523fs/V523fs}$ mice were smaller, had bilateral forelimb and hindlimb contractures, and absent cervical spine curvature. LH2b mRNA was near absent in *Plod2*$^{V523fs/V523fs}$ mouse calvaria. LH2 protein levels in *Plod2*$^{V523fs/V523fs}$ osteoblasts were also decreased compared to wild type. Type I collagen C-telopeptide lysine residue hydroxylation was significantly reduced in *Plod2*$^{V523fs/V523fs}$ bone suggesting that crosslinking is negatively impacted, contributing to impaired bone properties. Compared to wild type, *Plod2*$^{V523fs/V523fs}$ growth plates showed increased length of the hypertrophic zone, increased hypertrophic chondrocyte volume, and diminished collagen production as detected by picrosirius staining suggesting a role for *Plod2* in chondrocyte development. This mouse model will aid in determining the function of *Plod2* in the musculoskeletal system and help uncover the molecular mechanisms underlying Bruck Syndrome.

PrgmNr 1476 - Mutations in DNA ligase III cause mitochondrial neurogastrointestinal encephalomyopathy

Disclosure Block: **M. Taniguchi:** None.
Abnormal gut motility is a feature of several mitochondrial encephalomyopathies, and mutations in genes such as *TYMP* and *POLG*, have been linked to these rare diseases. The human genome encodes three DNA ligases, of which only one, ligase III (*LIG3*), has a mitochondrial splice variant and is crucial for mitochondrial health. We investigated the effect of reduced LIG3 activity and resulting mitochondrial dysfunction in seven patients from three independent families, who showed the common occurrence of gut dysmotility and neurological manifestations reminiscent of mitochondrial neurogastrointestinal encephalomyopathy. DNA from these patients was subjected to whole exome sequencing. In all patients, compound heterozygous variants in a new disease gene, *LIG3*, were identified. All variants were predicted to have a damaging effect on the protein. The *LIG3* gene encodes the only mitochondrial DNA (mtDNA) ligase and therefore plays a pivotal role in mtDNA repair and replication. *In vitro* assays in patient-derived cells showed a decrease in LIG3 protein levels and ligase activity. We demonstrated that the *LIG3* gene defects affect mtDNA maintenance, leading to mtDNA depletion without the accumulation of multiple deletions as observed in other mitochondrial disorders. This mitochondrial dysfunction is likely to cause the phenotypes observed in these patients. The most prominent and consistent clinical signs were severe gut dysmotility and neurological abnormalities, including leukoencephalopathy, epilepsy, migraine, stroke-like episodes, and neurogenic bladder. A decrease in the number of myenteric neurons, and increased fibrosis and elastin levels were the most prominent changes in the gut. Cytochrome *c* oxidase (COX) deficient fibres in skeletal muscle were also observed. Disruption of *lig3* in zebrafish reproduced the brain alterations and impaired gut transit *in vivo*. In conclusion, we identified variants in the *LIG3* gene that result in a mitochondrial disease characterized by predominant gut dysmotility, encephalopathy, and neuromuscular abnormalities.

PrgmNr 1477 - Significant burden of *de novo* damaging variants in novel genes in patients with congenital kidney malformations

Disclosure Block: **H. Milo Rasouly:** None.

Background: Congenital kidney malformations (CKM) are one of the most common cause of pediatric kidney failure. While multiple causative genes have been identified, they explain only 10-15% of cases. *De novo* variantsâ (DNV) analysis led to the identification of novel genes for congenital heart defects and neurodevelopmental disorders. We hypothesized that similar analyses could identify new CKM-causing genes. Methods: Patients enrolled through our study on genetics of kidney diseases underwent Exome sequencing (ES) or Genome sequencing (GS). ES was performed on 151 trios (i.e. affected child with CKM and unaffected parent), and GS on 53 additional trios.100 CKM trios were identified from the Deciphering Developmental Delay consortia (ES). The sequences were processed using a BWA/GATK 4.1 pipeline on the CAVATICA platform and annotated through Ensembl VEP. Custom bioinformatics pipelines were then used for data cleaning. Potential enrichment for DNV was analyzed with the denovolyzer package in R. Results: Out of the 304 trios analyzed, 10 cases (3%) had a DNV in one of the 172 genes known to be associated with dominant forms of kidney disease (3.2 fold-enrichment, p-value=1.41 x 10^{-3}). Those 10 cases included one protein-truncating variant (PTV) in *PAX2*, one in *HNF1B* and two PTV DNVs in *KAT6B*. Genome-wide, we observed a significant 2.8 fold-enrichment for PTV DNV (76 DNVs compared to 26.6 expected, p-value=4.3x10^{-15}) and a significant 1.3 fold-enrichment for missenses DNV (248 DNVs compared to 191.5 expected, p-value=5.1x10^{-5}). When constraining the analysis to genes highly expressed in nephron-progenitor cells at 18 weeks of gestation (Human fetus) and not known to be associated with kidney disease in Human, we observed significantly increased enrichment for PTV DNV (8 DNVs compared to 1.2 expected, OR=6.9, p=3.04 x 10^{-5}, list of 593 genes with a pLI>0.9 and a LOEUF>0.35), and for deleterious missense DNV (8 DNVs compared to 3.2 expected , OR= 2.51, p=0.016, list of 229 genes with a mis-z-score > 3.09). Gene-Set Enrichment Analysis uncovered a highly significant enrichment for genes down-regulated in ME-A cells (breast cancer) undergoing apoptosis in response to doxorubicin (FDR=1.5x10^{-11}) and in fibroblasts expressing mutant forms of ERCC3 after UV irradiation (FDR=5.5x10^{-8}).

Conclusions: We detected an excess of *de novo* variants in CKM, supporting potential pathogenetic mechanisms of disease. Globally, the DNV signal was partially driven by novel constrained genes that are highly expressed during early kidney development. Further gene-set analysis and replication in larger datasets may help pinpoint which genes are most likely driving this enrichment.

PrgmNr 1478 - Genome-wide genetic control of fetal placental genomics shows multiple associations with health and disease across the life course, informing the Developmental Origins of Health and Disease

View session detail

Disclosure Block: **A. Bhattacharya:** None.
The placenta is the master regulator of the intrauterine environment and is central to the Developmental Origins of Health and Disease (DOHaD). Studies show that fetal genetics and placental genomics can influence child health traits. An integrative analysis of genetics, placental genomics, and child health traits has not been done and would yield insight into the DOHaD hypothesis. Recently, we developed Multi-Omic Strategies for Transcriptome-Wide Association Studies (MOSTWAS), which uses mediation analysis to scan variants genome-wide, detect gene-trait associations (GTAs), and develop hypotheses for trait-associated gene regulation. Here, using genetic, transcriptomic, and methylomic data from the Extremely Low Gestational Age Newborn (ELGAN) Cohort Study (N = 272), we applied MOSTWAS to train genetic models of expression of all genes on the ELGAN RNA-seq panel, 2,994 of which showed strong in- and out-sample accuracy. With these models, we conducted TWAS for 40 traits from 5 categories (autoimmune, metabolic, cardiovascular, perinatal, neuropsychiatric) and identified 264 GTAs across 176 TWAS genes and potential transcription (TFs) or epigenomic factors regulating their expression. Of the 176 genes, 50 were associated with multiple traits, many not genetically correlated (e.g., *IDI1* with BMI and schizophrenia). Genetically-regulated placental expression, in aggregate, explained significant portions of three neonatal traits (total puberty growth, childhood BMI, start of puberty) at 5-8% of total SNP heritability. In addition, 91 GTAs showed significant associations through distal variants, with many mediated through 8 TFs associated with multiple TWAS genes. For example, *EPS15*, a maternally imprinted placental TF associated with fetal growth, showed a negative association with waist-hip ratio (WHR) and was negatively associated with two genes: *SPATA13* and *FAM214A*, both showing positive TWAS associations with WHR. In human placenta-derived trophoblasts, FANA silencing of *EPS15* led to upregulation of both *SPATA13* and *FAM214A*, providing evidence for placental TF regulation of these genes. Further transcriptomic and functional consequences of *EPS15* knockdown are under evaluation. Our study reveals potentially shared placental pathways associated with many traits across the life course. GTAs with traits across categories and different life periods suggest that placental dysregulation affects fundamental early-in-life traits, and these effects compound and manifest in later-in-life traits. Our work motivates increased sample sizes for early childhood trait GWAS and the placenta as a key tissue of study.

PrgmNr 1479 - Residual risk for clinically significant copy number variants in pregnancies with normal NIPS

View session detail

Author Block: **L. Sagi-Dain**[1], I. Maya[2], D. Brabbing-Goldstein[2], L. Basel-Salmon[2], L. Salzer[2]; [1]Carmel Medical Center, Haifa, Israel, [2]Rabin Medical Center, Petach Tikva, Israel
Disclosure Block: **L. Sagi-Dain:** None.
Background: Chromosomal microarray analysis (CMA) is the recommended first-tier in pregnancies with sonographic anomalies, while in low-risk pregnancies this test detects clinically significant copy number variants (CNVs) in about 1%. As the constantly growing wide use of non-invasive prenatal screening (NIPS) facilitates the detection of chromosomal aberrations, defining the residual risk for abnormal CMA following normal NIPS is of importance for informed decisions regarding prenatal testing and screening options. The objective of our study was to shed light on this issue. **Methods:** CMA results of all pregnancies undergoing amniocentesis between the years 2013-2021 in large hospital-based laboratory were collected. Pregnancies with major sonographic anomalies or multiple fetuses were excluded. Clinically significant (pathogenic and likely pathogenic) CNVs were divided into: 3-NIPS-detectable (trisomies 13, 18 and 21), 5-NIPS-detectable (including sex chromosome aberrations), 5-NIPS and common microdeletion-detectable (including 1p36.3-1p36.2, 4p16.3-4p16.2, 5p15.3-5p15.1, 15q11.2-15q13.1, and 22q11.2 deletions), and genome-wide NIPS-detectable (including variants >7Mb). The theoretical residual risk for clinically significant CNVs was calculated following exclusion of NIPS-detectable findings. **Results:** Of the 8,099 pregnancies, clinically significant CNVs were demonstrated in 70 pregnancies (1.4%). The residual risk following theoretically normal NIPS was 1.2% (1/85) for 3-NIPS, 0.92% (1/109) for 5-NIPS, 0.88% (1/113) for 5-NIPS including common microdeletions, and 0.82% (1/122) for genome wide NIPS. In the subgroup of 4,048 pregnancies with advanced maternal age, the residual risk for clinically significant CNVs following theoretically normal NIPS ranged from 1.3% (1/75) for 3-NIPS to 0.8% (1/122) for genome wide NIPS. In 3,187 pregnancies of women younger than 35 years, this residual risk ranged from 0.7% (1/145) for 3-NIPS to 0.5% (1/198) for genome wide NIPS. The residual risk was highest for the 559 pregnancies with abnormal serum screening and 305 pregnancies with soft markers - about 2.2% (1/45) for 3-NIPS and 2.0% (1/50) for genome wide NIPS. **Conclusions:** The residual risk of clinically significant CNVs in pregnancies without structural sonographic anomalies is appreciable, and depends on NIPS extent, maternal age, the results of biochemical screening and presence of soft markers. This knowledge is important for the patients, the obstetricians and the genetic counselors, in order to facilitate informed decisions regarding prenatal testing and screening options.

PrgmNr 1480 - A 100,000 Genome Project haplotype reference panel of 156,390 haplotypes and the improved imputation of UK Biobank

View session detail

Author Block: **S. Shi**[1], S. Rubinacci[2], S. Hu[3], L. Moutsianas[4], A. Stuckey[4], C. Cabrera[5,6], V. Cipriani[5,6], D. P. Smedley[5,6], M. J. Caulfield[7], S. R. Myers[1], J. L. Marchini[8]; [1]University of Oxford, Oxford, United Kingdom, [2]University of Lausanne, Ecublens, Switzerland, [3]Novo Nordisk Research Centre, Oxford, United Kingdom, [4]Genomics England, London, United Kingdom, [5]William Harvey Research Institute, London, United Kingdom, [6]Queen Mary University of London, London, United Kingdom, [7]Genomics England, Queen Mary, London, United Kingdom, [8]Regeneron Genetics Center, Tarrytown, NY
Disclosure Block: **S. Shi:** None.
The Genomics England (GEL) 100,000 genome project has sequenced over 85,000 genomes across England. By using high coverage whole-genome sequencing (WGS), this constitutes the largest human genetic variation resource ever collected in the UK, and represents a near-complete characterization of genetic variation in the population. We generated a GEL haplotype reference panel, comprising 341 million autosomal variants and 156,390 haplotypes from diverse ancestries. We exploit both the sample size and relatedness structure among individuals, 61.3% of whom possess at least one sequenced first-degree relative, to allow high-precision haplotypic phasing.
We used 1000 Genomes WGS data to assess the imputation performance across ancestries, and observe improvements in some populations. In samples of British origin the mean imputation r2 at 0.01% allele frequency is 0.45, 0.67 and 0.74 when using the HRC, TOPMed and GEL reference panel. In samples of South Asian origin the mean imputation r2 at 0.01% allele frequency is 0.04, 0.24 and 0.61 when using the HRC, TOPMed and GEL reference panel.
We used the GEL reference panel to impute the UK Biobank dataset, that was previously imputed at 39 million autosomal variants, using an HRC+UK10K reference panel. It results in a ~6 fold increase in the number of imputed variants. Mean information scores at imputed SNPs, from the GEL and HRC-UK10K reference panels, were 0.65 and 0.61 respectively. At low allele frequencies the differences were larger. For example, for SNPs with allele frequency between 0.01% to 0.1% mean information scores were 0.88 and 0.66 for the GEL and HRC-UK10K reference panels respectively. This translates into an appreciable boost in power to detect associations. The GEL-imputed UK Biobank dataset is being made available to all approved researchers of the UK Biobank.
We will also report results of experiments of examine the implications for fine mapping and burden association tests in the context of imputed GWAS for blood pressure and other traits.

PrgmNr 1481 - A powerful test of ancestral heterogeneity in the effects of gene expression on complex traits

View session detail

Author Block: **K. Knutson**[1], W. Pan[2]; [1]Division of Biostatistics, Univ Minnesota, Minneapolis, MN, [2]Univ Minnesota, Minneapolis, MN
Disclosure Block: **K. Knutson:** None.
The Transcriptome Wide Association Study (TWAS) is a widely used approach which integrates expression and GWAS data to study the role of cis-regulated gene expression (GEx) in complex traits. TWAS models GEx as a function of cis-eQTL genotypes. However, strong evidence suggests that the genetic architecture of GEx varies across populations. Furthermore, recent findings point to possible ancestral heterogeneity in the effects of GEx on complex traits, heterogeneity which may be amplified in TWAS by modeling GEx as a function of cis-eQTLs. We present a novel extension to TWAS which models heterogeneity in the effects of cis-regulated GEx which are correlated with ancestry. By jointly analyzing samples from multiple populations, our multi-ancestry TWAS framework can improve power to detect genes with shared expression-trait associations across populations through increased sample sizes, as compared to existing stratified TWAS approaches. Under our proposed model, we derive score tests for homogeneous, heterogeneous, and total GEx effects on a complex trait. Our preliminary simulations reveal conserved Type-I error rates and high power across a number of scenarios, holding promise for further simulations on larger simulated datasets. We apply our test to case-control genotypes from the Alzheimer's Disease Sequencing Project (ADSP) and publicly available prediction models from the Multi-Ethnic Study of Atherosclerosis (MESA) study. We identify a number of genes with suggestive heterogeneous effects between African American and Caucasian subjects on Alzheimerâ□□s Disease (AD), including *ASPHD2*, *SDSL*, *ZNF589*, *PGM2L1*, and *PPIL3*. Our preliminary application further identifies many putative AD risk genes which were not discovered through ancestry-stratified TWAS analyses, many of which have well established or biological plausible links to AD, including (but not limited to) *RTP4*, *ORAI2*, and *TOMM40L*. In forthcoming work, we will apply our test to a larger sample from ADSP, anticipating a greater number of significant findings due to the increased sample size. Additionally, we will apply our proposed test of heterogeneity to continuous endophenotypes from the UK Biobank (n â□□ 500,000), specifically considering a set of imaging derived phenotypes with strong associations to AD.

PrgmNr 1482 - Developing Trans-ethnic Polygenic Risk Scores Using Empirical Bayes and Super Learning Algorithm

Author Block: **H. Zhang**[1], J. Zhan[2], J. Jin[3], J. Zhang[3], T. U. Ahearn[4], Z. Yu[5], J. O. Connell[2], Y. Jiang[2], B. Koelsch[2], 23andMe Research Team, X. Lin[1], M. Garcia-Closas[4], N. Chatterjee[3]; [1]Harvard T.H. Chan School of Public Health, Boston, MA, [2]23andMe Inc., Sunnyvale, CA, [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [4]National Cancer Inst, Rockville, MD, [5]Broad Institute of MIT and Harvard, Cambridge, MA
Disclosure Block: **H. Zhang:** None.
Polygenic risk scores (PRS) are useful for predicting various phenotypes/outcomes; however, as most PRS have been developed with data generated in European Ancestry (EA) populations, performances of PRS are often poorer in non-EA populations, reflecting their degree of divergence from EA population.
To improve PRS performance in non-EA populations, we propose a novel method, Two-Dimensional Clumping and thresholding with Super Learning and Empirical Bayes (TDLD-SLEB), which takes advantage of both existing large GWAS from EA populations and smaller GWAS from non-EA populations. TDLD-SLEB uses a two-dimensional thresholding method to incorporate SNPs that have either effects in both the larger (e.g., EA populations) and the smaller (e.g., non-EA populations) target population or specific effects in the smaller population. It estimates effect sizes for SNPs in the target population using an Empirical Bayes method that borrows GWAS information across populations. Finally, it incorporates a super learning algorithm to combine series of PRS generated by various SNP selection thresholds for the target population.
Our simulation analyses mimicked real LD patterns using haplotype data of 1000 Genome Phase 3 for five ancestries. We considered various genetic architectures including different levels of negative selection and genetic correlation across ancestries. We found PRSs generated by TDLD-SLEB had significantly improved predictionary accuracy for non-EA populations in independent validation datasets, compared to single ethnic PRS, EUR derived PRS, or a weighted PRS that combines EUR and single ethnic derived PRS with weights selected to optimize prediction in the target population.
Using 23andMe data, we developed and validated population specific PRS for seven complex traits using GWAS data from Europeans (average N=2,442K), African American (average N=113K), Latino (average N=411K), East Asians (average N=94K), South Asians (average N=25K). We found TDLD-SLEB often led to large improvements in the performance of PRS compared to alternative methods for predicting traits in the African American population (average R^2 increased +277% compared to the weighted PRS method). For other ethnic groups, TDLD-SLEB also led to sometimes notable improvements in the performance of PRS, such as for the cardiovascular disease in the Latino population (AUC = 0.61 for TDLD-SLEB vs. AUC= 0.58 for the weighed PRS method).
In conclusion, we developed a computationally scalable and statistically efficient method for generating predictive PRS in non-European populations using GWAS datasets across diverse populations.

PrgmNr 1483 - Explainable and extendable machine learning models for identifying prognostic radiogenomic biomarkers from breast cancer multimodal imaging and genomic data

View session detail

Author Block: **Q. Liu**, P. Hu; University of Manitoba, Winnipeg, MB, Canada
Disclosure Block: **Q. Liu:** None.
Background: Radiogenomics is a field where medical images and genomic profiles are jointly analyzed to answer critical clinical questions. We proposed a novel framework to identify prognostic radiogenomic biomarkers from multi-modal breast cancer (BC) magnetic resonance imaging (MRI) and multi-omics data, which may serve as a substitute for genetic testing.
Methods: Bayesian tensor factorization (BTF) was used to extract the integrated multi-omics features from gene expression, DNA methylation, and copy number variation data of 762 BC patients. The potential biological functions of these BTF multi-omics features were explored using Gene set enrichment analysis (GSEA). A deep learning (DL)-based imaging segmentation model was built to extract multi-modal MRI radiomic features for 61 of the BC patients with MRI data. Two explainable tools (Gradient and Gradient*Input) were embedded into the DL model structure to explore biological implications of the radiomic features. Predictive least absolute shrinkage and selection operator (LASSO) models were trained to translate the radiomic features from the BTF multi-omics features for the BC patients without MRI data. Survival analyses were then performed to estimate the prognostic significance of each radiomic feature. Statistical mediation analyses were performed to further explore the underlying biological mechanisms of the identified biomarkers. Traditional semi-auto radiomic features and previously established single-omics features (e.g., BC risk gene expressions, pathway activity scores, and gene signature scores calculated from the gene expression profile) were used as baselines for comparison.
Results: Saliency maps of the multi-modal MRI radiomic features showed the excellent explainability of the built DL models. Three DL-based multi-modal MRI radiogenomic biomarkers were successfully identified. which were confirmed to have significant differences in overall survival (log-rank test, Bonferroni corrected *P* valueAPITD1, *HNF4*) and several metabolism related pathways (Purine metabolism pathway and Tryptophan metabolism pathway), which has a significant mediation effect on the relationship between one specific BTF multi-omics feature, representing the function of natural killer cells based on the GSEA analysis, and the BC survival time (adjusted *P* value**Conclusion:** The results may promote MRI as a non-invasive examination for BC prognosis and multi-level molecular status, and ultimately increase precision in BC prognosis and improve patient care.

PrgmNr 1484 - Identity-by-descent mapping in biobank-scale datasets

View session detail

Author Block: **L. E. Petty**[1], R. Bohlender[2], H.-H. Chen[3], J. Baker[4], G. Evans[4], J. E. Below[1], C. D. Huff[5]; [1]Vanderbilt Genetics Institute, Vanderbilt University Medical Center, Nashville, TN, [2]1155 Pressler Street, Houston, TX, [3]Vanderbilt University Medical Center, Nashville, TN, [4]Nashville, TN, [5]U.T. MD Anderson Cancer Ctr, Houston, TX

Disclosure Block: **L.E. Petty:** None.

Identity-by-descent (IBD) mapping is a gene mapping approach that utilizes IBD segments to identify loci that are enriched for sharing in disease cases compared to controls. This approach allows for detection of loci that harbor variants that are too low frequency for imputation to perform well, which may have a greater penetrance than common variants well-powered for genome-wide association studies (GWAS).

We have developed a tool for performing biobank-scale IBD mapping, IBDMap. We leverage IBD segment data, detected using an external segment detection tool, and perform permutation-based testing to determine enrichment of IBD sharing by comparing rates of sharing in case-case pairs to rates in case-control pairs at each segment breakpoint, genome wide. Calculations for each breakpoint are performed independently and parallelized via a process queue. A complementary Python package performs map-reduce on multiple rounds of permutations, for computational efficiency in large-scale datasets. IBDMap performs flexible multiple testing correction, utilizing a permutation-based family-wise error or false discovery rate approach to account for the correlation structure. We also introduce a new haplotype-based approach which filters IBD segments that are unlikely to harbor rare, pathogenic variants due to high population frequency.

We applied IBDMap to a range of cardiovascular phenotypes in BioVU, Vanderbiltâ□□s DNA biobank with linked electronic health records. Using diagnostic billing codes, we determined case status for 69,819 European ancestry individuals genotyped on the MEGA^{EX} array for myocardial infarction, atherosclerosis, dyslipidemia, dilated cardiomyopathy, and atrial fibrillation. We then applied IBDMap for each phenotype to consensus IBD segments detected using iLASH, hap-ibd, and GERMLINE. We identified regions on chromosome 2 and 8 with genome-wide significant enrichment of IBD sharing in atherosclerosis cases.

In a â□□gold standardâ□□ set of 112 genes with 207 established, highly penetrant pathogenic variants for Mendelian diseases, all but one were detected by applying IBDMap to the traits in BioVU. In GWAS of the traits in the same samples using Firth regression in PLINK2, only 83% of the genes had at least one variant significantly associated with the trait, demonstrating greater power for detection of these highly penetrant loci in IBD mapping. We evaluated the IBDMap haplotype filtering approach with these 112 genes, and found that it resulted in an ~2-fold increase in -log10 p-value in the same BioVU samples. Our results demonstrate the potential of our IBD mapping approach for gene discovery.

PrgmNr 1485 - Incorporating family disease history and controlling case-control imbalance for population based genetic association studies

View session detail

Author Block: **Y. Zhuang**[1], B. N. Wolford[2], K. Nam[3], W. Bi[1,4], W. Zhou[5], C. J. Willer[2], B. Mukherjee[1], S. Lee[1,3]; [1]Biostatistics, University of Michigan, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI, [3]Seoul National University, Seoul, Korea, Republic of, [4]Department of Medical Genetics, School of Basic Medical Sciences, Peking University, Beijing, China, [5]Massachusetts general hospital, Broad Institute, Boston, MA

Disclosure Block: **Y. Zhuang:** None.

In the genome-wide association analysis of population-based biobanks, the low prevalence in most diseases results in low detection power. If a family disease history is collected, the power can be improved by inferring the disease risks in control samples, which will be used as phenotypes in association analysis. In the presence of related samples, however, the existing methods, such as LT-FH, fail to address increased phenotypic correlation among closely related samples due to similar family history. In addition, existing approaches cannot adjust for the unbalanced phenotypic distribution. We propose a new method, TAPE (mixed-model-based Test with Adjusted Phenotype and Empirical saddlepoint approximation), which controls for increased phenotype correlation by introducing an additional variance component for closely related samples and accounts for case-control imbalance by using empirical saddlepoint approximation. We show through simulation studies that TAPE is computationally efficient and gains greater power than common GWAS without using family disease history (SAIGE) while controlling type I error. In power simulation, TAPE showed 21.0% increase in average chi-square statistics and 12.1% increase in causal SNP detection than SAIGE. While LTFH also had increased power over SAIGE, it suffered type I error inflation especially when analyzing related samples with low disease prevalence and MAF (118 times inflation at alpha=5E-8). We applied TAPE to 10 binary traits in UK Biobank among 408,898 white British samples and identified 659 genome-wide significant clumped variants, among which 127 were with MAF

PrgmNr 1486 - SUMMIT: An integrative approach for better transcriptomic data imputation improves causal gene identification

View session detail

Author Block: **Z. Zhang**[1], J. R. Bradley[1], L. Wu[2], C. Wu[1]; [1]Department of Statistics, Florida State University, Tallahassee, FL, [2]University of Hawaii Cancer Center, Honolulu, HI
Disclosure Block: **Z. Zhang:** None.
Transcriptome-wide association studies (TWASs), which integrate expression reference panels with genome-wide association study (GWAS) results to discover gene-trait associations, have deepened our understanding of genetic regulation in many complex traits. However, the number of analyzable genes and thus the power of TWAS is largely determined by the size of expression reference panels. One obvious but administratively onerous approach is to combine individual-level data from several consortia to increase the sample size. However, privacy concerns and sample consents often preclude access to individual-level genetic data, making a pooled individual-level expression panel unavailable. In this work, we introduce SUMMIT, a novel method that makes it possible to integrate a summary-level expression reference panel with a much larger sample size into GWAS to identify associated genes. In brief, we build gene expression prediction models in blood based on the summary data released by the eQTLGen consortium, which is to date the largest meta-analysis in 31,684 blood samples from 37 cohorts. Compared with benchmark methods, MR-JTI, TWAS-Fusion, PrediXcan, and UTMOST, SUMMIT built more gene expression prediction models (10,026 with R^2> 0.01) and achieved significantly higher prediction accuracy in different quantiles (p -9 by K-S test). To evaluate the performance of identifying significant associations, we applied SUMMIT to the summary statistics from 25 GWAS. Compared with benchmark methods, SUMMIT identified substantially more associations for each trait analyzed, showing 222% improvement compared with MR-JTI ($p=3.1*10^{-9}$ by the Wilcoxon rank test), 306% improvement compared with TWAS-fusion, 264% improvement compared with PrediXcan, and 211% improvement compared with UTMOST. Next, we compared different methods in terms of identifying the likely causal genes that mediate the associations between GWAS loci and the traits of interest by using a set of 1,424 likely causal gene-trait pairs curated by using the OMIM. We show that the SUMMIT yielded good sensitivity and specificity for identifying the silver standard genes and achieved the highest AUC (0.701) among all the methods compared (MR-JTI 0.6329; PrediXcan 0.6164; TWAS-fusion 0.6041; UTMOST 0.6213). More importantly, SUMMIT was applicable to analyze genes with smaller heritable expressions (0.005 2

PrgmNr 1487 - Allele-specific expression of SNPs involved in the immune response and gene transcription is associated with BMI

View session detail

Author Block: **A. Keshawarz**[1], T. Huan[2], R. Joehanes[1], C. Yao[3], C.-T. Liu[4], C. Demirkale[5], V. Ramachandran[6], L. A. Cupples[7], D. Levy[8]; [1]National Heart, Lung, and Blood Institute, Framingham, MA, [2]University of Massachusetts Medical School, Worcester, MA, [3]Framingham Heart Study, Framingham, MA, [4]Boston University SPH, Boston, MA, [5]National Institutes of Health, Bethesda, MD, [6]Boston University School of Public Health, Boston, MA, [7]Boston Univ Sch Pub Hlth, Boston, MA, [8]NHLBI/NIH, Framingham, MA

Disclosure Block: **A. Keshawarz:** None.

Background. Body mass index (BMI) is an estimate of general adiposity associated with numerous clinical outcomes, including subclinical and clinical cardiovascular and metabolic disease. Growing genome-wide association studies have identified hundreds of BMI-associated loci, but the transcriptomic signature of BMI is incompletely understood. The objective of this study was to quantify the association between allelic imbalance and BMI using allele-specific expression analysis in conjunction with GWAS of BMI. **Methods.** Whole genome sequencing and RNA sequencing data were collected from 720 Framingham Heart Study (FHS) Offspring participants (59% women, mean age 66Â±8 years) and 954 FHS Third Generation participants (52% women, mean age 46Â±9 years) as part of the Trans-Omics for Precision Medicine (TOPMed) program. Heterozygous SNPs (n=780,599) were evaluated for allele-specific expression, and the ratio of reference allele to total allele counts for SNPs was calculated. SNPs with significant allelic imbalance based on a Bonferroni-corrected p-value (0.05/780,599) in a binomial test were subsequently evaluated in multiple linear regression to test the association between the reference allele/total allele count ratio and BMI after adjustment for age, sex, and family structure. SNPs significantly associated with BMI at FDR cis-expression quantitative trait loci (eQTLs) to investigate other known functions and associations. **Results.** After adjustment for age, sex, and family structure, allelic imbalance in 139 SNPs was significantly associated with BMI. SNPs identified were annotated to genes that were enriched for cell activation and immune response pathways, and the top five most significant SNPs identified were annotated to *FLYWCH1, ZDHHC6, MYADM*, and *TCL1A*. Twenty-seven SNPs were in regulatory regions; of these, 18 were in promoter or promoter flanking regions. Seven SNPs identified in these analyses were associated with traits in the GWAS catalog, including BMI. Furthermore, these SNPs overlapped with 181 unique *cis*-eQTLs (pPLGLB2, HLA-J, TRIM31, DHDDS, AL671883.2, DPY19L1P2, AL022345.4). **Conclusion.** SNPs implicated in the immune response pathway and in gene regulation show significant allelic imbalance associated with BMI; thus, allele-specific expression may partially explain population-level variation in BMI.

PrgmNr 1488 - Genetic determinants of prostate-specific antigen levels improve cancer screening utility

View session detail

Author Block: **L. Kachuri**[1], R. E. Graff[1], J. P. Shelley[2], K. Schaffer[2], J. D. Mosley[2], P. J. Goodman[3], C. Till[3], I. Thompson[4], R. Klein[5], S. K. Van Den Eeden[6], T. J. Witte[7]; [1]University of California San Francisco, San Francisco, CA, [2]Vanderbilt University Medical Center, Nashville, TN, [3]Fred Hutchinson Cancer Research Center, Seattle, WA, [4]Christus Health, San Antonio, TX, [5]Icahn School of Medicine at Mt. Sinai, New York, NY, [6]Kaiser Permanente Northern California, Oakland, CA, [7]Univ California San Francisco, San Francisco, CA

Disclosure Block: **L. Kachuri:** None.

Prostate-specific antigen (PSA) testing is controversial due to issues related to sensitivity and specificity, resulting in overdiagnosis and overtreatment of prostate cancer (PCa). Genetic determinants of PSA in cancer-free men could be used to correct observed PSA values by accounting for PSA variation that does not reflect PCa.

We conducted the largest ever genome-wide association study (GWAS) of PSA in men without PCa (N=65,962; 63,338 European ancestry) using longitudinal measures from the UK Biobank (UKB; n=26,491), BioVU (n=8078), and Genetic Epidemiology Research on Adult Health and Aging (GERA; N=30,088) cohorts. Our GWAS discovered 87 variants associated with PSA levels (P-8), including 37 loci independent of previously reported associations (r^2PSA) constructed from these variants was validated in the Prostate Cancer Prevention Trial (PCPT; P=8.7Ã□10^{-54}). In the PCPT, which enrolled PCa-free men with PSAâ□¤3 ng/mL, PRS explained a larger proportion of PSA variation than age (4.0% vs. 1.3%).

Consistent with the hypothesis that genetic predisposition to elevated PSA increases the detection of low-grade PCa, PRS_{PSA} was inversely associated with Gleason score (â□¤6 vs. â□¥8: OR=0.83, P=8.4Ã□10^{-5}; 6485 GERA cases) and PCa mortality (HR=0.82, P=7.4Ã□10^{-9}; 8834 UKB cases). We then evaluated how genetically corrected PSA values affect reclassification at cut-offs used for biopsy recommendations in GERA. Among non-cases with a negative biopsy, 18.4% were reclassified below the referral threshold, while 2.7% moved upward. In cases, downward reclassification (3.9%) was higher than upward (1.9%) when considering PSA values â□¥2 years before diagnosis. This trend was more pronounced in cases with low-risk disease (Gleason Lastly, we explored the role of PSA-related selection bias on associations with PCa risk and mortality. There is substantial sharing of genetic loci between PSA and PCa, illustrated by the high correlation between their genetic scores (r=0.287, P-500) in UKB (n=164,669 not included in the PSA GWAS). Although this may partly reflect pleiotropy, there was evidence of bias due to screening (P=2.1Ã□10^{-130}). Re-fitting PRS_{PCa} using bias-corrected risk allele weights attenuated its correlation with PRS_{PSA} (r=0.049, P=5.5Ã□10^{-93}) and revealed a previously absent association with PCa mortality (HR=1.18, P=0.035).

Our work provides preliminary evidence that genetic correction of PSA levels may improve PCa screening. Larger and more diverse study populations are required to fully characterize the genetic basis of PSA variation and optimize its clinical utility.

PrgmNr 1489 - Joint intron splicing-based transcriptome-wide association study identifies new candidate susceptibility genes for breast cancer

View session detail

Disclosure Block: **G. Gao:** None.
In this study, we proposed a joint intron splicing-based transcriptome-wide association study approach (IntronXcan) that combined information from multiple excised introns in a gene across multiple tissues. IntronXcan used splicing prediction models trained in 47 tissues in the GTEx (v8) data with a multivariate adaptive shrinkage (mash) method, which can jointly estimate effects of splicing quantitative trait loci (sQTLs) in multiple tissues, accounting for correlation among nonzero sQTL effects in different tissues. We applied IntronXcan to the GWAS summary statistics from the Breast Cancer Association Consortium (BCAC) of about 229,000 women of European ancestry. We identified 550 genes significantly (P -^{6}) associated with breast cancer. We replicated 75 of these 550 genes at significance level (P -^{5}) when applied IntronXcan to GWAS summary statistics from an independent dataset on breast cancer extracted from UK Biobank. To determine if these genes are independent of previously identified breast cancer loci, we performed a conditional and joint analysis (COJO) by conditioning summary statistics on previously published (risk) index SNPs within +/- 10 Mb of each significant gene. We then re-performed IntronXcan using the conditional summary statistics. Results showed that 31 of the 75 replicated genes were still significant. We treat these 31 genes as conditionally independent of known breast cancer GWAS loci. Of these 31 genes, 13 novel candidate susceptibility genes are located beyond 500kb from their nearest GWAS index SNP. We similarly performed gene expression-based joint TWAS (S-MultiXcan) that integrated predicted expression data from multiple tissues. We identified 311 genes significantly associated with breast cancer using BCAC summary statistics (P â□□6). Among them, 23 genes were replicated (P â□□5) in our S-MultiXcan analysis of the independent UKB dataset. Six of the 23 replicated genes remained significant after conditioning on previously identified index SNPs. We further performed a meta-analysis to combine BCAC and UKB GWAS summary statistics and then applied splicing-based IntronXcan and expression based S-MultiXcan to the meta-analysis summary statistics. We identified an additional 162 and 68 significant genes, respectively. Our analyses indicated that the splicing based IntronXcan could identify a greater number of significant genes than the gene expression-based S-MultiXcan and individual intron splicing-based TWAS.

The elevated pressure in primary congenital glaucoma occurs subsequently to defects in the aqueous humor outflow passageway. Secretion of ocular anterior chamber fluid produced by the ciliary body is exhausted primarily through Schlemmâ□□s canal and uveoscleral passages. Here, we describe a neonate female conceived from a consanguineous couple who lost two early pregnancies and two males suffering from severe immunologic disorders, at the age of 2 and 7 months. She harbored severe facial dysmorphism, multiple malformations, postnatal growth impairment and a delayed psychomotor development with severe hypotonia and seizures crisis. She had in particular multiple ocular defects with hypertelorism, buphthalmos as in congenital glaucoma (diffuse enlargement of the eye with exophthalmia and a large cornea with a grey corneal arcus) with blindness related to optic nerve disorder. She had furthermore many angiomas and blue birthmarks related to venous dilatations, which were disseminated through the majority of her body skin. Standard karyotyping showed an unbalanced translocation with a deletion of the critical region of Wolf-Hirschhorn syndrome within 4p15.3-pter and a duplication of the 8q22-23 chromosomal region, subsequently to a transmitted der(4)t(4;8)(p15.3;q22-23) from her mother. Recently, ANGPT1-TEK signaling is demonstrated to be required for Schlemmâ□□s canal development in mice. Furthermore, hemizygosity for Tek in mice, led to the formation of severely hypomorphic Schlemmâ□□s canal and trabecular meshwork, as well as elevated intraocular pressure, demonstrating that anterior chamber vascular development is sensitive to Tek gene dosage and the resulting decrease in ANGPT1-TEK signaling. Even as ANGPT1 is the primary ligand of TEK in the irido-corneal angle and the inactivation or perturbation of ANGPT/TEK pathway leads to degeneration and/or irregular canal formation, increased intraocular pressure and glaucoma during development, abnormal ANGPT1 gene dosage and the resulting effect in ANGPT1-TEK signaling pathway may be expected as an alternative mechanism of neonate congenital glaucoma. In our case report, this abnormal gene dosage following ANGPT1 duplication may resulting in loss-of-function defects leading to glaucoma as well as venous malformations. To note that, gain-of-function TEK mutations were also linked to hereditary and sporadic venous malformations.

PrgmNr 2002 - Chromosomal abnormality -17/17P- in acute B-lymphoblastic leukemia (B-ALL) implies loss of heterozygosity of *TP53* gene

View session detail

Author Block: **J. Yan**, Q. Zheng, Y. Zhang, N. Chen, Z. Yin, X. Jia, D. Wang; Beijing Boren Hosp., Beijing, China
Disclosure Block: **J. Yan:** None.
Loss of heterozygosity (LOH) of tumor suppressive genes is an important factor for poor curative effect and prognosis in hematologic malignant diseases.The purpose of this research was to study the cases of B-ALL with *KMT2A-AFF1* fusion accompanied by deletion of chromosome 17 or the short arm of chromosome 17 (-17/17P-) and *TP53* gene mutation, and to preliminarily evaluate the occurrence of LOH and its impact on the outcome of these patients. The data of B-ALL patients with chromosomal 4 and 11 translocation [t(4;11)(q21;q23)] admitted to Beijing Boren Hospital from January 2019 to March 2021 were collected and analyzed. Additional abnormality of deletion of the *TP53* locus detected by FISH and *TP53* gene mutation detected by next-generation sequencing (NGS) together with clinical information was evaluated. Twenty-five patients with t(4;11)(q21;q23) of B-ALL were investigated. Fourteen of these patients are males and 11 are females, and their ages are from 5 months to 45 years (median age 10 years). Among the 25 cases, 23 cases were examined by FISH technique using P53 probe, and the deletion of *TP53* locus (positive) were found in 13 cases (56.5%). *TP53* gene mutation was detected in 13 of the 17 investigated cases (76.5%) by means of NGS technology. All the 25 patients received multicourse treatment. Among them, only 2 were first-diagnosed B-ALL, while all the rest had relapse in different clinical course. Seven of the 25 patients had once achieved temporary remission under different treatment regiments, and 4 of the 7 patients did not carry *TP53* gene mutation nor -17/17p- as indicated by sequencing technology and cytogenetics, respectively. This retrospective study demonstrated that the t(4;11)(q21;q23)/*KMT2A-AFF1* fusion gene-bearing B-ALL patients had frequent additional chromosomal abnormalities, of which the most common one was -17/17P-. Deletion of *TP53* loci detected by FISH in the same group of patients was consistent with karyotype results. Pathogenic *TP53* mutations, which was highly frequent among these patients as indicated by NGS was also highly coincidence with the FISH results. These findings suggest that the patients lost normal anticancer function of *TP53* gene due to LOH. Considering the high relapse frequency in this B-ALL group, we propose that additional genetic abnormalities, especially -17/17P-, tend to evolve during the disease development in t(4;11)(q21;q23)-bearing B-ALL patients, resulting in the LOH of *TP53* gene, which is directly related to the poor prognosis of this type of leukemia. Therefore, the deletion of *TP53* locus on chromosome 17 demonstrated by cytogenetic analysis implies LOH in the B-ALL.

PrgmNr 2003 - Clinical features and genetic analysis of pediatric pilomixoid astrocytomas

Pilocytic astrocytomas (PAs) are the most frequently encountered brain tumors with peak incidence in the first decade of life. Recently, a distinct group of tumors previously diagnosed as PA were identified and defined as pilomyxoid astrocytoma (PMAs) that presents unique histological characteristics and have more aggressive clinical course. The studies on genetics of PMA are scarce. In this study, we focused on one of the largest cohort of PMA samples to date to understand the genetics and cytogenetic makeup of this solid type of tumor. We examined and compared the clinical outcome of the 27 pediatric patients who were diagnosed with PA and PMA. These samples were also cytogenetically tested using Affymetrixâ□□s oncoscan arrays. The PMAs share alike features with PA; however, they were more aggressive and had shorter overall survival rate than the PAs. Our study yielded a previously reported duplication (KIAA1549-BRAF Fusion) in most of the tested samples. Besides the fusion gene, 11 samples had additional cytogenetic abnormalities. In conclusion, this study is the first report of Saudi patients with PMA/PA, and provides detail clinical picture and outcome of these rare pediatric tumors in Saudi population and hence may help better diagnosis and characterization of PMA.

PrgmNr 2004 - CYP polymorphisms and heart failure

View session detail

Author Block: **N. B. Abdelmoula**[1], R. Abdelhedi[2], UR17ES36 Team; [1]Genomics of signalopathies at the service of medicine UR17ES36, Med. Coronary artery disease is a complex multifactorial disorder. Its pathophysiology depends on a large number of lifestyle and environmental risk factors. Numerous genes and single nucleotide polymorphisms were reported to be associated, such as VEGF, VEGFA, SCARB1 and CYPs. Despite advances in stent technology, patients with coronary artery disease remain at risk for cardiovascular mortality, mainly because of myocardial infarction and development of heart failure. The aim of this study was to assess the impact of the loss-of-function polymorphisms of CYP2C19 in one hundred Tunisian patients affected by coronary artery disease. We enrolled 100 patients with acute coronary syndrome under-going percutaneous coronary stenting. Genotypes were determined using PCR-RFLP techniques. SNP genotyping of CYP2C19*2 (rs4244285) and CYP2C19*3 (rs4986893) was performed. PCR amplification was carried out using two couples of primers and RFLP was carried out using respectively Sma and BamHI restrictions enzymes. Data concerning demographic parameters, coronary heart disease risk factors and treatment were collected for each patient. The occurrence of major cardiovascular events between in the carriers and the non-carriers of SNPs was recorded. Comparison of categorical variables was performed using the chi-square test. Values were considered statistically significant at p A showed that 77% of patients were homozygous G/G and 23% were heterozygous G/A. The 636G>A polymorphism was absent in our population. After percutaneous coronary intervention, 3,9% of G/G patients versus 4,3% of G/A patients developed a left ventricular failure. All of them were females but without any statistical significant difference. When all major adverse cardiac events post-percutaneous coronary intervention are considered, a statistical significant difference (p=0.075) among the G/G and G/A groups was recorded. CYP2C19*2 carrier status associated with an increased risk of heart failure following coronary stent placement is not well reported. The association between CYP2C19*2 polymorphism and inflammatory markers concentrations could suggest that CYPs including CYP2C19 seem to be candidate genes for cardiovascular risks. It was shown recently that CYP2C19 genotype may be a risk factor for coronary microvascular disorder via inflammation but exclusively in the female population. A larger study is needed to better assess the role of CYP2C19 genotyping as an independent risk factor in the development of heart failure following percutaneous coronary intervention via an inflammarory process.

PrgmNr 2005 - Geographic differences of the distribution of the mutational spectrum of *BRCA1* and *BRCA2* genes in Algerian population

View session detail

Disclosure Block: **F. Cherbal:** None.

Background: Algeria is a country of continental dimension with admixed population of Berber descent with Sub-Saharan African, European and Middle East elements. The knowledge of recurrent mutations in *BRCA* genes and their geographical distribution is useful for the design of an efficient and affordable genetic testing for hereditary breast and ovarian cancer (HBOC) patients and families at risk. In this retrospective study, we report the mutational spectrum of *BRCA* genes in HBOC patients from North central region and North East region of Algeria which is called ' The Aures region', respectively. **Methods**: first**,** we analyzed the complete sequence of *BRCA1* and *BRCA2* of 70 HBOC families from North central region of Algeria using HRM-Sanger sequencing and MLPA techniques. Then, *BRCA* genes were screened using PCR-Sanger sequencing in a second cohort of 56 HBOC patients from the North central region and a cohort of 113 HBOC patients (109 women and 4 men) from the Aures region, respectively. The screening included all exons where a recurrent mutation was previously found in BRCA1 exons (3, 4 and 10) and in *BRCA2* e x o n (1 0) in our first screening. In addition, twelve HBOC patients from North East region were analyzed using a NGS analysis with a cancer panel of 30 hereditary cancer genes or BRCA1/2 genetic test. **Results:** We detected 4 recurrent mutations in the *BRCA*1 gene of HBOC patients from the North Central region: c.83_84delTG (7 unrelated families), c.181T>G (3 unrelated families), c.798_799delTT (3 unrelated families), c.2125_2126insA (3 unrelated families), Del exon 7 (2 unrelated families) and one recurrent mutation in the *BRCA2* gene : c.1310_1313delAAGA (2 unrelated families), respectively. The recurrent mutations in *BRCA1* and *BRCA2* genes already reported in HBOC patients from North central region of Algeria have not been detected in patients from the North East region. In addition, NGS analysis of *BRCA* genes in HBOC patients from North East region revealed 2 distinct mutations in *BRCA1* gene: Del exon 15 (2 unrelated families), c.5332 + 1G > A (one family) and 4 distinct mutations in *BRCA2* gene: c.1813dupA (one family), c.7654dupA (one family) c.8485C>T(one family) and c.8940delA (one family). Interestingly, all these mutations detected in *BRCA* genes in HBOC patients from the Aures region have never been reported in Algerian population. **Conclusions**: Our results showed differences in the distribution of the mutation spectrum of BRCA genes between the North central region and the Aures region of Algeria. The present study will help to implement affordable genetic testing and to improve the clinical management and better risk assessment of hereditary breast and ovarian cancer.

PrgmNr 2006 - Germline mitochondrial DNA non-coding region variants among sporadic breast cancer patients of two Sri Lankan ethnic groups

View session detail

Disclosure Block: **J.T. Kotelawala:** None.

Breast cancer is the main cancer occurring amongst women in Sri Lanka accounting for nearly 25% of cancers diagnosed. Studies have shown association of mitochondrial (mtDNA) variations with cancer. We previously reported mitochondrial variants among breast cancer patients and controls of Sri Lankan Sinhalese ethnicity, however these variants failed to show a significant association with breast cancer within the study sample. Interestingly, initial studies revealed that some variations such as 16189C occurred more frequently in patients of Sri Lankan Tamil ethnicity compared to Sinhalese and Sri Lankan Moor ethnicities, hence a larger sample was studied to determine if these variations are significantly associated with breast cancer. Here we report the mtDNA noncoding variants in 30 sporadic breast cancer patients and healthy control pairs each of Sri Lankan Tamil and Sri Lankan Moor ethnicities.

Genomic DNA was extracted from peripheral venous blood and PCR amplified using two pairs of mtDNA non-coding region specific primers. The amplified PCR product was sequenced using Sanger sequencing. The sequences obtained were compared against the revised Cambridge Reference Sequence (NC_012920.01) using Mutation Surveyor (v.4.0).

The following variants were commonly observed in patients and controls of Sri Lankan Tamil (SLT) ethnicity 73G (29 vs 28); 146C (8 vs 2); 152C (8 vs 10); 263G (28 vs 30); 489C (21 vs 13); 523-524 deletion (6 vs 5); 523 AC insertion (1 vs 1); 16189C (7 vs 2); 16223T (21 vs 6); 16311C (7 vs 4); 16519C (24 vs 24). The following variants were commonly observed in patients and controls of Sri Lankan Moor (SLM) ethnicity: 73G (24 vs 27); 146C (5 vs 8); 150T (7 vs 7); 152C (12 vs 10); 263G (30 vs 30); 489C (15 vs 11); 523-524 deletion (7 vs 4); 523 AC insertion (0 vs 2) 16051G (7 vs 9); 16189C (3 vs 1); (16223T (17 vs 14); 16311C (10 vs 5); 16352C (7 vs 4); 16497G (4 vs 6); 16519C (18 vs 15). Some variations occurred more frequently in patients. The prevalence of mtDNA variant 16223T was significantly higher in the patients than in the controls (Fischerâ□□s exact test: p=0.0002) among Sri Lankan Tamils but not among Sri Lankan Moors (present study) or Sinhalese (as previously reported). Although mtDNA variant 16223T can be suggested as a predictive biomarker for sporadic breast cancer among Sri Lankan Tamils, a larger sample is needed to confirm these findings before its clinical use. This study also highlights the importance of studying individual ethnic groups prior to recommending potential biomarkers in disease prediction.

This research is supported by the National Science Foundation of Sri Lanka (NSF/SCH/2016/04)

PrgmNr 2007 - Identification of RP gene and ERÎ± gene polymorphism as genetic markers for the improvement of breast cancer management in cameroon

View session detail

Author Block: **N. NGUEDIA KAZE**; Univ. of Yaounde I, YAOUNDE, Cameroon
Disclosure Block: **N. Nguedia kaze:** None.
Background : Breast cancer is a real public health problem in Cameroon, where more patients with this cancer usually die a year after diagnosis, as it is still based on histological examination, mortality due to that cancer is far from decreasing. **Rational**: Since cancer is an accumulation of molecular changes in gene, the +331 GA polymorphism of PR gene and 397TC and 351AG polymorphisms of ERÎ± gene could be investigated as breast cancer etiological factors. **Methods :**We carried out a case control study, in which 16 cases diagnosed positive for breast cancer at the Yaounde general hospital was recruited by consulting the patient file and Blood samples was also collected from them and 22 healthy women who were recruited using a questionnaire and an inform consent signed each of them. The +331 GA polymorphism in the PR gene was identified using NIaIV endonuclease and by PCR-RFLP and direct molecular haplotyping was used to determine the relationship between the 2 polymorphisms in the ERÎ± gene, 397TC and 351AG by restriction fragment-length polymorphisms. The data were analyzed using Statistical Package Social Sciences v20. **Results**: The population was mostly postmenopausal with an invasive ductal carcinoma with an average age of 53+-11,08 years. A mutant AA genotypic frequency of the PR gene was high in both, the case and control groups 100% and 94% respectively. We obtained an Odds Ratio of 1.067 with 95% Confidence Interval of 0.940-1.211 and P value of 0.421, making a non-significant association with the risk of developing breast cancer. In addition, we identified the mutant CG haplotype allele of the ER alpha gene with a predominance in the cancer group exclusively with a frequency of 56.25% with an OR of 2.022 with a 95% CI 0.432 - 9.461 with a p-value of 0,3, not significantly associated with breast cancer. However, the CG.CG mutant genotype of the ER alpha gene (31.25%) in the diseased population was significantly associated with breast cancer with an OR 1.455, CI 1.045-2.024 and a p-value of 0.05. **Conclusion**: This shows that the polymorphisms studied would predispose to a risk of developing breast cancer.

PrgmNr 2008 - Low Prevalence of Large Genomic Deletions and Duplications Observed in the Sequential Use of MLPA after Negative NGS Result in Thai Breast Cancer Cohort

View session detail

Author Block: **P. Mutirangura**[1], P. Lertwilaiwittaya[2], E. Routhumnong[1], S. Wiboonthanasarn[1], K. Pongsuktavorn[1], P. Dungort[1], C. Limwongse[3], W. Thongnoppakhun[1], M. Pithukpakorn[1]; [1]Faculty of Med. Siriraj Hosp., Bangkok, Thailand, [2]Mahidol Univ., Bangkok, Thailand, [3]Bangkok, Thailand
Disclosure Block: **P. Mutirangura:** None.
Introduction*BRCA1* and *BRCA2* mutations are the most common cause of hereditary breast cancer. Next generation sequencing (NGS) has been adopted to screen these genes in clinical scenarios. It is known that single nucleotide variants (SNVs) and small insertions/deletions (indels) contribute to the majority of all *BRCA1/2* mutations. However, large genomic deletions/duplications (del/dup), accounted for 10 percent of overall mutation mechanism in Western population, might be missed from the use of such technique. We aimed to report the diagnostic yield of the use of sequential multiplex ligation-dependent probe amplification (MLPA) to detect large genomic del/dup in *BRCA1/2* in Asian population.
MethodsA retrospective review of 440 breast cancer patients underwent NGS at Siriraj Hospital in 2016-2021 was done. Information including demographic data, patient characteristics, type of breast cancer, and result of genetic identification were recorded. The patients with high clinical suspicion or positive JSI yet negative NGS test underwent MLPA test. The patients with high clinical or bioinformatics (suggested by JSI medical systems or demonstrate a significant drop in sequencing read depth compared to pooled sample) suspicion were selected and sent for MLPA. We use descriptive statistics to analyze the yield of each criterion.
ResultsAmong 440 patients in this study undergoing NGS test, 105 patients (23.8%) had positive results of pathogenic or likely pathogenic variant in *BRCA1/2* genes.There were 66 patients with negative NGS underwent MLPA. Thirty patients (44%) had bioinformatics suspicion, while 36 patients (56%) had high clinical suspicion. Only one patient (1/66, 1.5%) had a positive result of *BRCA1* mutation in clinical suspicion group.
Discussion/ConclusionNGS demonstrated a high yield of SNVs and small indels in Thai populations (105/440 patients; 24%). Large genomic del/dup contribute to only a small percentage (1/66 patients; 1.5%) when compared to the Western populations. The sequential use of MLPA after a negative NGS result may not be fruitful in Asian populations. Further study should be done to explore other screening criteria.

PrgmNr 2009 - Renal cancer progression & contribution of chromatin remodeling complexes

View session detail

Author Block: **W. SMAOUI**[1,2], N. BOUAYED ABDELMOULA[3,2]; [1]Habib BOURGUIBA Univ. Hosp., Sfax Univ., TUNISIA, SFAX, Tunisia, [2]UR17ES36, Sfax, Tunisia, [3]Faculty of medecine of sfax, Sfax Univ., TUNISIA, SFAX, Tunisia
Disclosure Block: **W. Smaoui:** None.
Background:Renal cell carcinomas accounts for around 95% of the neoplasms arising from the kidney. These malignant adenocarcinomas initiates in the renal tubular epithelium and progresses leading to death of 40% of patients. Different histological subtypes are described including clear cell, papillary, and chromophobe renal cell carcinomas. Loss-of-function mutations in chromatin modifiers are now recognized as common in renal cell carcinomas and some of them play a central role in tumor progression. Our ongoing study includes 180 localized renal tumor samples from Tunisian patients, for which screening of recurrent and hot spot mutations of PBRM1, BAP1, SETD2, KDM5C and KMD6A genes will be conducted. Here, we focused our attention on the literature background of recurrent mutations of SETD2.Material and methods:A review of the literature has been conducted to state recurrent mutations of SETD2 in RCC as well as molecular techniques that can be applied according to our technical platform aptitudes.Results:We found that DNA sequencing revealed that mutations in SETD2 occur in 3 to 12 percent of clear-cell renal cell carcinomas cases (the third-most-commonly mutated gene) and are associated with poor clinical outcome. PCR primer sets to amplify and sequence all coding sequences and exon-intron boundaries of SETD2 as well as PCR amplification conditions and sequencing protocols using Sanger methodology are available. Recurrent pathogenic mutations in renal cell carcinomas samples have been reported.Conclusion:SETD2 functions as a histone methylation and as a microtubule methyltransferases. SETD2 is coding for a multi-domain protein with a central SET domain responsible of the methyltransferase activity and a C-terminus SRI domain mediating the interaction between SETD2 and the phosphorylated C-terminal domain of RNA polymerase II. Hundreds of distinct SETD2 mutations have been identified across a wide range of human tumors, including epithelial, nervous and hematopoietic types. SETD2 mutation was first described in clear cell renal cell carcinomas and the most common and recurrent mutations are described in SET domain suggesting loss of catalytic activity such as the R1625C and in SRI domain such as the R2510H.

The small nucleolar RNAs (snoRNAs), including the small Cajal body-specific RNAs (scaRNAs), have recently been suggested as intriguing players in cancer. To study their role in breast cancer (BC), we performed small RNA-sequencing in 195 fresh-frozen invasive BC and 20 benign breast tissue samples from the Eastern Finnish Kuopio Breast Cancer Project (KBCP), to explore differentially expressed snoRNAs with potential prognostic and predictive value in invasive local BC. Total RNA was extracted from fresh-frozen tissues using the Ambion mirVana miRNA Isolation Kit, processed using the Illumina TruSeq Small RNA Library Prep kit and sequenced. Bioinformatic analysis of non-miRNA/piRNA sncRNA expression included read quality assessment (FastQC), adapter trimming (TRIMMOMATIC), removal of e.g. rRNA reads (Bowtie2), and alignment (Tophat2) to human reference sncRNA transcriptome (subset of GENCODE v22). Differentially expressed sncRNAs were identified using DESeq2 in R from gene-wise read counts. Survival was analysed using survival::coxph in R.
Utilizing the comprehensive background, clinical, treatment, and follow-up data extending up to 25 years in the KBCP samples, we identified altogether 58 snoRNAs and scaRNAs that were differentially expressed in invasive local BC compared to benign breast tissue (P_{Adj}PPPP$_{Adj}$

ERCC6L2 belongs to the Snf2 family of helicase-like proteins that are involved in nucleotide excision repair, mitochondrial function and transcription regulation. Pathogenic variants in this gene have been related to bone marrow failure (BMF) with variable phenotypic expression, age of onset and somatic genetic findings in bone marrow. Up to date about 16 cases with bi-allelic variants in *ERCC6L2* have been reported in the literature. Clinical representation varied from myelodysplastic syndrome (MDS) which progressed to acute myeloid leukemia (AML) in some of the patients. Neurological and developmental findings were reported in one patient. We describe three patients in northern Israel from two unrelated families who reside in the same village. The first patient is a seven y.o girl, referred to genetic counseling due to mild developmental delay, behavioral disorders and pancytopenia. Bone marrow karyotype was normal. Exome sequencing revealed a homozygous splicing variant, c.3525+2T>G in *ERCC6L2*., predicted to damage splicing completely. The second patient is a 16 y.o boy who presented with MDS, progressed to AML after three months and passed away. Bone marrow demonstrated complex karyotype with 5qdel. Sequencing a panel of bone marrow disorders in fibroblasts derived from the patient revealed the same variant and an additional missense variant c.3493C>G p.Leu1156Val classified as vous. Segregation analysis exposed a 24 y.o healthy sister that was found homozygous for the variants. Carrier frequency testing within the village revealed 7 carriers out of 104 healthy individuals (1:15). There is a consensus among the hematological community that early hematopoietic stem cell transplantation (HSCT) is warranted for patients with MDS prior to the development of AML that is usually very aggressive.
Our data emerge the urgent identification of pre-symtomatic homozygous individuals to study the penetrance and the course of the disease in order to give accurate genetic and hematological counseling to the patients and family, and early treatment when indicated.

Introduction: The most common central nervous tumors are metastatic tumors. Metastatic spread to the brain causes a significant drop in survival rates, and it usually occurs in patients with sufficiently controlled extracranial disease. Over half of the patients die within a few months following the diagnosis of brain metastasis. **Methods:** We performed Oncomine Panel Next Generation sequencing (161 cancer genes) of 68 matched brain metastases, and primary tumors from consented patients in multiple institutions in Saudi Arabia. We also performed *PD-L1* IHC to compare its expressions in paired primary tumors. **Results and discussion:** Rate of *PD-L1* positivity varies by metastatic location. Decisions for individualized therapies in patients with brain metastasis are often made from primary-tumor biopsies. We demonstrate that clinically actionable alterations present in brain metastases are frequently not detected in primary biopsies. Our results show patients with Breast Cancer who had *ERBB2* amplifications detected only in the brain-metastasis samples. Moreover, those patients have also had *EGFR V698M* mutations in the brain metastasis that are absent in their primary tumor. Activating mutations in *KRAS*, which have been associated with tumor responses to *MEK* inhibitors were the most frequent alteration in colon cancer paired. Further amplifications of *FGFR3* were detected only in the brain metastasis. The *MAPK pathway inhibitor* family includes agents that inhibit *BRAF* and *MEK*, such as vemurafenib, dabrafenib, or trametinib. *BRAF V600E* only detected in the brain-metastasis samples in our thyroid cancer cases. This suggests that sequencing of primary biopsies alone may miss a substantial number of opportunities for targeted therapy. Our preliminary results showed that the rate of *PD-L1* positivity varies by metastatic location. For example, *PD-L1* expression was rare on tumor cells in both the breast and metastatic sites. The difference in *PD-L1* positivity rates between primary tumors and different metastatic sites should inform physicians when choosing sites to biopsy and suggests a difference in the immune microenvironment across metastatic sites. **Conclusion:** Overall, the reason for these apparent organ site-specific differences is unclear. Because more than 50% of patients with brain metastases will die of intracranial progression, targetable alterations present in cancer subclones specific to the brain metastasis represent an important opportunity for novel targeted therapeutic strategies to affect overall survival.

PrgmNr 2013 - Timer CAR-T (TCAR-T): A paradigm shift in CAR-T cell therapy

The development of effective targeted therapies with better survival and fewer side effects is crucial for cancer treatment. Although CAR-T cell therapy has shown immense potential in cancer treatment, off-target side effects, neurotoxicities, and cytokine release syndrome present unique challenges and have hindered its widespread use. Since CAR-T cells are designed to be alive in the body for their entire life span, it exacerbates the severe side effects. Thus, programming CAR-T cells to die after their assigned function can help overcome some of these challenges. Here, we propose the development of a new CAR-T approach to address these challenges. Briefly, we suggest that developing genetically modified CAR-T cells that can be eliminated using external modulations without compromising their therapeutic functions could address some of the shortcomings of the current cell therapy systems. These timer CAR-T (TCAR-T) cells can significantly act temporally, reduce long-term side effects, and be utilized during early tumorigenesis as they could be eliminated upon successful tumor remission. The development of such cells is possible by overexpressing the CAR protein and diphtheria toxin receptor together in the T-cells using a dual promoter virus vector. Since the modified TCAR-T cells contain comparatively more diphtheria toxin receptors, they could be highly sensitive and respond selectively to small doses of diphtheria toxin. The conditional removal of CART-T cells could also significantly reduce cytokine release during CAR-T cell therapy. We envisage that the validation TCAR-T approach could help ultra-personalize the cell and gene therapy offerings in the near future.

PrgmNr 2014 - A prospective Study Using Multigene Next Generation Sequencing panel to Evaluate the Prevalence of Familial Cancer in a Highly Consanguineous Population

View session detail

Author Block: **F. Alharthi**[1], M. Alharbi[2], N. Mobark[2], M. Abedalthagafi[1]; [1]King Abdulaziz City for Sci. and Technology, Riyadh, Saudi Arabia, [2]King Fahad Med. City, Riyadh, Saudi Arabia
Disclosure Block: **F. Alharthi:** None.
Introduction: 5-10% of all cancers are associated with an inherited mutation in a cancer predisposition gene. Saudi Arabia (SA), a highly consanguineous population has a sharp increase in cancer diagnosis to ~140% from 1990-2016. Family history is an important factor in determining cancer risk and prognosis. Understanding the population specific variations and frequencies is a major public health issue to establish informed screening programs. Here we conducted a prospective study using a multigene NGS panel and we established the first cancer genetic clinic in the SA.
Method: A prospective study was conducted between 2017-2020 on a total of 846 individuals. All ethical approval obtained. Cancer genetic clinic established and patients were seen by certified genetic counselors. A saliva or blood sample was obtained from 310 high risk patients including 166 index and 144 family members, and 536 controls. Cohort included 266 males and 580 females. gDNA sequenced using a 30 multigene panel important in hereditary cancers.
Results: Of the 310 subjects, 123 are index and 20 family members had previously been diagnosed with cancer, like breast, colon, brain. Out of these 310 subjects, 120 (38.7%) had positive genetic screening results for pathogenic or likely pathogenic mutations in APC, ATM, BRCA1, BRCA2, BRIP1, CDH1, CDKN2A, CHEK2, MLH1, MSH2, MSH6, MUTYH, NBN/NBS1, PALB2, PMS2, PTEN, RAD51D, and TP53. Variants of uncertain significance (VUS) were found in these genes, as well as in BARD1, BMPR1A, RAD51C, and STK11. No variants were found in BAP1, CDK4, EPCAM, GREM1, MITF, POLD1, POLE, or SMAD4. 24 of the controls also had pathogenic or likely pathogenic mutations in APC, ATM, BARD1, BRCA1, BRCA2, BRIP1, CDKN2A, EPCAM, MSH2, MSH6, PALB2, PMS2, including 3 individuals with more than one such mutation, and 260 had VUS, including 7 with pathogenic/likely pathogenic variants. Overall, there were 122 different variants in the 310 subjects, including 40 pathogenic or likely pathogenic variants, with many subjects having more than one variant, including having both pathogenic and likely pathogenic variants. In the control group, there were 378 different variants, but only 5 of these were also found in subjects.
Conclusion: Our study showed the high prevalence (38.7% in high risk, 5% in control, and 17% in average) of familial cancers in SA. Our data also support the importance of larger panel that contain a variety of hereditary cancer genes, even when patients lack classic clinical features or family history associated with some of the genes. Together, these findings further inform the clinical approach to hereditary genetic testing across a range of cancer types in SA populations.

PrgmNr 2015 - Genetic factors of differentiated thyroid cancer in French Polynesian population after exposure to nuclear tests, A suggested role of 3 loci

Disclosure Block: **M. Zidane:** None.

Background: Ionizing radiation (IR) exposure is the first established risk factor for differentiated thyroid cancer (DTC). However, most studies about DTC genetic factors in irradiated populations were performed in the Caucasian population, which was irradiated during the Chernobyl disaster, and did not evidence specific variants of genetic susceptibility to radiation-related DTC. Objective: To analyze the genetic factors of DTC risk among the French Polynesian population exposed to radioactive fallouts during the French nuclear tests. Methods: We studied 300,908 single nuclear polymorphisms (SNPs) genotyped in 283 DTC cases and 418 matched controls, all born in and resident French Polynesia, most of them being younger than 15 years at the time of the first nuclear test. We analyzed the genetic structure in our dataset to identify ethnic mixture subgroups. Then we completed a genome-wide analysis (GWAS) in the whole population, and also according to clinical features of the carcinoma. We performed local imputations for three genomic regions of interest showing significative association. We also performed gene-level and gene-set analyses subsequently.Results: We identified a strong genetic structure in the French Polynesian population related to admixture with Asian and European populations. GWAS results yielded three regions 10p12.2, 6q24.3, and 17q21.32 associated with DTC risk with respective p-values of the best three SNPs in these regions 8.40 x 10-8, 1.86 x 10-7, and 3.95 x 10-7. The respective allelic odds ratios (OR) were 1.95, 2.01, and 2.43. These results were similar in each ethnic admixture subgroup, but differentiated according to the clinical features of the thyroid carcinoma.To our knowledge, none of them have been associated previously with an increased risk of DTC. The gene-level analysis highlighted a probable interaction between RBFOX3 (17q25.3) and thyroid radiation dose in the risk of DTC.Conclusion: Our study suggests a novel role for the RBFOX3 and SKAP1 genes in addition to two genetic regions 10p12.2 and 6q24.3 in DTC risk.These results need to be further explored biologically.

PrgmNr 2016 - Hereditary Bilateral Breast Cancer: role of the Multi-Gene Panel Testing for detection of Pathogenic Variants

Disclosure Block: **C. Filorizzo:** None.
Bilateral breast cancer (BBC) is generally uncommon (1-2.6% of all patients with breast cancer), but its incidence increases particularly by up to 3% in *BRCA1* or *BRCA2* pathogenic variant (PV) carriers. The aim of our study was to evaluate whether all BBC patients should be offered multi-gene panel testing, regardless the criteria concerning personal and family history of cancer and age at diagnosis established by the current guidelines. We retrospectively collected and analyzed all clinical information of 150 BBC patients enrolled from October 2015 to April 2021, at the Sicilian Regional Center for the Prevention Diagnosis and Treatment of Rare and Heredo-Familial Tumorsâ of the Section of Medical Oncology of University Hospital Policlinico â P. Giacconeâ of Palermo. Recruited patients have been genetically tested for germline PVs in other gene beyond *BRCA1* and *BRCA2* by NGS-based multi-gene panel testing. In our investigation 58 (38.6%) out of 150 BBC patients harbored germline PVs in high and intermediate-penetrance breast cancer (BC) susceptibility genes, including *BRCA1*, *BRCA2*, *PTEN*, *PALB2*, *CHEK2*, *ATM*, *RAD51C*. Twenty-two out of 58 positively tested patients harbored a PV in a known BC susceptibility gene (no-*BRCA*). Interestingly, a noteworthy correlation between PVs in *PALB2* or *CHEK2* and BBCs was observed. In addition, our study showed that *CHEK2* PVs are correlated with a luminal A/B phenotype and *ATM* PVs with a luminal B subtype. Most of BBC-related *BRCA1/2* PVs were frameshift variants primarily located inside the exon 11 for *BRCA1*, and near the PALB2 binding site (at the N-terminus) and the DNA binding helical domain (at the C-terminus) for *BRCA2*. In conclusion, we found that, in the absence of an analysis performed via multi-gene panel, a significant proportion (14.7%) of PVs in genes different from *BRCA1/2* would have been lost. Our investigation led us to hypothesize that a deeper genetic analysis, through NGS-based multi-gene panel testing, could increase the detection rates of germline alterations in BBC patients. Particularly, in the near future, the evaluation of PVs could help to identify family members with a greater risk of developing BC (or other tumors) and consequently implement prevention and surveillance programs for these subjects. However, larger study cohorts are needed in order to define more accurate rates of PVs in BBC patients with previously negative *BRCA* genetic testing.

PrgmNr 2017 - Statistical Efficiency of Meta-analyses in Testing Gene-environment Interactions with Rare Variants

View session detail

Author Block: **X. Jin**, G. Shi; Xi'dian Univ., Xi'an, China
Disclosure Block: **X. Jin:** None.
Meta-analysis of results from multiple studies is a routine practice in genome-wide association studies, which offers a large effective sample size necessary for detecting associations with small effects. It is well established that the meta-analysis with common variants is statistically efficient and the power loss is minimal. However, the power loss of meta-analysis with rare variants is largely unexamined and has been suspected to be more sizable. In this work, we first propose four meta-analysis methods for testing gene-environment interaction (GÃE) effects with rare variants: HOM-INT-FIX, HOM-INT-RAN, HET-INT-FIX and HET-INT-RAN. Our methods consider homogeneous or heterogeneous GÃE effects across studies and treat the genetic main effect as either fixed or random. Then, we compare the statistical power of our meta-analyses with those of the pooled analyses that conduct a single interaction test with individual-level data from all studies. Through simulations, we show that HOM-INT-FIX and HOM-INT-RAN provide power comparable to those of the pooled analyses when the interaction effect is homogeneous across studies, which demonstrates that there is no power loss for the meta-analyses of GÃE with rare variants. On the other hand, when the interaction effect is heterogeneous across studies, HET-INT-FIX and HET-INT-RAN provide higher power than those of the pooled analyses. This is because that HET-INT-FIX and HET-INT-RAN treat genetic heterogeneity appropriately when synthesizing the summary results across studies. In contrast, the pooled individual-level data contain mixed interaction effects for the same variants, which violates the underlying assumption of the pooled analysis. Therefore, the meta-analysis of GÃE with rare variants is statistically efficient.

PrgmNr 2018 - DNA repair genes in polyposis susceptibility

Hosp., Helsinki, Finland

Disclosure Block: **A. Olkinuora:** None.

Background: Adenomatous polyposis is a relatively common predisposing factor to colorectal cancer. Germline mutations in the *APC* gene underlie familial adenomatous polyposis (FAP). Up to 10% of patients with profuse disease (>100 polyps) and 80% of those with attenuated disease (AFAP) remain molecularly unexplained. While defective DNA repair may contribute to AFAP predisposition (e.g., germline mutations in the base excision repair genes *MUTYH* and *NTHL1*), repair defects are more common causes for other cancer syndromes, such as Lynch syndrome (DNA mismatch repair) or hereditary breast and ovarian cancer syndrome (DNA double strand break repair). We previously identified a homozygous founder variant of *MLH3* (c.3563C>G, p.Ser1188Ter) in five families with profuse or attenuated polyposis (PMID 30573798). Additionally, we found *MSH2* variants in two AFAP cases. To address the contribution of defective DNA repair to polyposis cases with the established susceptibility genes excluded, we scrutinized Finnish and South American cohorts with exome-wide and targeted methods.

Methods: Whole exome sequencing was conducted on 77 index cases and families with unexplained polyposis from the Helsinki University Hospital as well as nationwide Finnish and South American cancer registries. Variants with low population frequencies and predicted potentially pathogenic were selected. Co-segregation and mutational signature analyses were conducted whenever possible.

Results: We observed possibly pathogenic mono-and biallelic germline mutations in 59.7% of the patients. Several DNA repair genes were affected, most notably: *FANCM*, *MLH3*, *MSH2*, *MSH3*, *MUTYH*, *NTHL1*, *POLE* and *POLD1*. An additional polyposis family carrying the MLH3 (c.3563C>G, p.Ser1188Ter) founder variant was discovered. Strikingly, mutation signature analysis on the *MLH3* mutation carriers revealed a conserved signature 3 (defective homologous recombination-based DNA damage repair).

Conclusions: Overall, our results suggest that germline alterations in established and novel predisposition genes contributing to DNA repair may be present in a significant proportion of molecularly unexplained familial adenomatous polyposis cases.

PrgmNr 2019 - Bioinformatics analysis of gene expression profile in haematologic malignancies

View session detail

Author Block: **T. N. Patel**, P. Bhattacharya; Vellore Inst. of Technology, Vellore, India
Disclosure Block: **T.N. Patel:** None.
The study of gene expression profile in cancer enables the researchers to improve classification and characterization of tumors and define novel prognostic parameters. With development of microarray technology, the gene expression signatures have been thoroughly examined to translate this technology into â□□bench to bedsideâ□□. In the present study, we aimed to computationally analyze the differentially expressed genes (DEGs) in haematologic malignancies. The GEO (Gene Expression Omnibus) database was used to curate publicly available Affymetrix microarray datasets correspond to CML, AML, B-CLL, T-ALL, Hodgkinâ□□s and non-Hodgkinâ□□s lymphoma. The datasets were screened via GEO2R to identify the highly upregulated and downregulated genes for which |log (fold change)|â□¥1 and pFLT3, *MYC*, *HDAC9*, *RAD52*) were subjected to molecular docking with ATRA (All-trans retinoic acid) and ATRA like compound, Pumiliotoxin (Natural compound of *C. caesia Roxb.*). The overall results revealed three MMR genes- *MLH3* (upregulated), *MSH4*, and *PMS1* (downregulated) to be differentially expressed in AML, Hodgkinâ□□s lymphoma, and B-CLL respectively. The network analysis aided in identification of 12 DEGs associated with MMR through various pathways further depicting their functional interdependency in haematologic cancers. The enrichment analysis showed involvement of these genes in transcriptional regulation (positive and negative), DNA and transcription factor binding, and DNA repair. The molecular docking predicted that the overexpression of myc/flt3 and hdac9/rad52 can possibly be targeted by Pumiliotoxin and ATRA respectively. We conclude that the molecular perturbation of these 12 DEGs networked with MMR can pose detrimental impact on the genomic integrity and subsequently affect the functionality of mismatch repair. This will eventually accelerate the process of tumorigenesis in blood related cancers. Our study provides a novel insight on the role of â□□robust biomarker signatureâ□□ in modulating MMR in haematologic malignancies.

PrgmNr 2020 - Cancer informatics survey of different grades and subtypes of glioma

View session detail

Author Block: **P. KAUR**[1,2], R. Roy[2], K. W. Johnson[3], B. S. Glicksberg[4,5], L. Subramanian[6], K. Shameer[3], K. Yadav[7]; [1]M. S. Ramaiah Univ. of Applied Sci., Bangalore, India, [2]Molecular Robotics, Cochin, Kerala, India, [3]Mount Sinai Hlth.System, New York, NY, [4]Icahn Sch. of Med. at Mount Sinai, New York, NY, [5]Hasso Plattner Inst. for Digital Hlth.at Mount Sinai, Icahn Sch. of Med. at Mount Sinai, New York, NY, [6]Courant Inst. of Mathematical Sci., New York Univ., New York, NY, [7]Engineering Med., Texas A&M Univ., Houston, TX

Disclosure Block: **P. Kaur:** None.

Gliomas are brain tumors that originate in the glial cells. 'Glioma' is a blanket term used for defining different kinds of glial tumors, including astrocytoma, oligodendroglioma, and glioblastoma. The aggressiveness or malignancy of gliomas varies. While some are slow-growing and potentially treatable, others are invasive, proliferative, and tend to recur. This work aims to investigate the molecular trajectories of different grades of glioma to see how similar they are using a cancer informatics framework. We hypothesize that such a data-driven approach may aid in the discovery of new drug targets and miRNA that can potentially regulate tumor formation, which may benefit treatment and prognosis studies. We have used a translational bioinformatics approach to proceed with the investigation. We used the Disgenet database to retrieve canonical disease gene sets (18 diseases), including three WHO grade-wise tumors and eight WHO grade-wise subtypes of Diffuse astrocytic and oligodendroglia tumors, five other astrocytic tumors, and two high and low-grade tumor datasets. Enrichr-based pathway enrichment analysis revealed Viral myocarditis, Hepatitis B and C, Malaria, Measles, Influenza, Tuberculosis, and Alcoholism were enriched across different sub-types. STRING-db was used to compute protein networks using graph-based metrics, and critical genes such as *LRRC59, CCDC67, TRMT11,* and *TMEM135* were identified in Glioblastoma multiforme, while Cytoscape was used to prioritize candidates. Further evaluation of these targets could lead to identifying shared and distinct pathways associated with gliomas that could be targeted to develop new treatment approaches.

PrgmNr 2021 - Chromatin domains affect the clustered breakpoint formation in complex chromosomal rearrangement

View session detail

Author Block: **H. Inagaki**[1], T. Kato[1], A. Toyoda[2], Y. Makita[3], H. Kurahashi[4]; [1]Fujita Hlth.Univ., Toyoake, Japan, [2]Natl. Inst. of Genetics, MIshima, Japan, [3]Asahikawa Med. Univ. Hosp., Asahikawa, Japan, [4]ICMS, Fujita Hlth.Univ., Toyoake, Aichi, Japan
Disclosure Block: **H. Inagaki:** None.
The next generation sequencing technologies provide us novel views of chromosomes in the cells, such as interactions of the chromosomes, or chromosome conformations in nuclei. The rise of the long-read sequencing technology may offer further information of complex structural variations. We analyzed an autism patient carrying a complex chromosomal rearrangement using a long read sequencer. FISH analysis indicated rearrangements associated with chromosome 1, 2 and 14 as well as Yq12 repeated region. By using 30x high quality reads of around 20 kb library, Pacbio Sequel system successfully identified more than 40 breakpoint junctions. Yq12 shattered fragments as well as chromosome 2 and 14p fragments from ribosomal DNA repeats, ranging within 100 kb, were incorporated randomly into chromosome 1 and 2 breakpoints, representing a chromothripsis-like phenomenon. When the breakpoints were mapped onto the reference sequence, most breakpoints were located in gene bodies in both chromosomes 1 and 2. In addition, the breakpoints in chromosome 2 were found to be clustered in three regions, 2p22.1, 2p21, and 2p16.3. In each cluster, breakpoints were located within a single topologically associated domain, suggesting the fragmented breakage occurred in chromatin domain-dependent manner. On the other hand, such clustered manner was not found in chromosome 1 breakpoints. When the breakpoints in both chromosomes 1 and 2 were mapped with the ENCODE regulation tracks in UCSC web site, most of the breakpoints or breakpoints clusters were near the histone mark, H3K27Ac peaks, determined by ChIP-seq assays. Since the Yq12 repetitive region is specifically transcribed in male germ cells, it is suggested that the all fragmentation including Yq12 likely are transcription-dependent phenomenon. The results suggest that a subset of complex chromosomal rearrangements is related to the transcription, or chromatin states, possibly in spermatogenesis.

PrgmNr 2022 - Deep generative neural network for accurate drug response imputation

Drug response in cancer patients varies dramatically due to inter- and intra-tumor heterogeneity. While many studies have been conducted to identify signature genes or biomarkers to infer drug sensitivity or resistance, few have investigated the significant roles of transcriptome contexts in shaping the eventual treatment outcome. In this study, we developed a deep variational autoencoder (VAE) model to compress thousands of genes into latent vectors in a low-dimensional space which were subsequently used to build prediction models for a total of 251 compounds from two pharmacogenomics projects, Cancer Cell Line Encyclopedia (CCLE) and Genomics of Drug Sensitivity in Cancer (GDSC). The VAE models allowed non-linear compression of >6000 genes and thus, had the advantage to inform rich information across the whole transcriptome, such as the activities of various pathways, transcriptome contexts, and the relative expression levels of genes which might individually play minor roles. We applied rigorous quality assessment and validation to ensure the accuracy of the models in both cell lines and cancer samples. These included assessing the impact of cell line lineage, cross-validation, cross-panel evaluation, and validation in six independent clinical data sets. We demonstrate that using the embedding vectors could accurately impute drug response, outperform standard signature-gene based or linear-compression based approaches, and appropriately control the overfitting problem. Specifically, the component of the observed drug response that can be explained by gene expression achieved a high correlation across the CCLE and the GDSC panels for the 14 shared drugs. When applied to The Cancer Genome Atlas (TCGA) data, we showed that drugs with well-annotated targets confirmed the high quality of the predicted response, such as the ERBB2 inhibitor (Lapatinib), MET inhibitors (Crizotinib/PF2341066, Foretinib, and PHA-665752), BRAF inhibitors (PLX4720 and RAF265) and several MEK inhibitors. Furthermore, drug similarity was replicated using the predicted response both in CCLE cell lines and TCGA cancer samples. Finally, we demonstrated that drug response was associated with tumor microenvironment and tumor heterogeneity. In summary, our deep learning method and the results provided a useful resource to further explore genomic signatures that are associated with drug response.

PrgmNr 2023 - Distinctive miRNA expression profiling of pediatric solid tumors in relation to doxorubicin treatment

View session detail

Introduction: microRNAs (miRNAs) are important posttranscriptional regulators consisting of 20-25 nucleotides that regulate hundreds of mRNA target genesâ expression. Each miRNA can act as oncogene or tumor supressor gene during the proliferation or oncogenesis. miRNAs are predicted to be potential prognostic/diagnostic biomarkers for various diseases in the last decade. Thus in this study we aimed to identify the expression profile of selected miRNAs in childhood tumors for its being the second cause of death between the ages of 5-14 and cardiotoxicity of treatment strategies such as doxorubicin. **Materials methods:** Thirty patients treated with doxorubicin in 2 groups of high and low dose (n=15 in each) who had childhood solid tumors and completed the treatment 2 years ago. Fifteen healthy age and sex matched children as a control group were also included. Forty miRNAs that had been selected due to metaanalysis in relation to disease perpetuation were studied. Total RNA were isolated, then the miRNA expression analysis were performed via Fluidigm, Biomark, USA. **Results:** Sixteen of 40 (40%) miRNAs (miR-126-3p, miR-142-3p, miR-142-5p, miR-148a-3p, miR-150-5p, miR-15a-3p, miR-182-5p, miR-18a-5p, miR-191-5p, miR-20b-5p, miR-223-3p, miR-23b-3p, miR-28-5p, miR-326, miR-423-5p, miR-93-5p) in patients receiving low-dose doxorubicin had a distinctive expression when compared to the control group. However, only 8 (20%) miRNAs (let-7b-5p, miR-150-5p, miR-191-5p, miR-20b-5p, miR-223-3p, miR-23b-3p, miR-342-3p, miR-93-5p) had a significant difference in high dose treated group. Additionally, 3 of 30 patients independent of doxorubicin dose had an ECG monitoring abnormalities. Most interestingly, only miR-191-5p expression was significantly decreased in these patients (p=0.031969). **Conclusion:** miRNA expression profiling is still a promising translational medical research area in relation to adverse events in different treatment modalities such as we present herein pediatric solid tumors.

PrgmNr 2024 - Exploration of hypomorphic variants from VUS in multigene panel testing for Japanese breast cancer patients

View session detail

Author Block: **C. Hata**[1], H. Nakaoka[2]; [1]Natl. Inst. of Genetics, Mishima, Japan, [2]Sasaki Inst., Chiyoda-ku, Japan

Disclosure Block: **C. Hata:** None.

The next generation sequencing technologies together with target enrichment systems dramatically reduce the cost to determine the sequences of multiple genes simultaneously. Thus, multigene panel testing allows us to detect pathogenic mutations that are not discovered by single gene testing. On the other hand, the use of multigene panel produces a large number of variants of uncertain significance (VUS) that have unknown functional effects and uncertain associations with cancer risk. We hypothesize that a small fraction of VUSs detected in multigene panel testing are hypomorphic variants that cause a partial loss of gene function and would be associated with cancer risk. In this study, we scrutinized hypomorphic variants in Japanese breast cancer patients. We used the target sequencing data for 11 breast cancer-related genes in 18,290 Japanese female individuals from Japanese Genotype-phenotype Archive (JGA, http://trace.ddbj.nig.ac.jp/jga), under accession number JGAS000140. The data contains 7,049 patients with breast cancer and 11,241 controls who were 60 years of age or older and did not have a past history nor family history of cancers. Single nucleotide variants and insertions and deletions were detected with the GATK. Variants were classified according to pathogenicity as follows: First, variants were classified as â□□benignâ□□ if their frequencies were greater than 1.0% in the public database in the 1000 Genomes or gnomAD project. Second, nonsense, splice site mutations, and indels were classified as â□□pathogenicâ□□. Third, we explored missense variants with previously established pathogenic or benign effects based on the ClinVar. Fourth, the other missense variants were classified as â□□VUSâ□□. Finally, we used frequency information in general populations and functional prediction scores by bioinformatics tools to detect candidate hypomorphic variants from the VUS.We confirmed that pathogenic variants in BRCA1/2 and PALB2 were significantly overrepresented in the patients with breast cancer. We selected hypomorphic variants from the VUS in 11 breast cancer-related genes. We showed that the detected hypomorphic variants in several genes were associated with breast cancer. The results suggest that a part of VUS have functional effects on cancer-related genes and are associated with the risk of developing breast cancer. Biological and biochemical assays to assess the impact of the candidate hypomorphic variants on protein function are needed.

Introduction: *BRCA1/2* mutations play a significant role in cancer pathogenesis and predisposition particularly in breast, ovarian and prostate cancers. Thus, the detection of germline analysis of *BRCA1* and *BRCA2* is essential for clinical management strategies. Aiming at the identification of recurrent and novel mutations that could be used as a first screening approach. **Material Methods:** We analyzed next generation sequenced germline variants of *BRCA1/2* genes for 2168 individuals who had cancer diagnosis or high risk assessment due to BRCAs related cancers, referred to 10 health care centers distributed across 7 regions covering the all Turkish landscape. **Results:** Overall, 200 and 306 distinct mutations were identified in *BRCA1* and *BRCA2*, respectively. Twenty-five novel variants were reported from both genes while *BRCA2* showed higher mutational heterogeneity. We here in report the collective data as BRCA Turkish consortium that confirm the molecular heterogeneity in BRCAs among Turkish population while also as the first study sharing the both geographical, demographical and gene based landscape of all recurrent and novel mutations which some might be a founder effect in comparison to global databases. **Conclusion:** This wider perspective leads to the most accurate variant interpretations which pave the way for the more precise and efficient management affecting the clinical and molecular aspects.

PrgmNr 2026 - HIVID2: an accurate tool to detect virus integrations in the host genome

View session detail

Author Block: **X. ZENG**; Huazhong Agricultural Univ., Wuhan, China
Disclosure Block: **X. Zeng:** None.
Background Virus integration in the host genome is frequently reported to be closely associated with many human diseases, and the detection of virus integration is a critically challenging task. However, most existing tools show limited specificity and sensitivity. Therefore, the objective of this study is to develop a method for accurate detection of virus integration into host genomes. **Results and discussion** Herein, we report a novel method termed HIVID2 that is a significant upgrade of HIVID. HIVID2 performs a paired-end assembly (PE-assembly) for potentially integrated reads. The resulting sequences are then remapped onto the reference genomes, and both split and discordant chimeric reads are used to identify accurate integration breakpoints with high confidence. HIVID2 represents a great improvement in specificity and sensitivity, and predicts breakpoints closer to the real integrations, compared with existing methods. The advantage of our method was demonstrated using both simulated and real data sets. HIVID2 uncovered novel integration breakpoints in well-known cervical cancer-related genes, including *FHIT* and *LRP1B,* which was verified using protein expression data. In addition, HIVID2 allows the user to decide whether to automatically perform advanced analysis using the identified virus integrations. **Conclusions** By analyzing the simulated data and real data tests, we demonstrated that HIVID2 is not only more accurate than HIVID but also better than other existing programs with respect to both sensitivity and specificity. We believe that HIVID2 will help in enhancing future research associated with virus integration. HIVID2 can be accessed at https://github.com/zengxi-hada/HIVID2/.

PrgmNr 2027 - Mutation profile of circulating cell-free DNA reflects the evolution of metastatic breast cancer

View session detail

Author Block: **J. Kujala**[1], J. M. Hartikainen[1,2], M. TengstrÃ¶m[3], R. Sironen[1,3,4], P. Auvinen[3], V-M. Kosma[1,2,4], A. Mannermaa[1,2,5]; [1]Inst. of Clinical Med., Pathology and Forensic Med., Univ. of Eastern Finland, Kuopio, Finland, [2]Translational Cancer Res. Area, Univ. of Eastern Finland, Kuopio, Finland, [3]Cancer Ctr., Kuopio Univ. Hosp., Kuopio, Finland, [4]Dept. of Clinical Pathology, Kuopio Univ. Hosp., Kuopio, Finland, [5]Biobank of Eastern Finland, Kuopio Univ. Hosp., Kuopio, Finland
Disclosure Block: **J. Kujala:** None.
Background. About 20-30% of breast cancer (BC) patients with early-stage disease will eventually develop recurrent disease and have higher risk for developing metastatic BC. Risk for recurrence can be estimated with clinical and molecular tumor characteristics. However, predictive biomarkers are not uniformly presented in all cancer cells and intratumoral heterogeneity remains as a main cause of therapeutic failure. Patient blood samples contain small fractions of cell-free DNA (cfDNA) that originates from tumor cells and carries tumor-specific somatic variants. Liquid biopsy offers non-invasive and easily repeated method to assess the dynamic landscape of BC and may help to overcome challenges related to intratumoral heterogeneity. Here, we compared the performance of cfDNA-based liquid biopsy to matched tumor biopsies and provide further evidence for the use of liquid biopsy in the molecular profiling of early-stage BC. **Objectives-** To investigate how cfDNA reflects the heterogenic nature of early-stage BC and how differences in the mutational spectrum of cfDNA and tumor reflect the tumor evolution of recurrent BC. **Methods.** Two cohorts of patients with 1) locally advanced breast cancer and 2) early-stage BC who developed recurrent disease despite the good initial prognosis was selected for this study. cfDNA was isolated from patient serum samples and sequenced with targeted sequencing. Results were compared to matched tumors to estimate the concordance between samples. Tumor evolution was modeled with computational and deductive methods. **Results.** Somatic variants were detected especially in common BC associated genes such as *TP53*, *AKT1*, and *PIK3CA*. About 40% of detected variants were predicted as potential driver mutations and 7.5% of the variants as potential drug targets. Mean concordance between matched samples was 53.7%. Strong correlation between the tumor variant allele frequency (VAF) and cfDNA VAF was observed. Tumor evolution models illustrate the accumulation of somatic variants over time and share the characteristics of linear and branched tumor evolution. We were able to track recurrent disease back to primary tumor and detect recurrent-specific somatic variants in the cfDNA prior to secondary diagnosis. **Conclusions.** Somatic variants of BC tumors can be detected from the cfDNA at the time of diagnosis and prior to recurrence. The presence of somatic variants follows the progression of disease and allows the tracking of the tumor evolution when longitudinal samples are available. Discordance between the matched samples highlights the challenges related to liquid biopsy and supports the parallel sequencing of matched tumor and cfDNA.

PrgmNr 2028 - Reversal of Anthracycline Resistance in Colon Cancer cell lines using natural compound Curcumin

View session detail

Author Block: **S. Kanwal**[1,2]; [1]Univ. of the Punjab, Lahore., Lahore, Pakistan, [2]Sch. of Biochemistry and Biotechnology, Lahore, Pakistan
Disclosure Block: **S. Kanwal:** None.
The development of drug resistance is a major limitation of anthracycline usefulness in colon cancer.Multi drug resistance MDR reduces the effect of chemotherapeutics.MDR is mainly caused by overexpression of drug pumps that becomes a hurdle in chemotherapies. The present study aimed at the reversal of the epirubicin resistance in colon cancer cell line HCT116 EPI^{R} by curcumin as a reversal agent.Activity of the Curcumin was examined as a reversal agent by inhibiting the ABCC1 efflux pump by using HCT116 EPI^{R} 250nM cell line.The effective concentration of curcumin was found 5uM by MTT Assay and confirmed by Efflux assay with epirubicin via fluorescence microscopy.Drug accumulation in HCT116 EPI^{R} cells is confirmed when compared to their wild type counterparts and proved epirubicin is reversed by using curcumin. Further research is needed to understand the molecular basis of this resistance.

PrgmNr 2029 - Single cell transcriptomics of Pituitary Neuroendocrine Tumors (PitNETs)

View session detail

Author Block: **M. Brunner**, J. Meylan, A. Messina, M. Messerer, F. Santoni; CHUV, Lausanne, Switzerland
Disclosure Block: **M. Brunner:** None.
The pituitary gland, a master controller of hormones production and secretion driven by the hypothalamus, is a main component of the endocrine system. It is composed of five major cell types of different endocrine functions; somatotropes, corticotropes, lactotropes, gonadotropes and thyrotropes which produce growth hormone (GH), corticotropin (ACTH), prolactin (PRL), follicule stimulating hormone and luteinizing hormone (FSH, LH) and thyroid stimulating hormone (TSH) respectively. As in many other glands or organs, any individual or multiple cell types can abnormally differentiate into tumor cells. But unlike other organs, Pituitary Neuroendocrine Tumors (PitNETs) are almost exclusively adenomas (benign tumors). These tumors are classified based on 3 main characteristics; diameter (micro- or macro-adenoma Â± 1 cm), hormone secreting or non-secreting and invasiveness grade. PitNETs have been extensively characterized over the last decades with several methods; DNA sequencing to discover genome alteration differences between tumor types, Bulk RNA and DNA methylation in order to link those features with tumor invasiveness, prognosis and possible relapses. However, no single cell transcriptomic analysis of PitNETs have been published so far. Here, we present the results of a single cell analysis on our two first tumors, a plurihormonal (GH-PRL) tumor and a corticotropic (*POMC*) macro-adenoma. Characterization of the GH-PRL tumor showed heterogeneous cell populations; structural cells (endothelial and fibroblasts), immune cells (T and dendritic) and tumorigenic cells (GH+ and PRL+). Single cell RNA sequencing based copy number alteration analysis (CopyKat) revealed two distinct cell subset with different alteration pattern. Around 30% shows extensive alterations in chromosomes 9 and 13 while the rest exhibit few or no detectable alterations. Single cell characterization of the second tumor, mainly expressing *POMC* and *TBX19*, showed a major difference: the presence of a proliferating cluster of cells expressing *MKI67* and *TOP2A* markers. Intriguingly, *IQGAP3*, a gene already known to be implicated in different type of carcinomas, was highly expressed in this cluster, raising the question about common features between PitNETs and other types of tumors of endocrine origin. Pseudo-time analysis indicates a possible differentiation path from proliferating cells to *TBX19*+ cells passing by *POMC*+ cells. We planned more analysis of other PitNETs to help the interpretation of these findings and to give a new perspective on the comprehension of the structural composition and the dynamic progression of pituitary tumors.

PrgmNr 2030 - Spatial transcriptomics reveals unique molecular features of fluorescence sorted 5 minolevulinic acid positive infiltrative tumor cells associated with recurrence and poor survival in glioblastoma

View session detail

Author Block: **S. Chakraborty**[1], G. Andrieux[2], T. Das[1], S. Smith[3], R. Rahman[3]; [1]Univ. of Dhaka, Bangaldesh, Dhaka, Bangladesh, [2]Faculty of Med., Med. Ctr.-Univ. of Freiburg, Inst. of Med. Bioinformatics and Systems Med., Univ. of Freiburg, Freiburg, Germany., Freiburg, Germany, [3]Childrenâ□□s Brain Tumour Res. Ctr., Sch. of Med., Univ. of Nottingham, Nottingham, UK, Nottingham, United Kingdom
Disclosure Block: **S. Chakraborty:** None.
Spatiotemporal-heterogeneity of glioblastoma (GBM) originating from the genomic and transcriptional variation in spatially distinct sites, may contribute to subtype switching in GBM prior to and upon recurrence. Fluorescence-guided neurosurgical resection utilizing 5-aminolevulinic acid (5ALA) has enabled the isolation of infiltrative margin tumor cells (5ALA+ cells) from a background of non-neoplastic cells. We have explored the spatial-transcriptomic (ST) landscape to interrogate molecular signatures unique to infiltrating 5ALA+ cells in comparison to GBM core, rim, and invasive margin non-neoplastic cells. ST analysis reveals that GBM molecular subtype plasticity is not restricted to recurrence, but manifests regionally in a cell-type-specific manner. Whilst GBM core and rim are highly enriched with Classical and Proneural subtypes, the unique enrichment of the Mesenchymal subtype (MES) in 5ALA+ cells supports the hypothesis that MES 5ALA+ cells may drive GBM recurrence. Upregulation of the wound response pathway in 5ALA+ cells signifies the possibility of hijacking the wound healing pathway of neural cells to promote tumor growth. Exon-intron split analysis revealed an upregulation of exonic counts for MES and wound-response genes in 5ALA+ cells, implying that these genes are under active post-transcriptional control. Network analysis suggests that wound response genes, including chemokine *CCL2* that recruits regulatory T-cells and monocytic myeloid-derived suppressor cells, are controlled by an IRF8- mediated transcriptional program in 5ALA+ cells. A higher stemness signature both in 5ALA+ cells and non-neoplastic cells of the invasive margin emphasizes the role of this microenvironment in stemness acquisition and defines 5ALA+ cells as a rare sub-population of GBM stem cells. Finally, we establish a link between the unique molecular-signatures of 5ALA+ cells and poor survival and GBM recurrence. Characterization of the 5ALA+ infiltrative sub-population offers an opportunity to develop more effective GBM treatments and urges focus away from the GBM proliferative core, upon which failed targeted therapies have been predicated.

PrgmNr 2032 - *LPA*, KIV2, serum Lp(a), and the risk for Cancer and Cardiovascular disease related pathologies: A retrospective autopsy study

View session detail

Author Block: **M. Yamasaki**[1], M. N. Mieno[2], T. Arai[3], M. Sawabe[4], N. Tanaka[1]; [1]Dept. of Hlth.Data Sci. Res., Hlth.y Aging Innovation Ctr. (HAIC), Tokyo Metropolitan Geriatric Med. Univ., Tochigi, Japan, [3]Dept. of Pathology, Tokyo Metropolitan Geriatric Hosp., Tokyo, Japan, [4]Dept. of Molecular Pathology, Graduate Sch. of Med. and Dental Sci., Tokyo, Japan

Disclosure Block: **M. Yamasaki:** None.

High Lp(a), lipoprotein (a), is known to be a risk factor of cardiovascular disease, while in cancer, low Lp(a) is reported to be a risk factor in our previous study. Lp(a) is composed of apolipoprotein (a) (apo(a)) and apolipoprotein B. Apo(a) contains highly polymorphic kringle domain, encoded by KIV2 (Kringle IV type 2) which is multiallelic copy number variation with about 5.5 kb sequence per copy and have 1 to > 40 copies per allele. High copy number of KIV2 shows low efficiency of membrane permeation and lead low Lp(a) concentration in blood. Heritability of Lp(a) is ~ 90% in European and African population and largely explained by *LPA* gene. Genetic study revealed association of KIV2 copy number and SNPs in *LPA* with cardiovascular disease. However, genetic association between cancer and KIV2 were not largely studied. Therefore, in this study we analyzed association of lifetime risk of cancer with Lp(a), SNPs in *LPA*, and KIV2 among autopsy samples in addition to lifetime risk related to cardiovascular disease. Participants were 304 autopsies from the Tokyo Metropolitan Geriatric Hospital. Lp(a) concentration was measured from fresh blood of the participants using a latex- enhanced turbidimetric immunoassay. DNA was extracted from the renal cortex by the phenol-chloroform method and stored frozen until use. Exome array were performed previously. To measure KIV2 copy number, droplet digital PCR (ddPCR) for these samples were conducted. Following pathological outcomes were used in our analysis; cancer, myocardial infarction, ischemic heart disease, brain infarction, cerebrovascular disease, degree of arteriosclerosis and intracranial atherosclerotic index. In the presentation, we will report association of Lp(a) with SNPs in *LPA* region and KIV2 copy number. In addition, analysis of above outcomes and with Lp(a), SNPs in *LPA* region and KIV2 copy number, adjusting sex, age at death, smoke, alcohol, diabetes, BMI, HDL-C and total cholesterol, will be performed.

PrgmNr 2033 - Trans-ancestry GWASs for ECG markers of ventricular depolarization and repolarization in 250,730 individuals identifies shared and distinct mechanisms

View session detail

Author Block: **W. Young**[1], A. Isaacs[2], N. Lahrouchi[3], B. Mifsud[4], P. B. Munroe[5], C. H. Newton-Cheh[6], N. Sotoodehnia[7], CHARGE consortium EKG working group; [1]Queen Mary Univ. of London, London, United Kingdom, [2]Univ. of Maastricht, Maastricht, Netherlands, [3]Univ. of Amsterdam, Amsterdam, Netherlands, [4]Hamad Bin Khalifa Univ., Doha, Qatar, [5]Queen Mary Univ. of London, London, United Kingdom, [6]Massachusetts Gen Hosp, Boston, MA, [7]Univ. of Washington, Seattle, WA
Disclosure Block: **W. Young:** None.
Background: The QT interval is an important ECG measure of cardiac ventricular electrophysiology. It is the sum of QRS duration and JT interval, which are markers of ventricular depolarization (VD) and repolarization (VR) respectively. Therefore, analyses of QRS and JT give insight into each phase of ventricular electrophysiology. These ECG traits are heritable and are independent predictors of ventricular arrhythmia and sudden cardiac death (SCD). Previous genome-wide association studies (GWAS) for QRS and JT highlighted pathways regulating cardiac ion channels, calcium signalling, myocardial mass and myocyte internal structure. Their heritability, however, remains largely unexplained. We performed the largest GWAS to date for QRS and JT to identify new candidate genes and elucidate novel mechanisms underlying arrhythmogenesis relating to VD and VR. Methods: This trans-ancestry GWAS, using 35 studies imputed with 1000 Genome / HRC reference panels, comprised a total sample of 252,730 individuals (84% European, 7.7% Hispanic and 6.7% African ancestry). Candidate gene prioritisation and gene-set enrichment analyses were performed using DEPICT. Results: We identified 155 and 121 independent loci for JT and QRS, of which 96 and 77 were novel. 41 loci overlapped and at 34 of these, the lead variants were genome-wide significant in both analyses. Discordant directions of effect were observed at 27 (79.4%) of these loci. Lead variants explained approximately 54% and 42% of the heritabilities of JT and QRS. A negative genetic correlation was observed between the traits (r_g = -0.25, P = 0.003). Gene-sets for JT and QRS were highly expressed in cardiac tissues. Additionally, for QRS, connective tissue cell-types, including cardiac valves and chondrocytes, were significant. Common top Gene-Ontology terms included biological processes involved in cardiac/muscle cell differentiation, muscle tissue development and embryonic development (FDR GLUT4, *PIGQ* and *ABCC8*. For QRS, heart/organ growth and transmembrane receptor protein serine/threonine kinase signalling pathway regulation were significant, including genes *GATA4* and *ID2,* which encode a cardiac transcription factor and a transcription regulator. Conclusions: Our analyses highlight novel genes and processes for VD and VR, with shared and distinct mechanisms. These findings may expose new pathways which contribute to arrhythmogenesis and SCD, and could serve as new therapeutic targets.

PrgmNr 2034 - A Novel Method of Identifying Inherited High-risk Population of Atherosclerotic Cardiovascular Disease Using Polygenic Risk Scores of Metabolic Diseases

View session detail

Author Block: **H. Song**[1], Y. Koh[2], T-M. Ree[2], S-Y. Choi[2], S. Kang[3], S-P. Lee[2]; [1]Genome Opinion, Inc., Seoul, Korea, Republic of, [2]Seoul Natl. Univ. Hosp., Seoul, Korea, Republic of, [3]Gangnam Severance Hosp., Seoul, Korea, Republic of

Atherosclerotic cardiovascular disease (ASCVD) is the leading cause of death worldwide and the development of methods to identify high risk population of ASCVD is an important health issue. According to recent studies, the polygenic risk score (PRS) could predict ASCVD risk by use variants associated with the disease itself. However, we do not yet know that how to use polygenic risk of metabolic diseases to predict inherited risk of ASCVD. In this study, we established metabolic disease PRSs and to demonstrate its clinical utility in predicting incident ASCVD using over 40,000 Korean genotypes. We constructed the PRSs for eight quantifiable metabolic phenotypes - systolic/diastolic blood pressure, body mass index, four blood lipid components, and fasting blood glucose - from genome-wide association studies of derivation cohorts (n=37,285) and conducted a grid search of combination of these metabolic disease PRSs to identify the optimal set and weighted score for incident ASCVD prediction. In the independent validation cohorts (n=4,333), the participants in the 5th quintile of each metabolic disease PRS show 1.4~1.9-fold increased risk of incident hypertension, obesity, hyperlipidemia, and diabetes. Using combined metabolic disease PRS model, we identified 6.7% of the population as a high risk group demonstrating a 3.3-fold (1.7-6.1, 95% C.I.; P

PrgmNr 2035 - A translational bioinformatics investigation of the human gut microbiome and hypertensive diseases

Understanding the complex relationship between the human gut microbiota and cardiovascular disease is emerging and of particular interest as diet plays a critical role in the severity and outcome of cardiovascular diseases. We hypothesize that understanding host-microbe dynamics could help understand novel disease pathways and help develop microbiome-driven therapeutics. This study explores the role of human gut microbiota in individuals with hypertension using a translational bioinformatics analytics framework involving meta-analyses, gene enrichment analysis, cross-genome metabolic pathway comparisons, and drug repositioning. Eight major hypertensive disorders, namely, diastolic hypertension, elderly hypertension, grade 3 hypertension, pulmonary artery hypertension, portal hypertension, systolic hypertension, preeclampsia, and primary hypertension, were selected. We linked important microbial genera to these disorders using a data discovery approach. We identified 12 taxa (*Bacteroides, Blautia, Faecalibacterium, Bifidobacterium, Escherichia, Prevotella, Streptococcus, Eubacterium, Akkermansia, Parabacteroides, Roseburia,* and *Clostridium*) using data compiled in MuPhenome. According to our findings, 915 human genes were associated with eight hypertensive diseases. We discovered 75 metabolic pathways shared by these microorganisms and distinct hypertensive disorders. Pathways co-modulated by host and microbes implicated in hypertensive genes include amino-acid metabolism, mannose degradation, glycerolipid metabolism, nucleotide metabolism, metabolism of tRNA, folate metabolism, and fatty acid beta-oxidation. Few drugs were found to be effective against the three genomic targets, namely *PAH* (Sapropterin), *PDE5A* (Sildenafil, Tadalafil, Udenafil, and Vardenafil), *PDGFRB* (Sorafenib), XDH (Allopurinol), which are suggesting potential drug repositioning opportunities. Further research focusing on co-metabolic pathways and genes implicated in host-microbe interaction might aid in developing gut-microbiome-based therapies against hypertensive diseases.

PrgmNr 2036 - Genome-wide association study of lipids in Greenlandic Inuit show large-effect size and independent associations and reveals a unique genetic architecture

Objective: Perturbation of the lipid homeostasis is a key risk factor for cardiovascular disease (CVD), the leading cause of death worldwide. We aimed to investigate the role genetics plays for lipid levels, and via these CVD, in Greenlanders. **Methods:** Using imputed data from 4473 Greenlanders, we performed a genome-wide association study (GWAS) of levels of six blood lipids and lipoproteins: triglycerides, LDL-cholesterol, HDL-cholesterol, total cholesterol, apolipoprotein A1, and apolipoprotein B. For relevant genome-wide significant variants, we then tested for associations with additional traits and outcomes, including risk of CVD and RNA expression. Finally, we investigated the combined effect of the independent genome-wide significant variants using genetic risk scores (GRSs). **Results:** The GWAS identified 11 genome-wide significant loci, of which 9 were known. Two were potentially novel, however, they were more frequent in Europeans and not Bonferroni significant and therefore need independent replication to be validated. In the *PCSK9* locus, we identified an association signal, which was independent of the well-described *PCSK9* loss-of-function variant rs11591147. The derived allele of the lead SNP, rs4927191, in this locus was associated with lower levels of LDL-cholesterol (beta(SD)=-0.226, p=1.24e-12) and total cholesterol (beta(SD)=-0.169, p=2.28e-9). Interestingly, it was also associated with a lower risk of peripheral artery disease (hazard ratio=0.30 per allele, p=0.01), and was a top eQTL signal for *PCSK9* across all tissues in GTEx. A variant (rs12117661) in LD with the lead SNP showed similar results, and there were furthermore indications of rs12117661 being located in a predicted regulatory element. When combining the GWAS hits into GRSs using 10-fold cross-validation, these scores alone explained up to 16.3% of the variance of the lipid traits. Furthermore, the GRSs for LDL-cholesterol, total cholesterol and apolipoprotein B were associated with increased risk of several types of CVD events. **Conclusion:** We identified a possible causal variant that affected lipid levels and CVD risk by regulating the expression of *PCSK9*. Furthermore, we found that in the Greenlandic population much more of the variance in lipid levels can be explained with markedly fewer variants than in large European populations, supporting a marked difference in genetic architecture.

PrgmNr 2037 - Integration of biomarker polygenic risk score improves the prediction of coronary artery disease in UK Biobank and FinnGen

View session detail

Author Block: **J. Lin**[1], N. Mars[1], Y. Fu[1], J. P. Ripatti[1], FinnGen, S. Ripatti[1,2,3], M. Pirinen[1,2,4]; [1]Inst. for Molecular Med. Finland, Helsinki, Finland, [2]Publ. Hlth., Helsinki, Finland, [3]Broad Inst. of Massachusetts Inst. of Technology and Harvard Univ., Cambridge, MA, [4]Dept. of Mathematics and Statistics, Helsinki, Finland

Disclosure Block: **J. Lin:** None.

Smoking history, age, levels of blood pressure, cholesterol, lipoproteins and inflammation are established biomarkers for coronary artery disease (CAD). As canonical polygenic risk scores (PRS) have recently proven successful for CAD prediction, it remains of high interest to determine to what extend a meta-biomarker score (metaPRS) constructed from statistically relevant biomarkers can contribute upon the established CAD PRS predictions. We derived metaPRS scores using SNPs selected from 16 genome-wide association studies of CAD related biomarkers from the UK Biobank (UKB) with 322,058 (5.45% cases) white, unrelated subjects, subsampled into training and validation sets. Statin-adjusted optimal biomarker subsets for incident CAD were identified via data regularization using glmnet. The SNPs of interest were selected using PRS-CS (Ge et al.) and LD-pruning and p-value clumping and then integrated with the canonical genome-wide PRS score from Khera et al. (KheraBiomPRS). These scores were tested on the UK Biobank data and on 306,287 (10.04% cases) subjects within the Finnish FinnGen study. Within the UKB training set, we constructed and contrasted metaPRS scores from a 10 biomarker (optimal fit; 25,677 SNPs) and 15 biomarker (minimum cross-validation (mincv) error; 33,476 SNPs), mincv PRS-CS (1,103,911 SNPs) models and tested them on UKB validation and FinnGen cohorts. We found that PRS-CS biomarker PRS models yielded the highest adjusted variance explained (R^2) scores. Within the training set, the hazard-ratio (HR) for KheraPRS was 1.64 (1.61-1.67) per one standard deviation, and for KheraBiomPRS HR was 1.68 (1.64-1.73) for the optimal model 1.69 (1.66-1.73) for the mincv model and 1.72 (1.69-1.75) in the PRS-CS model. Within the FinnGen study, the HR for KheraPRS was 1.53 (1.51-1.55), and the HR for KheraBiomPRS was 1.55 (1.53-1.57) for both the optimal and mincv models while the HR for PRS-CS model was 1.57 (1.55-1.59). Comparing the 99% quantile against the 40-60% reference group in UKB, KheraPRS had HR of 4.39 (3.93-4.91) while the mincv model had HR of 4.80 (4.30-5.35), compared with 4.79 (4.29-5.35) for the PRS-CS model. In FinnGen, the corresponding 99% quantile HR values were 3.42 (3.16-3.70) for KheraPRS while KheraBiomPRS had HR 3.45 (3.19-3.73) for the mincv model and increased to 3.63 (3.36-3.92) for the PRS-CS model. The largest KheraBiomPRS HR gain of 24% was found in the early CAD onset (age Integration of meta-biomarker PRS improves on the existing canonical CAD PRS predictions although the gain might be smaller across populations.

PrgmNr 2038 - Multivariate genetic analysis of human plasma glycerophospholipids, glycerolipids, sphingolipids and sterols identifies novel associations near *LPGAT1*, *GRIP1*, *SGPL1* and *ERMP1*

Disclosure Block: **L. Ottensmann:** None.
The human plasma lipidome, composed of thousands of lipid species, captures information beyond the routinely clinically used lipids and have disease relevance in cardiometabolic diseases and beyond. Genome-wide association studies (GWAS) of individual lipid species (univariate analysis) have identified many lipid-associated loci, however the influence of genetic variants on lipid metabolism and cardiovascular disease risk is still not fully understood. Multivariate analysis of multiple correlated lipid species improves statistical power and could help identify additional lipid loci. We performed univariate and multivariate analysis using lipidome data.

We conducted univariate GWAS of 11.3 M variants and 7177 participants from the Finnish GeneRisk cohort with the software MMM for 104 glycerophospholipids, 44 glycerolipids, 15 sphingolipids and 16 sterols and sterol esters. We grouped the lipid species into 11 clusters based on their correlations and performed multivariate analyses for each cluster by metaCCA software. The univariate and multivariate associations were fine-mapped with FINEMAP to identify causal SNPs underlying the associations. The putative causal variants were examined for associations with cardiometabolic traits in FinnGen (Release 6), Gene Atlas (UKBB) and GWAS Atlas.

Multivariate analysis across 11 clusters identified 79 loci with P-value 3 Mb apart from each other. In addition to well-known lipid loci such as *FADS1-2-3*, *CPT1A* and *NTAN1*, we identified four new loci *LPGAT1* (*rs143208479*, *rs28432809*), *GRIP1* (*rs118025056*), *SGPL1* (*rs12763964*) and *ERMP1* (missense variant *rs140094646*), at a Bonferroni-corrected significance threshold of P-value SGPL1 reached the Bonferroni-corrected significance threshold in a univariate analysis (Cer42:2;2) highlighting the additional statistical power provided by multivariate association test. Additionally, in the univariate analysis, a novel association near *AP005242.1* (*rs554083837*) was identified for four phosphatidylcholine species. SNPs *rs143208479* and *rs28432809* near *LPGAT1* are associated with ulcerative colitis with primary sclerosing cholangitis in FinnGen (P=2e-5) and mean reticulocyte volume in Gene Atlas (P=2e-9) respectively.

Multivariate genetic analysis is a powerful tool for high-dimensional data such as lipidomics and helped us identify four novel lipid-associated loci: *LPGAT1*, *GRIP1*, *SGPL1* and *ERMP1*, of which only the locus *SGPL1* was also identified by the univariate analysis.

PrgmNr 2039 - Rare Variant Analysis for Coronary Heart Disease Cases and Controls using Whole Genome Sequencing in a Middle Eastern Population Identifies Potential Novel Genes

View session detail

Author Block: **E. Ullah**[1], K. Kunji[1], A. El-Menyar[2], I. J. Kullo[3], M. Saad[1], J. Al Suwaidi[2]; [1]Qatar Computing Res. Inst., Hamad Bin Khalifa Univ., Doha, Qatar, [2]Hamad Med. Corp., Doha, Qatar, [3]Dept. of Cardiovascular Med., Mayo Clinic, Rochester, MN
Disclosure Block: **E. Ullah:** None.
Background: Rare variants can contribute to the missing heritability of complex diseases such as coronary heart disease (CHD). With advances of next generation sequencing and their decreasing cost, the analysis of rare variants has become more feasible. Rare variant analysis can provide new insights to the etiology of complex diseases.
Methods: In a Middle Eastern cohort from the Qatar Cardiovascular Biorepository, Qatar Genome Programme, and Qatar Biobank, whole genome sequencing (WGS) with 30x coverage was conducted on coronary heart disease patients (n=1,067, mean age Â± SD = 59.96 years Â± 10.99; 70.32% males) and controls (n=6,170, mean age Â± SD = 40.02 years Â± 12.56; 43.45% males). Burden and SKAT gene-based analyses were performed via a linear mixed model accounting for age, sex, BMI, and principal components using SMMAT. We included rare variants within genes with MAF **Results:** All statistical distributions were well controlled. Using a Bonferroni threshold (*P*-6), a total of 10 and 15 genes were significant using burden and SKAT analyses, respectively. These genes are *SLC22A5* (2 variants, burden $P=1.14x10^{-13}$, SKAT $P=3.79x10^{-18}$), *RP11-468E2.6* (2 variants, burden $P=1.22x10^{-9}$, SKAT $P=1.94x10^{-10}$), and *WBSCR22* (3 variants, SKAT $P=9.42x10^{-7}$). Mutations in *SLC22A5* can cause carnitine deficiency and the gene is a regulator of lipid metabolism. Common SNPs within this gene were also associated with low density lipoprotein cholesterol. *WBSCR22* has been associated with Williams-Beuren Syndrome, whose most significant medical problem is cardiovascular diseases caused by narrowed arteries. Among the less significant genes, we identified *APOB* (4 variants, burden $P=1.22x10^{-4}$, SKAT $P=6.04x10^{-5}$) and *NUP93* (2 variants, burden $P=1.78x10^{-3}$, SKAT $P=1.44x10^{-4}$). SNPs near *NUP93* have been associated with high density lipoprotein cholesterol, and ApoA1 and ApoB measurements.
Conclusions: Rare variant analysis has identified novel genes with potential biological link to CHD in a Middle Eastern WGS cohort. Further studies are needed to validate these genes.

PrgmNr 2040 - Sex-stratified whole genome sequencing association study for coronary heart disease in a middle eastern population suggests differential loci

View session detail

Author Block: **K. Kunji**[1], E. Ullah[1], A. El-Menyar[2], I. J. Kullo[3], M. Saad[1], J. Al Suwaidi[2]; [1]Qatar Computing Res. Inst., Hamad Bin Khalifa Univ., Doha, Qatar, [2]Hamad Med. Corp., Doha, Qatar, [3]Dept. of Cardiovascular Med., Mayo Clinic, Rochester, MN
Disclosure Block: **K. Kunji:** None.
Introduction: There has been a dearth of genome-wide association studies (GWASs) in Middle Eastern populations for complex diseases such as coronary heart disease (CHD). CHD diagnosis and progression are male/female differential. There are only a few sex-stratified CHD GWASs, which were performed in European ancestry cohorts.
Hypothesis: We hypothesize that there are differences in the genetic etiology of CHD between males and females.
Methods: We performed a sex-stratified GWAS on CHD using whole genome sequencing data in a Middle Eastern population consisting of 713 male CHD patients and 2,588 male controls (mean age Â± SD = 58.75 yrs Â± 11.54 and 39.76 yrs Â± 12.18, respectively) and 301 female CHD patients and 3,368 female controls (mean age Â± SD = 59.46 yrs Â± 9.54 and 40.22 yrs Â± 12.85, respectively). Association testing was conducted for the autosomal and X chromosomes in each sex separately using linear mixed models. Fisherâ□□s meta-analysis was performed on the X chromosome to identify SNPs associated in both sexes. We assessed the performance of a polygenic risk score, metaGRS, for each sex.
Results: Previously reported loci/genes were replicated in our analysis at P CDH13, *MIR548A3*, *PRKG1*/*A1CF*, and *REST* in females; *TRIM5*, *ARHGAP42*, *ILR6*, and *MYO9B* in males). We also found suggestive loci (P PCSK5 and *PTGS1* in females; *HRC*, *CSNK2A1* and *PLCB1* in males). Area under the receiver operating curve of metaGRS was similar between the sexes (~0.68). However, OR per 1 SD increase was lower in females (1.46 [1.29 - 1.64]) than in males (1.78 [1.58 - 1.99]). The top Fisherâ□□s SNP is by *P2RY4*, EDA (binds *EDA2R*, prior association).
Conclusions: Our study replicates different known CHD loci in females and males and suggests new genes. Good performance of metaGRS was observed for both sexes, but the lower OR per 1 SD in females suggests a stronger result for males.

PrgmNr 2041 - The penetrance of rare cardiomyopathy-associated DNA variants: a cross-sectional approach to estimate penetrance using large case series

View session detail

Author Block: **K. McGurk**[1], X. Zhang[2], P. Theotokis[1], K. L. Thomson[3], A. R. Harper[4], Cardiac Variant Interpretation Consortium, M. Farrall[4], H. Watkins[3], L. Bottolo[5], J. S. Ware[6]; [1]Natl. Heart and Lung Inst., Imperial Coll. London, London, United Kingdom, [2]European Bioinformatics Inst., Hinxton, United Kingdom, [3]Radcliffe Dept. of Med. and the Wellcome Trust Ctr. for Human Genetics, Univ. of Oxford, Oxford, United Kingdom, [4]Radcliffe Dept. of Med. and the Wellcome Trust Ctr. for Human Genetics, Univ. of Oxford, London, United Kingdom, [5]Dept. of Med. Genetics and the MRC Biostatistics Unit, Univ. of Cambridge and the Alan Turing Inst., Cambridge, United Kingdom, [6]Natl. Heart and Lung Inst., Imperial Coll. London; MRC London Inst. of Med. Sci.; Cardiovascular Res. Ctr. at Royal Brompton and Harefield Hosp., London, United Kingdom
Disclosure Block: **K. McGurk:** None.
Inherited cardiomyopathies (CM) are characterised by clinical and genetic heterogeneity, incomplete and age-dependent penetrance, and variable expressivity. Understanding the penetrance of disease-causing variants identified in families with disease or as secondary findings in the population is of paramount importance. Genes associated with CM account for 23% of the ACMG73 genes, where opportunistic screening for secondary findings is recommended, yet our understanding of penetrance for an individual â□□pathogenicâ□□ variant found in this setting is extremely limited.Current longitudinal cohorts may be informative for rare variants aggregated within a gene, but data for individual variants remain sparse given rarity. To address this, we estimated variant-specific penetrance for rare CM-associated variants through aggregation of data from large multi-centre case cohorts comprising >10,000 hypertrophic CM (HCM) cases and 2,300 dilated CM (DCM) cases, using a cross-sectional approach that compares variant frequencies between affected individuals and reference populations (UK Biobank and gnomAD), and avoids the biases inherent in family studies. We identified 1,290 rare variants in 3,724 HCM cases (37%) and 604 rare variants in 756 DCM cases (34%). We report three sets of variants; i) 1015 variants found in cases but not identified in the population (caseAC>0, popAC=0; HCM n=740, DCM n=275), ii) 573 variants observed in a single case (caseAC=1, popAC>0; HCM n=265, DCM n=308), and most importantly (iii) 306 variants found multiple times in cases and controls (caseAC>1, popAC>0; HCM n=285, DCM n=21) for which a penetrance estimate can be computed. Reliable penetrance estimates for even a modest proportion of variants will be hugely impactful. For example, the most prevalent 50 variants observed recurrently in cases (caseAC>=10) account for about 1/3 of genetically explained cases (50 variants found in 1,182 individuals represent 32% of all G+ cases). The mean penetrance for these 50 variants is 35% (+/- 29% SD). This is the first dataset to report penetrance of individual recurrent variants at scale, and will inform the management of families with CM, and of individuals undergoing opportunistic genetic screening for secondary findings.

PrgmNr 2042 - Transferability of genetic loci and polygenic scores for cardiometabolic traits in ~22,000 British Pakistani and Bangladeshi individuals from a real-world healthcare cohort

Disclosure Block: **Q. Huang:** None.

South Asian-ancestry individuals have higher risk of heart disease than other ancestries. However, most genetic research has focused on European-ancestry individuals. It is largely unknown whether genetic loci and polygenic scores (PGS) associated with cardiometabolic traits are transferable from European-ancestry to British Pakistani and Bangladeshi individuals. Clinical utility of PGS has been shown in research settings. However, these findings may not generalise well to a real-world clinical setting, because many research cohorts are composed of volunteers who are healthier than the general population (e.g. UK Biobank), with clinical measures taken more comprehensively. The robustness of PGS applied to non-European individuals in a real-world healthcare system is largely unknown. To address these questions, we analysed data in Genes & Health (G&H), a British Pakistani and Bangladeshi cohort with linked electronic health records (N=~22,000). Two-thirds of people were recruited in healthcare settings. 97.4% of G&H participants are in the lowest two quintiles of the Index of Multiple Deprivation in the UK. We conducted genome-wide association studies (GWAS) of coronary artery disease (CAD), body mass index (BMI), lipid biomarkers and blood pressure in G&H. Trans-ancestry genetic correlations between UK Biobank Europeans and G&H for the tested traits were not significantly lower than 1 except for BMI which was nominally so (r_g=0.85, p=0.02). We observed high transferability of established loci with high power to replicate (â□□transferableâ□□) in G&H. We found evidence for sharing of causal variants between the two populations at 47-56% of the transferable loci associated with lipids and 26% of the transferable loci associated with BMI. PGS that were developed using data from primarily European-ancestry individuals showed variable transferability in G&H, with the relative accuracy compared to individuals of European ancestry (ratio of incremental R^2) â□¥95% for HDL-C, triglycerides, and blood pressure, but relatively lower for BMI (78%) and CAD (42%; ratio of incremental AUC). We observed significant improvement in categorical net reclassification in G&H (NRI=3.9%; 95% CI: 0.9-7.0%) when adding a previously developed CAD PGS to a clinical risk score (QRISK3). In conclusion, the genetic loci for CAD and its risk factors are largely transferable from European-ancestry studies to British Pakistanis and Bangladeshis, whereas the transferability of PGS varies greatly between traits. Our analyses indicate clinical validity for addition of PGS to existing clinical risk prediction tools in primary prevention settings for this population.

PrgmNr 2043 - Whole Genome Sequencing Association Study for Coronary Heart Disease in a Middle Eastern Cohort Validates Polygenic Risk Scores and Replicates Known Loci

View session detail

Author Block: **M. Saad**[1], K. Kunji[1], A. El-Menyar[2], E. Ullah[1], I. J. Kullo[3], J. Al Suwaidi[2]; [1]Qatar Computing Res. Inst., Hamad Bin Khalifa Univ., Doha, Qatar, [2]Hamad Med. Corp., Doha, Qatar, [3]Dept. of Cardiovascular Med., Mayo Clinic, Rochester, MN
Disclosure Block: **M. Saad:** None.
Background: The potential use of polygenic risk scores (PRSs) in clinical practice is tempered by concern about their portability among diverse populations. To prevent disparities in genomic medicine, there is an urgent need to conduct genome-wide association studies in non-European ancestry cohorts.
Methods: We conducted whole genome sequencing (WGS) with 30x coverage on coronary heart disease patients (n=1,067, mean age Â± SD = 59.96 years Â± 10.99; 70.32% males) and controls (n=6,170, mean age Â± SD = 40.02 years Â± 12.56 SD; 43.45% males) in a Middle Eastern cohort to compare the performance of available PRSs for CHD (LDpred, metaGRS, lassosum, and P+T) and identify common variants associated with CHD (via generalized linear mixed models).
Results: Excepting lassosum, all PRSs performed well. LDpred and metaGRS performed similarly (AUC= ~0.685) and outperformed P+T (AUC=0.667). Based on the OR per 1 SD increase (OR_{1sd}), P+T (OR_{1sd}=1.85 [1.69-2.02], P=3.69x10^{-41}) outperformed other PRSs (OR_{1sd}=1.61 [1.48-1.74], P=3.02x10^{-31} for LDpred and OR_{1sd}=1.61 [1.49-1.75], P=9.47x10^{-31} for metaGRS). After binning PRSs into 10 deciles, the odds of CHD in the top decile compared to all others was highest for metaGRS (3.87 [3.07-4.88]) and LDpred (3.45 [2.74-4.341]). Thirty-two known GWAS loci (e.g., *ABCG8*, *CELSR2*, and *SLC22A4*) were replicated in our analysis with *P*-5. Seven suggestive new loci/genes (*P*-6) with relevant biological function were identified (e.g., *CORO7*, *RBM47*, and *PDE4D*). The well-established 9p21 locus was not replicated.
Conclusions: Genome-wide PRSs derived from European ancestry cohorts performed well in a Middle Eastern cohort. Further studies are needed to develop and validate an ancestry specific PRS and to confirm the suggestive loci/genes.

PrgmNr 2044 - A whole genome sequencing study in a three-generation consanguineous family with morbid obesity, learning difficulty and failure of weight loss surgery, to identify susceptibility variants for obesity

View session detail

Author Block: **L. Al-Olabi**[1], N. Chami[2], S. K. Radha[1], Y. Wu[2], K. Musa[1], Y. Itan[2], A. J. Buckley[1], R. J. F. Loos[2], N. Lessan[1]; [1]Imperial Coll. London Diabetes Ctr., Abu Dhabi, United Arab Emirates, [2]The Charles Bronfman Inst. for Personalized Med., Icahn Sch. of Med. at Mount Sinai, New York, NY
Disclosure Block: **L. Al-Olabi:** None.

Background

Family and twin studies show that genetic factors account for 40-70% of inter-individual variation in Body Mass Index (BMI). Monogenic obesity is rare, accounting for up to 6% prevalence in morbidly obese populations, with at least 10 genes currently identified. Within a population, genetic variation mediates inter-individual differences in susceptibility to the obesogenic environment and may also contribute to the inter-individual variation reported in weight loss outcomes following bariatric surgery.

Consanguinity has been key in the elucidation of many Mendelian and complex genetic diseases. Here, we combined the power conferred by consanguinity with genome sequencing for discovery of (rare) genetic variants in obesity.

Methods

We investigated a consanguineous Emirati family of 29 individuals with a history of morbid obesity. The proband had first-cousin parents and presented with morbid obesity, type 2 diabetes, with a history of gastric bypass which was later reversed and followed by a sleeve gastrectomy surgery years later. Onset of obesity in childhood was reported for the majority of individuals in the second and third generations. The proband was diagnosed with dyslexia, learning difficulty and Attention Deficit Hyperactivity Disorder (ADHD). Same features were self-reported in eight family members; one grandchild was diagnosed with ADHD. Nine of the eleven second generation siblings gave a history of at least one bariatric surgery; eight of these regained weight. Only one female sibling in the second generation, maintained a BMI within the normal range without surgical intervention. We looked for shared variants among individuals with the most severe obesity. Thus, analyses was performed in five individuals that still had obesity after at least one weight loss surgery, or those that did not have surgery but who have morbid obesity (BMI â¥40).

Results

The probandâ□□s karyotype was reported as normal. Array-based comparative genomic hybridization was negative and whole exome sequencing did not identify any causal variants in the proband. Thus, whole genome sequencing was carried out for 10 family members. Preliminary results from the genome analysis identified 25 rare nonsynonymous coding variants with a minor allele frequency

Conclusions

We have identified candidate variants including single nucleotide variations, deletions and insertions in genes, involved in signaling pathways that play an important role in processes linked to obesity. These results are currently being validated by Sanger sequencing.

PrgmNr 2045 - Deep shotgun metagenomic sequencing and functional profiling of the gut microbiota identifies associations with kidney function

View session detail

Author Block: **C. Nowak**[1], S. Sayols-Baixeras[2], G. Baldanzi[2], S. Ahmad[2], Y-T. Lin[2], K. F. Dekkers[2], GUTSY Research Collaboration, M. Orho-Melander[3], T. Fall[4], J. Ã□rnlÃ¶v[1,5,6]; [1]Karolinska Inst.t, Stockholm, Sweden, [2]Uppsala Univ., Uppsala, Sweden, [3]Lund Univ., MalmÃ¶, Sweden, [4]Uppsala Univ., Uppsala, Uppsala, Sweden, [5]Dalarna Univ., Falun, Sweden, [6]Region Dalarna, Falun, Sweden
Disclosure Block: **C. Nowak:** None.
Background: The human gut microbiota is composed of the bacteria, fungi and other microorganisms that live in the lower intestines in a symbiotic relationship with the host. Disruption of the gut microbiota has been associated with cardiovascular and metabolic diseases, but the association with kidney disease is still largely unknown. **Methods:** We studied the composition and predicted function of the gut microbiota based on shotgun whole-genome sequencing of microbial DNA in fecal samples collected from 9,788 adults enrolled in the longitudinal, population-based Swedish SCAPIS cohort study. Linear regression adjusted for technical variables, age, sex, Shannon diversity index and (in sensitivity analysis) established kidney disease risk factors was used to identify associations between the log(x+1)-transformed relative frequencies of 1,900 metagenomic species and estimated glomerular filtration rate (eGFR). The Benjamini-Hochberg false discovery rate (FDR) multiplicity correction was used. **Results:** We included 5,130 women (57.5Â±4.3 years) and 4,658 men (57.6Â±4.4 years). The mean eGFR was 86.5Â±11.3 for men, and 85.5Â±12.1 for women. Amongst all participants, 42% had an eGFR above 90, 39% had an eGFR between 75-90, 17% had an eGFR between 60-75, 2% had an eGFR between 45-60, and less than 0.1% had an eGFR below 45. In the age- and sex-adjusted model, we identified four bacteria that were associated with eGFR at an FDR Eubacteriales (two bacteria), *Coriobacteriales*, and *Veillonellales*. Gene set enrichment analysis indicated significant (FDR Conclusions: In the largest gut microbiome association study of kidney function in adults to date, we discovered four bacteria whose abundance was associated with glomerular filtration rate. The functional enrichment of kidney function-associated microbiota provides further insights into its possible role in kidney health.

PrgmNr 2046 - Estimation of variance explained by polygenic risk score of Crohnâ□□s disease and ulcerative colitis using Korean versus European GWAS

View session detail

Author Block: **S. Jung**[1], B. Ye[2], H-S. Lee[1], J. Baek[1], D. Park[1], Y. Kim[1], Y. Lee[1], S. Park[2], S-K. Yang[2], B. Han[3], J. Liu[4], K. Song[1]; [1]Dept. of Biochemistry and Molecular Biology, Univ. of Ulsan Coll. of Med., Seoul, Korea, Republic of, [2]Dept. of Gastroenterology, Asan Med. Disclosure Block: **S. Jung:** None.
Recently polygenic risk score (PRS) attracted increasing interest from clinical community for their predictive value for multiple common diseases. The PRS estimates an individualâ□□s genetic liability to disease based on genotype profile and relevant genome-wide association study (GWAS) data. One of the most challenging aspects of moving PRS to the clinical use is ensuring that they are equally applicable to all health care users across ethnic groups. In this study, we compared the performance of the variance explained by PRS of Korean Crohnâ□□s disease (CD) and ulcerative colitis (UC) (725 CD, 1001 UC, and 378 controls) based on Korean (KOR) versus European (EUR) data using PRSice-2. The effect sizes were extracted from independent CD (KOR: 896 cases & 4,041 controls, EUR: 12,194 cases & 28,072 controls) and UC (KOR: 573 cases & 4,041 controls, EUR: 12,366 cases & 33,609 controls) GWAS. Despite the European studies had much larger samples size, PRS derived from Korean data (PRS_{KOR}) explained up to 14.3 % of phenotype variance of CD whereas those derived from European data (PRS_{EUR}) explained 9.9%. In contrast, for UC, the variance explained by PRS_{EUR} was far better than those explained by PRS_{KOR} (11.8% vs. 7.3%). After removing all SNPs in the *TNFSF15* and *HLA* region with the largest effect size in CD KOR GWAS, the variance explained by PRS_{KOR} became smaller than the variance explained by PRS_{EUR}. This suggested that the large variance explained by PRS_{KOR} might have been driven by these two loci with population-specific effects. The results highlight the need to perform large-scale genetic analyses in diverse populations and create tools for population genetic admixture to achieve an equitable benefit of PRS for IBD patients.

PrgmNr 2048 - HLA haplotype determines treatment response to GAD-alum immunotherapy in Type 1 diabetes: An applied example of a genetic precision medicine approach to pivotal clinical trial design

View session detail

Author Block: **U. Hannelius**[1], M. Widman[1], J. Ludvigsson[2]; [1]Diamyd Med., Stockholm, Sweden, [2]Div. of Pediatrics, Dept. of BioMed. and Clinical Sci., Faculty of Med. and Hlth.Sci. and Crown Princess Victoria Childrenâ□□s Hosp., LinkÃ¶ping Univ., LinkÃ¶ping, Sweden
Disclosure Block: **U. Hannelius:** Major Stockholder/Ownership Interest; Diamyd Medical. Salary/Employment; Diamyd Medical.
Background: Type 1 diabetes (T1D) results from an autoimmune destruction of insulin-producing beta cells. There is a great unmet need for disease-modifying treatments and antigen-specific immunotherapy using recombinant glutamate decarboxylase (GAD65) protein has shown mixed results across the broad population of T1D patients. Disease heterogeneity poses great challenges for clinical development in T1D, and a precision medicine approach targeting genetically defined subgroups can provide a solution. Our meta-analysis of 521 children and young adults (Hannelius et al. *Diabetologia* 2020, PMID: 32754804) with recently diagnosed T1D positive for GAD antibodies showed that recombinant GAD65 conjugated to aluminium hydroxide (GAD-alum/DiamydÂ®) had a significant and dose-dependent effect on the preservation of endogenous insulin secretion (stimulated C-peptide) over a 15 month period in patients carrying the HLA DR3-DQ2 haplotype, whilst no effect was seen in patients lacking DR3-DQ2. An even stronger effect was seen in patients with HLA DR3-DQ2 lacking the DR4-DQ8 haplotype. These HLA-specific effects were subsequently confirmed in a randomized double-blind placebo-controlled phase IIb trial (DIAGNODE-2, Ludvigsson et al. *Diabetes Care* 2021, PMID:34021020). Updated meta-analysis including the phase IIb data (n = 627) strengthened the results for C-peptide preservation and showed a significant effect on blood glucose control (reduction in HbA1c). **Implementation**: Diamyd Medical is launching a randomized double-blind placebo-controlled 24-month phase III trial (DIAGNODE-3) in the genetically defined population of recent-onset T1D patients carrying the HLA DR3-DQ2 haplotype (ca. 35% of all patients). Randomization will be stratified by the presence or absence of DR4-DQ8 (ca. 50% of DR3-DQ2-positive patients) and co-primary endpoints will be change in stimulated C-peptide and HbA1c. We will summarise the results from the meta-analyses and phase IIb trial and present details on the genetic precision-medicine strategy used in the design of the DIAGNODE-3 trial, including a broader rationale for the role of HLA subtypes in the response to antigen-specific treatment in T1D. **Conclusion**: We highlight the strategic and scientific rationale for the first pivotal phase III trial of a disease-modifying treatment for T1D based on a precision medicine approach applying a genetic marker to identify patients most likely to benefit.

PrgmNr 2049 - Selection pressures affecting Type 2 Diabetes in a South Indian and Scottish population

View session detail

Author Block: **C. Nangia**[1], S. Srinivasan[1], R. Venkatesan[2], V. Mohan[2], C. N. A. Palmer[1]; [1]Univ. of Dundee, Dundee, United Kingdom, [2]Madras Diabetes Res. Fndn., Chennai, India
Disclosure Block: **C. Nangia:** None.
Evolutionary forces have shaped how human populations respond to complex diseases. Type 2 Diabetes (T2D) in particular, has shown extensive genetic and phenotypic diversity worldwide. Selection studies can help identify the mechanisms underlying the diversity within and between populations. In this study, we aim to identify signatures of positive selection that have contributed to the phenotypic diversity between a Scottish and a novel South Indian T2D population.The study cohorts consisted of Scottish T2D individuals from the Genetics of Scottish Health Research Register (GoSHARE) study (n=6,681) and Genetics of Diabetes Audit and Research Tayside (Go-DARTS) study (n=9,487). South Indian T2D individuals were from the Madras Diabetes Research Foundation (MDRF)-cohort 1 (n=6,056) and cohort 2 (n=4,562).Whole genome pairwise F_{ST} was done on 12,737 T2D individuals from GoSHARE and MDRF cohort 1. High F_{ST} Single Nucleotide Polymorphisms (SNPs) were taken for further analysis. This was followed by tests for selective sweep - Tajimaâ□□s D and Nucleotide diversity. Candidate SNP association study with 13 phenotypes including Age at onset, anthropometry, blood pressure and lipids (age and sex adjusted; and sex stratified) was done in both the populations. Conditional analysis, fine mapping and gene expression studies were also done. A metanalysis of 4,855 high F_{ST} SNPs in 16,168 Scottish T2D individuals (GoDARTS and GoSHARE) showed the *ADAMTS9* locus to be significantly associated with obesity parameters - BMI and weight (*rs4422297,* prs16891982 (*SLC45A2*, pHLA locus was found to be significantly associated with age at onset, HDL and Triglycerides (*rs9273242, rs9273415* and *rs9273410* respectively, pSLC45A2 locus only in the Scottish population. No association was found in a metanalysis of the 2 Indian T2D cohorts. The results showed positive selection and association of the alleles in the Scottish cohort. BMI results favoured selection in the protective alleles indicating a non-thrifty genotype. The selective forces of these variants in the Scottish population do not appear to be due to an obesity related trait and may possibly represent pleiotropy due to other pressures such as exposure to infectious diseases. HLA results suggested immune-mediated beta cell dysfunction which may result in a less dyslipidemic form of diabetes. Absence of positive associations in the South Indian cohort was possibly due to gene-environment interactions.

PrgmNr 2050 - Validation and risk score applicability of T2D related variants in populations of East Asians and Europeans

View session detail

Author Block: **Y. Kim**, H-M. Jang, M. Hwang, B-J. Kim; Div. of Genome Sci., Dept. of Precision Med., NIH, Heungdeok-gu, Chungcheongbuk-do, Korea, Republic of
Disclosure Block: **Y. Kim:** None.
Genome-Wide Association Study (GWAS) enabled us to obtain unprecedented number of variants responsible for various diseases and related traits. With growing number of variants, polygenic risk score using discovered variants has gathered much attention in its application to clinical practice. However, majority of GWASs have been conducted in populations with European ancestry. These Euro-centric bias would lead a reduction in predicting diseases for non-Europeans. Therefore, discovered variants should be validated in trans-ethnic populations along with more GWASs in non-Europeans. In this study, we validated previously reported variants associated with type 2 diabetes (T2D) and related traits and its risk score applicability in East Asians (Korea Biobank Array(KBA), n=125,872) and Europeans from UK Biobank (UKB, n=337,475). As of Jan 2021, there were 8,823 variants associated with glycemic traits, lipids, liver enzymes, and T2D in GWAS catalog database. Based on the availability of imputed datasets in both KBA and UKB, 4,466 variants were selected for further analysis. The selected variants were further reduced to 2,913 variants considering linkage disequilibrium among the variants (r^2 50,000) implicating possible insufficient statistical power in this study. Risk score applicability was observed using T2D genetic risk score (GRS). T2D GRS was calculated using the selected variants and effect sizes from KBA, UKB, and trans-ethnic meta-analysis using KBA and UKB summary statistics. As expected, T2D-GRS using effect sizes from same population (KBA: 6.3%, UKB 5.1%) showed enhanced variance explained over T2D-GRS using effect sizes from different populations (KBA: 5.3%, UKB 4.1%). Also, trans-ethnic meta-analysis based T2D-GRS showed comparable performance to those of GRS using effect sizes from same population. This implicates trans-portability of T2D-GRS among populations. The validation results from our study provide valuable scientific evidence in using discovered variants and its risk score applicability across populations.

PrgmNr 2051 - Whole genome analysis of 342 adult cases of obesity and related metabolic disorders in highly consanguineous population

View session detail

Background: Recent advantages allowing for direct sequencing of whole genomes or exomes offers the most comprehensive approach for extending discovery efforts to the detection rare sequence variants with large effects. Coupled with information about human disease and other traits, an unparalleled opportunity currently exists to identify rare coding variants with in genes that cause disease. Metabolic disorders like Obesity, Polycystic and type-2-diabetes (T2D) represent a worldwide epidemic that impose an enormous burden on public health. The Saudi population with one of the highest rate of consanguineous unions and high prevalence of both obesity and or T2D is ideal for identification, through whole-genome sequencing, of homozygous mutations with large effect on obesity and T2D. Method: A prospective study conducted at King Fahad Medical City (2019-2021) in Riyadh. All required ethical approval and consents obtained. Patients recruited from Obesity, and endocrinology clinics. DNA from 342 Saudi individuals (265 females and 83 males. Average age is 45-year-old. Average Body Mass Index (BMI) is 37.5) with high prevalence of obesity and/or T2D underwent whole-genome sequenced using illumine platform. 83 of the females also diagnosed with polycystic ovary syndrome (PCOS). Sequence variants called, annotated and screened for homozygous coding mutation that segregate with endocrinological disorders like obesity and/or T2D, PCOS within these patients. Result: Most samples show detectable inbreeding as expected. Average number of homozygous loss-of-function mutations per case is 0.9-1.2. Multiple known/expected pathogenic mutations identified in genes like *ABCC2, UPB1, HRG, FLT4, MSH3, TRAPPC2, CD36, CEL* and other. Likely pathogenic variants include: *PLIN1, LIPE, PAX4*. Homozygous/Hemizygous loss-of-function (LOF: essential splice, frameshift, stop gained) also reported as â□□Private â□□for our cohort in multiple novel genes (not in OMIM) like: *WDR54, ASB12, USP26, CTAG2, ZXDA*, and others. Conclusion: The Saudi population is one of the highest rate of consanguineous unions and high prevalence of both obesity and other related metabolic disorders. By analyzing whole-genome data from Saudis with obesity and/or T2D/ PCOS, we found homozygous mutations that identify novel genes that are causal in these conditions. Our data will provide insight into the pathophysiology of these conditions and potentially new targets for therapeutic developments.

PrgmNr 2052 - *HLA-A*11:01:01:01*, *HLA*C*12:02:02:01-HLA-B*52:01:02:02*, age and sex are associated with severity of Japanese COVID-19 with respiratory failure

Disclosure Block: **S. Khor:** None.

Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), the virus causing coronavirus disease 2019 (COVID-19) was announced as an outbreak by the World Health Organization (WHO) in January 2020 and as a pandemic in March 2020. The majority of infected individuals have experienced no or only mild symptoms, ranging from fully asymptomatic cases to mild pneumonic disease. However, a minority of infected individuals develop severe respiratory symptoms. The objective of this study was to identify susceptible HLA alleles and clinical markers for the early identification of severe COVID-19 among hospitalized COVID-19 patients. A total of 137 patients with mild COVID-19 (mCOVID-19) and 53 patients with severe COVID-19 (sCOVID-19) were recruited from the Center Hospital of the National Center for Global Health and Medicine (NCGM), Tokyo, Japan for the period of February-August 2020. High-resolution sequencing-based typing for eight HLA genes was performed using next-generation sequencing. In the HLA association studies, HLA-A*11:01:01:01 [P_c = 0.013, OR = 2.26 (1.27-3.91)] and HLA-C*12:02:02:01-HLA-B*52:01:01:02 [P_c = 0.020, OR = 2.25 (1.24-3.92)] were found to be significantly associated with the severity of COVID-19. After multivariate analysis controlling for other confounding factors and comorbidities, HLA-A*11:01:01:01 [P = 3.34E-03, OR = 3.41 (1.50-7.73)], age at diagnosis [P = 1.29E-02, OR = 1.04 (1.01-1.07)] and sex at birth [P = 8.88E-03, OR = 2.92 (1.31-6.54)] remained significant. Early identification of potential sCOVID-19 could help clinicians prioritize medical utility and significantly decrease mortality from COVID-19.

PrgmNr 2053 - Applying the regional heritability mapping method to primary biliary cholangitis in the Japanese population

The development of GWAS in the early 2000s has contributed greatly to the discovery of susceptibility genes associated with complex traits. At the same time, the limitations of single-SNP GWAS have also created a need for other approaches, such as the regional heritability mapping (RHM) method, which makes use of multiple adjacent SNPs jointly to estimate the genetic effect of a given region of the genome. Although simulation studies have shown that RHM in many cases has higher detection power than single-SNP GWAS, it has been used so far primarily in agricultural research. In this study, we applied the RHM method to primary biliary cholangitis (PBC) in the Japanese population to assess its potential for the discovery of new susceptibility genes in human diseases. We identified three novel loci (*STAT4, ULK4,* and *KCNH5*) at the genome-wide significance level, two of which (*ULK4* and *KCNH5*) have not been found associated with PBC in any population previously. Importantly, these three genes could not be detected by using conventional single-SNP GWAS. Our results underscore the potential of the RHM method for the discovery of new loci in human diseases, and provide strong empirical evidence that RHM is a useful tool that can be used as an effective complement to single-SNP GWAS. In addition, we conducted an analysis of liver tissue mRNA microarray data, which revealed higher gene expression levels in *ULK4* in PBC patients (P

PrgmNr 2054 - Common, low frequency, rare and ultra-rare variants contribute to COVID-19 severity

Disclosure Block: **A. Renieri:** None.

Host genetics is an emerging theme in COVID-19. A handful of common polymorphisms and some rare variants have been identified, either through GWAS or candidate gene approach. However, an organic model is still missing. We applied a gene based approach to Whole Exome Sequencing data of 2,200 SARS-CoV-2 infected subjects with different outcomes, from very severe to oligo-asymptomatic, within GEN-COVID cohort. Common, low frequency, rare and ultra-rare variants were tested separately. Autosomal genes were tested separately from genes on the X chromosome. LASSO logistic regression was applied under the assumption of either dominant or recessive phenotype. Both sexes were tested together and separately. Among 18,347 tested genes, about 2,000 genes were found to be involved after multiple train-test splits. Among these, Â¼ of genes was sex specific. These latter genes are under sexual hormone control, such as testosterone down-regulated TLR3 gene or estrogen down-regulated TLR5 gene, and exert their effect in one sex only. Integrated PolyGenic Score (IPGS) was calculated as ($n_{mildness}$ - $n_{severity}$ common) + F1 ($m_{mildness}$ - $m_{severity}$ low-frequency) + F2 ($x_{mildness}$ - $x_{severity}$ rare) + F3 ($y_{mildness}$ - $y_{severity}$ ultra-rare), where F is a weighting factor taking into account that the impact of protein function inversely correlates with frequency. The weighting factor for ultra-rare is so high that, when the ultra-rare is present, the model simulates Mendelian inheritance such that it happens in TLR7 ultra-rare variants, which we and others proved to be an inherited X-linked form of COVID-19. IPGS is able to improve prediction of clinical outcome in addition to the already known powerful factors, such as age and comorbidities, and profiles a specific genetic signature for adjuvant therapy. A platform of clinical trials based on genetic markers has been submitted to Italian Drug Agency AIFA. This is the first modelling of a genetic complex disease taking into account whole variability from common to ultra-rare variant and it can be translated to many other complex disorders.

PrgmNr 2055 - Comprehensive analysis of HLA association in Japanese with childhood-onset nephrotic syndrome

View session detail

Author Block: **X. Jia**[1], S-S. Khor[2], Y. Kawai[3], T. Horinouchi[4], K. Iijima[5], K. Tokunaga[3]; [1]Natl. center for global Hlth. and medicine, Tokyo, Japan, [2]Natl. Graduate Sch. of Med., Kobe, Japan, [5]Hyogo Prefectural Kobe Childrenâ□□s Hosp., Kobe, Japan
Disclosure Block: **X. Jia:** None.
Background: Idiopathic nephrotic syndrome (INS) is the most common kidney disease in children. Corticosteroids are used as the first-line treatment and are effective in around 80% pediatric patients (steroid-sensitive nephrotic syndrome, SSNS). About 10-20% patients showed resistant to the steroid therapy and have poor outcome, which are named as steroid-resistant nephrotic syndrome (SRNS). *HLA-DR/DQ* region has been highlighted as the most important genetic factor by previous genome wide association studies (GWASs) in multiple populations. Methods: To obtain a comprehensive understanding of *HLA* association with childhood INS, pediatric patients with SSNS (N=1,088), SRNS (N=266) and healthy adults (N=3,331) with Japanese ancestry were recruited. Samples were genotyped by Japanese-specific Affymetrix â□□Japonica Arrayâ□□. Fourteen HLA genes (*HLA-A, -C, -B, -DRB1, -DQB1, -DPB1, -DRA, -DQA1, -DPA1, -DPA2, -DMA, -DMB, -DOA* and *-DOB*) were imputed at 3-field level using Japanese-specific reference panel by â□□HIBAGâ□□. Results: In total, 838 SSNS patients, 220 SRNS patients and 2,822 controls passed the post quality control using a cut-off threshold (CT) >= 0.4 for the probability of imputed HLA genes. *HLA-DRB1*08:02:01-DQB1*03:02:01* was the most significant risk factor associated with Japanese childhood INS (SSNS vs. controls: OR=3.31 [2.55-4.29], P-corrected=1.33E-21; SRNS vs. controls: OR=6.29 [4.46-8.79], P-corrected=9.22E-35). *HLA-DQA1*01:02:01* was identified as the most significant protective allele for childhood INS (SSNS vs. controls: P-corrected=2.01E-28, odds ratio [OR]=0.28 [0.22-0.35]; SRNS vs. controls: P-corrected=7.36E-10, OR=0.22 [0.13-0.36]). *HLA-DRB1*08:02:01-DQB1*03:02:01* showed an increased frequency in SRNS patients than SSNS patients (13.2% in SRNS while 7.4% in SSNS, P-corrected=2.24E-03, OR=1.90 [1.34-2.67]). Conclusions: We clarified *HLA* factors associated with childhood INS and the responsiveness to steroid therapy in the Japanese population using high resolution HLA-imputation, providing deeper insight into the disease mechanism and useful biomarker for predicting patientsâ□□ responsiveness to steroid treatment.

PrgmNr 2056 - Effective way that determining mild or severe COVID-19 patient only using T-cell receptor(TCR) sequencing data

View session detail

Author Block: **J. Han**; Seoul Natl. Univ., Dept. of BioMed. Sci., Seoul, Korea, Republic of
Disclosure Block: **J. Han:** None.
Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) led to the coronavirus disease 2019 (COVID-19) pandemic situation. Furthermore, until now, people do not fully understand SARS-CoV-2 even though there are already a lot of mild or severe patient sequencing data who suffer from COVID-19. SARS-CoV-2 have ignored peopleâ□□s immune system including T cell activity, easily infecting many people, and at last have arisen the pandemic situation. Therefore, analysing these dozens of patients T-cell receptor(TCR) sequencing data is seriously important because it would give us insight into researching SARS-CoV-2 mutation phenotypes and preparing other severe viruses after COVID-19 situation. Here, we compare TCR clustering toolsâ□□ accuracy to which tool most nearly puts T-cells together normal control, mild or severe patientâ□□s groups by only using subject TCR sequencing data.

Background: Eosinophils play a key role in the allergic response in asthma by the release of cytotoxic molecules such as eosinophil cationic protein (ECP) and eosinophil-derived neurotoxin (EDN) that generate epithelium damages.
Objective: We aimed to identify genetic variants influencing ECP and EDN levels in asthma-ascertained families of European ancestry.
Methods: We conducted univariate and bivariate genome-wide association analyses of these proteins in 1,018 subjects from the EGEA study with follow-up in 153 subjects from SLSJ study and performed meta-analysis to combine evidence from the two datasets. We then conducted Bayesian statistical fine-mapping together with in silico quantitative trait locus and functional annotation analyses to identify credible sets of variants and target candidate genes.
Results: We identified four genome-wide significant loci (*P*-8) including six distinct signals associated with ECP and/or EDN levels. These six signals were located on 14q11, 7p21, 1p31 and 9q22 chromosomal regions. Four of the six distinct signals were fine-mapped to small credible sets of putative causal variants including at most 10 SNPs with sum of posterior inclusion probability (PIP) of at least 95%. Moreover, two of these credible sets related to 7p21 region included a SNP with high PIP (greater than 0.7). Functional annotation analyses and the literature showed that genes targeted by these SNPs have biological relevance related to the pathophysiological mechanisms of eosinophil activity and asthma: *RNASE2* and *RNASE3* (14q11) encode EDN and ECP respectively; *AK4* (1p31) codes for an adenylate kinase that has been shown to regulate several inflammatory genes; *NDUFA4* (7p21) codes for a component of the mitochondrial respiratory chain; and *CTSL* (9q22) encodes a lysosomal cysteine proteinase involved in the immune response and has previously been identified as part of a gene module associated with childhood-onset asthma.
Conclusion: This study highlights the interest of joint analysis of biological phenotypes involved in the pathophysiological mechanisms of asthma to increase power to detect new loci and potentially functional genes.

PrgmNr 2058 - Genetic diversity and epidemiology of human rhinovirus among children with severe acute respiratory tract infection in Guangzhou of China

View session detail

Author Block: **H. LI**, W. LI, B. Xue, Z. Deng; Jinan Univ., Guangzhou, China
Disclosure Block: **H. Li:** None.
Human rhinovirus (HRV) is one of the major viruses of acute respiratory tract disease among infants and young children. HRV is increasingly recognized not only as a cause of mild upper respiratory tract infection, but also in more severe lower respiratory tract infections, such as pneumonia, bronchiolitis and asthma. HRVs, members of the family *Picornaviridae* and the genus *Enterovirus*, are positive-sense, single-stranded-RNA (ssRNA) viruses of approximately 7,200 bp. The viral genome consists of a single gene whose translated protein is cleaved by virally encoded proteases to produce 11 proteins. HRVs were classified into three species, HRV-A, -B, and-C based on phylogenetic sequence criteria. Nasopharyngeal swabs from a total of 655 children with acute respiratory illness in the Guangdong Maternal and Child Health Hospital and Huaqiao Hospital were obtained from August 2018 to December 2019. HRV was screened for by a real-time reverse-transcription PCR targeting the viral 5â□²UTR. HRV was detected in 6.41% of the 655 specimens. Among these 40 positive samples, HRV infection was frequently observed in children under 2 years old (57.13%). HRV-A and HRV-C were detected in 18 (45%) and 22 (55%) specimens. Children who experienced rhinorrhoea were more common in the HRV-C infection patients than HRV-A. The viral load was higher in HRV-C detection group than HRV-A detection group (p = 0.0148). The median peak symptom score was higher in patients with HRV-C infection as compared to HRV-A (p = 0.0543), even though the difference did not reach significance. Our findings expand knowledge of HRV infectionsâ□□ clinical spectrum.

PrgmNr 2059 - Genetic Similarity Assessment of Qatar and Italy Populations in the context of COVID-19

COVID-19 continues to spread worldwide with over three million deaths to date and rising. However, this global spread is coupled with stark anomalies in morbidity and mortality. These differences can be observed not only between different populations but also within the same population. Host genomic information, specifically genomic variations, may characterize susceptibility to disease and identify people with a higher risk of harm, leading to a better targeting of care and vaccination. Italy was the epicenter for the spread of COVID-19 in Europe, the first country to go into a national lockdown and has one of the highest COVID-19 associated mortality rates. Qatar on the other hand, despite having one of the highest worldwide number of laboratory-confirmed cases, has a very low mortality rate.In this study we compared whole-genome sequencing data of 14398 adults and Qatari-national, to 925 Italian individuals. We also included in the comparison whole-exome sequence data from 196 Italian laboratory confirmed COVID-19 cases. We focused our study on a curated list of 3619 candidate genes involved in innate immunity and host-pathogen interaction. Two population-gene metric scores, the Delta Singleton-Cohort variant score (DSC) and Sum Singleton-Cohort variant score (SSC), were applied to estimate the presence of selective constraints in the Qatari population as well as the Italian cohorts.Results based on DSC & SSC metrics demonstrated a different selective pressure on some gene between Qatari and Italian populations. Example of these genes include TLR3 and IFNAR1 which are already reported by other recent studies to be involved in life-threatening COVID-19 cases.This study highlighted the genetic differences between Qatari and Italian populations and identified a subset of genes involved in innate immunity and host pathogen interaction.

With the aim of exploring host genetic factors underlying COVID-19 severity, the Genetics Of Mortality In Critical Care consortium (GenOMICC) and Genomics England are recruiting participants with severe and mild COVID-19. Our previous work in the GenOMICC consortium revealed therapeutically-targetable variants underlying life threatening COVID-19 (Pairo-Castineira et al. 2020). Working with the global Host Genetics Initiative consortium (HGI), we have shown that the strongest genetic signals are present in the critically ill population. However, most previous work, including our own, has used genotyping arrays and largely focused on a subset of common genetic variation. In order to facilitate a high-resolution analysis of the genome and exploration of all types of genetic variation underlying disease risk, we are performing whole-genome sequencing (WGS) of up to 35,000 participants with severe and mild COVID-19. To increase statistical power, we are combining these data with WGS data generated through the 100,000 Genomes Project from a wide range of ancestral backgrounds. Recruitment is ongoing with successive rounds of analysis and data freezes being made available in a cloud-based research environment to facilitate international research efforts. Our latest data freeze consists of over 10,000 individuals with COVID-19, including the largest WGS cohort of critically ill COVID-19 patients assessed to-date. GWAS analysis of data on a freeze of 4,677 patients, replicated genetic associations previously identified by us, HGI and other groups on chromosomes 3,12,19, and 21. The WGS data enabled precise fine-mapping that narrowed down the 3p21.31 association cluster to two independent signals. Trans-ancestry GWAS analysis showed that one of the association signals on 3p21.31 can be independently replicated in multiple ethnicities but with significantly different effect sizes, underscoring the heterogenous impact of genetic ancestry on COVID-19. Rare variant burden analyses have yet to identify robustly any genes associated with severe COVID-19, which is consistent with other recent findings (Kosmicki et al. 2021). Our study provides the first comprehensive investigation of the contribution of rare and common genetic variation on COVID-19 disease outcomes using large scale WGS data, which will be instrumental in elucidating the genomic architecture of the disease and inform therapeutic interventions.

PrgmNr 2061 - Identification of causal genetic variants in invasive pneumococcal diseases by exome analysis in children

View session detail

Author Block: **M. GÃ©lin**[1], S. Limou[1], P-A. Gourraud[1], A. Durand[1], O. Rousseau[1], C. Gras-Leguen[2], F. Lorton[2], E. Launay[2], N. Vince[2]; [1]CRTI, UniversitÃ© de Nantes, Nantes, France, [2]UniversitÃ© de Nantes, Nantes, France

Invasive pneumococcal diseases (IPDs) are still severe diseases in the pediatric population, despite major progress in vaccination and therapeutics. Apart from the pathogen virulence factors, host individual characteristics, including host genetic factors, are implicated in the susceptibility and severity to these diseases. Further understanding of the molecular factors involved in the development of these severe infections could lead to better treatment, prevention, and thus better outcome. Previous studies identified several candidate genes for IPDs, however, mostly because of methodological shortcomings, these results are yet to be confirmed. Our study aimed to identify rare coding genetic variants implicated in the development of IPDs through a large-scale genetic strategy using whole-exome sequencing (WES) of 32 children admitted in the pediatric intensive care unit for IPD. Contrary to most previous studies related to IPDs, we chose an untargeted approach to identify novel variants. We developed a bioinformatic analysis pipeline to identify rare, non-synonymous and possibly pathogenic variants implicated in IPDs. The pipeline was designed to identify genetic variants and annotate their Minor Allele Frequency (MAF) and their possible pathogenicity according to several tools: VEP, ANNOVAR, InterVar and CADD. Furthermore, we compared the variant distribution observed in our patients to an unrelated control population (n = 69) in order to validate our pipeline and discoveries. We identified 86 rare variants at the heterozygous state in 18 different genes, including 7 genes previously associated to immunological functions, inflammation, or infectious diseases: *AHNAK2, AK2, CFTR, CYP4F2, ESRRA, FCGBP* and *PABPC1.* The control population presented significantly fewer variants ($p=7.6x10^{-24}$) in fewer genes ($p=7.8\ x10^{-27}$): 5.8 variants in 3.1 genes / individual *vs* 14.9 variants in 10.5 genes / individual in the IPD population. Our results have therefore revealed multiple heterozygous variants in a restricted set of genes for each patient presenting an extreme phenotype of pneumococcal disease, emphasizing the likely polygenicity of IPD risk. We will pursue our effort in better characterizing these associations using *burden test* strategies. In conclusion, these first results suggest an unprecedented immune deficiency involving several rare mutations in immune-related genes.

PrgmNr 2062 - Identifying novel causative mutations forDOCK8 immunodeficiency syndromeusing whole exome sequencing

View session detail

Author Block: **R. Noroozi**[1,2]; [1]Jagiellonian Univ., Krakow, Poland, [2]Malopolska Ctr. of Biotechnology, Jagiellonian Univ., Krakow, Poland

DOCK8 immunodeficiency syndrome (DIDS) is a rare autosomal recessive (AR) disorder characterized by elevated serum IgE levels, eosinophilia, recurrent cutaneous infections, severe eczema, and sinopulmonary and gastrointestinal infections. This syndrome is a multisystem disease that is associated with both immune deficiency and neurological complications. In this study, we describe the clinical characteristics of two Iranian patients with DOCK8 deficiency and propose possible mechanisms for this condition. By using whole-exome sequencing (WES), we identified two novel mutations, namely c.3233_3234del AG (p.Q1078fs) in exon 6 and a large deletion with 94 kb (c.405-3231 deletion, p.K135fs), in these two patients. These variations are confirmed with Sanger sequencing and CGH array. The subsequent co-segregation analysis is performed to identify inheritance patterns. Both patients were homozygote, and their parents were heterozygote for the variations. For further investigation, prediction tools were applied to identify the pathogenicity of the variations and for modeling the truncated proteins. The patients did not show neurological abnormalities associated with a deficiency of the N terminal region of DOCK8. The absence of neurological complications in the first patient is justifiable due to the maintenance of the proline-rich region in DOCK8, but for the second patient with expanded deletion which is almost like null DOCK8 protein, it is not presumable, pointing to the fact that the C terminal region of the protein might have functions in the proliferation and migration neurons in the peripheral nervous system. Alternatively, neurological abnormalities may follow an age-dependent pattern, leading to the appearance of related symptoms later in life. Further multiple functional studies are needed to model different identified variants in animal models to confirm our results and suggest possible mechanisms associated with DOCK8 deficiency in this study.

PrgmNr 2063 - PADI4 and PADI2 enhance collagen-initiated inflammatory responses

View session detail

Author Block: **A. Suzuki**[1], T. Shibuya[1], K. Yamamoto[2]; [1]RIKEN, Yokohama, Japan, [2]RIKEN Ctr. for Integrative Med. Sci., Yokohama, Kanagawa, Japan

Previously, peptidylarginine deiminase type 4 (PADI4) was identified as a susceptibility gene for Rheumatoid arthritis (RA) by genome-wide association studies. Peptidyl citrulline is a target antigen of anti-citrullinated peptide antibodies (ACPAs), and only PADs (translated protein from PADI genes) can provide peptidyl citrulline via modification of protein substrates. Also the distribution of PADI4 and PADI2 has overlap in immune cells. The aim of this study was to investigate the relationship between PADI4 gene and PADI2 gene in the progression of RA. To clarify the physiological function of PADI4 and PADI2 in RA, we used collagen-induced arthritis (CIA), known as a RA model mouse. We examined that localization of PAD4 and PAD2 protein was indicated by immunohistochemistry in CIA mice. We also measured expression of Padi genes and various inflammatory cytokines in immune cells by real-time TaqMan assay and ELISA, respectively. We generated PADI4â□□/â□□ and PADI2â□□/â□□ mice and performed experimental arthritis. We demonstrated that the clinical disease score was significantly decreased in PADI4â□□/â□□ mice and PADI4 expression was induced by CII immunization. In PADI4â□□/â□□ mice sera, serum anti-type II collagen (CII) IgM, IgG, and inflammatory cytokine levels were also significantly decreased compared with those in wild-type mice sera. Interestingly, PADI2 expression was compensationally induced in CD11b+ cells of PADI4-/- mice. Furthermore, we examined that the clinical disease score of CIA mimce and expression levels of Padi genes in PADI2â□□/â□□ CIA mice. It appeared that collagen-initiated inflammatory responses were reduced in PADI2â□□/â□□ CIA mice. However, gene expression levels of CIA of Padi2 using wild type mice was not observed significant difference between CIA and control mice. As the one of the reason, it is possible that the loss of function of the Padi2 gene may affect the reduction of the arthritis score not due to gene expression levels.
This study was supported by Grants-in-Aid for Scientific Research (C).

PrgmNr 2064 - rs1944919 on human chromosome 11q23.1 and its effector genes *COLCA1* and *COLCA2* confer susceptibility to primary biliary cholangitis

Disclosure Block: **Y. Hitomi:** None.

Primary biliary cholangitis (PBC) is a chronic and cholestatic autoimmune liver disease caused by the destruction of intrahepatic small bile ducts. The higher monozygotic/dizygotic (MZ/DZ) ratio and the higher estimated relative sibling risk (Î»s) in PBC patients as compared to unaffected individuals indicates the involvement of strong genetic factors in the development of PBC. Our previous genome-wide association study (GWAS) identified chromosome 11q23.1 (including *POU2AF1*, *COLCA1*, and *COLCA2*) as the susceptibility locus for PBC in the Japanese population. Although candidate genes with well-known functions that are located in susceptibility loci (i.e. *POU2AF1*) have often been reported as disease susceptibility genes in GWASs, the identification of effector genes regulated by primary functional variants is necessary to understand the contribution of susceptibility loci to pathogenesis. Here, in order to analyze the disease susceptibility of all genetic variations, we carried out high-density association mapping of chromosome 11q23.1 based on single nucleotide polymorphisms (SNPs) imputation using data from a whole-genome sequence reference panel of 1,070 Japanese individuals and our previous GWAS. Subsequent *in silico* and *in vitro* functional analyses identified rs1944919 as the primary functional variant. Expression-quantitative trait loci (e-QTL) analyses in the esophageal mucosa showed that rs1944919 was significantly associated with expression levels of *COLCA1 and COLCA2* (P = 3.8 Ã□ 10^{-29} and P = 6.5 Ã□ 10^{-32}, respectively) whose function have not been fully elucidated. Concordant association was detected in e-QTL analysis in B-cell (P = 0.00023 and P = 0.00040, respectively). Despite a distance of 100 kb between the *COLCA* genes and rs1944919, chromatin interactions between rs1944919 and upstream sequences of the *COLCA1/COLCA2* was detected in GM12878 cells. Additionally, the effects of rs1944919 on *COLCA1/COLCA2* expression levels were confirmed using genotype knock-in versions of Raji (human B lymphocytes) and Jurkat (human T lymphocytes) constructed using the CRISPR/Cas9 system and differed between rs1944919-G/G clones and -T/T clones (P COLCA1 and *COLCA2* are the effector gene regulated by the primary functional SNP rs1944919, and that increased expressions of *COLCA1/COLCA2* might be involved in the pathogenesis of PBC.

Background: Recent studies on the association of SARS-CoV-2 variants with COVID-19 outcomes have been reported, focusing on variant of concerns (VOC). However, studies on the impact of other mutations within spike (S) protein of SARS-CoV-2 on COVID-19 illness are very limited. Moreover, virulence of SARS-CoV-2 might be affected by geographic condition. We determined: 1) association between SARS-CoV-2 variants within S protein besides VOC and COVID-19 outcomes, and 2) phylogenetic analysis of isolates from our region.

Methods: Whole genome sequences of SARS-CoV-2 was determined by Illumina MiSeq next-generation sequencer followed by phylogenetic analysis of full-genomes of SARS-CoV-2 from different regions.

Results: Clinical manifestations of 51 patients with COVID-19 were without any symptoms (13.7%), mild (47%), moderate (19.6%), severe (4%), critical (2%), and died (13.7%). Age of hospitalized patients (53.4 Â± 18 years) was higher than non-hospitalized patients (34.6 Â± 19) (p=0.001). A significant association between diabetes, hypertension, and anticoagulant and hospitalization was noted with p-value of 0.039 (OR=4.47 [95% CI=1.07-18.58]), 0.001 (OR=17 [95% CI=2-144]), and 0.02 (OR=27.97 [95% CI=1.54-507.13]), respectively; whereas a strong association between patientsâ□□ age, diabetes, anticoagulant, steroid and mortality was revealed with p-value of 0.016 (OR=8.44 [95% CI=1.5-47.49]), 0.019 (OR=8.5 [95% CI=1.43-50.66]), 0.001 (46.8 [95% CI=4.63-472.77]), and 0.009 (OR=15.75 [95% CI=2-123.86]), respectively. The viruses were classified as clade L (2%), GH (84.3%), GR (11.7%), and O (2%). Besides D614G, the most common variants in S protein were L5F (18.8%), V213A (18.8%), and S689R (8.3%). No significant association between multiple S protein variants and either hospitalization or mortality (p=0.11 and 0.69). Multivariate analysis showed that hypertension and anticoagulant were strong factors affecting hospitalization and mortality of COVID-19 patients with p-value of 0.009 (OR=17.06 [95% CI=2.02-144.36]) and 0.001 (OR=46.8 (95% CI=4.63-472.77), respectively. Interestingly, multiple S protein variants almost reached a significant level in affecting hospitalization (p=0.07). **Conclusions:** We showed for the first time the association between SARS-CoV-2 variants within S protein besides VOC and COVID-19 outcomes, revealing multiple S protein variants might affect COVID-19 severity, in addition to hypertension and anticoagulant. It further suggests the importance of genomic surveillance to monitor SARS-CoV-2 variants, particularly that might influence patientsâ□□ outcomes.

PrgmNr 2066 - Whole Exome Sequencing for Covid19 host in mild versus severe cases: A Saudi genome study

Background: The mortality and morbidity rates caused by the ongoing pandemic COVID-19 alerted the scientists to investigate the potential genetic patterns associated with symptom severity. From no or mild symptoms to severe life-threatening complications shed the light on the host genetic factors that incite the Covid-19 phenotypes. For Saudi Arabia, it was moderately affected by COVID-19, experiencing a case-fatality rate of 1.6 %, much lower than worldwide rate of 2.5 % according to WHO. In this perspective, exploring such genetic factors in Saudi population provides a deeper understanding of the heterogeneous phenotypes of the COVID-19 severity.Objective: We aimed to explore the genetic factors and variants associated with the reduced severity of symptoms seen in Saudi Arabian COVID-19 patients. Methods: Whole exome sequencing for 307 patients was performed where 149 patients were severe and 159 patients were mild. Exome library construction and Sequencing were done on ion torrent S5 XL system. Downstream analysis was performed to identify the common variants (MAF > 0.05), their allelic frequencies and gene ontology analysis in both severe and mild group. In silico validation of these variants was also performed.Results: Our study revealed 23 common genetic variants primarily connected to known co-morbidities which have not been reported to be of relevance to COVID-19 before. Gene ontology analysis revealed the involvement of a gene cluster associated with cytoskeletal functions. SNPs in 3 genes coding for keratin-associated proteins KRTAP10-4, KRTAP10-7, and Krtap5-5, are significantly associated with mild symptoms group, indicating a potential protective role.Conclusion: Our data highlights that the high level of autozygosity in this cohort not having apparent deleterious effects on mortality at the population level. The complete absence of common polymorphisms discovered previously to modulate COVID-19 symptomatology sheds the light on the genetic distinctiveness of different ethnicities. Our findings of the involvement of cytoskeletal components provides a better understanding of SARS-CoV pathogenesis, giving possible approaches for novel therapeutic targets.

Pelvic organ prolapse (POP) is characterized by a descent of the pelvic organs into the vaginal cavity. POP affects around 40% of women after menopause and is the most frequent reason for gynecological surgery. However, the etiology of POP remains to be elucidated and there is poor evidence guiding prevention and early detection of POP. In this study, we present the largest genome-wide association study (GWAS) meta-analysis using data from four European cohorts, including a total of 28,086 women with POP and 546,321 controls. We further integrate it with additional data layers, such as gene expression, to propose potential causal genes for the disorder. Moreover, for the first time, we aim to construct and validate the predictive ability of a polygenic risk score (PRS) alone or in combination with classical risk factors. Overall, we detected 26 genetic loci significantly associated with POP (pâ□□8), from which 19 loci were novel. The loci identified reinforces the role of connective tissue abnormalities (genes *EFEMP1*, *LOXL1*, *PLA2G6*), urogenital tract development (genes *WT1*, *DVL*, *WNT4*) and points towards an association with a range of cardiometabolic traits (genes *MAFF*, *LDAH*, *KLF13*), associations that were mirrored by genetic correlation analyses. The best fit PRS shows a hazard for incident POP of 1.63 times (95% CI: 1.46 to 1.79) higher in the top 5% PRS percentile compared to the remaining 95% percentile for the incident set, after adjusting for age. PRS in the incident subset shows higher predictive ability than clinical risk factors (Harrell C-statistic 0.583, sd= 0.007) and shows added value in combination with these (Harrell C-statistic 0.622, sd= 0.007), demonstrating that PRS in combination with clinical risk factors generates the best predictive model for POP. This study has the potential to improve our understanding of genetic factors underlying the polygenic architecture of POP and establishes the first evidence to base preventive strategies and early detection of POP including genetic risk factors.

PrgmNr 2068 - Explore the dynamic spatial and temporal regulation mechanism during embryonic sex development

Disorders of sex development (DSD) are congenital anomalies involving discordance between genotype to phenotype in gender identity. People with DSD suffer from ambiguous genitalia, impaired steroid hormone production, reduced or null fertility and partial to complete sex reversal, and many of them are vulnerable to severe psychological stress. Past genetic research mainly focused on proximal promoter activity or coding feature related to the diseases. Genes including *SRY*, *SOX9* and *NR5A1* have been reported to be critical for sex development. But the underlying genetic mechanism of most DSD is still unclear. With the advances in high throughput sequencing, stem cell and gene editing technologies, we aim to profile the spatial and temporal regulatory network based on scATAC-seq and complete stranded RNA-seq analysis and then validate our results in animal models and iPSC models. 3D chromatin topological interaction and non-coding RNA regulation are the research directions of interest, which may also help to explain the gene dosage regulation in development.

Introduction: The timing of human parturition is critical for neonatal survival and infant health, with preterm delivery (Methods: We performed a GWAS meta-analysis of gestational duration using maternal samples (n= 195K) and compared it to the genetic effects on birth weight and other female reproductive outcomes to disentangle the underlying genetics responsible for their relationship. The fetal effects on gestational duration and the maternal and fetal effects on birth weight were obtained from previously published GWAS meta-analysis. **Results:** We identified 24 independent loci (pADCY5 between the maternal effects on gestational duration and the fetal effects on birth weight. While the gestational duration index SNP (rs28654158) had a high population differentiation index (Africans and Europeans, Fst= 0.4, MAF= 0.01 vs 0.38, respectively), this was not the case for the birth weight index SNP (rs11708067); this is notable given the highest rate of preterm delivery in women from African ancestry. We observed significant genetic correlations with pre-eclampsia (r= -0.18, p= 2.1e-2) and testosterone in females (r= -0.24, p= 6.7e-5). **Conclusion:** Our results suggest that the maternal and fetal genomes shape fetal birth weight by acting on different phenotypes: timing of birth and growth rate, respectively.

PrgmNr 2070 - Genome-wide polygenic risk scores for hypertensive disease during pregnancy identify women at risk for long-term cardiovascular disease

Previous studies suggest that hypertensive disease during pregnancy (HDP) increases the risk of long-term cardiovascular disease later in life, and clinical guidelines recommend including HDP as an important female-specific factor in risk assessment. However, it has not been examined whether genetic predisposition for HDP affects the development of subsequent cardiovascular disease. In the current study, we developed polygenic risk scores for HDP (HDP-PRS) and evaluated its impact on long-term cardiovascular outcomes. We included unrelated European descent women (*n*=165,333) with at least one live birth and available genetic data from the UK Biobank. HDP-PRS was calculated using LDpred and summary statistics from the FinnGen Biobank. Subjects were divided according to the genetic risk categorized by HDP-PRS (High HDP-PRS (>75p) vs. low HDP-PRS (

PrgmNr 2071 - Large-scale GWAS meta-analysis unravels the genetic determinants of cervical biology and pathology

View session detail

Author Block: **T. Laisk**[1], M. Koel[1], U. VÃµsa[1], M. Lepamets[1], S. LemmelÃ¤[2], Estonian Biobank Research Team, FinnGen, H. M. Laivuori[3], M. J. Daly[2], P. Palta[1], R. MÃ¤gi[1]; [1]Inst. of Genomics, Univ. of Tartu, Tartu, Estonia, [2]Inst. for Molecular Med. Finland, Helsinki, Finland, [3]Univ Helsinki, Helsinki, Finland

Disclosure Block: **T. Laisk:** None.

The uterine cervix has an important role in female reproductive health, but not much is known about the genetic determinants of cervical biology and pathology. Here, we use data from large biobanks to characterise the genetics of cervical phenotypes (including cervical cancer) and leverage latest computational methods and gene expression data to refine the association signals for cervical cancer. Using Estonian Biobank and FinnGen data, we characterise the genetic signals associated with cervical ectropion (10,162 cases/151,347 controls), cervicitis (19,285/185,708) and cervical dysplasia (14,694/150,563). We present the results from the largest trans-ethnic GWAS meta-analysis of cervical cancer, including up to 9,229 cases and 490,304 controls from Estonian Biobank, the FinnGen study, the UK Biobank and Biobank Japan. We combine GWAS results with gene expression data and chromatin regulatory annotations in HeLa cervical carcinoma cells to propose the most likely candidate genes and causal variants for every locus associated with cervical cancer. We further dissect the HLA association with cervical pathology using imputed data on alleles and amino acid polymorphisms.

We report a single associated locus on 2q13 for both cervical ectropion (rs3748916, $p=5.1 \times 10^{-16}$) and cervicitis (rs1049137, $p=3.9 \times 10^{-10}$), and five signals for cervical dysplasia - 6p21.32 (rs1053726, $p=9.1 \times 10^{-9}$; rs36214159, 1.6×10^{-22}), 2q24.1 (rs12611652, $p=3.2 \times 10^{-9}$) near *DAPL1*, 2q13 ns1049137, $p=6.4 \times 10^{-9}$) near PAX8, and 5p15.33 (rs6866294, $p=2.1 \times 10^{-9}$), downstream of *CLPTM1L*. We identify five loci associated with cervical cancer: 1p36.12 (rs2268177, $p= 3.1 \times 10^{-8}$), 2q13 (rs4849177, $p=9.4 \times 10^{-15}$), 5p15.33 (rs27069, $p=1.3 \times 10^{-14}$), 17q12 (rs12603332, $p=1.2 \times 10^{-9}$), and 6p21.32 (rs35508382, $p=1.0 \times 10^{-39}$). Joint analysis of dysplasia and cancer datasets revealed an association on chromosome 19 (rs425787, $p=3.5 \times 10^{-8}$), near *CD70*.

Our results map *PAX8/PAX8-AS1*, *LINC00339*, *CDC42*, *CLPTM1L*, *HLA-DRB1*, *HLA-B,* and *GSDMB* as the most likely candidate genes for cervical cancer, which provides novel insight into cervical cancer pathogenesis and supports the role of genes involved in reproductive tract development, immune response and cellular proliferation/apoptosis. We further show that *PAX8/PAX8-AS1* has a central role in cervical biology and pathology, as it was associated with all analysed phenotypes. The detailed characterisation of association signals, together with mapping of causal variants and genes offers valuable leads for further functional studies.

PrgmNr 2072 - Meta-analysis of genome-wide association studies identified new loci associated with spontaneous preterm birth and gestational duration

View session detail

Author Block: **A. Pasanen**[1], M. K. Karjalainen[2], M. Ojaniemi[1], FinnGen, G. Zhang[3], L. J. Muglia[3,4], M. RÃ¤met[1], M. Hallman[1]; [1]PEDEGO Res. Unit, Med. Res. Ctr. Disclosure Block: **A. Pasanen:** None.
Preterm birth (birth EBF1 and *EEFSEC*, with roles in B-cell development and selenium metabolism, were associated with both gestational length and SPTB. To complement the knowledge of the genetic background of SPTB, we conducted a fixed effects meta-analysis of gestational duration and SPTB in up to 98,372 women of European ancestry with data from FinnGen and two other cohorts. We detected several associated loci, of which eight were not previously associated with SPTB or the length of gestation. As an example, variants in *KCNAB1* intron were associated with gestational duration, and the association was replicated in 2,700 women from two Nordic birth cohorts. Noteworthy, *KCNAB1* variants were previously associated with offspring birth weight. Downstream in silico analysis suggested regulatory functions as potential causal mechanisms for the novel loci. The genome-wide association study in the FinnGen data replicated previous associations near *EBF1* and *EEFSEC*, among others.Altogether, our findings provide new insight into the genetic background of preterm birth. Better characterization of genetic pathways of SPTB has potential to suggest novel opportunities to treat and prevent preterm birth.

PrgmNr 2073 - Novel bi-allelic Mutations in *DNAH10* cause multiple morphological abnormalities of the flagella

View session detail

Author Block: **R. Zheng**; SiChuan Univ., Chengdu, China
Disclosure Block: **R. Zheng:** None.
Asthenozoospermia is characterized by attenuated sperm motility, further resulting in male infertility. Multiple morphological abnormalities of the sperm flagella (MMAF) is a typical asthenozoospermia, exhibiting various malformed flagellar shape. However, the known pathogenic genes can explain at most two-third of the MMAF cases. Herein, bi-allelic variants (c.9494C>G, [p.T3165R]; c.8378G>A, [p.R2793H]) of *DNAH10* were identified in a MMAF male by whole-exome sequencing (WES). Furthermore, by immunofluorescence staining and western blotting, we found these variants induced significant decrease of DNAH10 expression, further negatively impacting expression of DNAH2 in the spermatozoa from men harboring the *DNAH10* variant. Moreover, the outcomes of intracytoplasmic sperm injection (ICSI) were unsuccessful on the patient. Collectively, our data provided strong evidence to support that *DNAH10* is the causative gene of MMAF, and the finding of the novel mutations in *DNAH10* enriches the gene variants spectrum for MMAF which further contribute to diagnosis, genetic counseling and prognosis for male infertility.

PrgmNr 2074 - Disentangling migraine risk loci by fine-mapping and colocalization

View session detail

Author Block: **H. Hautakangas**[1], A. Palotie[1,2,3], M. Pirinen[1,4,5]; [1]Inst. for Molecular Med. Finland (FIMM), Helsinki Inst. of Life Sci. Hosp., Boston, MA, [3]The Stanley Ctr. for Psychiatric Res. and Program in Med. and Population Genetics, The Broad Inst. of MIT and Harvard, Cambridge, MA, [4]Dept. of Publ. Hlth., Univ. of Helsinki, Helsinki, Finland, [5]Dept. of Mathematics and Statistics, Univ. of Helsinki, Helsinki, Finland
Disclosure Block: **H. Hautakangas:** None.
Migraine is a highly prevalent brain disorder and genome-wide association studies (GWAS) have identified over hundred loci contributing to migraine risk, yet the causal variants and genes remain mostly unidentified. Here, we performed a Bayesian fine-mapping (FINEMAP) for the 123 risk loci identified in the latest migraine meta-analysis to narrow down potential causal variants in correlated association regions. The data sources included 23andMe, Inc. and UK biobank with up to 63,000 cases and 560,000 controls. Further, to prioritize candidate genes, we ran colocalization analyses by COLOC with expression quantitative trait loci (eQTL) datasets from multiple tissues from sources such as GTEx Consortium and eQTL Catalogue.

Examples of two loci where fine-mapping provided a clear picture are PHACTR1 locus on chromosome 6 and LRP1 locus on chromosome 12. In both loci, FINEMAP suggested only one causal variant with a posterior probability (PP) of around 70%. For PHACTR1 locus, the strongest candidate variant was rs9349379, an intron variant of *PHACTR1*, with PP = 1 and 95%-credible set (CS) containing only the named variant itself. The colocalization analyses also suggested very robust colocalization for *PHACTR1* in three arterial tissues (aorta, tibial and coronary arteries, all with PP = 1), while for other nearby genes colocalization was not supported (PP LRP1, forming the 95%-CS alone. Colocalization analyses suggested colocalization for *LRP1* in four tissues (aorta, tibial artery, heart ventricle and sun exposed skin, PP > 0.93).

Our goal is to extend these analyses to a larger migraine meta-analysis with over 100,000 cases, but the challenges are that we lack complete linkage disequilibrium (LD) information of the underlying GWAS data and that there is variation in effective sample sizes (N_e) across variants. Therefore, we have evaluated how fine-mapping with an LD reference panel (from UK Biobank) performs. We observed that it was necessary to restrict the analysis to variants with similar N_e, but after that, the results using the reference panel were comparable to the results using in-sample LD.

To conclude, these results help to prioritize causal variants and genes in migraine risk loci for future translational research on migraine.

PrgmNr 2076 - Long-read sequencing analysis of Alzheimer risk gene*ABCA7* identifies risk-increasing novel alternative splicing events

View session detail

Hosp. Antwerp, Antwerp, Belgium

Disclosure Block: **L. Duchateau:** None.

ABCA7 (*ATP-Binding Cassette Subfamily A member 7*) is an Alzheimerâ□□s disease (AD) risk gene and encodes for a lipid transporter. Studies revealing novel splice events, including â□□rescue splicingâ□□ events that are able to rescue the effect of premature termination codon (PTC) mutations, suggest that the *ABCA7* splicing profile is complex. These splicing differences could potentially account for the large differences found in *ABCA7* expression inter-individually as well as differences in phenotype and age at onset (AAO) in mutation carriers. To study the *ABCA7* transcript, we used targeted longâ□□read cDNA sequencing on an Oxford Nanopore MinION platform in a unique population of 39 *ABCA7* PTC carriers and 10 non-mutation carriers, including 28 AD patients, 17 controls and 5 mild cognitive impairment patients. RNA was extracted from 47 lymphoblastoid cell lines, 4 hippocampi and 2 prefrontal cortices. Using the FLAIR (full-length alternative isoform analysis of RNA) pipeline and an in-house R script, alternative splicing was quantified and studied. In total we identified 199 previously undescribed splice events with an alternative/canonical ratio of at least 0.05, an almost 4-fold increase compared to the 52 known junctions. We found that both AD patients and PTC mutation carriers had a significantly higher degree of reads containing alternative splice events compared to controls (p=2.36*10-11 and pABCA7 splicing is much more complex than initially thought and is significantly increased in AD patients and outside of regions of structural or functional importance. This suggest that alternative splicing may affect ABCA7 function and through this have an influence on AD risk. Our data suggests that having a PTC mutation in *ABCA7* might increase susceptibility to (rescue) splicing.

PrgmNr 2077 - Polygenic risk scores as a marker for lifetime epilepsy risk

View session detail

Author Block: **H. O. Heyne**[1,2], FinnGen, M. J. Daly[3,1], R. KÃ¤lviÃ¤inen[4]; [1]Inst. for Molecular Med. Finnland: FIMM, Helsinki, Finland, [2]Hasso Plattner Inst., Potsdam, Germany, [3]Massachusetts Gen. Hosp., Boston, MA, [4]Kuopio Univ. Hosp., Kuopio, Finland
Disclosure Block: **H.O. Heyne:** None.
Epilepsy affects approximately 1% of individuals worldwide. Making an epilepsy diagnosis is often difficult with estimates that up to 25% of epilepsy could initially be misdiagnosed. The SNP heritability of genetic generalized epilepsy is high (32%) and it has recently been shown that individuals with epilepsy also have elevated epilepsy polygenic risk scores (PRS). However, investigation how epilepsy PRS may predict epilepsy risk in an individual across lifetime or in individuals with unclear seizure events has so far been lacking.Here, we studied epilepsy PRS in detailed longitudinal electronic health records of > 269k Finns including ICD codes and drug purchases of over 50 years. Our dataset included 9660 individuals with epilepsy related diagnoses. We could confirm previous studies describing an elevated PRS for generalized epilepsy (PRS_{gen}) in individuals with generalized epilepsy. This was particularly high for juvenile myoclonic epilepsy, which could be because it represented the largest diagnosis group of the GWAS that was used to construct the PRS. Individuals with a top 10% PRS_{gen} in FinnGen had a more than doubled lifetime risk (p-value $1x10^{-11}$, hazard ratio 2.3) to develop generalized epilepsy compared to the bottom 90% PRS_{gen}. We further found that over half of individuals with specific diagnoses of generalized or focal epilepsy were initially diagnosed with unclear convulsions (R56.8) or unclear epilepsy (G40.9). Their PRS_{gen} was significantly higher than of those individuals who had only one unclear seizure event and did not later receive an epilepsy diagnosis. Specifically, individuals with a top 10% PRS_{gen} had a hazard ratio of 2.4 (p-value $1x10^{-4}$) to progress to generalized epilepsy after an unclear seizure event below the age of 40 compared to the bottom 90% PRS_{gen}. These results indicate a future potential for epilepsy PRS to help in predicting progression to epilepsy.

PrgmNr 2078 - Protein interaction network reveals enriched genetic variation across signaling networks in frontotemporal dementia

View session detail

Author Block: **C. Kocoglu**[1,2], R. Ferrari[3], M. Roes[1,2], G. Vandeweyer[4], F. Kooy[4], C. Van Broeckhoven[1,2], C. Manzoni[5], J. van der Zee[1,2]; [1]Neurodegenerative Brain Diseases, VIB Ctr. for Molecular Neurology, VIB, Antwerp, Belgium, [2]Dept. of BioMed. Sci., Univ. of Antwerp, Antwerp, Belgium, [3]Dept. of Neurodegenerative Disease, UCL, London, United Kingdom, [4]Dept. of Med. Genetics, Univ. of Antwerp, Antwerp, Belgium, [5]Sch. of Pharmacy, UCL, London, United Kingdom
Disclosure Block: **C. Kocoglu:** None.
Frontotemporal dementia (FTD) is a complex early-onset neurodegenerative brain disorder. Several disease-causing genes have been identified for distinct clinical and pathological subtypes of familial FTD mainly via linkage analysis in large pedigrees. Yet, the genetic etiology of sporadic FTD is poorly understood and complicated by the highly heterogeneous disease presentation. To further unravel the complex genetic etiology on non-Mendelian FTD, we hypothesized that interactors of the protein products of known FTD genes might also play a role in disease onset. We therefore applied protein network analysis updating and automatizing an existing weighted protein-protein interaction network analysis (WPPINA) pipeline (Ferrari et al., 2017) to prioritize candidate genes for downstream rare variant association analysis on exome data. We created an FTD protein interaction network (**FTD-PIN**) starting from 14 known Mendelian FTD genes. Using these FTD genes as seeds, we downloaded 1st- and 2nd-degree physical interactors via the PINOT online server. We performed enrichment analysis for Gene Ontology - biological processes (GO:BP) terms on the genes from the FTD-PIN using g:Profiler. Enriched GO:BP terms were grouped into custom semantic classes and these were further prioritized based on weighted number of GO-BPs as a function of the term *P*-value and term size. This analysis identified the following most **overrepresented FTD processes**: *waste disposal, response to stimulus, immune system* and *cell death*. The FTD-PIN genes belonging to these overrepresented FTD processes made up the **prioritized gene list** (n=442). On a Belgian WES dataset of 228 FTD patients and 345 controls, we multiple rare variant association tests with the rvtest package on the prioritized gene list. Four genes showed suggestive enrichment of missense variants in all statistical models: *TNFAIP3*, *DNM2*, *RARA* and *UBR4* (*P* TNFAIP3 as the top gene with $P = 0.0007$, reaching near test-wide significance ($p=2.5x10^{-4}$). We subsequently extracted the TNFAIP3-interactome from the FTD-PIN and performed enrichment of GO:BP terms on this subset (n=50) to identify possible disease processes of TNFAIP3 which pointed towards signalling processes, specifically: *cell death - signalling, immune system - signalling - toll-like, immune system - signalling - cytokine*. Our study indicates that integration of protein interaction network and functional enrichment analyses is a useful approach to increase power to identify rare variants with low-effect size and genes contributing to the disease biology of FTD.

PrgmNr 2079 - Trans-ethnic fine-mapping in the major histocompatibility complex region on Parkinson's disease risk

View session detail

Author Block: **T. Naito**[1,2], W. Satake[2], K. Ogawa[1], K. Suzuki[3], J. Hirata[4], J. N. Foo[5], E. K. Tan[6], T. Toda[2], Y. Okada[7]; [1]Osaka Univ. Hosp., Singapore, Singapore, [7]Osaka Univ. Graduate Sch. of Med., Suita, Osaka, Japan
Disclosure Block: **T. Naito:** None.
Although different studies reported the genetic predisposition of human leukocyte antigen (HLA) to the risk of Parkinsonâ□□s disease (PD), the complex haplotype structure and highly polymorphic feature of the major histocompatibility complex (MHC) region has hampered a unified insight on the causal HLA variants. In addition, most previous studies focused on European populations and the evidence for non-European populations has been scarce. We conducted trans-ethnic fine-mapping for large cohorts to elucidate shared and distinct genetic features of the MHC region associated with PD risk. We targeted European populations (14,650 cases and 1,288,625 controls) and East Asian populations (7,712 cases and 27,372 controls). We adopted a hybrid fine-mapping approach including: (1) HLA genotype imputation of GWAS genotype data using our novel imputation method based on deep learning, DEEP*HLA; and (2) direct imputation of HLA variant risk from the GWAS summary statistics. The strongest association was observed at the protective effect of His13 in HLA-DRÎ²1 (P = 6.0 Ã□ $10^{â□□15}$), and this position explained the majority of the risk in *HLA-DRB1*. *In silico* prediction revealed that *HLA-DRB1* alleles with His13 (protective) and Arg13 (risk) had significantly weaker and stronger binding-affinity to an Î±-synuclein epitope than other alleles (P = 9.6 Ã□ $10^{â□□4}$ and 1.0 Ã□ $10^{â□□3}$, respectively). It might suggest that HLA-DRÎ²1 position 13 associates with the etiology of PD by altering the binding-affinity to the Î±-synuclein epitope and determining subsequent immune responses. Stepwise conditional analysis revealed additional independent association at Ala69 in HLA-B (P = 1.0 Ã□ $10^{â□□7}$). ï»¿Furthermore, a sub-analysis in Europeans suggested additional independent associations at non-HLA genes in the class III MHC region (*EHMT2*; P = 2.5 Ã□ $10^{â□□7}$) The current study highlights the genetic features of the MHC region associated with the risk of PD shared across ethnicities, enhancing our understanding of the immunologic pathophysiology of PD.

PrgmNr 2080 - Using non-Autologous Wharton's Jelly Mesenchymal Stem Cells and Chitosan/Poly ethylene oxide as a Synthetic Scaffold inhibit SNI-Induced Apoptosis in Rat

Background: The comorbidity of mood disorders, including bipolar disorder (BPD) and major depressive disorder (MDD), with substance use was common. In addition to a bidirectional relationship proposed by prospective studies and Mendelian randomization studies, a shared pathophysiology, such as common genetic architecture, could also contributed to the comorbidity. This study aimed to explore the association of polygenic liabilities for BPD and MDD with a range of substance use phenotypes by conducting a population-based study in Taiwan.
Method: The study subjects were recruited from the Taiwan Biobank. Genome-wide genotyping data was available for 77088 unrelated community participants without mood disorders. We applied polygenic architecture profiling and calculated polygenic risk score (PRS) for BPD and MDD in each individual. Data for substance involvement included tobacco, alcohol, and betel nut use phenotypes. Detailed information in terms of age at initiation, duration and current status was collected for participants who had used a substance. A regression model with adjustments for sex, age, and population stratification components was performed to estimate the strength of association of PRS with substance involvement. Sex difference in the PRS association was also explored.
Results: The MDD PRS was positively associated with regular alcohol use (OR in per SD increase in PRS=1.03, p=0.02), ever tobacco use (OR=1.05, p**Conclusion:** This study supported that the shared genetic architecture contributed to the comorbidity between MDD and substance involvement. Our results also suggested sex difference in genetic prediction, women with MDD susceptibility had a higher risk of tobacco and betel nut involvement than men.

PrgmNr 2083 - Brain eQTL of East Asian, African American, and European Descent Explains Schizophrenia GWAS in Diverse Populations

Previous studies integrating genome-wide association studies (GWAS) and brain expression quantitative trait loci (eQTL) data have discovered hundreds of risk genes associated with schizophrenia (SCZ). However, most studies focused on individuals of European Populations. Based on the differences in population structures such as linkage disequilibrium patterns and allele frequencies, we hypothesized that different populations had their own SNPs associated with brain gene expression; and population-relevant brain eQTL will improve interpretation of GWAS signals of the corresponding populations than the use of eQTL from other populations in SCZ.We first characterized the eQTL using RNA-seq and WGS data of brain samples from subjects of East Asian (EA, N = 228), Africa American (AFR, N = 175), and European (EU, N = 407) ancestries. Using FDR q-value Population shared (PS-), defined as the eQTL, of the identical SNP-gene pair, with the same effect in all three populations; or *Population-unique* (PU-), defined as the eQTL is only significant or has significantly different effect size in one population. Striking differences existed in eQTL across populations: only 3,999 genes were significantly associated with the same SNPs in three populations. We identified 1,308 and 333 PU-eQTL Genes in EA and AFR, respectively. Meanwhile, the SNP minor allele frequency and fixation index values of eQTLs are significantly higher in the PU-eQTL SNP than the PS-eQTL SNP (adjusted p

PrgmNr 2084 - Contribution of Glucoside Xylosyltransferase 1 gene variants in Schizophrenia

View session detail

Author Block: **B. Shekhar**; ICMR-Natl. Inst. for research in reproductive Hlth., Mumbai, India
Disclosure Block: **B. Shekhar:** None.
Schizophrenia (SCZ) is a chronic neuropsychiatry disorder affecting true perception of an individual. Impaired social interactions along with Hallucination and Delusions are the hallmark of the disorder. Polygenic and heterogenous nature of the disorder make it challenging to confer any concrete evidence for the onset of SCZ. Although, variant based genome wide association studies and rare variants detection using Next Generation Sequencing have helped to decipher numerous variants that are responsible for the onset of SCZ, but still various links are missing in order to understand this neuropsychiatry disorder in a better way. Using Whole Exome Sequencing we identified 4 heterozygous variants in Glucoside Xylosyltransferase 1 gene (GXYLT1, 12q12) having 8 exons in affected members of 6 families. These variants are predicted as damaging according to various prediction tool. Upon detailed analysis these 4 variants viz: rs79044728, rs1262821887, rs1462576913 and rs796100580 are found to be altering proteins as p.Y265C, p.G33X, p.Y264N and p.E249G. Out of these 4 protein variants one variants prematurely truncate the protein. Glucoside Xylosyltransferase 1 is a member of Glycosyl Transferase 8 family. GXYLT1 adds first xylose to O-glucose residues in 6 cysteines repeat of epidermal growth factor-like (EGF) repeats. EGF repeats are present in the extracellular domain of NOTCH and are conserved throughout the species. NOTCH signaling pathway has prominent role in neurodevelopment and adult brain homeostasis. It assists neurodevelopment and patterning by regulation of neurogenesis, axonal growth and synaptogenesis. There is substantial number of evidences present suggesting the role of NOTCH signaling pathway in the onset of SCZ. Also, it has been shown that the addition of Xylose to O-glucose has inhibitory effect on NOTCH signaling pathway. This study delineates the role of GXYLT1 in the onset of Schizophrenia through NOTCH signaling pathway that regulate neural patterning and neurogenesis in adult brain.

PrgmNr 2086 - Is chronotype a risk factor for neuropsychiatric disorders? A two-sample, multivariable Mendelian randomisation study

View session detail

Author Block: **S. Crinion**[1], L. Lopez[2], D. Morris[1]; [1]NUI Galway, Galway, Ireland, [2]Maynooth Univ., Maynooth, Ireland

Disruption of circadian rhythm is a common feature in many neuropsychiatric disorders including autism and schizophrenia. Chronotype, an individual's synchronisation to the 24 hour day, is commonly used as a proxy for circadian rhythm disruption. Being a morning person, someone who prefers waking and going to bed earlier, is genetically correlated with increased well-being and decreased risk of neuropsychiatric disorders. We performed a two-sample Mendelian randomisation (MR) study to determine the effect of chronotype on risk of six neuropsychiatric disorders (autism spectrum disorder, attention deficit hyperactivity disorder, bipolar disorder, insomnia, major depressive disorder and schizophrenia). We used 351 independent genome-wide significance loci (p

PrgmNr 2087 - Major depressive disorder and current psychological symptoms modify the polygenic predisposition to body mass index on obesity-related traits

View session detail

Author Block: **S-H. Wang**, C-Y. Su; China Med. Univ., Taichung, Taiwan
Disclosure Block: **S. Wang:** None.
Background: Major depressive disorder (MDD) and obesity are both leading serious public health problems and highly prevalent in modern society. A bidirectional relationship between MDD and obesity have been evidenced. Their comorbidity or complications might be attributable to genetic influence. Specific genetic variants for body mass index (BMI) have been shown to exhibit larger effect sizes in depressed individuals. This study aimed to explore the association of polygenic predisposition with obesity-related traits, and to examine whether such polygenic influence modified by MDD. **Methods:** The study subjects were recruited from Taiwan Biobank. Genome-wide genotyping was available in 80307 unrelated individuals. We applied polygenic architecture profiling and calculated the polygenic risk score (PRS), which refers to the cumulative additive effect of trait-associated variants across the genome, for BMI and for MDD. The PRS was then normalized to a Z score. Obesity-related outcomes included BMI, overweight (BMI â¥25), obesity (â¥30), waistline, hipline, waist-hip ratio (WHR) and body fat rat. MDD was measured by self-reported lifetime diagnosis and current psychological symptoms was measured by Patient Health Questionnaire-4 (PHQ-4). The significance of the PRS influence was evaluated using a linear regression model or a logistic regression model with adjustments for gender, age and population stratification components. The modified effects of MDD and current psychological symptoms were evaluated by an interaction term. The interaction between PRS for MDD and PRS for BMI was also examined. **Results:** The MDD PRS was positively associated with waistline (beta in per SD increase in PRS=0.12), hipline (beta=0.09), WHR (beta=0.04), body fat rate (beta=0.09), BMI (beta=0.05), overweight (OR=1.03), and obesity (OR=1.06). There was a significant interaction between BMI PRS and MDD and between BMI PRS and current psychological symptoms on obesity-related traits. The effect of BMI PRS on body fat rate was larger for individuals with MDD (beta=1.19 v,s. beta=0.98 for those without). The effect of BMI PRS on BMI was larger for individuals with MDD (beta=0.83 v,s. beta=0.70 for those without). The amplified effect of BMI PRS was also observed for individuals with current psychological symptoms. There was a synergistic interaction between MDD PRS and BMI PRS on obesity. **Conclusions:** Higher polygenic predisposition to MDD was associated with obesity. Lifetime MDD and current psychological symptoms amplify the effect of polygenic predisposition to BMI on obesity.

PrgmNr 2088 - A phenome-wide association study of Y-chromosomal haplogroups and 28 disease endpoints in 37,518 Finnish men

View session detail

Author Block: **A. Preussner**[1], J. T. Leinonen[1], S. Kerminen[1], M. Pirinen[1,2,3], FinnGen, T. Tukiainen[1]; [1]Inst. for Molecular Med. Finland (FIMM), Univ. of Helsinki, Helsinki, Finland, [2]Dept. of Publ. Hlth., Univ. of Helsinki, Helsinki, Finland, [3]Helsinki Inst. for Information Technology HIIT and Dept. of Mathematics and Statistics, Univ. of Helsinki, Helsinki, Finland
Disclosure Block: **A. Preussner:** None.
The Y chromosome is routinely excluded from genetic association studies due to the peculiar biology and analytical challenges specific to the Y chromosome. Consequently, potential impacts of Y-chromosomal genetic variation on complex disease remains largely uncharacterized.
To explore the role of the Y chromosome in complex disease, we performed a phenome-wide association study (PheWAS) of Y-chromosomal haplogroups in 37,518 Finnish men (24,160 for discovery + 13,358 for replication) from the FinnGen project. The analysis focused on the four most common haplogroups in Finland (N1c1, I1, R1a, R1b) and 28 common disease endpoints (â¥3000 cases in the dataset) selected from ICD-hierarchy level 2, e.g. hernias, hypertension and dorsopathies. As the haplogroup frequencies, for N1c1 in particular, were correlated with the autosomal genome, the logistic regression analyses were carefully adjusted for population structure in addition to other covariates.
Seven nominally significant associations were observed in the discovery analysis, and three of these associations remained nominally significant in the meta-analysis. All three replicated associations included cardiometabolic system diagnoses, namely both risk increasing and protective effects for ischemic heart disease (OR = 0.93, p = 0.023 for N1c1; OR = 1.08, p = 0.023 for I1), and a protective effect for diabetes (OR = 0.87, p = 0.018 for R1a). However, none of the associations remained statistically significant after correcting for multiple testing (p Nevertheless, the finding that haplogroup I1 (frequency 26% in Finland) may increase the risk for ischemic heart disease in Finland supports the previously reported link between haplogroup I1 and increased risk for coronary artery disease (OR = 1.11 in the UK), suggesting the Y chromosome contains robust disease associations. The potential protective role of haplogroup N1c1 (frequency 60% in Finland) further suggests the Y chromosome may harbor additional genetic variations that impact heart disease susceptibility. Overall, with this pilot study, which to our knowledge is the largest PheWAS of the Y chromosome including Finnish haplogroups, we show the feasibility of including Y-chromosomal data in genetic association analyses. The few suggestive associations observed propose further investigations and validation in larger datasets are warranted to define the speculated role of Y chromosome in complex disease.

PrgmNr 2089 - A selection pressure landscape for 870 human polygenic traits

View session detail

Author Block: **G. Lin**, W. Song, W. Wang; Shanghai Jiao Tong Univ., Shanghai, China
Disclosure Block: **G. Lin:** None.
Characterizing the natural selection of complex traits is essential for understanding human evolution, and both biological and pathological mechanisms. To fulfill this requirement, we leveraged genome-wide summary statistics for 870 polygenic traits and attempted to comprehensively quantify the selection pressure on traits of different forms in European ancestry across four different human development times. We found that 88% of traits underwent polygenic adaptation in the past 2000~3000 years. The selection at a later time was generally dependent on ancient selection pressures of the same trait. Traits related to pigmentation, body measurement, and nutritional intake exhibited strong selection signals across different time scales. In sum, we provided a first-step global overview of natural selection on human polygenic traits and their essential characteristics across human evolution, which could serve as a foundation for further populational and medical genetic studies.

PrgmNr 2090 - Analysis of genetic variants of SARS-CoV-2 host factors *ACE2*, *NRP1*, *TMPRSS2*, and *FURIN* in Japanese population from IRUD whole-exome sequencing data

View session detail

Author Block: **K. Satou**[1], K. Yanagi[1], M. Omata[1], A. Igarashi[1], T. Hidai[1], Y. Matsubara[2], T. Kaname[1]; [1]Dept. of Genome Med., Natl. Ctr. for Child Hlth.and Dev., Tokyo, Japan, [2]Natl. Ctr. for Child Hlth.and Dev., Tokyo, Japan
Disclosure Block: **K. Satou:** None.
Background: Coronavirus disease 2019 (COVID-19) is an ongoing global pandemic infectious disease caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). The first case was identified in China in December 2019 and a cumulative total of more than 176 million cases and 3.8 million deaths have been reported worldwide to date. Patients with the COVID-19 present a broad spectrum of clinical presentation and a large number of host risk factors are reported, including age, sex, underlying condition, and local population. The SARS-CoV-2 utilizes host (human) factors, including angiotensin converting enzyme 2 (*ACE2*), neuropilin 1 (*NRP1*), transmembrane serine protease 2 (*TMPRSS2*), and paired basic amino acid cleaving enzyme (*FURIN*), in its cell entry stage. Revealing genetic variant profiles among individuals or populations is essential for developing precision medicine.
Methods: In this study, we analyzed genetic variants of the SARS-CoV-2 host factor genes by using whole-exome sequencing data of 2,048 healthy individuals in Japanese population. We utilized the data from the Initiative on Rare and Undiagnosed Diseases (IRUD) project, which we are currently working on. Allele frequencies of the variants in the Japanese population were compared to local populations in the public database. Pathogenicity of the variants were evaluated by prediction score algorithms. Exonic nonsynonymous variants existing on virus-host protein-protein interaction surface were also evaluated for selected proteins by using molecular modeling.
Result: We found 66 variants for *ACE2* and 9 were exonic and nonsynonymous, 220 variants for *NRP1* and 15 were exonic nonsynonymous and 1 were stopgain, 223 variants for *TMPRSS2* and 19 were exonic nonsynonymous, and 112 variants for *FURIN* and 22 were exonic nonsynonymous. More than half of the variants found in each gene were not available in the database. The allele frequency of some variants showed differences among local populations.
Conclusion: We analyzed genetic variants of SARS-CoV-2 host factors *ACE2*, *NRP1*, *TMPRSS2*, and *FURIN* in Japanese population from IRUD whole-exome sequencing data. We found total 621 variants for four genes. More than half of the variants were not available in the public database and the allele frequencies were not sufficiently comparable. Revealing genetic variant profiles among individuals or populations is essential for developing precision medicine. We hope that our result will contribute as one of the basic data for developing COVID-19 genome medicine.

PrgmNr 2091 - Analysis of the genetic components behind the chronic back pain

View session detail

Author Block: **E. Elgaeva**[1,2], M. Freidin[3], F. Williams[3], P. Suri[4,5], Y. S. Aulchenko[6,1], Y. Tsepilov[1,2]; [1]Inst. of Cytology and Genetics, Siberian Branch of Russian Academy of Sci., Novosibirsk, Russian Federation, [2]Novosibirsk State Univ., Novosibirsk, Russian Federation, [3]Dept. of Twin Res. and Genetic Epidemiology, Sch. of Life Course Sci., King's Coll. London, London, United Kingdom, [4]Univ. of Washington, Seattle, WA, [5]VA Puget Sound Hlth.Care System, Seattle, WA, [6]PolyOmica, Maastricht, Netherlands

Disclosure Block: **E. Elgaeva:** None.

Background: Back pain is a highly prevalent disabling condition with a significant socioeconomic burden. In 10% of cases acute back pain converts to a chronic condition. Polygenicity and heritability up to 68% have been shown for this trait. Furthermore, there is evidence for shared genetic background of various pain conditions. Recently, ~80% of chronic musculoskeletal pain heritability was found to be shared across four locations. It is thought that shared genetic background may involve the psychosocial component of chronic pain as a major component. Similarly, an existence of genetic factors that are unique to chronic pain at specific locations can be assumed. Here we used novel methods to study the genetic factors shared by chronic pain traits and the unique genetic factors of chronic back pain (CBP). **Materials and methods**: The current study was performed using the GWAS results on various chronic pain traits (back, neck, hip, knee, stomach pain and headache). All the data were obtained from UK Biobank project #18219 (N = 456,000) and split into a discovery (N = 265,000, Europeans) and a replication set (N = 191,000, Africans, South Asians and Europeans). Firstly, for all traits we assessed phenotypic correlations as described by Stephens et al. and calculated genetic correlations and heritability using LD Score regression. We used these parameters to build the optimal linear combination of traits, maximizing their shared heritability (MaxSH methodology) and obtained GWAS results for the shared genetic component (SGC) of chronic pain traits. Finally, we adjusted CBP using SGC and obtained new GWAS data for the unique genetic component (UGC) of CBP. Loci associated with SGC or UGC of CBP at p Results: We isolated SGC of chronic pain traits and UGC of CBP. Nine loci were shown to be associated with SGC, five of them were observed earlier in Tsepilov et al. (2020) study and four loci were new with two of them replicated. Similarly, we identified one locus significantly associated with UGC of CBP. This association was previously found in a back pain GWAS by Freidin et al. in 2018. As expected, the regions associated with SGC were enriched for genes expressed in the nervous system, while regions associated with UGC of CBP were related to the musculoskeletal system. Hence, SGC is likely to primary reflect psychosocial aspects of CBP and chronic pain traits in general, while UGC primarily reflects the anatomical basis of CBP.

PrgmNr 2092 - Association of confounding factors with Adolescent Idiopathic Scoliosis in the population of Jammu andKashmir, India

View session detail

Author Block: **H. Singh**[1], S. Kowra[1], N. Gupta[2], G. Gupta[3], S. Pandita[4], V. Singh[1], E. Rai[5], S. Ikegawa[6], S. Sharma[7]; [1]Sch. of Biotechnology, Shri Mata Vaishno Devi Univ., Katra, India, [2]Dept. of Hlth.and Family Welfare, Jammu, India, [3]Dept. of Radiology, Shri Mata Vaishno Devi Narayana Superspeciality Hosp., Katra, Jammu, India, [4]Radiology section, Chest Disease Hosp., Bakshi Nagar, Jammu, India, [5]Shri Mata Vaishno Devi Univ., Katra, India, [6]IMS, RIKEN, Tokyo, Japan, [7]SHRI MATA VAISHNO DEVI Univ., KATRA, India

Disclosure Block: **H. Singh:** None.

Adolescent idiopathic scoliosis (AIS) is a complex 3D spinal deformity characterized by Cobb angle â¥ 10Â°. It affects 1-3% of adolescent population globally. In our study, 9500 adolescent individuals (5,001 males and 4,499 females) were screened for scoliosis in the population of Jammu region of Jammu and Kashmir. Anthropometric measurements including height, weight and BMI were recorded. Screening of the individuals were performed using Scoliosis-meter was that provides the measure of angle of trunk rotation (ATR), where ATR of 7Â° were suspected to be scoliotic and further examined radiologically. The prevalence of AIS in our population was observed to be 0.60% which is less than the global average estimate but greater than the previously reported studies in India. We tried to statistically evaluate the correlation and association of anthropometric factors with AIS in our study. The anthropometric factors were found to be uncorrelated correlated with ATR (r= -0.071, p value= 0.580, r= -0.104, p value=0.415 and r = -0.129, p value= 0.314 for BMI, height and weight respectively). Further, we have also tried to evaluated the association of anthropometric factors with AIS using independent t-test for BMI, height and weight among the AIS patients and healthy controls. No significant association was observed between anthropometric factors and AIS in overall screened population. However, BMI showed significant association with p value = 0.031 among AIS patients and the healthy controls in the age group of 12-16 years whereas no significant association has been observed for other anthropometric factors including height and weight in this age group with p-value of 0.251 and 0.304 respectively. The level of significance between BMI and AIS is not very high so, we can confer that BMI may act as a confounding factor for AIS but is not only a single contributory factor for the AIS predisposition. It seems that genetic factors might be a major contributor in the pathogenesis of the AIS along with some confounding factors such as BMI, height and weight. Therefore, it becomes pertinent to carry out genetic studies on AIS in our population group to get a clear picture of AIS predisposition.

PrgmNr 2093 - Can sex differences in GWAS variant effects be found with current sample sizes?

View session detail

Author Block: **L. Lehtonen**, T. Tukiainen; Inst. for Molecular Med. Finland (FIMM), Helsinki, Finland
Disclosure Block: **L. Lehtonen:** None.

Sex differences are common in human phenotypes, yet rarely discovered in genome-wide association studies (GWAS). Biobank-scale data has fuelled the search of sex differences in genetic associations but beyond waist-hip-ratio and testosterone the results have been largely negative.

To assess whether the lack of sex differences in genetic effects is due to the lack of power to discover these or simply because these do not exist, we examined the theoretical limits for the discovery of sex-biased associations in GWAS. We conducted power analyses for two strategies commonly applied for strata differences in GWAS: a genome-wide search for sex differences in genetic effects and a more focused approach assessing sex differences at variants reaching genome-wide significance in a sex-combined GWAS.

In the genome-wide strategy, with sample sizes similar to the UK Biobank (i.e. 150,000 per sex), the power to discover sex differences is minimal for anything but high effect variants with large differences. For example, to achieve 80 % power to detect differences at p=5e-8 for a variant explaining 1% of phenotype variance (R^2=1%) in one sex, R^2 should be 41% smaller in the other. For variants of R^2=0.1%, more common in GWAS, 80% power requires the variant to explain 13.4 times less variance in the other sex. Smaller differences and effects require substantial increases in sample size for well-powered assessments, e.g., N=440,000 per sex for R^2=0.1% and 25% difference in R^2 for 80% power. Expectedly, the focused approach has better power to discover variants with effects of concordant direction but different magnitude between the sexes, yet this approach misses variants with opposite effects. For such effects, the genome-wide search is well-powered, e.g., over 95 % power for all opposite direction effects when R2=0.1 % in the other sex with N=150,000 per sex.

These calculations demonstrate that even with the biobank-scale data currently available assessments of sex differences (or other two-strata differences) will likely be unsuccessful except for potential high-impact variants displaying considerable differences in effect magnitude. This result echoes the few sex differences discovered for most phenotypes, e.g., in the UK Biobank. Given the lack of power in these efforts, we can currently only exclude the large-scale existence of variants with large opposite effect sizes between the sexes. Unless manyfold sample sizes to these currently available can be collected, future analyses of sex differences should consider alternative strategies, such as genetic correlations and polygenic scores, that can reduce issues arising from the lack of power in individual variants.

PrgmNr 2094 - Challenges with X chromosome analyses and reporting in Genome-Wide Association Studies

Author Block: **Z. Wang**[1], L. Sun[2,3], A. D. Paterson[4,3]; [1]Fudan Univ., Shanghai, China, [2]Univ. of Toronto, Toronto, ON, Canada, [3]Dalla Lana Sch. of Publ. Hlth., Univ. of Toronto, Toronto, ON, Canada, [4]Hosp for Sick Children, Toronto, ON, Canada
Disclosure Block: **Z. Wang:** None.
Little has improved regarding the analysis and reporting of X-chromosome variants from genome-wide association studies (GWAS) in the eight years since Wise et al., (2013) brought the eXclusion of the X-chromosome to the attention of the community. Using the EBI-NHGRI GWAS catalog (date downloaded 2020-03-08) we identified studies that reported genome-wide significant loci on the X-chromosome, and then extracted details from each. Out of 3869 studies in the catalog (male-only studies excluded), 195 reported a total of 564 loci on the X-chromosome, drastically fewer than 1308 studies reporting 5593 loci on chromosome 7, which has similar size to the X-chromosome.
Limitations of the X-chromosome analyses includes that most used methods designed for the autosomes to the X-chromosome: with sex as a covariate and additive coding of genotype; jointly analysing males and females; presumably with 0/2 coding of males assuming random X-chromosome inactivation. Rarely are sex-specific analyses reported, or sex differences in trait prevalence/trait distribution provided.
One study of refractive error identified two different loci in the pseudo-autosomal region PAR1 (PMID: 29808027) but did not describe how the analysis was performed and did not report sex-stratified results. Another study reported variants in the controversial PAR3 region to be significantly associated with ANCA-associated vasculitis, but it did not provide the sex distribution of the controls (PMID: 22808956) potentially making the association subject to confounding by sex. Only one locus has been identified in PAR2 (rs306890, associated with BMI and lipids; PMID:29507422; 30108127) but sex-specificity of the associations were not reported. Recent work (Chen et al. 2021; Song et al., 2021) has shown that genetic effect size estimated from sex-combined analyses are not interpretable.
Despite the major success of GWAS, the X-chromosome continues to be ignored or analyzed and reported in a suboptimal fashion. In addition to association testing, incorporating X-chromosome variants into polygenic risk scores poses additional analytic challenges.

PrgmNr 2095 - Comprehensive genome-wide association study of different forms of hernia identifies more than 80 associated loci

Disclosure Block: **F. Geller:** None.

Introduction: A hernia is an outpouching of tissue through a preformed or secondarily established fissure. Epidemiologic studies suggest shared genetic etiology between different forms of hernia. Methods: Using data from the UK Biobank, we investigated five different forms of hernia classified with ICD 10 codes as inguinal (K40, 28,707 cases), diaphragmatic (K44, 31,193 cases), umbilical (K42, 6,402 cases), femoral (K41, 1,049 cases) and ventral hernia (K43, 4,644 cases). We also studied two combined groups: any hernia (65,492 cases) and any hernia excluding individuals who only had diaphragmatic hernia (38,762 cases). Results: We performed GWAS scans on the 7 described hernia groups, where each scan resulted in at least two associated loci. A replication study for inguinal hernia with almost 24,000 cases from four study groups confirmed 84 variants. Summing up all scans, we identified 114 independently associated variants in 81 loci (P -8). With MultiPhen we assessed a set of associated hernia types for each variant (P ADAMTS6, *ADAMTS16*, *ADAMTSL3*, *ELN*, *LOX*, *FBLN2* and *MFAP4*) or in the transforming growth factor Î² family (*TGFB2, BMP5*, *BMP7*, and *LTBP1*). Further evidence was derived by an inguinal hernia specific expression analysis with GeneNetwork resulting in 9 associated genes, 8 of which were in loci reaching genome-wide significance (*ADAMTS6*, *DNAJC27*, *EFEMP1*, *FBLN2*, *HAND2*, *LOX*, *MFAP4*). Conclusion: Overall, our study provides valuable insight into the genetics of herniation, identifying loci relevant for individual and multiple forms of hernia. The large number of associated loci for inguinal hernia point to several genes relevant for connective tissue homeostasis and general cell processes, which could be helpful to define genetic risk profiles or develop biomarkers indicating an increased vulnerability.

Polygenic risk scores (PRSs) are expected to play a critical role in achieving precision medicine. PRS predictors are generally based on linear models using either individual-level data or summary statistics. However, these predictors generally do not capture nonlinear relationships, epistatic interactions, or genotype-environment interactions. Here, we develop a deep learning framework (EIR) for PRS prediction which includes a model, genome-local-net (GLN), specifically designed for large scale genomics data. The framework supports multi-task (MT) learning, automatic integration of clinical and biochemical data and model explainability. We apply EIR to predict 338 health outcomes, representing a wide range of different diseases in the UK biobank. We find that the EIR generally outperforms LASSO prediction, and in particular for autoimmune disease which were previously shown to have significant epistatic interactions. We showcase the flexibility of the framework by training one MT model to predict the 338 diseases simultaneously. Furthermore, we find that incorporating clinical measurement data for PRSs improves performance for virtually all (93%) diseases considered (ROC-AUC improvement up to 0.36) and that including genotype data provides better model calibration compared to measurements alone. We use the framework to analyse what our models learn and find that they learn relevant disease variants and clinical measurements. EIR is open source and available at https://github.com/arnor-sigurdsson/EIR.

PrgmNr 2097 - Genome-wide association study of chronotype in Japanese direct-to-consumer genetic testing data

View session detail

Author Block: **S. Nogawa**[1], Y. Tahara[2], M. Chijiiwa[1], K. Saito[1], S. Shibata[2]; [1]Genequest Inc., Tokyo, Japan, [2]Waseda Univ., Tokyo, Japan
Disclosure Block: **S. Nogawa:** Salary/Employment; Genequest Inc..
[Background]
Chronotype refers to the trait of morning or evening type. Our sleep phase should fit our chronotypes to achieve good health. A study in European population has reported that many SNPs are associated to chronotypes. However, a genome-wide association study (GWAS) of chronotype has not been performed in East Asian populations. In this study, we performed a chronotype GWAS for the Japanese population to identify East Asian-specific SNPs associated to chronotypes.
[Methods]
Study subjects were about 12,000 consumers of a direct-to-consumer genetic testing service. Their genetic data was analyzed by genotyping arrays. Chronotype was calculated as a sleep-corrected midpoint of sleep in free days value (MSFsc) based on the self-reported questionnaire. MSFsc value enable the measurement of individual chronotypes accurately because of a continuous variable.
[Results]
The chronotype GWAS identified rs11066015 (*p-value*=7.51E-17) in 12q24 locus; 12q24 locus are East Asian-specific polymorphisms and include *ALDH2* related to alcohol metabolism. This association may show that alcohol habit has a significant impact on chronotype. We also compare this GWAS result with European GWAS data. This study was the first chronotype GWAS in East Asian population and provided new insights into circadian rhythm research.

PrgmNr 2098 - Genome-wide association study of varicose veins identifies a protective low-frequency missense variant in GJD3 enriched in Finnish population and highlights connexins as potential therapeutic targets

Disclosure Block: **S. Hassan:** None.
Varicose veins (VV) is the most common manifestation of chronic venous disease, increasing risk for severe vascular conditions, like venous thromboembolism (VTE). In a genome-wide association study of VV in Finnish population (17027 VV cases, 190028 controls), we identify 45 significantly associated loci (p10x enriched in Finns. A low-frequency protective missense variant in GJD3 (p.Pro59Thr; p=1.03e-14, OR(95%CI)= 0.62(0.55-0.70), member of the connexin gene family is exclusively associated with VV in a phenome-wide scan, pointing to the potential of connexin-modulating therapeutic strategies for VV. Our results provide novel insights into VV aetiopathology and highlight the power of isolated populations like Finland to discover genetic variants informing therapeutic development.

PrgmNr 2099 - Genome-wide phenome-wide association study for important diseases & quantitative traits based on the Taiwan Biobank data

Genome-wide phenome-wide association study provides a comprehensive search for pathogenic germline variants and novel candidate predisposition genes with pathways for diseases and quantitative traits (QTs). In this study, we conducted a genome-wide phenome-wide association study for 28 self-reported diseases and 37 QTs based on the Taiwan Biobank data. After data quality control, 21,043 out of 24,000 individuals and 600,066 out of 646,951 single nucleotide polymorphisms (SNPs) remained. SNPs and the clusters of SNPs with linkage disequilibrium susceptible for cardiomyopathy, diabetes, gout and hyperlipidemia are identified; 3,037 genetic association signals for QTs are also found. We constructed polygenic risk scores (PRS) for the studied diseases and QTs. The results of strong association and high prediction for QTs based on the constructed PRS are found. A SNP-based heritability analysis reveals a high genetic heritability of QT, but the heritability estimates for most of the studied diseases are limited. We also conducted the genome-wide gene-environmental interaction studies that account for the particulate matter (PM2.5). The analysis identifies a number of SNP-PM2.5 interactions for several diseases such as osteoporosis, peptic ulcer, postpartum depression as well as for several QTs such as fasting blood glucose and serum glutamic-pyruvic transaminase. Genetic network analysis for complex disorders and QTs based on the identified SNPs and PRSs establishes the disease and QT clusters and their connections. A knowledge database for the identified association signals is established. This study provides an evidence-based perspective for the complex mechanism of genetic etiology.

PrgmNr 2100 - Genotype-by-environment interactions for chronic back pain

View session detail

Author Block: **I. Kuznetsov**[1], Y. A. Tsepilov[2], Y. S. Aulchenko[3]; [1]Skolkovo Inst. of Sci. and Technology, Moscow, Russian Federation, [2]Novosibirsk State Univ., Novosibirsk, [3]PolyOmica, Maastricht, Netherlands
Disclosure Block: **I. Kuznetsov:** None.
Introduction Back pain (BP) is a common debilitating condition with a lifetime prevalence of 40% and a large social and economic impact. Known clinical risk factors for BP include age, female sex, and raised body mass index (BMI). In the majority of BP episodes, the symptoms are transient; however, about 10% of those experiencing acute BP develop a chronic condition. Studies of chronic back pain demonstrated this is a complex trait under highly polygenic control (Freidin et al., 2019). Genetic variation in response to the environment is fundamental in biology and has been described as genotype-by-environment interaction (GxE). Taking into account relevant environmental specificity of genetic effects can improve the fidelity and statistical power of genome-wide association analyses and raise implications for treatment and preventive measures for diseases (Shin and Lee, 2020). In this work, we studied the role of GxE interactions in the control of chronic BP.
Materials and Methods We analyzed ~335,000 unrelated white UK Biobank participants of British ancestry. The trait of interest was â□□Back pain for 3+ monthsâ□□, adjusted for the potential confounders. Age, sex, BMI, education level, and income were tested as covariates interacting with genotype. To estimate heritability explained by GxE we used whole-genome GxE analysis as implemented in GxEsum (Shin and Lee, 2020) - a method based on GWAS summary statistics, using an extension of the LD score regression approach.
Results We estimated the heritability of chronic BP explained by interactions of genotype with age, sex, BMI, education, and income. All estimates did not significantly differ from zero. The highest estimated h2 = 0.59% (SE=0.33%) was for sex.
Discussion GxE interactions for chronic back pain were not found with the whole-genome approach used here. This observation can be partly explained by modest effect sizes and insufficient sample size. The method we used is not sensitive to scale effects which could be the reason for observed GxE interactions in previous studies.
Conclusion No evidence for interactions of genotype by common environmental risk factors for chronic back pain was found.
Acknowledgements This research has been conducted using the UK Biobank Resource (project # 41601, â□□Non-additive effects in control of complex human traitsâ□□).

Disclosure Block: **Y. zhang:** None.
Genome-wide association studies have identified thousands of loci across the genome that influence risks for diseases, many of which have pleiotropic effects. Conversely, at the phenotypic level, certain diseases are frequently found to co-occur in individuals (multi-morbidities). We have developed an approach to unite these two perspectives. By incorporating hierarchical medical ontologies with an adapted version of latent Dirichlet allocation (LDA), we have developed â□□treeLDAâ□□ to model patterns of comorbidity. Such an approach both advances our understanding of relationships between diseases and allows us to analyse genetic association in a lower dimensional â□□topicâ□□ space, which may be more reflective of the underlying causal pathways for diseases.
We show, using simulation and empirical analysis of hospital episode statistic (HES) data from the UK Biobank, coded using the ICD10 ontology, that treeLDA identifies disease topics that align with current medical understanding, outperforms existing topic modelling methods in specific situations, notably when training data is small and/or individuals often have multiple disease topics, and provides us with additional power for genetic discovery. For example, at genome-wide significance we identified 2086 loci associated with disease topics (allowing up to 32 distinct topics), compared to 815 loci associated with single disease codes. We also show that common disease codes are often associated with multiple topics, which can improve genetic risk prediction. Conversely, we identified 126 loci associated with a â□□healthyâ□□ topic characterised by an absence of active disease codes.
Our topic modelling approach provides a data driven approach to model multi-morbidity that can address the challenges of sparseness and heterogeneous presentation and recording practice inherent in electronic healthcare record data. Finally, we show that modelling topics at different levels of resolution (i.e. numbers of topics), combined with genetic analysis, provides a means of identifying the level of phenotypic complexity at which genetic influences act.

PrgmNr 2102 - Machine-learning SNP-based prediction for Primary Biliary Cholangitis: A proof-of-concept study

View session detail

Author Block: **A. Gerussi**[1], D. Verda[2], L. Cristoferi[1], E. Paraboschi[3], G. Mulinacci[1], M. Muselli[2], M. Carbone[1], P. Invernizzi[1], R. Asselta[3]; [1]Univ. of Milano-Bicocca, Monza, Italy, [2]Rulex, Genova, Italy, [3]Humanitas Univ., Pieve Emanuele, Italy
Disclosure Block: **A. Gerussi:** None.
Background: Polygenic risk scores (PRS) are commonly used in risk prediction models for complex traits, but suffer from several limitations. Only one PRS was developed in Primary Biliary Cholangitis (PBC), based on alleles evidenced by genome-wide association studies (GWAS), but published before many novel variants were discovered through huge meta-analyses. Here, we aimed to evaluate the feasibility and accuracy of a Machine learning (ML)-based model for risk prediction, which has several methodological advantages over PRS.
Methods: Genome-wide significant variants identified in subjects of European ancestry in the recently released 2nd international meta-analysis of GWAS in PBC were used as input data. Quality-checked, individual genomic data from Italian patients and controls were used. The main analytic steps were the following: import of genotype and phenotype data, feature ranking, feature selection, supervised classification of phenotype by genotype, generation of if-then rules for disease prediction by logic learning machine (LLM). Ten-fold cross-validation was performed for validation. RulexÂ© software was used to build the ML model, while PLINK 1.9 was used for extraction of variants of interest and preliminary QC steps. A cost of function to penalize the model and improve accuracy of PBC prediction was added.
Results: 1345 individuals were included in the study, 444 were PBC cases and 901 healthy controls. 515 were males and 830 females. 105150 variants were imported in RulexÂ© and, after filtering missing values, 41899 variants were available for the analysis. Several configurations of parameters related to feature selection were simulated. The time for a complete run (from import to rules generation) is 2.30 hours on average on a 64gb working station. The final model had an accuracy of 0.73, a Youdenâ□□s value of 0.32, a sensitivity of 0.44, a specificity of 0.88, a positive predictive value of 0.64 and a negative predictive value of 0.76. Five rules where generated with a covering > 20%. The rule with the highest covering, (44%) had an error of 16% and seven conditions (female sex, and gene variants associated with genes *CD80*, *WDFY4* and *CLEC16A*). The rule with the lowest number of conditions had a covering of 27% and an error of 6% and was based on one variant within the HLA region and female sex.
Conclusion: This study represents the first illustration of a successful analysis of GWAS data with ML for PBC. ML is computationally feasible and generates accurate biological information that can be leveraged for disease prediction. Future steps will include external validation and comparison with a PBC-specific PRS based on the same set of variants.

PrgmNr 2103 - Phenome-wide association study of deleterious variant (s_{het}) burden using exome sequencing of 394,694 UK Biobank participants

View session detail

Author Block: **K. J. Carss**[1], O. Burren[1], Q. Wang[1], F. Hu[1], D. Vitsios[1], E. J. Gardner[2], M. E. Hurles[3], S. Petrovski[1]; [1]AstraZeneca, Melbourn, United Kingdom, [2]Wellcome Sanger Inst., Hinxton, United Kingdom, [3]Wellcome Sanger Inst., Cambridge, United Kingdom
Disclosure Block: **K.J. Carss:** Salary/Employment; AstraZeneca.
The selection coefficient (s_{het}) burden score was introduced by Gardner and colleagues as a statistic to reflect the exome-wide burden of deleterious variants carried by individuals.[1] They showed s_{het} burden to be negatively correlated with fecundity in humans. In this study we tested the hypothesis that a modified version of s_{het} burden score could be associated with a wider range of human traits. We calculated an s_{het} burden score for each of 394,694 UK Biobank participants by focusing on rare (MAFhet burden score against ~16500 phenotypes including binary clinical endpoints as well as quantitative traits, correcting for age and sex.
We identified a total of 132 binary and 61 quantitative traits that achieved a p-8 association with our modified version of the s_{het} burden score. These include the previously reported association between PTV burden and mental and behavioural disorders ($p=8.7x10^{-22}$) as well as associations with leukaemia, respiratory and metabolic disorders.
Future iterations will incorporate additional variant types such as deletions called using microarrays as well as deleterious-predicted missense variants occurring in constrained regions of the human exome. Already, however, the current results yield known and novel insights into the genetic architecture of many complex traitsâ□□including many that have not been thoroughly studied using sequencing technologiesâ□□especially those traits with high locus heterogeneity and where the genetic signals are driven by variants too rare to be detected by individual variant analyses.

Over the last decade, genome-wide association studies (GWAS) have discovered a substantial number of associated variants for many complex traits. However, even within European-centered GWAS data, there are local subpopulations significantly under-represented in these studies. For example, Russians, being one of the largest ethnic groups among the Europeans, remained significantly under-represented in GWAS for years.We used a pilot genotyping cohort of 239 individuals from Saint-Petersburg to investigate phenotypic variance explained by polygenic risk scores (PRS) for 11 phenotypes. We used UK biobank (UKBB) GWAS summary statistics for corresponding phenotypes and selected optimal p-value thresholds for maximizing R^2 for PRS.Several strategies for PRS calculation were tested, including effects of genotype imputation and usage of sex-specific GWAS summary statistics. In addition, we compared R^2 estimates for polygenic risk models in a scenario when UKBB GWAS summary statistics is applied to target data from UKBB itself or Biobank Japan (BBJ). The best utility of UKBB GWAS was observed for UKBB participants, with predictive value for Russian-descent individuals taking an intermediate place between UKBB and BBJ.

PrgmNr 2105 - Quantifying concordant genetic effects of de novo mutations on multiple disorders

View session detail

Disclosure Block: **H. Guo:** None.

Exome sequencing on tens of thousands of parent-proband trios has identified numerous deleterious *de novo* mutations (DNMs) and implicated risk genes for many disorders. Recent studies have suggested shared genes and pathways are enriched for DNMs across multiple disorders. However, existing analytic strategies only focus on genes that reach statistical significance for multiple disorders and require large trio samples in each study. As a result, these methods are not able to characterize the full landscape of genetic sharing due to polygenicity and incomplete penetrance. In this work, we introduce EncoreDNM (**En**richment **cor**relation **e**stimator for ***D****e* ***N****ovo* **M**utations), a novel statistical framework to quantify shared genetic effects between two disorders characterized by concordant enrichment of DNMs in the exome. EncoreDNM makes use of exome-wide, summary-level DNM data, including genes that do not reach statistical significance in single-disorder analysis, to evaluate the overall and annotation-partitioned genetic sharing between two disorders. Applying EncoreDNM to DNM data of nine disorders, we identified abundant pairwise enrichment correlations, especially in genes intolerant to pathogenic mutations and genes highly expressed in fetal tissues. These results suggest that EncoreDNM improves current analytic approaches and may have broad applications in DNM studies.

PrgmNr 2106 - Sources of Inequality at Birth: The Interplay Between Genes and Parental Socioeconomic Status

View session detail

Author Block: **A. Marees**[1], P. Biroli[2], T. Galama[3], P. Arce[2], J. Vollen[2]; [1]Vrije Univ.it Amsterdam, Amsterdam, Netherlands, [2]Univ. of Zurich, Zurich, Switzerland, [3]Univ. of Southern California, Los Angeles, CA

Disclosure Block: **A. Marees:** None.

The start of a humanâ□□s life can be characterized by two lotteries: that of your genes (nature) and that of the family you were born into (nurture). These lotteries set in motion a trajectory, from birth onward, in health and human-capital formation. Genetic factors are implicated in virtually any human trait, and early-life experiences strongly influence long-term outcomes, with children born into high socio-economic status (SES) families generally in better health and of higher SES in later life. Leveraging three longitudinal social-science data sets, the Health and Retirement Study (HRS), the Wisconsin Longitudinal Study (WLS), and the English Longitudinal Study of Aging (ELSA), containing rich genotypic and phenotypic information, we systematically analyze the relationship between an individual's genetic predisposition towards a trait (genotype), their actual trait in adulthood (phenotype), and the social and economic status of the families they grew up in. We proxy the individual's genetic predisposition to a trait by a polygenic score (PGS) and the SES of the families they were born into by a latent factor of parental SES, constructed from parental education and the fatherâ□□s (former) occupational status. We then investigate how genetic predispositions, socio-economic background, and their interaction contribute to later-life outcomes, across a range of forty-five socioeconomic, anthropometric, health, behavioral, and personality traits. We find strong genetic and socio-economic associations but no evidence for sizeable interactions between them. We discuss several possible implications of this result.

PrgmNr 2107 - Systematic comparison of family history and polygenic risk across 27 common diseases

Disclosure Block: **N. Mars:** None.
Family history is the standard measure of inherited disease susceptibility in clinical practice, while polygenic risk scores (PRS) have recently been shown to capture efficiently personal genetic risks in many diseases. No studies have systematically compared how they overlap and complement each other in a wide range of common complex diseases.
Here we leverage family relationships, information about parental causes of death, and genome-wide genotyping of 306,418 individuals within the FinnGen study, to systematically examine the interplay of first and second-degree family history of diseases, parental causes of death, and genome-wide PRSs. With up to 50 years of follow-up within nationwide health registries, we study 27 diseases, covering a large proportion of the burden of non-communicable diseases in adults. The 27 genome-wide PRSs were constructed using PRS-CS.
The effects of PRS and family history were largely independent and provided complementary information for risk prediction. Both high PRS and family history were strongly associated with respective diseases, but a high PRS (>90th percentile) conferred larger risks than family history in cardiometabolic diseases and in the three common cancers studied. Among 39,444 individuals with a first-degree relative in the dataset, the impact of adjusting the PRS with first-degree family history was small (mean decrease in betas -3.4%, s.d. 1.8%). Similarly, the decrease was small adjusting the effect of first-degree family history with the PRS (-4.9%, s.d. 3.3%). The decreases were even smaller for second-degree family history (N=47,154), and for parental causes of death (N=227,982). In 23/27 diseases, PRS improved risk discrimination beyond first-degree family history, with largest increases in rheumatoid arthritis, asthma, and prostate and breast cancer.
PRSs were effective also for risk stratification among individuals with positive family history. In most diseases, a positive family history with a high PRS was associated with a considerably elevated risk, whereas a low PRS compensated completely for the risk implied by a positive family history. For instance, in type 2 diabetes, individuals with positive family history and high (>90th percentile), average (33-90th) or low (This study provides a catalogue of risk estimates and prediction accuracy for both family history of disease and PRSs. We demonstrate that these metrics are largely independent and complementary measures of familial susceptibility.

PrgmNr 2108 - Systematic comparison of performance of over 50 PRS across ancestries for 14 diseases

View session detail

Author Block: **V. Plagnol**, S. Selzam, W. Tarran, R. Moore, D. Wells, F. Riveros-Mckay, P. Donnelly, G. McVean, M. E. Weale; Genomics plc, Oxford, United Kingdom
Disclosure Block: **V. Plagnol:** Salary/Employment; Genomics plc.
There has been intense recent interest in the performance of PRSs across ancestry groups, in particular in the extent of performance deterioration in non-European individuals. This is particularly pressing as the technology moves closer to use in healthcare.
However, like-for-like comparison of reported performances is often difficult, for example because of differences in cohort recruitment, phenotype definition, population characteristics or use of covariates such as age/sex in reported metrics. Even if the same evaluation cohort was used, many of these interpretation issues remain. To overcome these issues we established a uniform PRS comparison pipeline. This leverages the UK Biobank and several ethnically diverse cohorts (Multi-Ethnic Cohort, BioMe, ARIC, MESA, PAGE) to enable direct comparison between over 50 published and internally developed PRS models for 14 complex diseases in four ancestry groups (European, South Asian, East Asian, African), where sufficient case numbers were available for analysis.
Maximum AUC values were observed for individuals of European ancestries, followed by East Asians (average AUC reduction 2.36%), South Asians (average AUC reduction 4.51%) and Africans (average AUC reduction 10.8%). A few publicly available PRS are optimised for a specific ancestry, but for these we did not observe a predictive boost in the target ancestry. Genome-wide PRS including millions of variants were systematically more effective than sparser models, even when European linkage disequilibrium (LD) was applied to non-European ancestries (e.g. cross ancestry AUC boost of 8.2% in breast cancer). Inclusion of functional annotations yielded slight improvements (average ÎAUC 0.005) across ancestries and diseases. Internal optimization using population specific LD maps and bespoke cross-ancestry methodologies generated a detectable increase in the target ancestries, provided that a training set with an effective sample size â¥20% of the European set was available. For example, type 2 diabetes prediction improved across all ancestries, for a minimum of 10% for African ancestries (ÎAUC 0.06) to a maximum of 16% for East Asian ancestries (ÎAUC 0.09).
Systematic comparisons of PRS models across ancestry groups shows that the expected deterioration of performance was relatively limited between European and East/South Asian ancestries, but much more marked in individuals with African ancestries. Choice of PRS methodology substantially impacted predictive performance, suggesting that methodological developments as well as increasing data availability from non-European studies, will improve PRS performance across ancestries.

PrgmNr 2109 - Web-based, participant-driven research platform discovered novel genetic associations for stress-related complaints and food-related behaviors in Japanese population

Genome-wide association studies (GWAS) have identified thousands of loci linked to human complex diseases and traits mainly in European ancestry populations. However, non-European studies are needed to fully understand genetic architectures across diverse populations. Since 2014, we have provided the direct-to-consumer genetic testing service MYCODE for the Japanese population, which is an Asian population with a more genetically homogeneous community than other populations such as Europeans. This homogeneity is a suitable feature for GWAS. To date, the service has reached more than 100,000 users. We have also created a research platform, MYCODE Research, where 90% of the users give consent for use of their genome-wide SNP data and health-related information for research. We used this web-based research framework to enable rapid recruitment of research participants and collect large volumes of data, thereby accumulating over 4 million self-reported phenotypic data. Users can participate in research of interest, and receive personalized feedback, such as analyzed results or lifestyle advice. We performed GWASs against over 50 self-reported traits such as biochemical and psychological traits, using up to 53,000 Japanese individuals. A total of 141 genome-wide significant associations were obtained, including 134 known genetic associations. Importantly, 12 out of them were previously reported from traditional medical record-based studies, demonstrating the reliability of our self-reported phenotypic data for population genomics. We newly identified 7 genetic associations for stress-related complaints and food-related behaviors, and 5 of them were located on or close to gene regions. The alcohol-related *ALDH2* gene variant showed pleiotropic associations. The allele with a decreasing effect on alcohol consumption increased fruit consumption and snack purchasing behavior, while decreased difficulty staying asleep.These association signals disappeared after adjusting for drinking behavior, suggesting that the *ALDH2* genotype modifies these phenotypes via alcohol consumption. The *HCN2* gene locus was associated with irritability, and this locus included a missense variant (rs113534512) associated with febrile seizure and generalized epilepsy. The 6q25.2 locus was associated with difficulty falling asleep, and eQTL datasets showed a significant correlation between the lead SNP, rs533737, and expression of *MTRF1L*, whose variants were associated with chronotype. These results suggested shared biological mechanisms involving *MTRF1L* between chronotype and sleep-related complaints.

Narcolepsy type 1 (NT1) is a hypersomnia characterized by excessive daytime sleepiness and cataplexy. NT1 is caused by a loss of orexin-producing cells in the posterior hypothalamus, however, why the neurodegeneration occurs is still unclear. Previous studies suggested a strong association with *HLA-DQB1*06:02* and the involvement of other immune-related genes such as *CCR1/CCR3*, indicating that abnormalities in the immune system might be involved in disease development. Recently, autoreactive CD4+ and CD8+ T cells specific for orexin and proteins specifically expressed by orexin-producing cells respectively were reported to be associated with narcoleptic etiology and the importance of these T cells in narcolepsy has been suggested. In this study, we performed a microarray-based epigenome-wide association study (EWAS) of DNA methylation for NT1 using CD4+ and CD8+ T cells separated from PBMC of the same origin using magnetic beads (Case; N = 28, Control; N = 28). With proper filtering and normalization, we obtained data on methylation rates for 746,913 CpG sites. PCA using the methylation rate of all the sites found that the variance of PC1 and PC2 could be largely explained by the methylation rate of T-bet and GATA3-binding sites, respectively. Then we examined whether the ratio of subtypes of the CD4+ or CD8+ T cells differed between NT1 and control subjects. We performed estimation of cell components with both reference-based and reference-free analytical methods and found that the ratio of these T cell subtypes did not differ greatly between NT1 and control subjects. Finally we performed EWASs of CD4+ and CD8+ T cells and replication EWASs (Case; N = 14, Control; N = 14) and searched differentially methylated regions (DMRs) of which associations with NT1 were replicated. As a result, 15 DMRs and 5 DMRs were identified in the CD4+ and CD8+ T cells respectively. Most DMRs were common in both T cells; the associations in CD8+ T cells tended to be weaker than those in CD4+ T cells, and only 5 DMRs were identified both in the initial and replication EWASs, however, many of the DMRs detected in CD4+ T cell analysis were detected in either the initial or replication EWAS of CD8+ T cells. Although gene enrichment analysis using DMR-neighboring genes did not suggest any particular immune pathway, several DMRs in CD4+ T cells were located upstream of genes such as *CCL5*, *ALOX12,* and *EIF4G1* related to positive regulation of cell death. In particular, *CCL5* was detected in both CD4+ and CD8+ T cell analyses and is a chemokine-related gene that has been reported to be associated with NT1, suggesting that *CCL5* is an interesting candidate gene for further investigation.

PrgmNr 2111 - Functional characterisation of *GJB2 cis*-regulatory elements and WGS of heterozygous patients with NSHL

View session detail

Three-dimensional chromatin organization plays a key role on gene expression. Gene regulation depends on *cis*-regulatory elements which can interact with gene promoter by chromatin loop. Alteration of chromatin architecture and/or *cis*-acting elements can lead to *enhanceropathies*. Several unelucidated nonsyndromic hearing loss and deafness 1 (*DFNB1)* cases carrying out only one heterozygous pathogenic mutation on Gap Junction Beta 2 (*GJB2*) gene, led to strongly suggest the presence of distant *cis*-regulation. Thanks to chromatin conformation study, we previously identified several *cis*-regulatory elements (CRE) which have enhancer action and silencer effect on *GJB2* expression. Analysis of CTCF binding allowed to purpose a *DFNB1* 3D looping model. We identified cooperative effects between enhancers. To confirm an endogenous enhancer activity, we develop CRISPR interference (CRISPRi), new approach for targeted silencing of transcription in human cells. We target *GJB2 cis*-acting elements with dCas9-KRAB. Preliminary results show a decrease of *GJB2* expression. Moreover, we develop 4C technique to analyse interactions of *GJB2* CREs and confirm a cooperative effect. Then, we focus on 10 patients with incomplete genotype. We realize a whole genome sequencing with HiSeq 4000 by IntegraGen Genomics. WGS analysis allowed to redress three genotype. Moreover, we realize functional assays to analyse a variant in *GJB2* promoter and continue analyses for the others genotypes. This work is supported by grants from the French foundation â□□La Fondation pour lâ□□Auditionâ□□, the â□□RÃ©gion Bretagneâ□□ and the association â□□GaÃ©tan SalaÃ¼nâ□□.

PrgmNr 2112 - Genome-wide Analysis of DNA methylation in 106 Schizophrenia family trios in Han Chinese

View session detail

Author Block: **L. Shen**; Shanghai Jiao Tong Univ., Shanghai, China
Disclosure Block: **L. Shen:** None.
Schizophrenia (SCZ) is a severe neurological disorder, affecting approximately 0.75% of population worldwide. It is well known that schizophrenia tends to run in family while both genetic and environmental factor contribute to its etiology. Overwhelming evidence suggested that alterations in DNA methylations occurred in SCZ patients. To investigate potential inheritable pattern of DNA methylation in SCZ family, we carried out a genome-wide analysis of DNA methylation of peripheral blood samples from 106 Chinese SCZ family trios. Genome-wide DNA methylations of CpG islands were quantified by Agilent 1Ã□244k Human Methylation Microarray. In this study, we proposed a loci inheritance frequency model to characterize differential methylated regions as SCZ biomarkers. Based on this model, 112 hypermethylated and 125 hypomethylated regions were identified. 121 hypermethylated and 139 hypomethylated genes were annotated. By functional enrichment analysis, hub gene networks indicated that many DMGs involved in Notch/HH/Wnt signaling, MAPK signaling, GPCR signaling, immune response signaling. Notably, the hypomethylated genes were significantly tissue-specific enriched in cerebral cortex and functionally enriched in nervous system development. The findings not only proved previous well-characterized SCZ risk genes but also provided novel candidate DMGs in SCZ. In sum, our results may further the understanding of altered DNA methylations in SCZ.

PrgmNr 2113 - Genome-wide DNA methylation profiling of leukocytes identifies CpG methylation signatures of treatment-resistant schizophrenia

View session detail

Author Block: **K-M. Lu**[1], S. Hsieh[2], S-H. Lin[1]; [1]Inst. of Clinical Med., Coll. of Med., Natl. Cheng Kung Univ., Tainan City, Taiwan, [2]Dept. of Psychology, Coll. of Social Sci., Natl. Cheng Kung Univ., Tainan City, Taiwan
Disclosure Block: **K. Lu:** None.
Background Treatment-resistant schizophrenia (TRS) is one of the schizophrenia subgroups, defined as a non-response to at least two trials of antipsychotic medication of adequate dose and duration. To establish epigenetic DNA methylation changes for treatment-resistant schizophrenia in the genome, methylation signatures have been tested to reflect how influences the brain functions and neuronal activities and identify potential mechanisms. We aimed to evaluate the discriminant abilities of DNA methylation probes between treatment-resistant schizophrenia and nontreatment-resistant schizophrenia. **Methods** In this study, 8 treatment-resistant schizophrenia patients and 8 nontreatment-resistant schizophrenia patients (ages ranging from 20 to 65 years old) were recruited. The blood samples of patients were collected and the resulting DNA samples were used for human MethylationEPIC 850K BeadChip scanning of global DNA methylation pattern and DNA methylation Î²-values at individual candidate CpG sites in the 850K arrays. And we conducted enrichment analysis by significant probes. **Results** Based on genome-wide scans of 8 treatment-resistant schizophrenia versus 8 nontreatment-resistant schizophrenia, 111 differentially methylated probes were identified at FDR30% differences DNA methylation Î²-values. These differentially methylated CG probes and the CpG island-associated genes were analyzed with gene Set Enrichment Analysis. Our results identified four genesets that might associate with treatment-resistant schizophrenia : (1) Cell-cell signaling (FDR q-value=0.0127); (2) Response to nitrogen compound (FDR q-value=0.0127); (3) Catalytic complex (FDR q-value=0.0127); (4) Reactome notch-HLH transcription pathway (FDR q-value=0.0266). **Conclusion** In our current analysis, the results showed DNA methylation differences between treatment-resistant schizophrenia and nontreatment-resistant schizophrenia patients, and that further converge into key signal pathways include cell-cell signaling, response to nitrogen compound, catalytic complex and reactome notch-HLH transcription pathway. Further analysis may help discover the roles of candidate genes linked to treatment-resistant schizophrenia.

PrgmNr 2114 - High genetic load of the *GREB1L* gene and auditory rehabilitation in the severe form of cochlear malformation

View session detail

Author Block: **B. Kim**[1], S-Y. Lee[2], J. Han[3], N. Yi[1], M. Kim[3], K. Park[3], Y. Kim[3], Y. Kim[3], B. Choi[3]; [1]Munhwa-ro 282, Chungnam Natl. Univ. Coll. of Med., Daejeon, Korea, Republic of, [2]Seoul Natl. Univ. Hosp., Seoul, Korea, Republic of, [3]Seoul Natl. Univ. Bundang Hosp., Seongnam, Korea, Republic of
Disclosure Block: **B. Kim:** None.
Inner ear malformations (IEMs) are challenging in both etiologic diagnosis and treatment. Most patients with IEM have profound hearing loss, which requires cochlear implantation (CI). However, audiologic outcomes may vary. Etiologic diagnosis was elusive until recently, however recessive *ROR1* and de novo *GREB1L* variants have just been being elucidated, providing a hint of the molecular basis of this cochlear anomaly. Fueled by recent discoveries, we investigated the enigmatic genetic etiologies of such IEMs in Korea and their underlying mechanism as well as reporting the successful audiologic outcomes after CI. Four patients with IEMs were recruited. None of their parents had hearing loss. Exome sequencing was performed. CI was done in all patients and audiological outcomes were reviewed. First-line exome sequencing identified no convincing candidate variants accounting for such IEMs, however, through further bioinformatics analysis, we came across an observation that *GREB1L* variants (c.5618T>C, c.982C>T, c.1079T>A) were detected from three of four patients, which *per se* were most likely to be pathogenic and thus would have been otherwise considered a causative variant based on the population database and several in *silico* studies, were disqualified solely due to their segregation from normal-hearing mother to hearing-impaired son. Given the previous proposal of genetic imprinting for parent-origin kidney phenotype expression of this gene and also the fact that all three male probands consistently inherited the maternal mutant *GREB1L* allele in our study, variable expressivity of the hearing loss more likely suggests incomplete penetrance or genetic imprinting, rather than disqualification of these variants from candidate ones. If this is the case, the genetic load of *GREB1L* variants in this disease entity reached upto 75% in this study. Audiological outcomes showed successful auditory rehabilitation after CI. Based on the results from this study, we suggest potential high genetic load of *GREB1L* in severe IEMs and also that the parent-origin phenotype expression that potentially suggests genetic imprinting could have been the culprit for which the causative gene has not been identified for a long time in the majority of these IEMs. If this is the case, our study will be the first case series that strongly suggest genetic imprinting in this deafness field where Mendelian inheritance predominates by reporting three probands similarly exhibiting the maternal- origin expression. Contrary to concerns of outcome of CI in these IEMs, their audiological outcomes after CI are relatively good enough to enable successful language development.

PrgmNr 2115 - Mapping the cis-regulatory landscape of ABCA4 in adult human retina

View session detail

Author Block: **V. Lopez Soriano**[1], S. Van de Sompele[1], A. DueÃ±as Rey[1], E. D'haene[1], M. Bauwens[2], E. De Baere[3]; [1]Ghent Univ., Ghent, Belgium, [2]Ghent, Belgium, [3]Ghent Univ. and Ghent Univ. Hosp., Ghent, Belgium
Disclosure Block: **V. Lopez Soriano:** None.
Purpose: Stargardt disease (STGD1) is a frequent inherited retinal disease (IRD) affecting ~1/8,000 people. Significant advances have been made over the recent years in elucidating the molecular basis of STGD1, with over 600 pathogenic coding variants and with a substantial number of deep-intronic splicing variants in the disease gene ABCA4. The cis-regulatory domain of ABCA4 is unexplored so far and may represent an attractive target for non-coding disease-causing or modifying variants. By mapping and functionally validating putative cis-regulatory elements (CREs) of ABCA4, we aimed to gain more insights into the regulation of ABCA4 expression.Methods: In order to identify candidate CREs, we integrated published and in-house human retinal epigenomics datasets. CRE predictions were based on chromatin accessibility (ATAC-seq), chromosome conformation capture combined with ChIP-seq (Hi-ChIP), histone modifications (ChIP-seq) and transcriptomics data (RNA-seq), all generated on human donor retina. To functionally validate in silico predicted CREs, dual luciferase reporter assays using pGL4.23 vectors were performed in hTERT RPE-1 cells. A chromatin interaction profile of the ABCA4 locus was obtained via UMI-4C experiments on neural retina and RPE from human donors.Results: A total of 21 predicted CREs were cloned both in their native and reverse orientation in order to assess their regulatory effect in vitro. Five regions showed an increase of reporter activity, three of which display active enhancer marks (H3K4me1 and H3K27ac) in photorreceptors, and three regions showed a significant decrease in luciferase activity. The UMI-4C data showed a decrease in background compared to previously generated 4C-seq data and an improved sensitivity and resolution. The generation of replicates and reverse experiments to confirm the interactions are currently ongoing.Conclusions: Using an integrated approach based on data mining of retinal datasets, in vitro functional validation of putative retinal CREs and targeted chromosome conformation capture (UMI-4C), we have gained insight into the cis-regulatory landscape of ABCA4. The CREs identified and validated here can represent targets of non-coding pathogenic and modifying variants in cases with unsolved ABCA4-associated disease. An improved annotation of tissue-specific cis-regulatory domains of IRD genes may advance the interpretation of non-coding variants.Funding: EU H2020 ITN No. 813490.

PrgmNr 2116 - Methylation quantitative trait loci of type 2 diabetes in a middle eastern population

View session detail

Author Block: **N. Yousri**[1], S. C. Hunt[1], O. Albagha[2]; [1]Weill Cornell Med.-Qatar, Doha, Qatar, [2]Hamad Bin Khalifa Univ., Doha, Qatar
Disclosure Block: **N. Yousri:** None.
Background: With more than 15% prevalence of T2D in Qatar, it is essential to study the methylation patterns associated with T2D along with the genetic and lifestyle/environmental factors that affect methylation. GWAS studies have identified hundreds of T2D loci, yet their functional association with other biological entities still needs several years of investigation. DNA Methylation is of particular interest in this area as it has not been touched frequently when studying causality of SNPs with methylation levels. Most studies in this direction have focused on genotype arrays and earlier DNA methylation technologies. **Objectives**: We present a study on the association of DNA methylation sites with T2D in Qataris and cross that with their whole genome sequence data to investigate possible causal signals. We aim to identify CpGs associated with T2D in Qatari samples with 40% patients and identify their quantitative trait loci using whole genome data. **Materials and Methods**: 835 samples from the Qatar Bio-Bank (QBB) were profiled for >850,000 methylation sites using illumina EPIC arrays. Methylation data was normalized using 'funnorm' functions in R minfi package. CpG sites that overlap with SNPs were removed. A total of 835,000 CpG sites remained for the analysis after quality control steps. Whole genome data was filtered for a maf of >0.05, a call rate of > 98% and a hwe p value of 10^{-6}. A linear regression model for association of CpG sites with T2D was used after correction for all relevant covariates including actual cell counts that were available at the QBB, and genomic principal components. The GenABEL package was used for the CpG-SNP association analysis, correcting for kinship. Annotation data available from minfi package and Seattle-Seq server were used for the annotation. **Results**: A total of 74 CpG sites were identified to be associated with T2D at an epigenetic wide association threshold of p -8 in the discovery cohort of 454 individuals and replicated in 381 individuals. Preliminary analysis identified methylation quantitative trait loci (methQTLs) of 22 CpG sites in 29 unique genes at p -10. Half of the 22 CpG sites with methQTLs were located in the body of the CpG gene. Of all the identified methQTLs, two were *trans* associations, with the CpG site associated with SNPs in two different chromosomes. Two of the CpG sites were associated with missense and stop-gained variants, where the CpGs were located in a TSS and in exon body or gene body. More investigations are required to study and replicate the methQTLs. **Acknowledgment**: Work is supported by Qatar National Research Funds (QNRF) PPM2 #: 0226-170020, Qatar Genome Project (QGP) and Qatar Bio-Bank (QBB).

PrgmNr 2117 - Mitochondrial-nuclear gene expression co-regulation is compromised in immune system cells of COVID-19 patients: rewiring towards glycolysis

View session detail

Author Block: **H. Medini**[1], Z. Amit[1], D. Mishmar[2]; [1]Ben Gurion Univ. of the Negev, Beer Sheva, Israel, [2]Ben Gurion Univ., Beer-Sheva, Israel
Disclosure Block: **H. Medini:** None.
Mitochondria is pivotal to cellular bioenergetics and in response to viral infections. Although several SARS-CoV-2 proteins localize and interact with the mitochondria, the role of mitochondrial activities in the etiology of COVID-19 has been largely overlooked. As a first step to address this caveat, we analyzed three publicly available bulk RNA-seq datasets (two from peripheral blood and one from the respiratory tract) from COVID-19 patients and corresponding healthy controls. This analysis consistently revealed significantly reduced mitochondrial DNA (mtDNA) gene expression in peripheral blood of COVID-19 patients. In contrast, mtDNA gene expression was not significantly altered in patients' respiratory tract samples. As these findings implied cell type-dependent mitochondrial response in COVID-19 patients, we analyzed 362,758 cells from single-cells RNA-seq datasets from peripheral blood mononuclear cells (PBMC), nasopharyngeal (NP) or Broncho alveolar lavage fluid (BALF). Although significantly reduced mtDNA gene expression was observed in multiple patients' cell types, such change was more prominent in immune system cells. Notably, the reduced mtDNA gene expression associated with altered expression of candidate mtDNA transcriptional regulators, suggesting downregulation. Conversely, expression of nuclear DNA-encoded OXPHOS subunits was generally elevated in patients, suggesting a departure from mito-nuclear co-regulation. Elevated expression of ROS-response genes in patients support compromised mitochondrial function. Elevated expression of glycolysis enzymes in patients suggests rewiring towards glycolysis in patient' cells. Since SARS-CoV-2 replication requires glycolytic environment which promotes cytokine storm in immune system cells, we argue that such environment is achieved via compromised mitochondrial gene expression regulation, suggesting that mitochondrial dysfunction is central in COVID-19 etiology.

PrgmNr 2118 - UMI-4C chromatin interaction profiling, *in vitro* and *in vivo* enhancer assays to dissect the *cis*-regulatory mechanisms underlying North Carolina macular dystrophy, a retinal enhanceropathy

View session detail

Author Block: **S. Van de Sompele**[1,2], E. D'haene[1,2], B. Munevver Cicekdal[2,3], S. Vergult[1,2], T. Van der Snickt[1,2], F. S. Shaya[4], K. Vleminckx[2,3], P. Liskova[5], K. W. Small[4], E. De Baere[1,2]; [1]Dept. of Biomolecular Med., Ghent Univ., Ghent, Belgium, [2]Ctr. for Med. Genetics, Ghent Univ. Hosp., Ghent, Belgium, [3]Dept. of BioMed. Disclosure Block: **S. Van de Sompele:** None.

North Carolina macular dystrophy (NCMD) is a rare autosomal dominant retinopathy, characterized by loss of central vision. With the identification of noncoding single nucleotide variants (SNVs) and duplications overlapping with a DNase I hypersensitive site (DHS) near *PRDM13* or *IRX1* as the genetic cause of NCMD, it is hypothesized to be a retinal enhanceropathy. Here we aim to dissect the *cis*-regulatory domains of *PRDM13* and *IRX1*, to provide mechanistic insight into the molecular pathogenesis of NCMD.

Chromosome conformation capture, in particular UMI-4C sequencing, was performed on retinas from human donor eyes to fine-map interactions of *cis*-regulatory elements (CREs) with the *PRDM13* and *IRX1* promoters. This data was integrated with other human retinal (epigen)omics data (ChIP-seq of histon modifications and retinal transcription factors, ATAC-seq, RNA-seq, DNase-seq of embryonic retina at five different stages) in a genome-wide UCSC browser session to identify candidate retinal CREs. Twenty-five unrelated NCMD families underwent targeted testing followed by whole genome sequencing (WGS) in the unsolved cases (n=11). Subsequently, *in vitro* luciferase assays in ARPE-19 cells and *in vivo* enhancer detection assays in Xenopus leavis using a ZED vector were performed to evaluate candidate CREs and (likely) pathogenic SNVs.

This multi-omics analysis mapped the retinal chromatin interaction profile of both disease loci, and revealed 7 and 6 candidate CREs for *PRDM13* and *IRX1* respectively, two of which are hotspots of pathogenic SNVs. The genetic architecture of NCMD was expanded with a novel noncoding SNV and duplication with a likely effect on *PRDM13* regulation. Interestingly, UMI-4C showed an interaction of the CRE this variant is located in with the PRDM13 promoter. This CRE is active at a specific developmental stage (D103) compatible with the timepoint when retinal progenitor cells of the central retina exit mitosis. Finally, luciferase assays demonstrated that the known and novel noncoding SNVs, located in the two hotspots, display higher activation and silencing, respectively. Overall, we have provided insight into the *cis*-regulatory mechanisms underlying NCMD, an examplary retinal enhanceropathy.

PrgmNr 2119 - ZNF143, an important factor for CTCF-bound chromatin interactions

View session detail

Author Block: **Q. Zhou**[1], M. Yu[2]; [1]Natl. Univ. of Singapore, Singapore, Singapore, [2]Univ. of California San Diego
Disclosure Block: **Q. Zhou:** None.
CCCTC binding factor (CTCF) is an important factor in the maintenance of chromatin-chromatin interactions, yet the mechanism regulating its binding to chromatin is unknown. We demonstrate that zinc finger protein 143 (ZNF143) is a key regulator for CTCF-bound promoter-enhancer loops. In the murine genome, 10,544 pairs of ZNF143 and CTCF motifs located 37 bp away from each other, and 99.9% (10,529) formed the convergent orientation. Furthermore, deletion of ZNF143 leads to loss of CTCF binding on promoter and enhancer regions associated with gene expression changes. CTCF-bound promoter-enhancer loops are also disrupted after excision of ZNF143. Furthermore, deletion of ZNF143 in hematopoietic system leads to embryonic lethal, suggesting an essential role in hematopoiesis. Indeed, systematically analysis demonstrates that both embryonic and adult hematopoietic stem cells completely loss the ability to reconstitute the hematopoietic system in recipient mice without ZNF143. In line with that multiple pathways and genes critical for hematopoiesis are downregulated, associated with significant reduction of CTCF binding on their promoter-enhancer loop anchors and decreased loop intensities, we hypothesize that CTCF-bound promoter-enhancer loops regulate gene expression patterns essential for maintenance of murine hematopoietic stem and progenitor cell integrity. Our data suggest a common feature of gene regulation that ZNF143 is a critical factor for CTCF-bound promoter-enhancer loops.

PrgmNr 2120 - Epigenome-wide association study of the human IgG N-glycome composition

View session detail

Author Block: **A. Frkatovic**[1], F. Vuckovic[1], J. F. Wilson[2,3], G. Lauc[1,4], L. Klaric[2]; [1]Genos GlycoSci. Res. Lab., Zagreb, Croatia, [2]MRC Human Genetics Unit, Inst. of Genetics and Cancer, Univ. of Edinburgh, Edinburgh, United Kingdom, [3]Usher Inst., Univ. of Edinburgh, Edinburgh, United Kingdom, [4]Faculty of Pharmacy and Biochemistry, Univ. of Zagreb, Zagreb, Croatia
Disclosure Block: **A. Frkatovic:** None.
N-glycosylation of immunoglobulin G (IgG) is a post-translational modification which affects protein stability and its effector functions. IgG N-glycosylation is influenced by both genetic and environmental factors. Epigenetic mechanisms, such as DNA methylation, may provide further insight into the link between IgG N-glycome heritability and environment. We performed an epigenome-wide association study (EWAS) in the ORCADES cohort of volunteers from Northern Scotland (n=967) to identify CpG sites associated with the composition of the IgG N-glycome, quantified by ultra-performance liquid chromatography. Nine glycan traits were defined to reflect biologically relevant traits by summing up the glycan structures containing a specific sugar unit in the total IgG N-glycome, such as fucose. Genome-wide methylation levels were measured from whole blood DNA samples with the Illumina HumanMethylation 850K BeadChip, followed by QC and correction for technical and biological covariates. Linear regression was performed with each glycan trait as outcome and CpG M value as the independent variable, with correction for age and sex in the basic model. The adjusted model further included smoking, BMI, and age-by-sex interaction. In addition, we performed a sex-stratified test. The significantly associated CpG sites were assessed for potential confounding by the surrounding SNPs (Â±50 kb). At p-8, basic and adjusted models resulted in eight and five associated CpG sites, respectively. The association of cg08178031 and sialylation ($p=4.39x10^{-9}$) was confounded by a SNP in the 5â□□UTR region of the *ST6GAL1* gene which is known for its role in the addition of sialic acid to the glycan chain. In a sex-stratified test, we demonstrated that the association of galactosylation and cg06072257 is sex-specific (female-only), noting that this association is only suggestive ($p=3.17x10^{-7}$), likely due to lower power for the smaller sample size in the sex-stratified analysis. Results of eFORGE tool for exploration of transcription factor binding sites show that cg06072257 is found near to the binding motif for ESR1. Two additional associations were significant in the female-specific test: cg08946781 (with sialylation and galactosylation) found in the open sea region next to the *CCR7* gene and cg27419075 (bisection) located in a CpG island upstream of the *PDE2A* gene. A single male-specific association (cg16564136) mapped to the 5â□□UTR region of the *NMNAT3* gene. Despite the limited power, there is an implication that the methylation of the associated CpG sites might be sex-specific, thereby affecting the composition of the IgG N-glycome in a sex-specific manner.

PrgmNr 2121 - eQTL Catalogue: A compendium of uniformly processed human gene expression and splicing QTLs

Alasoo[4,2]; [1]Inst. of Computer Sci., Univ. of Tartu, Tartu, Estonia, [2]Open Targets, Hinxton, Cambridge, United Kingdom, [3]EMBL-EBI, Hinxton, Cambridgeshire, United Kingdom, [4]Univ. of Tartu, Tartu, Estonia

Disclosure Block: **N. Kerimov:** None.

An increasing number of gene expression quantitative trait locus (eQTL) studies have made summary statistics publicly available, which can be used to gain insight into complex human traits by downstream analyses, such as fine mapping and colocalisation. However, differences between these datasets, in their variants tested, allele codings, and in the transcriptional features quantified, are a barrier to their widespread use. Consequently, target genes for most genome-wide association study (GWAS) signals have still not been identified. Here, we present the eQTL Catalogue (https://www.ebi.ac.uk/eqtl/), a resource that contains quality controlled, uniformly re-computed QTLs from 21 eQTL studies. We find that for matching cell types and tissues, the eQTL effect sizes are highly reproducible between studies, enabling the integrative analysis of these data. Although most cis-eQTLs were shared between most bulk tissues, the analysis of purified cell types identified a greater diversity of cell-type-specific eQTLs. Consequently, the number of independent GWAS loci for which we could detect at least one colocalising eQTL increased by 25% when we added eQTL Catalogue datasets to the GTEx v8. Our summary statistics can be downloaded by FTP, accessed via a REST API, and visualised on the Ensembl genome browser. Fine mapped associations (credible sets) can also be explored using our user-friendly website (https://elixir.ut.ee/eqtl/). New datasets will continuously be added to the eQTL Catalogue, enabling the systematic interpretation of human GWAS associations across many cell types and tissues.

Approximately 45% of the human genome are occupied by transposable elements or transposons, which are selfish mobile DNA sequences, translocating around the genome. The translocation of transposons, also refer as transposition often leads severe genic breakage and chromosomal instability, consequently the species conservation is threatened. In the germline cells, specialized machineries to repress transposons have been acquired, which is PIWI-interacting RNA (piRNA)-mediated RNA silencing. piRNA is a largest class of small non-coding RNA and is mostly arisen from the specified genomic loci, called piRNA clusters, which usually harbors transposon fragments and remnants, thereby targeting transposons. Although piRNAs are predominantly expressed in the germline, the elevated expression has also been observed in somatic cells and cancer cells in animal. Transposons, in particular retrotransposons, move around the genome by copy and paste mechanism, thereby amplifying their own sequences in number quickly. Importantly, on the piRNA analysis, the transposition causes genetic diversity between individuals, which may interrupt the bioinformatics analyses such as reduced mappability, incompatibility between samples, and missing orphan piRNAs. In order to assess the impact of genetic diversity on piRNA analysis, we first sought small RNA-seq data sets from normal human testis and found three data sets from the testis of Caucasians and a data set isolated in China. We next defined 697 common piRNA clusters between two human reference genomes, standard reference genome GRCh38/hg38 and Han Chinese reference genome HG00514, and then performed the mapping of the data sets to these reference genomes. Note that GRCh38/hg38 is mostly based on Caucasian and African ancestry. Unexpectedly, all four data sets were mapped to HG00514 higher than GRCh38/hg38, suggesting that although the number of samples is small in this study, the nucleotide diversity may not be an important factor in determining the mappability of piRNA reads, and further suggesting that piRNA reads would be better to be analyzed utilizing several reference genomes to avoid the missing of functional piRNAs in individuals.

PrgmNr 2123 - Loss of PTEN disrupts 5-hydroxymethylcytosine landscape along mESC neuronal differentiation

View session detail

Author Block: **K. Miu**, Z. Wang, S. Fung, C. Yu, C. Huang, W. Wang, F. Ou, S. Hao, W. Law, W-Y. Chan; The Chinese Univ. of Hong Kong, Hong Kong SAR, China

DNA hydroxymethylation dynamics have been implicated in normal development and differentiation. 5-hydromethylcytosine (5hmC), created by Tet proteins-catalysed oxidation of 5-methylcytosine (5mC), is most abundantly found in the brain, but the genome-wide 5hmC landscape along diverse neuronal differentiation remains unknown. Interestingly, we found that Pten ablation effectively disrupted the lineage differentiation of midbrain/hindbrain neural progenitors, resulting in immature neuronal progenitors.Here, we differentiated mouse embryonic stem cells (mESCs) into ventral midbrain and hindbrain neural progenitors and characterized the global 5hmC distribution using nano-5hmC-seal approach. The 5hmC pattern was found remodelled in promoters, exons and enhancers, associated with gene activation and repression. Notably, ventral midbrain marker (Lmx1a, Otx1, Th) and hindbrain marker (Hoxa1, Zic1, Tph1) acquire 5hmC and thereby up-regulated during differentiation. Furthermore, dynamic changes in 5hmC within the same neural lineages were investigated when the mESCs were subjected to Pten ablation. Indeed, we identified 4111 and 203 differentially hydroxymethylated regions (DhMRs) in differentiation of Pten-/- mESCs into ventral midbrain and hindbrain progenitors. Gene ontology analysis showed that the majority of these DhMRs were associated with neurogenesis and relevant signal transduction pathways along ectoderm differentiation. To conclude, our findings demonstrate active hydroxymethylation remodels lineage-specific differentiation of pluripotent stem cells during early neural development.

PrgmNr 2124 - Nuclease deficiencies alter plasma cell-free DNA methylation profiles

The effects of DNASE1L3 or DNASE1 deficiency on cell-free DNA (cfDNA) methylation was explored in plasma of mice deficient in these nucleases and in DNASE1L3-deficient humans. Compared to wildtype cfDNA, cfDNA in *Dnase1l3*-deficient mice was significantly hypomethylated, while cfDNA in *Dnase1*-deficient mice was hypermethylated. The cfDNA hypomethylation in *Dnase1l3*-deficient mice was due to increased fragmentation and representation from open chromatin regions (OCRs) and CpG islands (CGIs). These findings were absent in *Dnase1*-deficient mice, demonstrating the preference of DNASE1 to cleave in hypomethylated OCRs and CGIs. We also observed a substantial decrease of fragment ends and coverage at methylated CpGs in the absence of DNASE1L3, thereby demonstrating that DNASE1L3 prefers to cleave at methylated CpGs. Furthermore, we found that methylation levels of cfDNA varied by fragment size in a periodic pattern, with cfDNA of specific sizes being more hypomethylated and enriched for OCRs and CGIs. These findings were confirmed in DNASE1L3-deficient human cfDNA. Thus, we have found that nuclease-mediated cfDNA fragmentation markedly affected cfDNA methylation level on a genome-wide scale. This work provides a foundational understanding of the relationship between methylation, nuclease biology and cfDNA fragmentation.

Transcription factor (TF) regulation played an important role in human osteoblastsâ function. The molecular features of TFs in human osteoblasts were not fully understood. We used single-cell RNA sequencing (scRNA-seq) to perform a systematic cellular taxonomy dissection of freshly isolated human osteoblasts. Then, based on human hg19 transcriptional regulator database, we calculated regulation modules by single-cell regulatory network inference and clustering (SCENIC). Additionally, we performed cell-specific network (CSN) analysis among 4 important regulons (*CREM, FOSL2, RUNX2* and *CREB3L1*), and the total number of significant edges in the whole transcriptome CSN was returned as the network degree matrix (NDM) value for each TF. Then, we constructed regulon activity-based osteoblast development trajectories by Monocle (v2.14.0). Our research revealed cell development and function state changes of primary osteoblasts by using SCENIC analysis and CSN construction. *CREM* and *FOSL2* regulons were relatively active in preosteoblast-S1. Strong CSN connections of immunity, cell proliferation/differentiation related target genes in *CREM*, *FOSL2* regulons further proved their particular functional state. Our results also support that osteoblast differentiation and development were influenced by different TFs in different cell stage. For example, the key time point of *RUNX2* and *CREB3L1*âs regulation may be in the mature stage of osteoblast. As expected, preosteoblast-S1 showed the highest NDM value of *CREM* and *FOSL2*, mature osteoblast showed the highest NDM value of *RUNX2* and *CREB3L1,* which indicated their wide influence at the whole transcriptome level through directly regulating gene targets or other indirect interactions, co-expression, alternative splicing and so on. This is the first study to describe the unique features in cellular regulon active landscape of human osteoblasts *in vivo* and identify the gene associations/network for osteogenesis at single-cell resolution. Our results may provide valuable resources to reveal the advanced mechanisms of bone metabolism and associated disorders based on the TF regulation network.

PrgmNr 2126 - TDG contributes to male subfertility through dysregulation of male germline stem cell development

View session detail

Author Block: **T-L. Lee**, J. Liao, W. Lee, H. Suen, K. Chow, A. Luk; The Chinese Univ. of Hong Kong, Shatin, China
Disclosure Block: **T. Lee:** None.
Thymine DNA glycosylase (TDG) is a key enzyme in active DNA demethylation, which could excise 5-formylcytosine (5fC) and 5-carboxylcytosine (5caC). To investigate the impact of *Tdg* on male fertility, we created a mouse strain with male germline-specific *Tdg* knockout using Stra8-Cre system. Our breeding assay showed *Tdg*-conditional knockout (*Tdg*-CKO) males had fewer accumulated progenies over a 35-week period compared to heterozygous males, indicating sub-fertility. Testis section showed complete spermatogenesis in *Tdg*-CKO males but an abnormally lower number of spermatocytes in the leptotene/zygotene stages. TUNEL assay also showed an increased number of apoptotic cells in *Tdg*-CKO testes. Meanwhile, our RNA-Seq analysis on neonatal KIT- spermatogonial stem cells (SSC) identified 110 differentially expressed genes (DEGs) between KO and WT. Interestingly, *Tdg* deletion led to suppression of genes in the FGF signaling pathway while enhancement in the competing GDNF pathway in undifferentiated SSC. Finally, ATAC-Me showed hypo-demethylation during SSC differentiation (KIT transition) in promoter regions of *Id4* and *Solhl1*, which are important spermatogenesis regulators, suggesting *Tdg* is regulating site specific demethylation.

PrgmNr 2127 - Whole-genome and small RNA sequencing-based microRNA-eQTL mapping in Japanese elucidates variant-microRNA-disease connections

View session detail

Author Block: **K. Sonehara**[1], S. Sakaue[1], Y. Maeda[1], J. Hirata[1], T. Kishikawa[1], K. Yamamoto[1], H. Matsuoka[2], M. Yoshimura[2], T. Nii[1], S. Ohshima[2], A. Kumanogoh[1], Y. Okada[1]; [1]Osaka Univ. Graduate Sch. of Med., Suita, Japan, [2]NHO Osaka Minami Med. Ctr., Kawachinagano, Japan
Disclosure Block: **K. Sonehara:** None.
Expression quantitative trait loci (eQTL) analysis of non-coding RNA (ncRNA) is an essential step toward elucidating the ncRNA involvement behind the genetics of complex diseases. Among several classes of ncRNAs, microRNAs (miRNAs) are key post-transcriptional gene regulators and implicated in diverse diseases. Despite its biological importance, existing miRNA-eQTL studies have focused mostly on European individuals, underrepresented in other populations. As an initial miRNA-eQTL study in the Asian population, we conducted miRNA-eQTL mapping for 343 miRNAs in 141 Japanese individuals using small RNA sequencing (sRNA-seq) of peripheral blood mononuclear cells (PBMCs) and whole-genome sequencing (WGS). We identified 1,275 *cis*-miRNA-eQTL variants for 40 miRNAs (false discovery rate cis-regulatory variants not captured by the conventional miRNA-eQTL mapping (e.g., miR-933). We identified a copy number variation (CNV) associated with miRNA expression (e.g., miR-570-3p, P = 7.2 Ã 10^{â6}), which contributes to a more comprehensive landscape of miRNA-eQTLs. To elucidate a post-transcriptional modification in miRNAs, we created a catalog of miRNA-editing sites, including ten canonical (A-to-I and C-to-U) and six non-canonical sites (other base substitutions). Finally, by integrating the miRNA-eQTLs and the large-scale Japanese genome-wide association studies (GWASs) of 25 complex traits (mean n = 192,833), we conducted a transcriptome-wide association study (TWAS) and colocalization analysis. We identified miR-1908-5p as a potential mediator for adult height, colorectal cancer, and type 2 diabetes (P â5). Our study broadens the population diversity in ncRNA-eQTL studies and contributes to functional annotation of disease-associated loci found in non-European populations.

PrgmNr 2128 - Identification of hubb genes in retinoblastoma using network analysis

View session detail

Author Block: **S. Bhatia**; Univ. of South Florida, Tampa, FL
Disclosure Block: **S. Bhatia:** None.
Background: Retinoblastoma (RB) is a rare cancer usually initiated by biallelic mutation of the retinoblastoma gene (*RB1*). This study was performed to identify genes related to RB using network-based analysis. **Methods:** The differentially expressed genes (DEGs) were analyzed using GEO2R from GSE97508 of the Gene Expression Omnibus (GEO) database. Gene enrichment analysis, and protein-protein interaction (PPI) network construction were performed on the DEGs by the Gene Ontology (GO), Search tool for the retrieval of interacting Genes (STRING), and Cytoscape to identify hub genes. Finally, the network was analyzed and genes were ranked based on several centrality indices. **Results:** A total of 250 DEGs were identified that mainly play role in visual transduction processes. The networks were analyzed and high centrality genes were identified. Exploration of functional modules and complexes showed that the majority of high centrality genes integrated in biological pathways that drive retinoblastoma pathogenesis. **Conclusions:** In this study, the network-based analysis was proposed that could explicate the complex interplay between biological processes underlying RB. Furthermore, an experimental validation of these candidate genes could lead to identification of promising targets.

PrgmNr 2129 - Detecting gene-gene interactions from GWAS using diffusion kernel principal components

View session detail

Author Block: **A. Walakira**[1], J. Ocira[2], D. Duroux[2], R. Fouladi[2], M. MoÅikon[1], D. Rozman[1], K. Van Steen[2]; [1]Univ. of Ljubljana, Ljubljana, Slovenia, [2]Univ. of Liege, Liege, Belgium

Genes and gene products function as components of complex networks of macromolecules through physical or biochemical interactions. Dependencies of gene mutations on genetic background (i.e., epistasis) play a role in understanding molecular underpinnings of complex diseases like inflammatory bowel disease (IBD). However, the process of identifying such interactions is complex due to the curse of high dimensionality, dependencies in the data and non-linearity. We propose a novel epistasis detection analysis workflow that 1) takes GWAS SNP data as input, 2) develops gene-level summaries via diffusion kernels on graphs, and 3) uses a Bayesian framework and kernel PCs as new units of analysis to discover gene-gene interactions in relation to a complex trait.We applied our analysis workflow on GWAS data on IBD from the IIBDGC consortium (www.ibdgenetics.org). We pruned out SNPs that were in linkage disequillibrium ($r^2 > 0.75$) and considered only common variants (minor allele frequency > 5%) and those in Hardy-Weinberg equilibrium (p-value > 0.001). We used FUMA to functionally map SNPs to genes (significant eQTL SNP-gene expression in colon). Bivariate synergy was used to construct SNP-based graphs within a gene and the resulting within-gene edge weights were used to obtain informed summaries of genes. For analysis of within-gene network, the 'Maximum Relevance Minimum Redundancy' algorithm in the minet package in R was used for meaningful node selection. This resulted in a reduced gene SNP set that was analysed with the igraph R package. Furthermore, for each gene, diffusion kernels were constructed over genotypes based on matrix exponentiation. The first principal component for each gene was retained and considered a â□□summaryâ□□ explanatory variate in Bayesian gene-gene interaction models. Interactions were highlighted based on posterior inclusion probabilities greater than zero.Generally, within gene networks differed among genes, with genes such as *PARK7, CD40, NUCKS1, MST1R* and *SLC22A4,* known to be associated with IBD (CD or UC), showing higher-end densities. Gene size (number of SNPs) was not the determining factor for epistasis detection. Seven genes involved in 2-way interactions namely *LINCO1475, TAP2, RGS14, OTUD3, SLC22A4, NICN1* and *NOTCH4* have been associated with IBD, CD or UC in DAVID and DisGeNET. Our method identified four genes namely MAP1LC3A, RGS14, CNFTR and AHSA2 to be of interest in IBD. We show that our approach is able to recover known IBD associated genes and additional genes of interest linked to disease. The trait-informed dimensionality reduction step in our analysis workflow enhances the detection of gene-gene interaction effects.

PrgmNr 2130 - Epigenetic and RNA profiling of cancer using multi-omics data on the Cancer Genomics Cloud powered by Seven Bridges

Author Block: **V. Pajic**[1], N. Vukojicic[1], J. Babic[1], A. Danicic[1], M. Matic[1], A. Stankovic[1], D. A. Dean,II[2], J. W. Grover[2], M. Ray[2], S. Subramanian[3]; [1]Seven Bridges, Belgrade, Serbia, [2]Seven Bridges, Boston, MA, [3]Seven Bridges, Sugar Land, TX

Disclosure Block: **V. Pajic:** None.

Integrative analysis of multi-omics data is a promising approach for revealing the functionality of complex biological systems and processes in cancer. The Cancer Genomics Cloud (CGC) powered by Seven Bridges is an NCI-funded computational platform for accessing and analyzing large cancer datasets and facilitating collaborative research on the cloud. It is a comprehensive resource that provides access to complex datasets generated by diverse omics technologies and computational tools that can be used for their analysis. In order to enable multi-omics analysis on CGC, we present an end-to-end bioinformatics pipeline for processing epigenetic data on the CGC.The customizable pipeline is modular and implemented in the Common Workflow Language (CWL) on the CGC. A user can initiate the analysis from either raw FASTQ files coming from RNAseq, ATACseq and ChIPseq experiments, or from already processed data (gene expression tables or peak lists). If raw reads are used, the files are first processed with an adequate set of tools, specific for each type of experiment. For RNAseq, we use a pipeline that includes basic quality control, alignment and quantification steps. ATACseq and ChIPseq data are processed based upon ENCODE consortium specification, which includes reads alignment, peak calling, quality control and reporting steps.The resulting files, expression tables from RNAseq experiments and peaks from ATACseq and ChIPseq, are further jointly processed within the pipeline. This joint analysis starts with comparing the transcript count and peak set data to identify differentially expressed genes and binding regions. The detected differential features are then overlapped and used for gene set enrichment and pathway analysis, in order to explore the correlation of chromatin accessibility or transcription factor binding and gene expression in cancer samples. The analysis is implemented in two forms: as a workflow that can be used as a one-click solution through the CGC webuser interface, or as an interactive analysis through an R studio notebook, also available on the CGC.In summary, we present a bioinformatics pipeline that allows researchers to study the epigenetic mechanisms involved in transcriptional regulation in cancer. The CGC empowers the users to complete their entire research workflow on the platform while streamlining collaboration and speeding the time from hypothesis to conclusion.

Disclosure Block: **C. Ruiz Arenas:** None.

Epimutations are rare alterations in the methylation pattern at specific loci. Epimutations can lead to cancers, such as Lynch syndrome, rare diseases such as Prader-Willi syndrome, and are associated with common disorders, such as autism. Nonetheless, no standard methods are available to detect and quantify these alterations. Two methods for epimutations detection on methylation microarray data have been reported: (1) based on identifying CpGs with outlier values and then cluster them in epimutations (Barbosa et al, 2018); (2) define candidate regions with bumphunter and test their statistical significance with a MANOVA (Aref-Eshghi et al, 2019). However, the implementation of these methods is not publicly available and these approaches have not been compared. We have implemented these two methods (called â□□barbosaâ□□ and â□□manovaâ□□, respectively) in the epimutacions R package. Additionally, we implemented four additional approaches, using a different distribution to detect CpG outliers (beta), or a different model to assess region significance (mlm, mahdistmcd, and isoforest). epimutacions can infer epimutations based on a case-control design, or using a leave-one-out approach, conforms with Bioconductor guidelines and is publicly available at https://github.com/isglobal-brge/epimutacions. First, we explored the effect of sample size on the detection of 4 epimutations experimentally validated from 2 GEO datasets. In this setting, methods based on bumphunter (manova, mlm and mahdistmcd) had a higher recall. Next, we run all methods in Illumina 450K methylation microarray data from 378 DNA samples from cord blood of the INMA cohort, a general population cohort. beta, barbosa, mlm, and manova identified few epimutations per individual, while mahdistmcd and isoforest detected tens or hundreds of epimutations per individual. Next, we assessed the effect of normalization algorithms and the inclusion of different batches on epimutation detection. In both cases, methods based on CpG outlier identification (beta and barbosa) returned more consistent results. Finally, we run beta, barbosa, mlm, and manova in the DNA methylation microarray data from blood of 210 children of INMA (4 years old) and 860 children of HELIX (8 years old), a general cohort containing 220 children from INMA. We observed a lower burden of epimutations in blood DNA of children (1-15%) than in cord blood DNA (18-30%), and we found

PrgmNr 2132 - Pathway analysis enhances characterization of cell types and sample groups in single-cell RNA sequencing

Introduction: Non-alcoholic fatty liver disease (NAFLD) and alcohol-related liver disease (AC) share similar pathologic findings although the inciting agents are different. We sought to better characterize the biological pathways involved in these two diseases using single-cell RNA sequencing (scRNA-seq) data. **Methods:** This study was conducted on peripheral blood mononuclear cells (PBMCs) from patients enrolled and consented for an IRB-approved study in the Southern California Alcoholic Hepatitis Consortium (SCAHC) with alcohol-related cirrhosis (AC, n=1), non-alcoholic fatty liver disease (NAFLD, n=1), and healthy control (HC, n=1). The PBMC samples were prepared for 10X Genomics scRNA-seq, and sequenced on an Illumina platform. Seurat version 4.0.1 was used to perform the integrated analysis. Ingenuity Pathway Analysis (IPA) was used for pathway analysis of the differentially expressed genes (DEGs) found by comparing the three comparison groups: AC vs. HC, AC vs. NAFLD, and NAFLD vs. HC. We identified common and unique pathways on the basis of most significant p-values and z-scores across the different cell types and comparison groups. **Results:** We identified 9 cellular subgroups in the PBMC samples using cell-type markers. The significant DEGs for each cell type and disease comparison group were input into IPA. We found significant pathways which were associated with immune response, inflammation, and fibrosis. Some common pathways were identified across multiple cell types, such as: Integrin signalling (B and NK cell types), regulation of Actin-based motility by Rho (Memory T, B, and NK cell types), and RhoA Signalling (CD14 monocytes, B, and NK cell types). Additionally, we found that certain unique pathways were only enriched in a particular cell type of a comparison group. For example, for AC vs. HC, IL-15 signalling was found in B cells. For AC vs. NAFLD, chemokine signalling was significant in FCGR3A monocytes, and IL-7 signalling in CD8T cell type. For NAFLD vs. HC, IL-23 signalling was significant in Memory T cells, and Interferon signalling in NK cells. These pathways play major roles in AC and NAFLD and have the potential to distinguish between diseases and cell types. **Conclusion:** Using scRNA-seq data analysis from PBMCs, we identified several pathways mapped from DEGs and cell types in two common liver diseases, AC and NAFLD. Understanding of physiological parameters and mechanism of liver diseases at the single cell level will be critical for development of new and effective treatments for alcohol-associated and non-alcohol-associated liver diseases.

PrgmNr 2133 - Spatial changes in the human genome indicated by the consensus-based structural variants in selected human families

View session detail

Author Block: **M. Chilinski**[1,2], S. Gadakh[1], P. Dariusz[1,2]; [1]Ctr. of New Technologies, Univ. of Warsaw, Warsaw, Poland, [2]Faculty of Mathematics and Information Sci., Warsaw Univ. of Technology, Warsaw, Poland

Disclosure Block: **M. Chilinski:** None.

In this work, we present a comprehensive analysis of spatial changes indicated by the genomic variability. We have used Oxford Nanopore sequencing technology along with short-read Illumina, focusing on detection of the structural variants (SVs). SVs are DNA segments of at least 50 bp in length that are often unique for personal genomes, as identified by various studies, including the 1000 Genomes project. We present an attempt to improve the quality of the Structural Variants identification from the whole genome sequencing (WGS) experiments by using the consensus approach. The biological samples being analysed originate from the 1000 Genomes Project (three healthy Trios, specifically daughters from those three families). Fifteen gold-standard silico callers were used for obtaining the polished list of Structural Variants for each family; these were obtained from next generation sequencing experiments performed by both short-read (Illumina) and long-read (Oxford Nanopore). The results of the SV callings were merged using the novel ConsensuSV algorithm, which integrates the SV sets using machine learning by combining decision trees and neural networks trained and benchmarked on the high-quality SVs from the The Human Genome Structural Variation Consortium. We provide the validated sets of high-confidence Structural Variants identified for each of the analysed daughters from Trios. Having identified the SVs from the both short-read and long-read techniques, we have mapped them onto reference (GM12878) high-order structures, including chromatin contact domains (CCDs) and ChIA-PET loops, and compared them with in-situ ChIA-PET data for the given cell lines. The case studies provide insight on the changes of spatial chromatin conformation, potentially related to the Structural Variants that are present in the given sites.

PrgmNr 2134 - CNV characteristics in Chernobyl power plant catastrophe clean-up workers from Lithuania suggest unique genetic variation structure

View session detail

Author Block: **I. Domarkiene**, G. Zukauskaite, A. Matuleviciene, A. Urnikyte, V. Kucinskas, L. Ambrozaityte; Dept. of Human and Med. Genetics, Inst. of BioMed. Sci., Faculty of Med., Vilnius Univ., Vilnius, Lithuania

Disclosure Block: **I. Domarkiene:** None.

Background. Copy number variants (CNVs) are one of the forms of genomic variation that are important in evolutionary processes, involved in determining population diversity and in the etiopathogenesis of certain diseases. We hypothesize that Lithuanian clean-up workers of Chernobyl nuclear disaster (LCWC) who survived and are of relatively good health, might have a unique genomic variation, that might have influenced withstanding of high ionizing radiation doses and adaptation.

Methods. LCWC (93) completed the questionnaire which includes health, lifestyle, pedigree and Chernobyl catastrophe clean-up related information. Each individual was examined by clinical geneticist. Microarray genotyping (~700 000 SNPs) was performed on 93 DNA samples extracted from peripheral venous blood of LCWC. For primary data analysis, the Illumina GenomeStudioâ□¢v2.0 Software was used. Genotyping data was called for CNVs by QuantiSNPv2.0 Software. Statistical analysis of CNV characteristics was performed and Mann-Whitney-Wilcoxon or Pearson *ï*□^{2} tests were applied (Î±=0.05). Results were compared with CNV characteristics of the control group - 286 self-reported healthy individuals from the general Lithuanian population [1].

Results. In total, there were 216 autosomal high-confidence CNVs identified in 81.8% of LCWC. 167 different CNVs were identified after the frequency analysis. The length of the CNVs was in 2.3 Kbp - 13.3 Mbp range with the mean size of 766.8 Kbp, median - 271 Kbp, and mode - 896 Kbp. The distribution of CNV size in the LCWC group and Lithuanian population differed significantly ($p=1.05*10^{-21}$). The average number of CNVs per person was 3 in LCWC group. It significantly differed from the Lithuanian population average of 9 CNVs per person ($p=2.36*10^{-5}$). Moreover, frequency of deletions (34.3%) and duplications (65.7%) differed in LCWC group (p=0.03), as well as in comparison with Lithuanian population where 50.3% deletions and 49.7% duplications were identified ($p=6.09*10^{-6}$).

Conclusions. More than 30 years after the tragedy, we provide basic CNV characteristics of the LCWC for the first time. CNV characteristicsâ□□ comparison with the Lithuanian population shows significant differences. These primary results suggest the unique genetic variation structure in LCWC group and point towards further detailed CNV analysis.

The study meets ethical standards. Informed written consents of all study participants are obtained.

This project has received funding from the Research Council of Lithuania (LMTLT), agreement No. S-MIP-20-35.

Olfaction is an ancient, evolutionarily critical sense important for detecting chemical signals in our environment and mediating our safety, nutrition, sensation of pleasure and general well-being. Odorant detection begins with the binding of a plethora of odorant molecules to olfactory receptors. To date, olfactory receptor genes constitute the largest multigene family in the human genome. Yet, much is unknown about this gene family and itsâ variants in underrepresented populations. We compiled a list of 879 olfactory receptor genes and identified their associated variants, using Human Genome Diversity Project (HGDP) data with the inclusion of data we derived from whole-genome sequencing of 16 *Orang Asli*, who represent indigenous communities in Peninsular Malaysia. We performed database searches in GTEx, Ensembl, GWAS Catalog and GeneCards to investigate these variants with their associated genes, phenotypes, traits and pathogenicity predictions. From calculations of delta derived allele frequencies (âDAF) and F_{ST}, we identified several biallelic SNPs of high impact (rs2647574, rs16930998, etc.) and over 150 SNPs of moderate impact (missense variants) that showed high differentiation in HGDP populations. The comparison of variants frequencies between the HGDP and OA revealed that rs2647574C>T in *OR51Q1* appeared to be under strong selection pressure in OA. The âwildtypeâ gene is expressed in testis, whole blood and brain. The T allelic variant is strongly selected in the OA investigated, with a frequency of 0.9375, which is substantially higher than what has been reported in populations represented in the 1000 Genomes Project described in Ensembl. Based on the single-tissue eQTLs data in GTEx, this variant decreases gene expression in testis. We continue to investigate this and other variants of interest in the olfactory receptor genes.

PrgmNr 2136 - Evaluating the accuracy of genotype imputation in the MHC region in selected African populations

View session detail

Author Block: **R. Nanjala**[1,2], N. Mulder[2], M. Mbiyavanga[2], S. Hashim[1,3], S. de Villiers[1,3]; [1]Pwani Univ., Kilifi, Kenya, [2]Univ. of Cape Town, Cape Town, South Africa, [3]Pwani Univ. BioSci.s Res. Ctr., Kilifi, Kenya

Genome wide association studies (GWAS) traditionally use genotyping arrays to genotype large sets of individuals and thus determine which Single Nucleotide Polymorphism (SNPs) are significantly overrepresented in the cases compared to the controls and in this way determine association with disease. Genotyping arrays are cheaper than sequencing but only measure a portion of selected SNPs across the genome. To increase the number of SNPs available, one can use a reference panel of whole genome sequence data from related populations to impute SNPs from those on the array. Some regions in the human genome such as the Major Histocompatibility Complex (MHC) are highly variable and thus difficult to impute. The MHC region in humans has been associated with autoimmune and infectious diseases, adaptive and innate immune responses, and adverse responses to organ transplantation. The aim of this study is to therefore evaluate the accuracy of MHC imputation especially in African populations as they have high diversity and an extended linkage disequilibrium. The study sets will be selected from the Gambian individuals within the Gambian Genome Variation Project and simulated data from the South African population. The reference dataset will be chosen from the whole 1000 Genome population, the African sub-population within the 1000 Genome population, the Gambian sub-population within the 1000 Genome population and the H3Africa reference panel through their imputation service. Human Leukocyte Antigen (HLA) typing will be done using the OptiType tool. HLA alleles will be imputed from SNP data using HIBAG, SNP2HLA, CookHLA and Minimac4. The assessment metrics will be concordance rate, squared Pearson correlation coefficient and call rate. It is anticipated that the most appropriate software and reference panel for MHC imputation in African populations will be identified. The study will also be able to determine whether genotyping array influences accuracy and efficiency of MHC imputation.

PrgmNr 2137 - Genetic diversity in host immune genes involved in responses against intestinal parasitic infections in the Orang Asli community in Malaysia

View session detail

Author Block: **H. Kumar**[1], M. E. Phipps[2], C. S. Chuen[1], M. Ashaie[1], Y. A. Lim[3], Q. Ayub[4]; [1]Sch. of Sci., Monash Univ. Malaya, Kuala Lumpur, Malaysia, [4]Monash Univ. Malaysia, Bandar Sunway, Malaysia
Disclosure Block: **H. Kumar:** None.
The â□□Orang Asliâ□□ (OA) indigenous tribes constitute 0.6% of the Malaysian population. They reside in Peninsula Malaysia and are generally classified as Negrito, Senoi and Proto-Malays. Among the Negrito group, the rural hunter-gatherer Jahai population has a high incidence of intestinal helminthic infections (68% of the samples; n=28 collected were positive for at least 1 infection.). Using whole exome sequencing, we examined genetic variation in innate and adaptive immune response genes that modulate outcome of helminthic infections in OA tribes. We also characterized variation in these genes using the Human Genome Diversity Project (HGDP) dataset, comprising of whole genome sequences of individuals belonging to 54 indigenous populations from seven geographical regions across the world. The analysis highlights variants in interleukin-7 (*IL-7*) and interleukin-34 (*IL-34*) genes that are highly differentiated between African and non-African populations and their implications for intestinal helminthic infections in the OA.

PrgmNr 2138 - Genomic and ancestral variation underscores the severity of COVID-19 disease presentation

View session detail

Author Block: **R. Das**[1], P. Upadhyai[2], G. Suresh[1], R. Parit[2]; [1]Yenepoya Res. Ctr., Yenepoya (Deemed to be Univ.), Mangalore, India, [2]Kasturba Med. Coll., Manipal Academy of Higher Ed., Manipal, India
Disclosure Block: **R. Das:** None.
Introduction: The coronavirus disease (COVID-19) is characterised by a wide spectrum of clinical manifestations ranging in severity from asymptomatic to symptomatic with mild, moderate or severe disease presentations. COVID-19 susceptibility, severity and recovery has shown discernible variability across the world. In this study we sought to identify novel SNPs that show significant frequency variation between asymptomatic versus severely affected COVID-19 patients, employing genotyping dataset generated by the AncestryDNA COVID-19 host genetic study. We further assessed the ancestral affiliations of the COVID-19 patients by combining their genetic data with ancient and modern-day human genome data.**Method**: We categorized patients into five categories denoting the acuteness of manifestation, namely asymptomatic, mild, moderate, severe and unknown, based on self-reported responses. Genome-wide association study (GWAS) was performed in PLINK v1.9 between asymptomatic individuals (controls) and severely infected patients (cases). The ancestral affiliations were determined using Principal Component Analysis (PCA), ADMIXTURE v1.3 and qpAdm algorithm implemented in AdmixTools v5.1.**Results and Discussion**: Our data revealed striking genomic differences between asymptomatic and acutely symptomatic COVID-19 patients. We identified 33,321 novel genetic variants including those associated with pathways regulating host immunity, such as innate and adaptive immune system, interferon regulated antiviral defence, interleukin signalling based immune responses, the complement cascade and known COVID-19 comorbidities, such as, hypertension and type 2 diabetes. Further, variants modulating drug responses to anti-retroviral agents, such as tenofovir, raltegravir and efavirenz were found to vary significantly between asymptomatic and severe patient groups. Using PCA, Admixture and linear regression models we showed that asymptomatic individuals contain significantly larger fractions of Bronze and Iron Age British and ancient Central European ancestries such as Bell Beaker and Corded Ware (Yamnaya related), which introduced ANE and EHG ancestries to Europe. Consistent with this, ancestry analysis using qpAdm algorithm revealed that asymptomatic individuals possess discernibly higher proportions of Ancestral North Eurasian (ANE)/Eastern Hunter Gatherer (EHG) ancestry and lower fractions of Western Hunter Gatherer (WHG) ancestry, while severely symptomatic patients have higher fractions of WHG and lower ANE/EHG ancestral components, thereby delineating the putative ancestral differences between the two groups.

PrgmNr 2139 - Gut microbiome analyses of ancient individuals, so called â□□Jomonâ□□, lived in Japanese archipelago

View session detail

Recent advancements of sequencing technologies allow facilitating ancient DNA analyses. Those ancient DNA studies have revealed not only ancient peopleâ□□s characteristics but also the ancient microbesâ□□ ones. Those microbial data may provide information about the ancient peopleâ□□s behaviors. Especially, paleofeces or coprolites are beneficial to infer diet at the ancient time. Also, we can assume the health conditions through detecting pathogenic microbiomes in the gut, which have a significant impact on our health and disease. However, there are no studies using coprolites of ancient people in Japan, and the microbial contents are unknown. Here, we utilized four paleofeces of Jomon individuals who lived in the Japanese archipelago around 16,000 to 2,900 years ago for metagenomic analyses. We conducted whole genome sequencing with the NovaSeq6000 system and aligned those obtained reads to known reference sequences. We detected several pathogenic viral sequences, such as the Human herpesvirus 2. Also, the alignment results indicated some viruses coexisted with their host species, which also exist in the modern human. It means the host-viral relationships have continued for more than thousands of years. Moreover, we detected some eukaryotic sequences, such as salmon presumably derived from food remnants. Our results indicate that the paleofeces of ancient Jomon people are helpful to understand host-viral evolutional processes and diet at the Jomon periods.

PrgmNr 2140 - Hematological, epigenetic and genetic adaptations in Tibetans

Disclosure Block: **N. Basak:** None.
Tibetans from high altitudes have been studied in great detail for genetic and physiological adaptations. However, the adaptation pattern of high altitude Tibetans has not yet been compared to their low altitude counterparts. We studied two groups of Tibetans; one from high altitudes (â¥4500 meters above sea level (masl)), and another from low altitudes (~850 masl) in India, who share common genetic ancestry, to compare their hematological profile and epigenetic landscapes. Additionally, we explored signatures of genetic adaptation among them. Various hematological parameters from 79 high altitude Tibetans and 89 low altitude Tibetans were studied, comparing complete blood profiles evaluated by manual and automated hematology analyzer, respectively. ELISA was performed to measure serum erythropoietin. Whole genome bisulfite sequencing (WGBS) was carried out in 10 Tibetans (5 from each altitude) to compare their DNA methylomes. Thirty-six Tibetans (18 from each altitude) were genotyped and the data were compared with the already available data of the Han Chinese in Beijing (CHB), the closest low altitude population to the Tibetans . Within-population selection test (iHS) and cross-population selection tests (XP-EHH and Rsb) were performed to detect signatures of natural selection. Analyses were performed using GraphPad Prism, Bismark, and R. Significant differences in multiple hematological parameters, such as Hb, HCT, RBC, MCH (only in males) and MCV, were detected. Seventy-one significantly differentially methylated regions (DMRs) were revealed by WGBS analyses, showing >15% difference in DNA methylation levels (FDR TMPRSS6, *DUSP22*, *CIZ1*, *LRCOL1, PF4V1*). Logistic regression revealed that 10 DMRs in males and 6 DMRs in females were significantly associated with hemoglobin concentration. Results from iHS revealed 95 markers (p-value EPAS1, TMEM247, ATP6V1E2, RHOQ, PIGF, CRIPT, SOCS5*, TRPM3*. To conclude, our study identified significant hematological and epigenetic differences between the Tibetans from high and low altitudes that are likely due to the local adaptations.

PrgmNr 2141 - Historical Demography of Lithuania and Relationship to other Populations

View session detail

Author Block: **A. Urnikyte**[1], A. Molyte[1], E. Pranckeviciene[1], Z. Kucinskiene[2], V. Kucinskas[1]; [1]Dept. of Human and Med. Genetics, Inst. of BioMed. Sci., Faculty of Med., Vilnius Univ., Vilnius, Lithuania, [2]Dept. of Physiology, Biochemistry, Microbiol. and Lab. Med., Inst. of BioMed. Sci., Faculty of Med., Vilnius Univ., Vilnius, Lithuania
Disclosure Block: **A. Urnikyte:** None.

The analysis of geographically specific regions and the characterization of fine-scale patterns of The prehistory of the Lithuanian population and genetic relationship to other populations are poorly studied. Thus, the Lithuanian population, as an object of study, is interesting due to its partial isolation with genetic distinctiveness within the European context and with preserved ancient genetic composition. The main objects of this study was to infer demographic parameters, effective population size (*Ne*), and divergence time using highâ□□density single nucleotide polymorphism (SNP) genotyping data generated with the Illumina HumanOmmiExpressâ□□12v1.1 array in 295 individuals from the Lithuanian population and to compare our data with other populations from the Human Genome Cell Line Diversity Panel (HGDPâ□□CEPH). We also aimed to reconstruct past events between the main ethnolinguistic regionsâ□□AukÅitaitija and Å½emaitija of Lithuania. Historically, these regions probably developed as two independent Baltic tribes. Our results of *Ne* in the Lithuanian population through time demonstrated a substantial reduction of *Ne* over the 150,000-25,000 years before present (YBP). The estimated longâ□□term *Ne* of the Lithuanian population is quite lowâ□□it equals 5404, which likely is a consequence of the bottlenecks associated with the last glacial period of 25,000-12,000 YBP in Europe. The obtained divergence time estimates between the study populations are in agreement with recent studies. The reconstructed past events in AukÅitaitija and Å½emaitija showed significant differences between these two regions of Lithuania.This study is a part of the ANELGEMIA project, which has received funding from the Research Council of Lithuania (LMTLT), agreement No. S-MIP-20-34.

PrgmNr 2142 - Incidence of patients with methylenetetrahydrofolate reductase (MTHFR) gene mutations in a Tunisian population cohort

View session detail

Author Block: **R. Abdelhedi**[1], B. Abdelmoula[2], R. Louati[3], N. Kharrat[1], A. Rebai[4], N. B. Abdelmoula[2]; [1]Ctr. de Biotechnologie de Sfax, Sfax, Tunisia, [2]Med. Univ. of Sfax, Sfax, Tunisia, [3]FMS, Sfax, [4]centre de Biotechnologie de Sfax, Sfax, Tunisia

Disclosure Block: **R. Abdelhedi:** None.

Objective :Methylenetetrahydrofolate reductase (MTHFR) plays a central role in folate-dependent homocysteine metabolism, and severe enzyme deficiency results in elevated plasma homocysteine concentration, which is a risk factor for many pathologic conditions. Three clinically important mutations of MTHFR: C677T, A1298C, and T1317C are reported to be associated with various pathological conditions. These variants have an impact on enzyme function: 677T is affecting the catalytic and 1298C the regulatory MTHFR domain. This study was conducted to evaluate the frequency of the C677T MTHFR polymorphism in a Tunisian population cohort.Material and Methods:Our study included 85 Tunisian individuals. After genomic DNA, PCR amplification was performed using forward and reverse primers at exon 4. Genotyping for the MTHFR 677C>T polymorphism was performed by restriction digestion of PCR products with HinfI. The C677T mutation introduces a new HinfI restriction site, which results in the digestion of the 110 bp amplicon into 87 and 23 bp fragments. Results: The C677T MTHFR polymorphism was detected in 12.5 % of our population study. Eight cases were heterozygous and only one was homozygous. Conclusion: The frequency of the MTHFR 677T allele varies substantially in different regions of the world and among ethnic groups. The mean of these frequencies ranges from 27,2% to 46,2%.Conclusion:Our results of this study on MTHFR polymorphism enhance the variability of this gene worldwide and can serve as a basis for further association studies on the role of MTHFR mutation in the susceptibility of different multifactorial diseases.

PrgmNr 2143 - Population-specific adaptation to malaria infection in endemic regions of Asia

View session detail

Author Block: **E. Gusareva**[1,2,3], P. A. Lorenzini[1,3], N. A. B. Ramli[1,2,3], A. G. Ghosh[1,3], H. L. Kim[1,2,3]; [1]Asian Sch. of the Environment, Nanyang Technological Univ., Singapore, Singapore, [2]Singapore Ctr. for Environmental Life Sci. Engineering, Nanyang Technological Univ., Singapore, Singapore, [3]The GenomeAsia 100K Consortium, Singapore, Singapore
Disclosure Block: **E. Gusareva:** None.
Objective. Malaria-causing parasites (*P. falciparum, P. vivax, P. malariae, and P. ovale*) appeared in human population about 100 thousand years ago (kya) and expanded into large territories in the last 10 kya. At present, there are many human populations across Asia routinely exposed to malaria infection. Evolutionary mechanisms of adaptation to malaria are understudied in Asian endemic regions despite a high prevalence of this infection. **Methods.** By implementing three metrics (Integrated Haplotype Score - iHS, Cross-Population Extended Haplotype Homozygosity analysis - XP-EHH, and Population Branch Statistic - PBS), we have exhaustively screened for footprints of natural selection in a whole-genome sequencing dataset generated from 907 healthy individuals. Eight population groups living in malaria endemic regions across Asia (Tibeto-Burmans, Temuan-Senoi, Eastern Indonesians, Mainland Southeast Asians, Indo-Europeans, Malaysian Negritos, Melanesians, Indian Austroasiatic) and one African (Yoruba) group were compared with two non-endemic groups (Europeans and Mongols). The significance of the statistic metrics was assessed through percentile rank of the genome-wide SNPs in each population group. **Results.** We report 285 genes under positive selection in malaria-endemic populations. The identified selection signals were robust across the three statistical methods. The smallest number of malaria adaptive genes was identified in nomadic hunter-gatherers Malaysian Negritos (18 genes), while the highest in the Indian Austroasiatic group (77 genes), which is characterized by one of the highest endemicity. Interestingly, most of the identified genes (82%) were found to be under selection in a single population group, while adaptive genes shared across populations were rare. This is likely due to the independent adaptation history in different endemic populations. The most concordant adaptive genes were found to be *PTPRD*, *DPP6*, *FHIT*, *CSMD1*, *CTNNA3*, *ARHGEF7*, and *RBFOX1*. The gene ontology (GO) analysis of the 285 adaptive genes (including the most concordant ones) highlighted functional processes related to the nervous system development. The GO:0007399GO term was found to be the most over-representative (*p*-value = $1.6*10^{-7}$); 26.3% of the genes (75 out of 285) were annotated to this term. **Conclusions.** The identified adaptive genes could be related to cerebral malaria and may reduce the inflammatory response and the severity of malaria symptoms. Remarkably, our novel population genomic approach identified population-specific adaptive genes against malaria infection without the need for patient samples or individual medical records.

PrgmNr 2144 - Positive selection to altitude and phenotypic associations in Papua New Guinean highlanders

View session detail

Author Block: **M. AndrÃ©**[1], N. Brucato[2], M. Leavesley[3,4], M. Mondal[1], F-X. Ricaut[2]; [1]Estonian Biocentre, Inst. of Genomics, Univ. of Tartu, Tartu, Estonia, [2]Laboratoire Ã volution and DiversitÃ© Biologique (EDB UMR5174), UniversitÃ© de Toulouse Midi-PyrÃ©nÃ©es, CNRS, IRD, UPS, Toulouse, France, [3]Strand of Anthropology, Sociology and Archaeology, Sch. of Humanities & Social Sci., Univ. of Papua New Guinea, National Capital District, Papua New Guinea, [4]ARC Ctr. of Excellence for Australian Biodiversity and Heritage, Coll. of Arts, Society and Ed., James Cook Univ., Cairns, Australia
Disclosure Block: **M. AndrÃ©:** None.
Papua New Guinea not only has one of the oldest continuous human occupations outside Africa, but its highlands have been permanently inhabited for 20 thousand years. Previous studies have shown that Papua New Guinean highlander groups display phenotypic variation potentially linked to altitude. These results suggest that their genomes might display signatures of positive selection as observed in other high-altitude populations. Although high altitude has been one of the strongest environmental pressures for human populations for thousands of years, until now no signals of positive selection to altitude have been found in Papua New Guinean highlanders. This might be explained by the absence of genomes of Papua New Guineans living at altitudes higher than 1,500 meter above sea level. We hypothesized that the genomes of Papua New Guinean highlanders might display signatures of positive selection to altitude. We performed Cross Population Extended Haplotype Homozygosity (XPEHH) and Population Branch Statistics (PBS) selection tests using 49 newly sequenced genomes of unrelated Papua New Guinean highlanders living between 2,300 and 2,800 meter above sea level. Once genomic regions under selection were identified, we used CLUES, an approximate full-likelihood method for inferring selection, to detect the SNP most likely to drive selection in each region. We then conducted an association study between the SNPâ□□s and 13 different phenotypes found to differ between lowlanders and highlanders. Our preliminary results provide new insight on the genetic adaptation of Papua New Guinean highlanders to a hypoxic environment.

PrgmNr 2145 - TogoVar; providing integrated genomic information of Japanese population

View session detail

Author Block: **L. Toyo-oka**[1], N. Mituhashi[2], M. Kawashima[1], T. Katayama[3], S. Kawashima[4], T. Takagi[1]; [1]Japan Sci. and Technology Agency, Chiyoda-ku, Japan, [2]Res. Organization of Information and Systems, Kashiwa, Japan, [3]Database Ctr. for Life Sci., Kashiwa, Chiba, Japan, [4]Res. Organization of Information and Systems, Chiba, Japan
Disclosure Block: **L. Toyo-oka:** None.
Considering population-specific information when interpreting the result in genomic studies is important. Many genetic researches using Japanese population have been conducted due to its uniqueness for having low genetic heterogeneity. However, allele frequency information of Japanese population was scattered in each website of the research projects. The Genome Aggregation Database (gnomAD) from Broad Institute and the Allele Frequency Aggregator (ALFA) dataset from dbSNP have contributed to genetic research with its allele frequency data among several populations generated by consistent analysis protocol, however, the sample number of Japanese population in the gnomAD is only seventy-six and the sample number of Japanese in ALFA is unknown due to merging to the East Asian population. Thus, we made and have run a web service, TogoVar (https://togovar.biosciencedbc.jp) database to aggregate and provide allele frequency information among Japanese population since 2018. TogoVar included three datasets, JGA-SNP from SNP chip data, JGA-NGS from whole-exome sequence data, and GEM-J WGA from whole-genome sequencing (WGS) data whose sample numbers are 183,884, 125, and 7,609, respectively. The WGS data of GEM-J WGA dataset are deposited in our NBDC Human Database and AMED Genome group sharing Database. The collaborative work between Tohoku Medical Megabank Organization (ToMMo), BioBank Japan, and RIKEN conducted joint-calling and provided the result to TogoVar. Because the deposited data of Japanese is collected from various parts of Japan, it leads to less regional bias on the allele frequency information and its huge sample number of WGS data helps to find rare variants. Two other Japanese allele frequency database information, HGVD and ToMMo 4.7K JPN, ExAC, and ClinVar database information are imported. Variant Effect Predictor is utilized for adding annotation information and the data is converted to Resource Description Framework data. To collect more comprehensive publications of each variant, RDF converted data from PubTator Central and LitVar information via web API are merged. The APIs of TogoVar are provided in public to be easy to download information of multiple variants programmatically.In the poster, the recent achievements including an advanced search function to query complicated conditions and gene view aggregating information on each gene will be presented.

PrgmNr 2146 - Variations in genes associated with recurrent miscarriages in the HGDP CEPH dataset

View session detail

Author Block: **Q. Ayub**[1], M. Pulijala[1], K. P. Song[1], B. Silvia[2], V. Colonna[3]; [1]Monash Univ. Malaysia, Bandar Sunway, Malaysia, [2]Univ. of Campania, Caserta, Italy, [3]Inst. of Genetics and Biophysics, Natl. Res. Council, Naples, Italy
Disclosure Block: **Q. Ayub:** None.
Human reproduction is highly inefficient and appropriately 30% of all human conceptions result in live birth. Miscarriage, also known as spontaneous pregnancy loss before 24 weeks of gestation, occurs in 10-15 % of all pregnancies. The most common genetic cause of miscarriage is chromosomal aneuploidies. Genome-wide analysis and manual curation identified 972 genes associated with recurrent miscarriages or stillbirths. We conducted an *in silico* analysis to catalogue genetic variations in these 972 genes using the publicly available whole genome sequenced Human Genome Diversity Project Centre dâ□□Etude du Polymorphisme Humain (HGDP-CEPH) dataset. The analysis identified a total of 2.071,033 variants in these genes, which were further annotated by Ensembl VEP to classify impact of variants across the seven regional population groups in the HGDP-CEPH dataset. We examined the overall distribution of variants in these genes and assessed their impact. No high impact variants were found, but there were several moderate impact missense mutations that were characterized using SIFT and PolyPhen. SIFT highlighted 37% as deleterious whereas PolyPhen characterized 25% as probably damaging mutations in this apparently healthy adult population sample. Further analysis of these genes in healthy humans will aid in understanding the mutation spectrum and pathways involved in miscarriages and early human development.

PrgmNr 2147 - Classifying uncertainty and impact of uncertainty on decision-making: How do medical students handle uncertainty in prenatal exome sequencing?

View session detail

Author Block: **J. E. Klapwijk**[1,2], M. G. Polak[2], K. E. M. Diderich[1], M. I. Srebniak[1], H. T. BrÃ¼ggenwirth[1], S. Lou[3], I. Vogel[3,4,5], K. Dijkstra[2], S. R. Riedijk[1]; [1]Dept. of Clinical Genetics, Erasmus Med. Ctr., Rotterdam, Netherlands, [2]Dept. of Psychology, Ed. & Child Studies, Erasmus Univ. Rotterdam, Rotterdam, Netherlands, [3]Ctr. for Fetal Diagnostics, Aarhus Univ. Hosp., Aarhus, Denmark, [4]Dept. of Clinical Med., Aarhus Univ., Aarhus, Denmark, [5]Dept. of Clinical Genetics, Aarhus Univ. Hosp., Aarhus, Denmark

Disclosure Block: **J.E. Klapwijk:** None.

Introduction. With prenatal Exome Sequencing (ES), a higher diagnostic yield is possible. However, the number of uncertain results can also increase. It is important to elucidate what effect uncertainty has on decision-making and whether intolerance of uncertainty (IU) may impact this decision-making. This study is part of a broader and ongoing (international) research line aimed to optimize prenatal ES-centred healthcare.

Method. Based on literature and interviews with healthcare providers (HCPâ□□s) and patients, our international multi-disciplinary team identified and defined ten uncertainty types (e.g. limited prenatal phenotype presentation, possible incomplete result) in prenatal ES. Three of these uncertainty types (pathogenicity/variants of unknown significance, incidental findings, and variable expression) were used to develop eight vignettes that were then presented to 5th year medical students who just finished a prenatal genetics course (N = 51). This enabled us to pilot-test our vignettes. These students indicated per vignette whether they would report the ES result to the patient, how certain they were of their choice, and they ranked the vignettes on perceived uncertainty.

Results. Based on the uncertainty rankings, vignettes were categorized into low, moderate, and high uncertainty results. Highly uncertain results were reported less often (59%) than results low in uncertainty (98%), p **Discussion and Conclusion.** This study demonstrated that the level of perceived uncertainty influenced decision-making as well as the experience of uncertainty with these choices. Intolerance of uncertainty however did not affect studentsâ□□ decision-making. Differences in decision-making may lead to differences in care, which may not always be necessary or desirable. Moving forward, this study should be extended to experienced HCPâ□□s. It would also be relevant to investigate this paradigm further including other centres and countries. Classifying uncertainty promotes development of a common language. Gaining insight into impact of uncertainty on (HCP) decision-making will help us understand how we deal with uncertainty elicited by prenatal ES.

PrgmNr 2148 - Population biobank participantsâ response to a range of genomic results reported

Return of results (ROR) to biobank participants is considered a good approach for participant engagement while also responding to the interest towards genetic information expressed by the general public. Estonian Biobank is a population biobank with 200 000 participants. We piloted an approach of offering individual results to participants expressing interest through participant portal. Participants were offered a report delivered to them at a 30 minute face-to-face counselling session. The report included polygenic risk scores (PRS), pharmacogenomics, moderate and high impact genetic findings. Expectations and feedback were collected through the portal before ROR, shortly after ROR and six months later.

Over two years 2957 participants received results from the biobank. Overall, participants tended to feel calm, relaxed and content, with a marginal minority reporting to feel worried, tense and upset. There was a significant increase in positive feelings reported after ROR, and conversely a decrease in uncomfortable feelings reported. The significant risk factor for feeling worried, tense and upset after ROR was feeling worried, tense and upset before ROR. Information received was considered valuable, understandable and not scary. Receiving high risk information had an impact on uncomfortable feelings reported after ROR only with certain findings, such as high PRS for ischemic heart diseases or specific risk variants for thrombophilia. Meanwhile, receiving information on thrombophilia, HBOC or HNPCC were associated with feelings of content. After six months, a majority considered registering for ROR as the right decision while one percent reported regret. Most commonly, participants mentioned enjoyable and understandable communication as a positive, while unmet expectations to receive more information in general or answers to specific health concerns were frequently mentioned as negative.

Overall, participants perceived the information received as valuable even when high risk reported was causing worry at first. More transparency of the plans regarding ROR and educating the public on limitations of ROR from a biobank are needed to handle unrealistic expectations. Face-to-face delivery of results was limiting the number of participants receiving results. Although this communication was valued by the participants, to improve the feasibility of offering results on a large scale, other means of communication would need to be considered. The feedback collected gives valuable insight on participantâs value judgements and on potential response to genetic risk information when the national personalized medicine initiative is implemented.

PrgmNr 2149 - Psychological burden of preimplantation genetic testing (PGT) on couples with multiple monogenic disorders and the role of genetic counselling in Saudi Arabia

View session detail

Author Block: **M. Alshehri**[1], A. Qari[1,2], M. Al-Sayed[1,2], A. Balobaid[1,2], W. AlQubbaj[1,3]; [1]Alfasisal Univ., Riyadh, Saudi Arabia, [2]Dept. of Med. Psychological burden of preimplantation genetic testing (PGT) on couples with multiple monogenic disorders and the role of genetic counselling in Saudi Arabia. **BACKGROUND** Preimplantation genetic Testing (PGT) is a technique that provides a practical alternative to prenatal diagnosis and termination of pregnancy for couples who are at substantial risk of transmitting a serious genetic disorder to their offspring. The interplay between multiple familial genetic diseases, preimplantation genetic testing (PGT) and uncertain outcomes can have a detrimental, long-lasting psychosocial impact as it can drain individuals mentally, emotionally and physically. **OBJECTIVES** As the presence of multiple genetic disorders increases the risk of yielding affected embryos, this study focused on the emotional, social, economical burdens and attitudes towards PGT and the role of genetic counselling in IVF/ PGT clinic. **METHODS** This study was performed by interviewing 31 couples by phone. The couples were presented to the clinic with two monogenic disorders and had underwent PGT between January 2009 and March 2020 at King Faisal Specialist Hospital and Research Centre (KFSHRC), Riyadh. This study focused on participantâ□□s sociodemographic background, reproductive history, types of genetic conditions, number of children (healthy/affected), number of PGT cycles undergone, and attendance at genetic counselling sessions, and their knowledge about recurrence risk and chances of having unaffected children by multiple diseases and prenatal diagnosis (PND). The data was analysed by SPSS. **RESULTS** As the PGT was provided free of charge at KFSHRC , the main concern in this study was the psychosocial impact. Several psychosocial variables were found to have a profound impact on those couples. Therefore, it is of importance to implement a tailored genetic counselling sessions for couples with multiple genetic diseases attending the IVF/PGT clinics. **Conclusion**. More measures and adjustments to the genetic counselling sessions must be implemented for patients with multiple genetic diseases in IVF/PGT clinics.

PrgmNr 2150 - Role of whole genome sequencing in detecting compound heterozygotes for single nucleotide variant and structural variant: Two illustrative patients

View session detail

Disclosure Block: **M. Yamada:** None.
In the molecular diagnosis of autosomal recessive diseases, identification of both pathogenic alleles and their parental origin is essential for accurate recurrence risk counseling. Exome analysis, the current mainstay of genetic testing, can reproducibly detect single nucleotide variants whereas the method can offer limited ability in detecting structural variants. When a patient with an autosomal recessive disorder is a compound heterozygote for single nucleotide variant and structural variant, exome analysis often fails to detect the latter variant. Here, we report two such compound heterozygotes diagnosed successfully by whole-genome sequencing and recurrence risk of 25% were given to both parents. 1) 2-year-old male who presented with severe neonatal asphyxia, severe intellectual disability, and intractable seizures. He was a compound heterozygote for *SMPD4* pathogenic alleles: hemizygous (apparently â□□homozygousâ□□) nonsense variant NM_017951.4 c.832C>T, p.(Arg278*) and 56-kb deletion spanning *SMPD4*, *MZT2B*, and *TUBA3E*. 2) 19-days-old male who presented with congenital pulmonary hypoplasia, fetal hydrops, and cerebellar hypoplasia. He was a compound heterozygote for *SLC25A46* pathogenic alleles: hemizygous (apparently â□□homozygousâ□□) splice acceptor site NM_138773.2 c.385-1G>A and 80-kb deletion spanning *SLC25A46* and *TMEM232*. If deletions had not been detected, *de novo* occurrence of the single nucleotide variant or uniparental isodisomy might have been considered. In both situations, recurrence risk would have been zero. These two examples illustrate importance of pursuing structural variation when evaluating potentially pathogenic single nucleotide variants.

PrgmNr 2151 - Stigma-power around Fragile X Syndrome: a tale of a royal family and a community in a rural village in Cameroon

Abstract

Fragile X Syndrome (*FXS*) is a neurogenetic condition that significantly impacts the lives of affected individuals and their families due to its association with intellectual disability (ID) and stigma. In this paper, we present the findings of an ethnographic study in the community of a patient who received the genetic diagnosis for *FXS* in Cameroon. This study builds on data from 28 participants of a royal family and 58 from the community who participated in 20 in-depth interviews and nine focus group discussions.

We identified two types of stigma in this community: public stigma directed towards the royal family and associative stigma experienced by royal family members. We outline the stereotyping labels used for the family and its children with Fragile X Syndrome and describe the stigma-power dynamic between the community members and the royal family. First, most villagers use less stigmatizing terms to addressing *FXS* children from the chieftaincy because of their position in society. Secondly, due to their social position, the royal family uses their status to negotiate marriages with community members. From these observations, we can suggest that the primary role of stigma in this community is to keep people away from *FXS* and keep them down through domination and exploitation.

We advocate that other researchers examine if the same pattern exists in other inheritable forms of ID and conduct more qualitative research on FXS in Africa.

Disclosure Block: **M. NÃµukas:** None.

The role of CNVs is well established in children with neurodevelopmental disorders (NDDs). However, more research is needed towards systematic understanding on how: i) CNVs affect health in the adult population and ii) to responsibly disclose findings to CNV carriers at high genetic risk for complex disorders.

We screened the cohort of Estonian Biobank (EstBB; n=132,770) for 81 recurrent CNV regions associated with susceptibility to NDDs. In the first stage, we used the â□□genotype-firstâ□□ approach to fetch health data from the EstBB, linked electronic health registries (EHRs) and mapped each ND-CNV with their co-occurring disease traits. In the second stage, we selected 10 ND-CNVs as a paradigm to return of genetic risk data and analysis of at-risk individualsâ□□ experience and the impact of disclosed genetic finding on their health support.

Our results show that the prevalence of CNVs associated with susceptibility to NDDs in the EstBB is 2.6% (n=3,404). Further prioritization of CNVs listed in the DECIPHER database suggested a population prevalence of 0.5% (n=710) for clinically well-established CNV syndromes. According to EHRs, nearly half of them have previously documented neurological or mental and behavioural problems. Notably, only 4 out of 710 are aware of their genetic diagnosis.

Our results along with reports by others confirm that CNVs associated with NDDs are cumulatively common, but still understudied health problem in general population. This work was supported by the Jacobs Foundation Research Fellowship (Dr MÃ¤nnik), Swiss National Science Foundation grant (Dr A.R) and the Estonian Research Council grant (Dr TÃµnisson).

PrgmNr 2153 - Use of MOOCs for inclusive, flexible professional development and wider public engagement in human genomics and genetics

View session detail

Author Block: **D. Nikolic**[1], R. Berkson[1], T. Creavin[1], I. Rafi[2], J. Hayward[3], D. Hipps[4], W. Evans[5], A. Middlton[1], J. Roberts[1]; [1]Wellcome Connecting Sci. (WCS), Hinxton Cambridgeshire, United Kingdom, [2]St Georgeâ□□s, Univ. of London, London, United Kingdom, [3]Shipley Med. Practice, Shipley, United Kingdom, [4]The Exchange Surgery, London, United Kingdom, [5]NHS Leeds, Leeds, United Kingdom
Disclosure Block: **D. Nikolic:** None.
Background: Human genetic and genomics knowledge and technology are becoming increasingly prevalent, creating an urgent need to integrate them into a wide range of professions, especially healthcare. Patients increasingly experience genomics as part of their daily lives; therefore, healthcare providers should be informed about the basic science and implications, so that they can provide appropriate guidance. The availability of commercial (DTC) genomic testing has increased this need. Scalable, inclusive education/training on genomics, flexible to fit professionalsâ□□ busy lives, is difficult to achieve.
Objectives: WCS produced two advanced training courses aimed at practitioners in genetic counselling (GC) and primary care (PC) to help address this need. The main aims were to provide inclusive, free and accessible courses for a global audience of healthcare professionals but also for a wider public interested in the topics. The objectives of the PC course included studying the role of genomics within primary care and management of patients with direct to consumer test results. The objective of the GC course was to raise awareness of the role of genetic counselling in the genomic era, from both professional and public points of view, presenting diverse approaches and challenges to genetic counselling in different countries around the world. Both courses addressed some of the ethical issues connected to genetic testing.
Methods: The courses were run on a massive, open, online platform (MOOC), attended by global audiences of thousands of learners. Conversation-based pedagogy was applied to harness social learning and encourage exchange among different types of experts from around the world. Asynchronous, written and lightly facilitated by PC and GC experts, they offered opportunities for learners to study at their own pace. Both courses made extensive use of realistic, clinically relevant case studies, which the learners investigated and discussed.
Results: Between 2019-21, 2 courses had 5 runs altogether. They reached nearly 12000 learners from more than 122 different countries. Emerging themes from the qualitative analysis of learnersâ□□ comments include generally high learner satisfaction, especially with provision of opportunities to explicitly integrate the theory learned on the course within their work practice, and acquisition of tools and resources for further use. Learnersâ□□ intention to apply knowledge acquired on the course in professional practice or personal life was detected, which points to the use of MOOCs as a viable option in both updating professionals and for wider public engagement in genomics and genetics topics.

PrgmNr 2154 - Novel CRISPR system with modified cas12 and nanoliposome based delivery can destroy SARS covid2 virus in human lung tissue

View session detail

Author Block: **A. Haghighatfard**; Arvin gene company,Tehran, Iran, Tehran, Iran, Islamic Republic of

SARS-CoV-2 virus is a RNA virus that may cause severe respiratory disorder with unclear rate of death. Genome editing systems may target viruses with both vaccines and pharmaceutical approach. Previously we designed a CRISPR system to reduce the expression level of a LncRNA that was involved in depression and addiction in human. The system was successful to inhibit the LncRNA in both cell line and transgenic mouse.We designed and synthesized CRISPR RNAs (crRNAs) which targeting conserved viral and functional regions of SARS-CoV-2 sequence. The same deep learning analysis of previous study on LncRNAs were used to design and choose the most effective seven crRNAs that target 98 percent of all coronaviruses and have none off target sequence in human or microflora genome. Also most suitable sequence of synthetic Cas protein for CRISPR-Cas and prophylactic antiviral CRISPR (PACMAN) were choose by deep learning and protein design analysis. Synthesized CRISPR-Cas system delivered to covid19 affected human lung epithelial cells, neuronal cells and heart cells as well as SARS and covid19 positive rats for 48 hours. Then experiment group of cell lines and rats examined for degradation of viral RNA of SARS-CoV-2. Also harmlessness for host genome expression profile was assessed in control group that received only CRISPR system as well as experiment group. Expression study for viral RNA on covid19 affected human cell lines and lung, brain and heart tissue of SARS and covid19 positive rat models were conducted by using Real time PCR, flowcytometry and western blotting. Also RNA sequencing performed for analysis of gene expression changes in human genome and rat genome for cell lines and rat models respectively.Results were showed 84 to 97 percent down regulation of covid19 and SARS RNAs in different dosage of CRISPR system. Also no significant changes were detected in gene expression patterns of human cell lines and rat tissues compared with control group. Results could suggest the effectiveness of CRISPR system to attack corona viruses or maybe other viruses with no side effects on human body. In addition further analysis on cell lines that get the CRISPR system before infection by covid19 may reveal the vaccination effect of our PACMAN system.

PrgmNr 2155 - Targeted Therapies for Hereditary Peripheral Neuropathies: Systematic Review and Steps Towards a 'treatabolome'

View session detail

Author Block: **A. Lochmuller**[1], M. J. Jennings[1], A. Atalaia[2], R. Horvath[1]; [1]Univ. of Cambridge, Cambridge, United Kingdom, [2]Sorbonne UniversitÃ©, Paris, France
Disclosure Block: **A. Lochmuller:** None.
Background: Hereditary peripheral neuropathies are inherited disorders affecting the peripheral nervous system, including Charcot-Marie-Tooth disease, familial amyloid polyneuropathy and hereditary sensory and motor neuropathies. While the molecular basis of hereditary peripheral neuropathies has been extensively researched, interventional trials of pharmacological therapies are lacking. Objective: We collated evidence for the effectiveness of pharmacological and gene-based treatments for hereditary peripheral neuropathies. Methods: We searched several databases for randomised controlled trials (RCT), observational studies and case reports of therapies in hereditary peripheral neuropathies. Two investigators extracted and analysed the data independently, assessing study quality using the Oxford Centre for Evidence Based Medicine 2011 Levels of Evidence in conjunction with the Jadad scale. Results: Of the 2046 studies initially identified, 119 trials met our inclusion criteria, of which only 36 were carried over into our final analysis. Ascorbic acid was shown to have no therapeutic benefit in CMT1A, while a combination of baclofen, naltrexone and sorbitol (PXT3003) demonstrated some efficacy, but phase III data are incomplete. In *TTR*-related amyloid polyneuropathy tafamidis, patisiran, inotersen and revusiran showed significant benefit in high quality RCTs. Smaller studies showed the efficacy of L-serine for *SPTLC1*-related hereditary sensory neuropathy, riboflavin for Brown-Vialetto-Van Laere syndrome (*SLC52A2/3*) and phytanic acid-poor diet in Refsum disease (*PHYH*). Conclusion: The 'treatable' variants highlighted in this project will be flagged in the treatabolome database to alert clinicians at the time of the diagnosis and enable timely treatment of patients with hereditary peripheral neuropathies.

PrgmNr 2156 - A global omics data sharing and analytics marketplace: Case study of a rapid data COVID-19 pandemic response platform

View session detail

Author Block: **G. Lalli**[1,2], I. Farah[3,2,4], K. Van Steen[1], D. J. Baker[2,5], A. Schumacher[2]; [1]BIO3 â Lab. for Systems Med., Katholieke Univ.it Leuven, Leuven, Belgium, [2]Shivom Ventures Limited, 71-75 Shelton Street, Covent Garden, London, England, WC2H 9JQ, London, United Kingdom, [3]Div. of Psychiatry, Univ. Coll. London, London, United Kingdom, [4]Novo Nordisk Res. Ctr. Oxford, Innovation Building, Old Road Campus, Roosevelt Drive, Oxford, United Kingdom, [5]GoldenHelix Fndn., London, England, WC2N 5AP, London, United Kingdom
Disclosure Block: **G. Lalli:** None.
The sudden, rapid spread of the coronavirus (more specifically, SARS-CoV-2) that hit the world in December 2019, triggering a pandemic that is still ongoing today, has made the lack of proper coordination between public and private healthcare sectors even more evident. These deficits caused the global health system to respond too late to the initial SARS-CoV-2 outbreak, thus slowing the identification of the pathogen triggering the disease condition, as well as understanding how the host genome influences disease severity.â¯â¯

Even though an ever-increasing amount of data is continuously being generated, their use is too often limited because they present complicated access hurdles, limited data-sharing capabilities, and missing interoperability and analytics capabilities that limit their usefulness.â¯Newly generated data, however, not only incurs the problem of siloing but also shows that it does not meet adequate quality standards due to the small sample size, which limits its re-usability, a quality necessary to make the information usable and valuable.â¯

Here we describe an approach that we implemented to provide healthcare professionals with a platform to retrieve and analyse genetic data, and securely and share sensitive patient data while ensuring the deidentification of the patient. Individuals can not be identified because only algorithms can access the raw data and researchers querying the data hub do not have access to the source of the genetic data. â¯

The Shivom platform (https://www.shivom. io/), is built on a principle of open science, transparency and collaboration, and designed to give researchers a unique ecosystem to easily, securely and quickly share and analyse omics data, thereby simplifying the data acquisition and analysis processes. The platform can help the global research community to rapidly discover new preventive measures and optimise logistical solutions. Researchers can upload data and analyse it using predefined bioinformatics and AI algorithms in a trusted environment where they can store data in a secure, anonymised, and highly ecrypted manner, the latter to prevent malicious attacks or unauthorized access.â¯

Through proof-of-concept case studies, we show the necessities and potentials of our precision medicine platform, including providing the global research community with an online marketplace for rapid data-sharing, managing & analytics capabilities, and delivering AI insights that can better understand complex diseases, ageing & longevity, apart from global pandemics, at the molecular and epidemiological level.â¯â¯

PrgmNr 2157 - An atlas of associations between polygenic risk scores from across the human phenome and circulating metabolic biomarkers

View session detail

Author Block: **S. Fang**[1], M. V. Holmes[2], T. R. Gaunt[1], G. Davey Smith[1], T. G. Richardson[1,3]; [1]MRC Integrative Epidemiology Unit (IEU), Population Hlth.Sci., Bristol Med. Sch., Univ. of Bristol, Bristol, United Kingdom, [2]Clinical Trial Service Unit & Epidemiological Studies Unit, Nuffield Dept. of Population Hlth., Univ. of Oxford, Oxford, United Kingdom, [3]Novo Nordisk Res. Ctr., Oxford, United Kingdom

Disclosure Block: **S. Fang:** None.

Polygenic risk scores (PRS) are becoming increasingly popular for predicting complex traits and diseases, although they also hold the potential to develop insight into the molecular profiles of patients with an elevated genetic predisposition to diseases. We constructed an atlas of associations between 130 PRS for different traits and diseases with 249 circulating metabolic biomarkers measured using the Nightingale Health platform in up to 83,004 participants from the UK Biobank (UKB).We demonstrate the value of this atlas in exemplar by a hypothesis-free evaluation of genetically predicted associations with glycoprotein acetyls (GlycA), a marker of inflammation. In total, there were 49 PRS (using SNPs with r^2-09) and cigarettes per day (Beta=0.115, 95% CI=0.066 to 0.163, P=4.09x10^{-06}) on GlycA levels rather than the reverse direction of effect, suggesting that a causal effect of GlycA is unlikely to underlie the PRS associations identified in our analysis.Next, associations between PRS and metabolic biomarkers were generated within age tertiles to investigate the influence of contingent mediators which may undermine inference. To highlight the utility of this sensitivity analysis, we compare lipoprotein lipid profiles associated with the PRS for coronary artery disease (CAD) within subgroups with differing numbers of individuals undergoing statin therapy. For example, the CAD PRS was strongly associated with circulating apolipoprotein B (apo B) amongst participants in the lowest age tertile (statin users 5%, Beta=0.059, 95% CI=0.048 to 0.069, P-300), whereas weak evidence of association was found amongst participants in the oldest age tertile with the beta coefficient directionally opposite (statin users 29%, Beta=-0.009, 95% CI=-0.021 to 0.003, P=0.141). Given the incontrovertible evidence that circulating apo B causes CAD, these findings illustrate the detrimental impact of a complex mediator (e.g. statin medications) in distorting findings when analysing metabolic biomarkers in UKB.We envisage that our atlas of associations will help to develop a greater understanding of genetic liability to disease and metabolic profiles. All results can be interactively visualised at http://mrcieu.mrsoftware.org/metabolites_PRS_atlas.

PrgmNr 2158 - Human genetics is great: A genomic structural variant map of 945 Han Chinese individuals using long-read sequencing data

View session detail

Author Block: **J. Gong**[1], Y. Huang[1], Y. Ling[2], R. Cao[2], M. Pan[1], J. Tan[1], Y. Ma[1], J. Li[1], S. Wang[2], J. Wang[1], G. Zhang[2], L. Jin[1], F. Sedlazeck[3], S. Fan[1]; [1]Fudan Univ., Shanghai, China, [2]Shanghai Inst. of Nutrition and Hlth., Chinese Academy of Sci., Shanghai, China, [3]Baylor Coll. of Med., Houston, TX
Disclosure Block: **J. Gong:** None.
Structural variants (SVs) are a major source of genetic diversity that have strongly shaped human evolution and, among many other physiological impacts, continue to influence the differential susceptibility and responsivity of individuals and populations to disease. Here, we used Oxford Nanopore technology to sequence the genomes of 945 Han Chinese individuals and then characterized the SV diversity of this population and conducted extensive comparative analyses using our SV catalogue. Specifically, we identified 96,494 SVs, among which 51.98% have not been reported before. Genotyping analysis with a data for a separate group of 208 Han Chinese genomes confirmed that many of the discovered SVs are true genomic polymorphisms. After identifying 50 Mb and 255 Mb of SV mutation 'hotspot' and 'desert' genome regions, we detected SV mutation in the genome. A gene-set enrichment for pathways related to both carbohydrate and protein metabolism. We noted that the SV deserts have clearly experienced significantly stronger purifying selection compared to the hotspots, and the deserts harbor genes that are predicted to be 'essential' in humans. We uncovered 302 'natural knockout genes' in which more than 72% (217 out of 302) have not been reported before. Further, 228 SVs overlap and 1,099 SVs border SNPs previously associated with phenotypic and disease traits from GWAS. Finally, our dataset included 38 Mbp of sequence that is missing from the current human reference genome (GRCh38), which we supported with comparative analyses of non-human primate genomes. Our genomics and SV datasets are publicly available at https://www.biosino.org/chsvdb/, and represent a valuable resource for researchers in the evolutionary and population genetics, functional genomics, and medical communities.

PrgmNr 2159 - Measuring sensitivity of semi-automated Clingen-ACMG classification framework for CNVs through comparison with manual classification of 1437 clinical cases

View session detail

Author Block: **S. Tzur**[1], I. Maya[2,3], S. Kahana-Pasternak[2], I. Agmon-Fishman[2], C. Klein[2], I. Vustianiuk[1], V. Lamtieva[1], K. Sund[1], T. Talmy[1], R. Attali[1], R. Matar[2], L. Basel-Salmon[2,3,4]; [1]Genomic Res. Dept., Emedgene Technologies, Tel Aviv, Israel, [2]Recanati Genetics Inst., Beilinson Hosp., Rabin Med. Disclosure Block: **S. Tzur:** Major Stockholder/Ownership Interest; Emedgene. Salary/Employment; Emedgene.
To assist laboratories in classifying copy number variants (CNVs), ACMG and ClinGen have introduced a quantitative, evidence-based, scoring framework divided into five sections. Emedgene Technologies has developed a semi-automatic classification tool following the frameworkâ□□s criteria (excluding literature survey and family history) to allow for rapid and effective CNV classification.In this study, we estimated the sensitivity of the framework and the automated tool in detecting pathogenic variants. We compared the toolâ□□s classifications with manual classifications of 5773 CNVs identified among 1437 unrelated samples. These samples were tested during 2020 by the clinical laboratory at the Rabin Medical Center using an Applied Biosystems CYTOSCAN 750K array.In 112/1437 cases (7.8%), an abnormal result was reported, including 37 samples (2.6%) with aneuploidy and 75 samples (5.2%) with 82 pathogenic (P) or likely pathogenic (LP) CNVs. Of the 82 P/LP variants reported by the laboratory, 60 were also classified as P/LP by the automated tool (sensitivity of 73%, CI[62,82]). In most of the remaining 22 variants, classified manually as pathogenic (and VUS by the tool), the variant did not overlap with a dosage-sensitive gene/region or failed to contain a sufficient number of genes. Of them, 19 overlapped with at least one known ClinVar pathogenic variant. In total, 96% of the variants were classified as P/LP by the framework or annotated with Clinvar known variant.The most impactful framework metric was 2A, which indicates overlap with a dosage-sensitive gene or region; it was indicated 49 times (score 1). Tags 3C (17 times, score 0.9) and 3B (11 times, score 0.45), which reflect the number of genes within the affected region, were also impactful. Other tags were applied less frequently.Overall, we found that the Clingen/ACMG framework, in combination with the ClinVar database, was sensitive for detecting the majority of pathogenic events, specifically in the case of a very large CNV or full overlap with a region of dosage sensitivity. The remaining portion of the pathogenic variants still demand a deeper manual investigation. Machine learning approaches surveying other features in an integrative manner could potentially help reduce the time of analysis of CNVs.

PrgmNr 2160 - SpliceAI algorithm identified potentially pathogenic variants in patients with hereditary hearing impairment

View session detail

Author Block: **C-Y. Tsai**[1,2], M-Y. Lo[3], C-J. Hsu[4,2], J. S. Hsu[5], C-C. Wu[2], P-L. Chen[6,1]; [1]Graduate Inst. of Med. Genomics and Proteomics, Natl. Taiwan Univ. Coll. of Med., Taipei, Taiwan, [2]Dept. of Otolaryngology, Natl. Taiwan Univ. Hosp., Taipei, Taiwan, [3]Inst. of Molecular Med., Natl. Taiwan Univ., Taipei, Taiwan, [4]Dept. of Otolaryngology, Taichung Tzu Chi Hosp., Taichung, Taiwan, [5]Natl. Taiwan Univ. Coll. of Med., Taipei, Taiwan, [6]Dept. of Med. Genetics, Natl. Taiwan Univ. Hosp., Taipei, Taiwan
Disclosure Block: **C. Tsai:** None.
Background: Hereditary hearing impairment (HHI) is a common inherited disorder. More than 200 genes have been identified as causally related to HHI, and the types of genetic variants that may lead to HHI are highly diverse. Although next-generation sequencing (NGS) technology has revolutionarily improved the genetic diagnosis of HHI, many families remain unsolved. Emerging bioinformatic tools, such as the â□□SpliceAIâ□□ algorithm (Illumina), provide an opportunity to analyze previously unexplored DNA regions and identify obscure pathogenic variants. **Method:** Forty unsolved HHI families, including 30 simplex families without confirmatory diagnoses on panel-based examination and 10 multiplex families without confirmatory diagnoses on the whole genome sequencing, were recruited. Their NGS data were subjected to SpliceAI analyses to search for causative variants. The probability (scoring from 0 to 1; the effective threshold is 0.5) of each variant to gain/lose the splicing donor/acceptor was assessed, followed by the loci predicted to cause alternative splicing. **Result:** The SpliceAI algorithm identified 5 potentially pathogenic variants in 5 families, including 3 recessive variants in 3 of the 30 simplex families and 2 dominant variants in 2 of the 10 multiplex families. For the former 3 families, two intronic variants c.6591-3T>G of *PTPRQ*, c.3894+5G>C of *OTOF*, and one synonymous variant c.3864G>A (p.A1288=) of *OTOF*, were predicted to cause alternative splicing. Identification of these 3 variants ascertained biallelic mutations in the 3 affected probands and confirmed the genetic diagnosis, with the genotypes being *PTPRQ* c.[6591-3T>G];[6591-3T>G], *OTOF* c.[3894+5G>C];[5098G>C] and c.[3864G>A];[5098G>C], respectively. For the latter two multiplex families, two intronic variants c.1183+5G>A of *GSDME* and c.1013+5G>A of *MITF*, which were predicted to cause alternative splicing, also co-segregated with the phenotype of hearing impairment in the affected family members. **Conclusion:** The SpliceAI algorithm can identify variants that may result in aberrant splicing, and help achieve genetic diagnoses in HHI families unsolved by current analytical protocols. However, subsequent functional assays are warranted to elucidate the exact mechanisms of alternative splicing for these variants.

PrgmNr 2161 - Towards a more usable database: MGeND 2021 update

View session detail

Disclosure Block: **M. Kamada:** None.
The success of global genomic medicine requires data collection that takes into account genomic diversity. Therefore, we have developed and are operating the Medical Genomics Japan Database (MGeND), a database that aggregates genomic data and corresponding clinical information for the East Asian population. Our database was developed focusing on cancer, rare diseases, infectious diseases, dementia, and hearing loss. In addition, MGeND aggregates and integrates variant data across monogenic and polygenic diseases. More than 150,000 variants have been published in MGeND, which are accessed not only from Asia but also worldwide. The fact that 80% of the variants registered are only in MGeND demonstrates the importance and usefulness of data aggregation in Asian populations. In addition, user comments have been used to improve usability since its release in 2018. In 2020 and beyond, we developed the specific view for GWAS datasets, linked variants between genome assemblies (hg19 and hg38), expanded downloadable data, and developed APIs. In this presentation, we will report updates of the database a detailed statistical analysis of the registered data.

PrgmNr 2162 - Variations in Nomenclature of Clinical Variants between Annotation Tools

View session detail

Author Block: **K-J. Park**[1], J-H. Park[2], H-T. Kim[1], C-H. Park[1], Y-J. Kim[1]; [1]Samsung Changwon Hosp., Changwon, Korea, Republic of, [2]Samsung Med. Ctr., Seoul, Irwon, Korea, Republic of
Disclosure Block: **K. Park:** None.
Background: Accurate nomenclature of variants is an essential element for genetic diagnosis and patient care. The aim of this study was to investigate the difference in annotation of the clinical variants from the HGMD between ANNOVAR and snpEff, which are the most commonly used free tools in the clinical setting.6,7 Furthermore, the accuracy of the annotation tools was evaluated based on the standardized HGVS nomenclature. **Methods:** Clinical variants (n = 229,161) registered in the HGMD (professional version 2019.01) were described at the cDNA level and protein level according to the HGVS nomenclature. Multiple nomenclatures based on RefSeq transcripts were provided using both ANNOVAR and snpEff. Multiple nomenclatures from several alternative transcripts for each variant were annotated. **Results:** The concordance rates between ANNOVAR and snpEff of coding and protein variants were 93% and 73%, respectively. Discordant coding variant nomenclature was more identified in deletion-insertion (100%), duplication (52%), or insertion (17%) variants than substitution variants (1%). Based on the Human Genome Variation Society (HGVS) nomenclature, snpEff was more accurate than ANNOVAR (coding variants: 97% vs. 94%, protein variants: 98% vs. 73%). When annotating each variant with both ANNOVAR and snpEff, the accuracy was improved up to 99%. **Conclusions:** There were substantial differences of between ANNOVAR and snpEff annotations. This study suggests that simultaneous use of multiple annotation tools could decrease nomenclature errors and contribute to providing of standardized clinical reporting.

PrgmNr 2163 - Two new patients with focal dermal hypoplasia: A novel PORCN variant and insights on the differential diagnostic considerations

View session detail

Author Block: **R. Elhossini**[1], m. Abdel-Hamid[1], H. Dawoud[2], M. Aglan[1], M. ElRoby[1], E. Ashaat[1]; [1]Natl. Res. Ctr. of Egypt, Cairo, Egypt, [2]Tanta Univ., Cairo, Egypt
Disclosure Block: **R. Elhossini:** None.

Two new patients with focal dermal hypoplasia: A novel PORCN variant and insights on the differential diagnostic considerationsâ□□

Mutations in the *PORCN* gene cause an X-linked dominant condition, focal dermal hypoplasia (FDH), characterized by atrophic skin, pigmented skin lesions, several ocular and skeletal malformations. FDH is rare with around 275 cases reported so far from diverse ethnic groups. Herein, we provide the first report of two new patients with FDH from Egypt. In addition to the typical clinical manifestations of the disease, infrequently reported clinical findings in the form of broad metaphysis, bilateral short broad femurs and dermal sinus over the sacrum were seen in Patient 1 and partial fusion of labia majora was present in Patient 2. Two heterozygous protein truncating *PORCN* mutations were identified in our patients, a known nonsense (c.370C>T, p.Arg124Ter) and a novel frameshift (c.375delG, p.Ala126HisfsTer3). Segregation analyses confirmed that the two mutations were â□□de novoâ□□ and not inherited from any of the parents. Our study expands the clinical and mutational spectrum of focal dermal hypoplasia and emphasizes the importance of investigating the different body systems and organs for early management of patients.

PrgmNr 2164 - A human importin-Ã-related disorder: Syndromic thoracic aortic aneurysm caused by bi-allelic loss-of-function variants in *IPO8*

Importin 8, encoded by *IPO8*, is an ubiquitously expressed member of the importin-Î² protein family that translocates cargo molecules such as proteins, RNAs and ribonucleoprotein complexes into the nucleus in a RanGTP-dependent manner. Current knowledge of the cargoes of importin 8 is limited, but TGF-Î² signaling components such as SMAD1-4 have been suggested to be amongst them. Here, we report that bi-allelic loss-of-function variants in *IPO8* cause a syndromic form of thoracic aortic aneurysm (TAA) with clinical overlap with Loeys-Dietz and Shprintzen-Goldberg syndrome. Seven individuals from six unrelated families showed a consistent phenotype with early-onset TAA, motor developmental delay, connective tissue findings and craniofacial dysmorphic features. A C57Bl/6N *Ipo8* knock-out mouse model recapitulates TAA development from 8-12 weeks onwards in both sexes, but most prominently shows ascending aorta dilatation with a propensity for dissection in males. Compliance assays suggest augmented passive stiffness of the ascending aorta in male *Ipo8*$^{-/-}$ mice throughout life. Immunohistological investigation of mutant aortic walls reveals elastic fiber disorganization and fragmentation along with a signature of increased TGF-Î² signaling, as evidenced by nuclear pSmad2 accumulation. RT-qPCR assays of the aortic wall in male *Ipo8*$^{-/-}$ mice demonstrate decreased *Smad6/7* and increased *Mmp2* and *Ccn2 (Ctgf)* expression, reinforcing a role for dysregulation of the TGF-Î² signaling pathway in TAA development. As importin 8 is the most downstream TGF-Î²-related effector implicated in TAA pathogenesis so far, it offers opportunities for future mechanistic studies and represents a candidate drug target for TAA.

PrgmNr 2165 - A novel *NOTCH3* terminal exon variant causes the rare lateral meningocele syndrome in an Asian child

View session detail

Author Block: **W. Ong**[1], M. Syuhebullah[1], D. Gunaseelan[1], N. Mohammad[2], W. T. Keng[1]; [1]Dept. of Genetics, Hosp. Kuala Lumpur, Kuala Lumpur, Malaysia, [2]Dept. of Radiology, Hosp. Sultan Ismail, Johor Bahru, Johor, Malaysia
Disclosure Block: **W. Ong:** None.
Lateral meningocele syndrome (LMS), or Lehman syndrome, is an exceedingly rare disorder characterized by multiple lateral spinal meningoceles with distinctive craniofacial features, hypotonia, joint hyperextensibility, developmental delay and variable skeletal, cardiac, and urogenital anomalies. It is caused by heterozygous pathogenic variants in the terminal exon 33 of *NOTCH3* gene, resulting in a truncated NOTCH3 intracellular domain protein with prolongation of its signalling effects in the highly conserved NOTCH signalling pathway. Most cases are de novo.
We present a 2.5-year-old girl, first child of a non-consanguineous Indonesian couple. She was a term baby with no antenatal nor postnatal complications. She had no feeding difficulties but her growth faltered postnatally and she was developmentally delayed particularly in gross motor and speech. Clinically she had a tall forehead, arched eyebrows, shallow supraorbital ridges with proptosis, midface hypoplasia, slightly upturned nose, thin and tented upper lip, full lower lip, micrognathia, low-set ears, pre-auricular pit, long halluces and hypotonia. There were no concerns with her hearing and vision. Chromosomal microarray, metabolic and biochemical indices and ultrasound of her urinary system were normal. WES identified a heterozygous variant, c.6705_6730del (p.Phe2235Leufs*10) in exon 33 of *NOTCH3* gene. This was classified a VUS as it was unreported in both disease and population databases, but multiple *in-silico* analyses suggest it disease-causing, and clinical features concurred with our patient. Following this result, MRI brain and spine revealed low-lying cerebellar tonsils, dural ectasia with multiple lateral meningoceles at thoracolumbosacral levels causing left posterolateral compression of the spinal cord at T11-L3 level, and mild posterior scalloping of the involved lumbar segments. Examination of parents were normal.
There had been fewer than 25 reported cases of LMS to our knowledge and our patient shared many of the clinical and radiological features previously described. This case also illustrated the power of reverse phenotyping in consolidating the clinical diagnosis, and in directing more precisely genetic counselling, long-term care and surveillance. This is especially important as lateral meningoceles can result in neurologic complications such as Chiari 1 malformation, neuropathy, paraparesis and bladder dysfunction. Other recommendations include cardiovascular monitoring for cardiac malformations and aortic dilatation, hearing assessment for mixed/conductive hearing loss, and ongoing neurodevelopmental and growth assessment.

PrgmNr 2166 - A novel variant in the *WNT10A* gene in a consanguineous Malian family with Odonto-Onycho-Dermal Dysplasia syndrome: First sub-Saharan African case

Introduction: Odonto-onycho-dermal dysplasia (OODD) is a rare autosomal recessive form of ectodermal dysplasia including severe oligodontia, nail dystrophy, palmoplantar hyperkeratosis, and hyperhidrosis. To date, no genetically confirmed case has been reported in Sub-Saharan Africa. Aim: To clinically characterize a Malian family with ectodermal dysplasia features and identify the underlying genetic defect.Methods: Patients and their relatives were ascertained upon a pediatrician initiated-referral. They were enrolled after giving written consent, and clinical data were obtained from medical records. DNA was extracted from peripheral blood via standard procedures for genetic analysis. Initially, the EDA, EDAR, EDARADD genes were tested in the proband. Then we sequenced the entire coding region of the WNT10A gene. PCR was performed with specific primers designed in our laboratory. Mutation screening was performed by a visually inspected for homozygous base changes and compared to the corresponding wild type sequences using the â□□BLASTâ□□. Once a nucleotide change was found, SNP databases were searched to determine its frequency. Pathogenicity was confirmed by in silico analysis using PolyPhen, SIFT and ClinVar. Results: We investigated a large consanguineous family of Fulani ethnicity. Six individuals of 11 to 28 years old were found to be affected. The disease onset was variable from birth to 15 years old with teeth agenesis and palmoplantar hyperkeratosis that worsened gradually. The clinical examination found a missing primary tooth ranging from 20 to 23 teeth, and palmoplantar hyperkeratosis itching with ulcerations in all the six patients. Sequencing of common ectodermal dysplasia genes (EDA, EDAR, and EDARADD) was negative. However, testing of the WNT10A gene identified a homozygous missense variant located at position c.1199G>A (p.Cys400Thr). This variant was not found in several SNP databases including in gnomAD/ExAC, dbSNP and 1000genomes, and is reported as pathogenic by several in silico prediction tools. Comments: We report here a novel homozygous missense variant in the WNT10A gene causing OODD syndrome. To the best of our knowledge, this is the first report of genetically confirmed OODD case with WNT10 mutation in the sub-Saharan African population, expanding its genetic epidemiology. Keywords: OODD, WNT10, novel variant, Mali, Africa

PrgmNr 2167 - A Palestinian patient with Wiedemann-Rautenstrauch like syndrome: expanding the phenotypic spectrum of PYCR1 mutations

View session detail

Author Block: **M. Ghannam**; Makassed Hosp., Jerusalem, Palestinian Territory
Disclosure Block: **M. Ghannam:** None.
Wiedemann-Rautenstrauch syndrome (WDRTS) is a rare autosomal recessive neonatal progeroid disorder characterized by intrauterine growth retardation, failure to thrive, progeroid appearance, decreased subcutaneous fat, hypotrichosis, hypotonia, and variable mental impairment. WDRTS is caused by biallelic variant in the POLR3A gene.
We report a female baby born for a consanguineous couple from Palestine. She presented with a relatively large head, distinctive facial features, progeroid appearance, and thin translucent skin with reduced subcutaneous fat. Trans-fontanel ultrasound showed agenesis of corpus callosum. Echocardiogram showed small patent ductus arteriosus, moderate patent foramen oval, and trivial peripheral pulmonary stenosis. Ophthalmic exam, skeletal survey, renal ultrasound, and karyotype were normal.
Whole exome sequencing revealed the presence of a homozygous pathogenic variant in *PYCR1* gene (c.616G>T)(p.Gly206Trp)). Recessive mutations in *PYCR1* were initially associated with Cutis Laxa Type IIB with progeroid features. However, further descriptions of patients bearing biallelic PYCR1 mutations revealed a remarkable clinical heterogeneity and phenotypic continuum ranging from isolated wrinkly skin syndromes, gerodermia osteo-dysplastica, De Barsy syndrome to severe progeria syndromes. The identified variant in our patient was reported before in a Palestinian child diagnosed with wrinkly skin syndrome and in another child form Qatar diagnosed with Geroderma osteodysplasticum. This highlight the phenotypic diversity that is associated with *PYCR1* gene even in patients with same genetic variant.
Clinical features in our patient were overlapping with that of WDRTS. Patient initially presented with upslanted palpebral fissures, thin translucent skin and reduced subcutaneous fat rather than wrinkled saggy skin appearance. However, patient reassessment at age of 40 days showed some lax and wrinkled skin with normal slanting palpebral fissures.
This report illustrates the wide spectrum of phenotypic features that could be associated with PYCR1 gene by showing that they can resemble WDRTS especially in the early neonatal period.

PrgmNr 2168 - Acromesomelic skeletal dysplasia with severe short stature due to a biallelic *KIF24* variant

View session detail

Author Block: **N. u. Ain**[1], T. Ishaq[2], O. Makitie[3,1], S. Naz[4]; [1]Karolinska, Inst.t, Stockholm, Sweden, [2]Univ. of the Punjab, Lahore, Pakistan, Lahore, Pakistan, [3]Univ. of Helsinki, Helsinki, Finland, [4]Univ. of the Punjab, Lahore, Pakistan

Disclosure Block: **N.U. Ain:** None.

Several types of skeletal dysplasia have been described and molecularly characterized. Studies have identified skeletal dysplasia to occur due to impaired ciliogenesis in some cases. We investigated a Pakistani consanguineous family to underpin the genetic cause of skeletal dysplasia, similar in phenotype to acromesomelic dysplasia. Clinical and radiographic investigations were performed for two affected individuals of the family. Whole genome sequencing (WGS) was completed using DNA from one affected family member. Data obtained after WGS was analyzed and filtered to identify the possible disease causing variant. Sanger sequencing was performed to confirm the segregation of the identified variant with the disease phenotype and to determine its allele frequency in controls. Affected individuals in the family had severe short stature (KIF24, which segregated with the disease phenotype in the family. The variant was absent from public databases as well as DNA of 200 ethnically matched controls. *KIF24* encodes a 1368 amino acids protein belonging to the kinesin family. KIF24 has a role in ciliogenesis and microtubule polymerization. The identified variant affects an amino acid that is conserved not only in all vertebrate species, but also among different kinesin proteins. This study describes a novel form of skeletal dysplasia associated with biallelic variant in *KIF24*.

PrgmNr 2169 - Clinically actionable secondary findings in 390 whole genome sequence data from sub-Saharan African families with nonsyndromic orofacial clefts

View session detail

Author Block: **L. Gowans**[1], A. Oladayo[2], W. O. Awotoye[2], A. Alade[3], B. Tamara[2], T. Naicke[4], M. A. Eshete[5], W. L. Adeyemo[6], J. Bidinger[7], E. Zheng[2], O. Adamson[6], C. Disclosure Block: **L. Gowans:** None.

In 2017, the American College of Medical Genetics and Genomics (ACMG) argued for the need to return secondary findings in genomic data on 59 genes that are associated with conditions that are clinically actionable. This list of 59 genes was updated further to 73 genes by ACMG in 2021. In this study, we carried out whole genome sequencing of 150 case-parent trios; only the probands had orofacial clefts. Participants were recruited from Ghana and Nigeria. Of the 150 families, a total of 130 families passed various quality control checks and were screened for secondary findings based on the 59 clinically actionable genes released by ACMG in 2017. In all, we observed 144 unique genetic variants in 44 out of the 59 genes released by ACMG in 2017. Of the 144 unique variants, about 97% (140) were variants of unknown significance (VUS) whereas about 3% (4) of the variants were classified as pathogenic or likely pathogenic. A heterozygous missense variant in *PRKAG2* gene (p.Glu183Lys) was classified as pathogenic, whereas three other heterozygous variants in *RYR1* (p.Arg2163Leu) and *LDLR* (p.Ala431Thr and p.Asn564Ser) were predicted to be likely pathogenic. The p.Asn564Ser variant in *LDLR* was observed in a mother in one of the families. The other three variants (p.Glu183Lys, p.Arg2163Leu and p.Ala431Thr) were observed in both mothers and probands in three different families. *PRKAG2, RYR1* and *LDLR* are associated with Wolff-Parkinson-White (WPW) Syndrome, Malignant hyperthermia and Familial hypercholesterolemia 1, respectively. These conditions are all clinically actionable. We will therefore follow-up on these patients and collaborate with clinicians to offer the necessary genetic counseling and other clinical care. In conclusion, we have shown that clinically actionable secondary findings were observed in 1.79% (7/390) of participants, which is slightly higher than about 1% reported for diverse ethnicities. Our results further corroborate the ACMGâ□□s position on the need to intentionally search clinical genomics sequence data for actionable secondary findings based on the ACMGâ□□s list of actionable genes.

PrgmNr 2170 - Congenital bilateral anophthalmia: A case report

View session detail

Author Block: **A. Kondo**[1], A. Hayashi[1], A. Tachibana[1], M. Morine[1], K. Hinokio[1], T. Kirino[1], T. Iwai[1], Y. Kuroki[1], N. Okamoto[2], K. Maeda[1]; [1]Shikoku Med. Ctr. for Children and Adults, Zentsuji, Japan, [2]Osaka Women's and Children's Hosp., Osaka, Japan

Disclosure Block: **A. Kondo:** None.

Anophthalmia means absence of ocular tissue in the orbit and it can be unilateral or bilateral. It may occur in isolation or as part of a syndromic condition. Association with other systemic malformations often involving cardiac, musculoskeletal and central nervous system. A few known pathogens that can cause anophthalmia are Toxoplasma, rubella, and certain strains of the influenza virus. Other known environmental conditions that have led to anophthalmia are maternal vitamin A deficiency, exposure to X-rays during gestation, solvent abuse, and exposure to thalidomide. Some chromosomal abnormalities are reported associated with this condition, but as for monogenic causes, only SOX2 has been identified as a major causative gene.A boy was bone at 37w4d, 2632g, Apg7/10 as normal vaginal delivery. He was referred to childrenâ□□s hospital because of blepharophimosis at first. Head CT showed very small eyeballs and Extraocular muscles and Rt optic nerve. General examination systemic work-up showed that he had hearing issues and cryptorchidism. His weight gain was poor and it was related to dysphagia. Until he got 5 y/o, parents were not interested in making diagnosis, but later at age 6 y/o, he had genetic analysis at different hospital and it revealed a mutation in SOX2-OT gene which is a causative gene of his condition. 6 years later, mother showed up to our clinic to ask the meaning of genetic test. At that time, he was 12 y/o and had some more symptoms, such as epilepsy, GH insufficiency, hypogonadism. Head MRI showed thin corpus callosum and thin brain stem. His development was delayed as suspected before, however he has been recognising his mother gradually and could turn over himself even he cannot hold a sitting position. He is now enjoying his school for the visually impaired person. His mother was happy with his development and having settled daily life with him. Her worry was the possibility of inheritance of this condition to his younger brotherâ□□s future children at last. Genomic test for making definite diagnosis is done as general clinical medicine these days. However, this patient and his family have not been interested in the genomic test so much consistently. They have decided to have genetic analysis because of strong recommendation from local paediatrician and the family did not understand well about the result. It is very informative for us to know genetic mutation and phenotype, still we have to remember that patient familyâ□□s wish is more about the way to find happy life of their children. Some patient family need more easy, relaxed â□□Genetic counsellingâ□□ easing their fear rather than informative lecture.

MN1 C-Terminal Truncation (MCTT) syndrome is a rare autosomal dominant disorder characterized by intellectual disability, mid-face hypoplasia, severe expressive speech delay, and an atypical form of rhombencephalosynapsis (Mak et al. 2020 and GeneReviewsÂ®). The *MN1* gene is comprised of only two exons. Individuals with truncating variants at the C-terminal end of *MN1* (within exon 2 or the last 55bp of exon 1, and therefore escaping nonsense-mediated decay (NMD)) present with the distinct syndromic features of MCTT. Only seven individuals affected by N-terminal truncations (predicted to induce NMD) have been published so far, and have milder developmental phenotypes than MCTT patients (Mak et al. 2020, Shu et al. 2021 and Vegas et al. 2021). We performed a multicentre study to review an expanded case series (n=45) of 27 male and 18 female subjects (M:F ratio 1.5:1, mean age 12.9, range 2-44) from North America, Europe and Asia to characterize and compare the clinical and molecular spectrum of C-terminal (n=32) and N-terminal (n= 13) truncating mutations. Thirteen previously unreported patients (29%) are presented here. Review of 25 known and 7 unreported MCTT cases show that the characteristic dysmorphic features are consistently observed, which include midface hypoplasia, downslanting palpebral fissures, hypertelorism, exophthalmia, short upturned nose, and dysplastic low-set ears. Three recurrent variants are found (c.3778G>T, c.3883C>T and c.3903G>A), with the c.3883C>T variant occurring in 9 of 32 individuals (28%). We also report the oldest MCTT patient known to date, a 44-year-old male diagnosed at the age of 40. All patients have some degree of intellectual disability (100%), motor delay (100%) and speech delay (100%). For expressive speech delay, 33% of individuals with MCTT rely on non-verbal communication only, with the remaining expressing first words at the mean age of 4.03 (range 2-6.75 years). Remarkably, of the 13 individuals with N-terminal variants, one had typical facial dysmorphic features of MCTT. Cleft palate (33% vs 7%) and conductive hearing loss (82% vs 35%) are more commonly observed in association with N-terminal vs C-terminal truncations. Fewer individuals affected by N-

terminal truncations have intellectual disability (17% vs 100%) and motor delay (33% vs 100%). Despite this, 73% have some degree of expressive speech delay with first words at the mean age of age 2 (range 1.3-3 years). Globally our study supports the previous observation that patients with N-terminal truncations have milder neurodevelopmental outcomes than MCTT patients.

PrgmNr 2172 - Delineation of the phenotype and genotype in ten individuals with de novo variants in ZBTB18

Multiple sources have hypothesised that pathogenic variation within the gene ZBTB18 contributes to 1q43/44 microdeletion syndrome. This condition is characterised by intellectual disability, seizures, corpus callosum anomalies along with shared dysmorphic features. Previously a number of individuals have been identified with variants in ZBTB18 in the literature, although phenotypic information is sparse and inconsistent. We present the clinical details of 10 individuals with de novo variants in ZBTB18, classified as pathogenic or likely pathogenic, identified from the Deciphering Developmental Disorders study. We report previously unreported features such as sleep disturbance and hypertrichosis. We present facial features, growth parameters, interrogation of developmental milestones along with details of neuroimaging. Our work also involves detailed examination of each variant identified in conjunction with analysis from protein modelling experiments. This work strengthens the case for the inclusion of ZBTB18 on gene panels for intellectual disability. We hope that by sharing further phenotypic information this work will aid clinicians in considering ZBTB18 when formulating a differential diagnosis or interpreting variation within this gene.

PrgmNr 2173 - Expanding the phenotype of cerebello-facio-dental syndrome in female with a novel pathogenic variant

View session detail

Cerebello-facio-dental syndrome (MIM#616202:CFDS) is an autosomal recessive condition characterized by intellectual disability, microcephaly, cerebellar hypoplasia, dysmorphic features and short stature. In CFDS, six different pathogenic variants in BRF1 gene (5 missense and 1 nonsense variants) have been reported. Herein we additionally present a female with CFDS, expanding the phenotype and involving a novel pathogenic variant. The patient is 5-year-old girl of healthy and non-consanguineous parents. Birth weight was 2807g. She was born at 40 weeks of gestations after uneventful pregnancy and needed to have operations for congenital heart malformations(DORV,VSD)and laryngomalacia. In infancy, she repeatedly showed severe conditions caused by respiratory tract infection, resulting in the need for hospitalization and IVIGs. At age of 2 years, short stature, failure to thrive, microcephaly: OFC 42.5cm at 33months(-4.5SD) and severe global developmental delay have emerged. Facial dysmorphism includes sparse eyebrows, almond-shaped eyes, down-turned corners of mouth and prominent upper incisors. Kyphosis, hypothyroidism and hypermetropic astigmatism were observed since 3 years of age. Brain MRI showed a cerebellar hypoplasia. Postnatal marked growth retardation was also prominent at age of 5 years; height 84.6cm(-5.4SD), weight 10.3kg(-3.0SD) . G-banded chromosomal analysis revealed normal female karyotype. SNP-array detected no causative copy number variant. Whole exome sequencing identified compound heterozygous variants in BRF1 gene; p.(Thr259Met) previously reported and p.(Ser293Leufs*15), segregated in the parents. Thus far, ten biallelic carriers affected with CFDS have been reported. We detected additional two findings not reported to date, including thyroid dysfunction and repetitively severe infection in infancy. The latter could be a potential life-threatening manifestation in infancy, because there is one deceased infant at 21 months of age due to respiratory complications in a previous report. As noted above, both conditions should be screened in diagnosed infants with CFDS. The further description of patients with CFDS is essential to better delineate the phenotypic and genotypic spectrum.

PrgmNr 2174 - Long-read whole genome sequencing identified a partial *MBD5* deletion in an exome-negative patient with neurodevelopmental disorder

View session detail

Author Block: **S. Ohori**, N. Matsumoto; Yokohama City Univ. Graduate Sch. of Med., Yokohama, Kanagawa, Japan
Disclosure Block: **S. Ohori:** None.
Whole exome sequencing (WES) can detect not only single nucleotide variants in causal genes, but also pathogenic copy number variations using several methods. However, there may be overlooked pathogenic variations in the out of target genome regions of WES analysis (e.g. promoters), leaving many patients undiagnosed. Whole genome sequencing (WGS) can potentially analyze such regions. We applied long-read nanopore WGS and our recently developed analysis pipeline â□□dnarrangeâ□□ to a patient who was undiagnosed by trio-based WES analysis, and identified a heterozygous 97 kb deletion partially involving 5â□□- untranslated exons of *MBD5*, which was outside the WES target regions. The phenotype of the patient, a 32-year-old male, was consistent with haploinsufficiency of *MBD5*. The deletion breakpoint PCR analysis in the patient and his parents showed that the deletion of *MBD5* occurred de novo. The transcript level of *MBD5* in the patientâ□□s lymphoblastoid cells was reduced. American College of Medical Genetics and Genomics (ACMG) guideline for the interpretation of copy-number variants suggests that this de novo deletion partially involving 5â□□ untranslated region of *MBD5* was likely pathogenic (0.90) for the patient based on evidences of 1A (0), 2C-2 (0.45), 3A (0) and 5A (0.45). Taken together, we considered the 29-kb partial *MBD5* deletion as disease-causing SV. Furthermore, we found other rare structural variations (SVs) in this patient, i.e., a large inversion and a retrotransposon insertion, which were not seen in 33 controls. Although we considered that they are benign SVs, this finding suggests that our pipeline using long-read WGS is useful for investigating various types of potentially pathogenic SVs. In conclusion, we identified a 97-kb deletion which causes haploinsufficiency of *MBD5* in a patient with neurodevelopmental disorder, demonstrating that long-read WGS is a powerful technique to discover pathogenic SVs.
Acknowledgment: We would like to thank Drs. Rie S. Tsuburaya, Masako Kinoshita, Etsuko Miyagi, Takeshi Mizuguchi, Satomi Mitsuhashi, Martin C Frith for their participation to this study.

PrgmNr 2175 - Loss-of-Function mutations of *USP9X* as the differential diagnosis for CHARGE syndrome

View session detail

Author Block: **H. Futagawa**[1], S. Ito[1], M. Honda[1], H. Suzuki[2], M. Yamada[3], T. Uehara[4], T. Takenouchi[5], K. Kosaki[2], H. Yoshihashi[6]; [1]Tokyo Metropolitan Childrenâ□□s Med. Loss-of-function mutations in *USP9X*(Xp11.4) is known to cause Mental retardation, X-linked 99, syndromic, female-restricted (MIM#300968:MRXS99F). Clinical features include developmental delay, distinctive facial features, short stature and multiple congenital anomalies, for example choanal atresia, heart anomalies and anal anomalies. These features may overlap with CAHRGE syndrome (CS). Here, we report additionally two Japanese cases of MRXS99F and discussed the differentiation of MRXS99F and CS. 3-year-old girl. At the second trimester, she diagnosed cystic hygroma and conventional chromosomal analysis revealed normal female karyotype. After birth, she diagnosed congenital heart anomalies, anal atresia, unilateral hydronephrosis, lower limb asymmetry and hypopigmentation along Blaschko line. Her dysmorphic facial features included prominent forehead, long face, facial hemangioma, short palpebral fissures, symmetrically bilateral ear malformations, long nose, smooth and long philtrum. Now, her height and body weight were -1.4SD and -1.8SD respectively and she had global developmental delay. WES (IRUD) revealed de novo pathogenic variant in *USP9X* (NM_00103950.2:c.1153C>T p.Arg385*). 9-year-old girl. Her mother had keratoconus. After birth, she diagnosed anal atresia, unilateral choanal atresia and hearing loss, and she was suspected for CS. Now, her height and body weight were -3.6SD and -2.5SD respectively and she had global developmental delay. Her dysmorphic facial features included relative macrocephaly, square face, prominent forehead, hypertelorism, symmetrically bilateral ear anomalies and long philtrum. WES revealed de novo missense variant in *USP9X* (NM_00103950.2:c.3148G>A p.Asp1050Asn). Patients with MRXS99F have some clinical features overlap with CS. Our case 2 was suspected for CS. Present cases did not have coloboma, cranial nerve abnormalities and asymmetrical ear anomalies, which help to define the diagnosis of CS. These features rarely have reported with MRXS99F. Detailed physical assessment would make it possible to distinguish these two syndromes, and atypical CS may be the clue for the diagnosis of MRXS99F. Reviewing the literature, prominent forehead, low nasal bridge, prominent nose, long philtrum and ear anomalies were considered as distinctive facial features. Prominent forehead, square face and long philtrum might be the characteristic facial manifestations and MRXS99F would be categorized as a recognizable syndrome. The female case of atypical CHARGE syndrome with facial dysmorphism may be suggestive features of MRXS99.

PrgmNr 2176 - Objective evaluation of dysmorphism by automated analysis of facial photographs

The evaluation of â□□dysmorphismâ□□ remains challenging. The presence of three or more minor anomalies is often used as clinical criterion. However, this requires expertise in the evaluation of facial features. The fields of dysmorphology and syndromology are rapidly advancing, triggered by developments in testing technologies such as next generation sequencing, as well as well as automated sorting of syndromes. There is a need for tools that offer a more objective and faster recognition of dysmorphism and syndromes. Face2Gene (F2G) is a widely adopted tool for recognition of syndromes from 2D facial photographs.In the present study, we explored how this tool could aid in the recognition of facial dysmorphism and how it could react to factors such as age, sex and ethnic background. Different cohorts were studied including unselected Congolese newborns, Congolese children with intellectual disability, children with Down syndrome (DS) from DR Congo and Rwanda (African ethnicity), from Belgium (Caucasian) and Guadeloupe (mixed ethnicity), and a cohort of healthy adult Congolese volunteers.We used F2G to extract facial features from facial photographs, calculate dysmorphism scores and study the effect of ethnic origin, age and gender in different cohorts.We observed that F2G overestimated the incidence of individual minor facial features in the cohort of Congolese newborns. F2G detected facial dysmorphism, defined as the simultaneous presence of three or more minor facial anomalies, with a sensitivity of 37.5% and a specificity between 94-98%. This suggest that F2G performs better in a holistic approach rather than feature based approach in African individuals.In addition, F2G was able to clearly distinguish Congolese children aged above 15 years from those between 10-14 years based on their facial photographs (AUC=0.874). F2G also distinguished Congolese boys versus girls only from the age of 25 years (AUC=0.998). We concluded that age and gender play a significant role in baseline morphology and in dysmorphism after puberty.It was not possible to separate unselected Congolese newborns based on the geographical province of parents within DRC. Interestingly, a clear distinction was made between children with DS from different countries. The African (DR Congo and Ruanda) DS patients were very distinct from Caucasian DS patients from Belgium (AUC=1.000 and AUC=1.000) within the same range of age. Moreover, mixed ethnicity DS patients from Guadeloupe were clearly distinct from Belgian patients (AUC=1.000) but closer to Congolese DS patients (AUC=0.741). This suggests that ancestral genetic background influences the phenotypic expression of DS.

PrgmNr 2177 - Say-Barber-Biesecker-Young-Simpson syndrome (SBBYSS) and the importance of Whole Exome Sequencing in finding the accurate diagnostic. A case report

View session detail

Author Block: **D. Sabau**[1], L. C. Bohiltea[2], V. E. Radoi[2,1]; [1]Personal Genetics, Bucharest, Romania, [2]Carol Davila Univ. of Med. and Pharmacy, Bucharest, Romania
Disclosure Block: **D. Sabau:** None.
Introduction: Say-Barber-Biesecker-Young-Simpson variant of Ohdo syndrome (SBBYSS) is a genetic, autosomal dominant syndrome caused by *KAT6B* mutations. *KAT6B* - related disorders have variable expression and are characterized by developmental delay, hypotonia, dysmorphic features, congenital cardiac defects, genital abnormalities, skeletal abnormalities, dental anomalies.
Material and methods: A 3-year-old Caucasian boy was referred to the Department of Clinical Genetics because of developmental delay and dysmorphic features. The boy is the first child of healthy unrelated parents. He was born at term, with a gestational age of 40 weeks and one day and his birth weight was 3,425 g and length was 52 cm. The clinical evaluation revealed developmental delay, dismorphic features: hypertelorism, epicanthus, blepharophimosis, small and dystrophic teeth, long toes, atrial septal defect, and generalized hypotonia, bilateral cryptorchidism. Metabolic screening, array CGH and WES were performed for the patient.
Results: Metabolic screening and array CGH (8x60k Agilent) had both normal results. The next step in diagnosis algorithm was to perform WES analysis. The result of WES was an atypical *KAT6B* mutation, a de novo synonymous variant, located in exon 16 (c.3147G>A, p.(Pro1049Pro)). This mutation was previously identified in three unrelated patients. This exonic mutation was predicted in silico to cause protein truncation through aberrant splicing.
Conclusion: Our medical team decided to perform WES instead of *KAT6B* mutation screening, and recommends this method for further investigation of *KAT6B* - related phenotypes. There is no doubt that WES has increased the success rate when trying to identify the genetic cause of rare Mendelian disorders.

PrgmNr 2178 - The first East Asian adult case with rare *NEPRO*related skeletal dysplasia caused by a novel missense homozygous variant in *NEPRO*

View session detail

Author Block: **M. Minatogawa**[1,2], Y. Tsukahara[3], A. Sawaumi[4], T. Kosho[1,2,5]; [1]Dept. of Med. Genetics, Shinshu Univ. Sch. of Med., Matsumoto, Japan, [2]Ctr. for Med. Genetics, Shinshu Univ. Hosp., Matsumoto, Japan, [3]Dept. of Radiology, Shinshu Univ. Sch. of Med., Matsumoto, Japan, [4]Dept. of Orthopedics, Azumino Red Cross Hosp., Azumino, Japan, [5]Res. Ctr. for Supports to Advanced Sci., Matsumoto, Japan

Disclosure Block: **M. Minatogawa:** None.

Background: Biallelic pathogenic variants in *NEPRO* is known to cause one of the skeletal dysplasia characterized by severe short stature, brachydactyly, skin laxity, joint hypermobility, and radiographic skeletal abnormalities. *NEPRO* related skeletal dysplasia (NEPSD) was first reported by Shaheen et al. in 2016 and is an ultrarare disease with only 5 children with NEPSD reported so far. Here we report the first individual of NEPSD in a Japanese adult female with a novel missense homozygous variant in *NEPRO*. **Case report:** The propositus is a 44-year-old woman with clinical features including short stature of 130cm (â□□5.7SD), brachydactyly of the digits and toes, hypoplastic nails, pectus excavatum, skin laxity, joint hypermobility, and scoliosis. She also presented with congenital hip dislocation and acetabular dysplasia requiring surgery, epilepsy controlled by pharmacological treatment, bilateral congenital cataracts, and intentional myoclonus. She had constant joint pain due to severe joint hypermobility, and she gradually became difficult to walk. As a result, she has lived in a wheelchair since late childhood and has always used painkillers. Whole exome sequencing (WES) revealed a novel missense variant homozygously in *NEPRO* (NM_015412:exon4:c.442C>G:p.Arg148Gly). **Conclusion:** This is the first detailed description of the clinical course of NEPSD from childhood to adulthood, which will expand the knowledge of the natural history of this syndrome. The present case showed short stature, brachydactyly, skin laxity, joint hypermobility, acetabular hypoplasia, and scoliosis, which are those reported in previous NEPSD cases. We have also found several findings (congenital cataracts, seizures, and intentional myoclonus) in the present case that have been unreported in NEPSD so far. Although no variants in the genes responsible for cataracts and myoclonus were detected in WES, it remains to be clarified whether cataracts and myoclonus were associated with NEPSD. Further functional analysis and accumulation of cases would clarify these issues.

PrgmNr 2179 - The genotypic and phenotypic spectrum of pycnodysostosis in Saudi Arabia: Novel variants and clinical findings

View session detail

Author Block: **A. Mushiba**[1], E. A. Faqeih[2], M. Saleh[1], K. Ramzan[3], F. Imtiaz[4], M. AlOwain[5], A. Alhashem[1], A. F. Alswaid[6]; [1]King Fahad Med. City, Riyadh, Saudi Arabia, [2]King Fahad Med City, Children Specialist Hosp., Riyadh, Saudi Arabia, [3]King Faisal Specialist Hosp. & Res. Ctr., Riyadh, Riyadh, Saudi Arabia, [4]KFSH, Riyadh, Saudi Arabia, [5]King Faisal Specialist Hosp. and Res. Ctr., Riyadh, Saudi Arabia, [6]King Abdulaziz Med City, Riyadh, Saudi Arabia

Disclosure Block: **A. Mushiba:** None.

Pycnodysostosis is characterized by short stature, osteosclerosis, acro-osteolysis, increased tendency of fractures, and distinctive dysmorphic features. It is a rare autosomal recessive disease caused by biallelic CTSK mutations. The clinical details of 18 patients from Saudi Arabia were reviewed. Short stature, osteopetrosis, acroosteolysis, and distinctive facial dysmorphism were documented in all cases. Our results highlight the significant complications associated with this disease. The large anterior fontanelle is one of the cardinal signs of this disease; however, half of our patients had small fontanelles and a quarter had craniosynostosis, which caused optic nerve compression. Sleep apnea was of the major complications in three patients. Bone fracture can be a presenting symptom, and in our patients it mainly occurred after the age of 3 years. Bone marrow suppression was seen in a single patient of our cohort who was misdiagnosed initially with malignant osteopetrosis. In this study, we also describe two novel (c.5G > A [p.Trp2Ter], c.538G > A [p.Gly180Ser]) and two reported (c.244-29 A > G, c.830C > T [p.Ala277Val]) CTSK mutations. Our results indicate that the recurrent intronic variant, c.244-29 A > G is likely to be a founder mutation, as it was found in 78% (14/18 patients) of our cohort belonging to the same tribe.

PrgmNr 2182 - A novel variant in the *GNE* gene in a Malian with distal muscle weakness

View session detail

Author Block: **A. Maiga**[1], S. Bamba[1], S. Diarra[2,1], S. Diallo[3], S. Diallo[1,3], T. Coulibaly[1,4], A. YalcouyÃ©[1,5], L. CissÃ©[1,6], B. Maiga[7], G. LandourÃ©[1,4], C. Guinto[1,4]; [1]Univ. of Sci., Techniques and Technologies of Bamako, Bamako, Mali, [2]NIH, ROCKVILLE, MD, [3]Ctr. Hosp.ier Univ.ire 'Gabriel TourÃ©', Bamako, Mali, [4]Ctr. Hosp.ier Univ.ire 'Point G', Bamako, Mali, [5]Univ. of CapeTown, CapeTown, South Africa, [6]HÃ´pital Namakoro Fomba, Segou, Mali, [7]HÃ´pital SominÃ© Dolo, Mopti, Mali
Disclosure Block: **A. Maiga:** None.
Introduction: GNE myopathy is an ultra-rare autosomal recessive muscle disease with an estimated prevalence of 1 to 9:1,000,000. It is characterized by progressive distal muscle weakness and ultimately leads to wheelchair binding. The disease is caused by a mutation in the *GNE* gene that encodes the enzyme sialic acid epimerase, which is responsible for the last step of sialic acid biosynthesis. Although close to 200 variants were reported worldwide in different populations, cases in sub-Saharan Africa are scarce. **Aims**: To characterize both clinically and genetically patients with distal muscle weakness in the Malian population **Methods**: Patients with distal muscle weakness and their relatives were evaluated, after giving written consent, by a multidisciplinary clinical team including neurologists and cardiologists. Electromyography was performed and peripheral was collected for blood chemistries and to extract DNA for genetic testing. **Result**: A 19-year-old man from a consanguineous family was seen for progressive walking difficulty. The disease started at age 17 with a walking difficulty that worsened over time and has led to frequent falls. Clinical examination was consistent with distal muscle weakness and atrophy, reduced reflexes, and distal sensory loss. EMG has shown reduced distal motor and sensory amplitudes. These clinical and laboratory findings were in favor of distal neuropathy. However, CMT gene panel testing was negative. But WES revealed a novel pathogenic missense variant in the *GNE* gene (c.1841G>T [p.S614I]). This mutation segregates with the disease status in the family. **Conclusion**: This is likely going to be the first *GNE*-related myopathy diagnosed in the continent but the second reported in the sub-Saharan African population; suggesting that genetic diseases, in general, are underexplored in the African population, and that a better clinical assessment and access to diagnostic tools could uncover many others in this part of the World. Keywords: *GNE* gene, novel variant, Mali, Africa.

PrgmNr 2183 - A rare double diagnosis identified via exome sequencing in a patient with complex cerebellar ataxia

The growing use of next generation sequencing over the last decade has led to a dramatic increase in medical knowledge of Mendelian disorders and also to better awareness of the underestimated phenomenon of multiple diagnoses. The co-occurrence of more than one pathogenic variant in an individual is estimated to occur in up to 5% of patients and may generate different clinical situations depending on the phenotypes associated with these variants and how much they clinically overlap. These situations can be challenging for physicians to recognize, requiring particular attention and knowledge.In this work, we describe the case of a patient referred to our Genetics Department for syndromic gait disorders with childhood onset and a family history of gait disorders. Intertingly, while the proband's phenotype was compatible with complex cerebellar aatxia with upper motor neuron signs and cognitive impairment, her father's phenotype was the one of pure spastic paraplegia. Using exome sequencing, we identified 2 pathogenic missense variants, one in BSCL2 that was inherited from her symptomatic father and one in MT-ATP6 that was inherited from her asymptomatic mother, allowing us to untangle this challenging situation and provide an accurate diagnosis for each family member. While raising awareness on an underappreciated phenomenon, this informative report illustrates the diagnostic challenge that multiple diagnoses can represent and how clinical expertise and exome sequencing can help solve them.

PrgmNr 2184 - An exonic LINE-1 insertion and a novel missense variant in *CC2D2A* identified in siblings with Joubert syndrome using Long-Read Sequencing

View session detail

Author Block: **K. YANAGI**[1], J. Coker[2], K. Miyana[3], M. Omata[1], T. Hidai[1], A. Igarashi[1], K. Satou[1], A. Richman[4], S. Indupuru[4], Y. Matsubara[1], H. Thapar[4], T. Kaname[1]; [1]Natl. Ctr. for Child Hlth.and Dev., Tokyo, Japan, [2]OmniTier, Inc., Rochester, MN, [3]Japanese Red Cross Med. Ctr., Tokyo, Japan, [4]OmniTier, Inc., Milpitas, CA
Disclosure Block: **K. Yanagi:** None.
Joubert syndrome (JBTS) is a genetic and phenotypic heterogeneous disorder characterized by an MRI appearance called 'molar tooth sign', hypotonia in infancy, neonatal breathing dysregulation and developmental delay. *CC2D2A (coiled-coil and C2 domain containing 2A)* is known as a causative gene for JBTS 9 (OMIM 612013). Whole exome analysis by shot-read sequencing could make diagnosis of JBTS. However, there still remain undiagnosed cases. We report that long-read NGS with phasing analysis can reveal the causative biallelic SV and SNV in a family with two Japanese siblings suspected of JBTS. **Case:** The affected siblings, a 24-year-old sister (proband) and a 20-year-old brother, were born to non-consanguineous parents. Both presented hypotonia in infancy, neonatal breathing dysregulation and severe psychomotor developmental delay. They also had an occipital encephalocele. Although JBTS was clinically suspected as one of the different diagnoses, it was not explicitly diagnosed. **Genetic analysis:** We performed whole genome sequencing in the proband using a PacBio Sequel II with CLR (continuous long read) mode. Variant calling displayed an approximately 6.2 kb large insertion in exon 7 and a novel missense variant, c.4454A>G, p.(Tyr1485Cys) in *CC2D2A* (NM_001080522.2). The long insertion sequence was highly similar to LINE-1 (GU477636.1). The affected brother and her mother had the insertion confirmed by long range PCR. The missense variant, which was not recorded in gnomAD and was predicted to be deleterious by SIFT, PolyPhen-2 and other programs, was identified in the brother but not in the mother by Sanger sequencing. Deep sequencing using a MiSeq also could not detect the missense variant in the mother. We could not investigate the variants in the father because he was deceased. Therefore, we performed phasing analysis using SNV calling data from CLR sequences, which clearly showed that the two variants were in *trans* in the patient. SNV calling data around *CC2D2*A from the CLR sequences were verified by target re-sequencing using MiSeq. **Discussion:** We diagnosed and concluded the patients were JBTS affected by the biallelic variants in *CC2D2A*. Our calling program is effective to detect not only SVs but also SNVs even from the CLR sequencing data, which could also be used for phasing analysis. Our analyses can be applicable to identify pathogenic biallelic variants in such patients without samples from parents.

PrgmNr 2186 - Bi-allelic variants in neuronal cell adhesion molecule (*NRCAM*) lead to a novel neurodevelopmental disorder characterized by developmental delay, hypotonia, peripheral neuropathy or spasticity

Cell adhesion molecules (CAMs) are membrane-bound proteins predominantly expressed in the central nervous system (CNS) along principal axonal pathways. CAMs play key roles in nervous system development, neural cell differentiation and migration, axonal growth and guidance, myelination, and synapse formation. The most abundant CNS-expressed CAMs are L1CAM, NRCAM, CHL1 and NFASC, all belonging to the L1-CAM subgroup; these proteins are predominantly expressed along principal axonal pathways, such as the corpus callosum, corticospinal tract and the optic nerve. To date, pathogenic variants only in *L1CAM* and *NFASC* have been associated with neurodevelopmental disorders. In this study, we describe 10 patients from eight families with bi-allelic variants in the neuronal cell adhesion molecule *NRCAM*, leading to a novel neurodevelopmental syndrome of varying severity. This syndrome is characterized by developmental delay/intellectual disability, hypotonia, peripheral neuropathy and/or spasticity. Computational analyses of *NRCAM* variants, which mostly cluster in the third fibronectin type III (Fn-III) domain, strongly suggest a deleterious effect on NRCAM protein structure and function, potentially hindering its ability to interact with other proteins. These findings are corroborated by previous *in vitro* studies of murine *Nrcam*-deficient cells, revealing abnormal neurite outgrowth, synaptogenesis and formation of nodes of Ranvier on myelinated axons. We performed studies on zebrafish *nrcama* mutants lacking the Fn-III domains, revealing significantly increased amounts of acetylated Î±-tubulin fibers in the dorsal telencephalon (p=0.02) and the cerebellum (p=0.04), and increased amounts of dp-ERK positive cells in the dorsal telencephalon (p=0.04) and the cerebellum (pnrcama mutant larvae displayed significantly reduced swimming (pNRCAM disruption causes a variable form of a neurodevelopmental disorder, and broadens the knowledge on the role of NRCAM in nervous system development, and the growing role of the cell adhesion molecules family in the nervous system.

PrgmNr 2187 - Comprehensive genetic investigation of penta-nucleotide tandem repeats at *RFC1* locus in Indian ataxia and ALS cohort

View session detail

Monogenic etiologies for cerebellar ataxias and related disorders are ever expanding and till date more than 200 causal genetic loci have been elucidated. A significant numbers of tandem nucleotide repeat expansion associated loci are the prevalent mutations globally. Among these loci, a recently, described biallelic (AAGGG)n expansion in intron 2 of *RFC1* has emerged as a causal loci for CANVAS (Cerebellar ataxia, Neuropathy, and Vestibular areflexia syndrome) and sporadic cases of late onset ataxias. Subsequent studies have linked $(AAGGG)_{exp}$ in association with a common caucasian haplotype. We aimed to determine the occurrence of $(AAGGG)_{exp}$ in a cohort of genetically unknown ataxias and a cohort of Amyotophic Lateral Sclerosis (ALS) and to estimate the *RFC1* disease rik alleles/haplotype in Indian population. A systematic screening of *RFC1*-TNR in ~2000 (ataxia:1908, ALS:476) cases by repeat length dependent PCR selection (flanking PCR, repeat-primed PCR, long-range PCR) of risk alleles and repeat length estimation using short read and long read sequencing. We found three patients with biallelic $(AAGGG)_{exp}$ at *RFC1* i.e. 1/773 late-onset ataxia, 1/95 SCA12-like and 1/476 ALS cases. We found 29 $(AAGGG)_{exp}$ carriers and a new repeat configuration of AAAGGG through next-generation sequencing. We found that the risk haplotype is present in 8% of Indian control population (IndiGen data and 1000 genome SAS population). Study suggests the rarity of biallelic *RFC1*-TNR mutation; observation of a significant % of risk haplotype warrants further study in Indian population among phenotype segregated cohorts e.g. ALS cohort and SCA12 phenocopies.

Introduction: Genetic disorders with predominant central nervous system white matter abnormalities (CNS WMAs), referred to as leukodystrophies, are phenotypically and genetically heterogeneous entities. At least 422 disorders with CNS WMAs have been reported with largely monogenic etiology and a handful of chromosomal and microdeletion duplication syndromes.

Methods: We performed clinical and genetic evaluation of families with CNS WMAs. Targeted genetic testing was performed in families with a clinical diagnosis. Families without a diagnosis after targeted genetic testing or without a clinical diagnosis underwent broad spectrum genetic testing. **Results:** We evaluated 104 individuals with CNS WMAs from 94 unrelated families. Fifty-eight individuals (55.76%) in the present cohort were males and 46 (44.23%) were females. The age ranged from new-born to 59 years, however a majority (n=98, 94.23%) of individuals were of paediatric age. Consanguinity was noted in 55.31% (52/94) of the families. Targeted genetic testing was performed in 13 families with a clinical diagnosis, ten families received diagnosis. Chromosomal microarray (CMA) was performed for two families, one received a diagnosis. Mendeliome sequencing was performed in 10 families, all received diagnosis. Whole exome sequencing (WES) was performed in 77 families and was diagnostic in 51 (66.23%). Singleton exome sequencing was performed in 73/77 families of which 49 (67.12%) families received a genetic diagnosis. Overall, a genetic diagnosis was obtained in 70 families (74.46%). Twenty-two of 42 distinct disorders observed in this cohort have not been reported in Indian individuals previously. Notably, disorders of nuclear mitochondrial pathology were most frequent (8 disorders in 19 families). Thirty-four of 66 (51.51%) disease-causing variants are novel.

Conclusion: The present cohort describes phenotypic and genotypic spectrum of genetic disorders with CNS WMAs in our population. It demonstrates WES, especially singleton WES, as an efficient tool

in diagnosis of these heterogeneous entities. Additionally, it highlights possible founder events and recurrent disease-causing variants in our population and their implications on the testing strategy.

Introduction: Disorders with deficient myelination of central nervous system (CNS) manifest either as permanent hypomyelination, delayed myelination, or often as secondary hypomyelination and are predominantly genetic in origin. Forty-six conditions have been consistently reported with permanent hypomyelination. Of these, 45 are monogenic, presenting predominantly with a recessive mode of inheritance and one attributed to chromosomal abnormalities. Genetic disorders with delayed and secondary hypomyelination are significantly heterogeneous and often associated with impairment of CNS function. **Methods**: We performed clinical and genetic evaluation of Indian families with deficient myelination of CNS. Families with clinical diagnoses of disorders without genetic heterogeneity and known to be caused by recurrent variants/variants in small genes underwent targeted genetic testing. Families with genetically heterogenous disorders, defects in large genes, no clinical diagnosis, or undiagnosed by targeted genetic testing underwent broad spectrum genomic testing. **Results**: We evaluated 31 individuals with deficient CNS myelination from 26 unrelated families. Twenty individuals (64.5%) are males and 11 (35.5%) females with age range of four months to 15 years. Consanguinity was noted in 53.8% (14/26) families. Of the six families with clinical diagnoses, 4 (66.66%) received genetic diagnosis by targeted testing. Twenty-two families including two families undiagnosed by targeted genetic testing, underwent genomic testing. Of these, 15 (71.42%) families received diagnosis by exome sequencing, and 1 (14.28%) by chromosomal microarray. Overall, 20 families had genetic diagnoses (76.92%). Ten families (50%) had disorders associated with permanent hypomyelination, 2 (10%) had secondary hypomyelination and 8 (40%) had delayed myelination. We observed 17 disorders in 20 families, of which 5 (29.4%) are previously not reported in Indian population. We observed 21 variants, of which 15 are single nucleotide variants and four are copy number variants. Of these, 52.38% (11/21) are homozygous. Ten (47.61%) variants in this cohort are novel. **Conclusion**: This ongoing study aims to define clinical and genomic spectrum of genetic disorders with deficient CNS myelination in India and elucidate pathomechanisms underlying these disorders. The study lays groundwork for diagnosis and possible therapeutic interventions for Indian families with these disorders.

Introduction: Allan-Herndon-Dudley syndrome (AHDS, OMIM #300523) is an X-linked disorder caused by hemizygous pathogenic variants in the *SLC16A2* gene. Clinically, AHDS is characterized by neurologic findings, dysthyroidism and pathognomonic thyroid test results (high free T3 and low reverse T3, low free T4, and normal or slightly elevated TSH). The neurocognitive phenotype includes hypotonia, feeding difficulties in infancy, developmental delay, intellectual disability ranging from mild to severe, pyramidal signs, extrapyramidal findings, and late-onset seizures. Dysthyroidism signs include poor weight gain, reduced muscle mass, cold intolerance, sweating, elevated heart rate and irritability. To date, over 100 different genetically confirmed cases were reported. Here, we present two newly identified patients harboring two novel *SLC16A2* variants, aiming to expand the AHDS clinical and mutational spectrum. **Case reports**: Two unrelated boys were referred for genetic evaluation at 3 and 10 years of age, respectively. Both patients presented with severe global developmental delay, hypotonia, absence speech, and dystonia. The older child also had pyramidal signs, and dysthyroidism features including feeding difficulties, poor weight gain, reduced muscle mass and variable cold intolerance. Family history was suggestive of an X-linked inheritance pattern. Clinical exome sequencing revealed two hemizygous variants: *SLC16A2* (NM_006517.3) c.1057A>C p.(Thr353Pro) in proband 1, and *SLC16A2* (NM_006517.3) c.695C>T p.(Ser232Phe) in proband 2, classified as variants of unknown significance. Both variants were neither present in population databases nor reported in the literature. *In silico* analysis suggested that variants were disease causing. Segregation analysis revealed that mother and grandmother were carriers in both families. Further, retrospective evaluation confirmed abnormal thyroid function: normal TSH, low free-T4, high free T3 and low reverse T3. With the available evidence, we reclassified both variants as likely pathogenic, establishing the diagnosis of AHDS. **Conclusions**: Here, we identified two previously unreported missense variants in *SLC16A2* gene. Both patientsâ phenotypes were consistent with other reported cases. Reverse phenotyping through thyroid hormonal profile and segregation analysis were essential for confirmation of variants pathogenicity and establishment of molecular diagnosis. Additionally, this report further broadens the AHDS genotypic spectrum, and provides additional information for genotype-phenotype correlations.

PrgmNr 2191 - Genotypic spectrum and its clinical implication in disorders with epilepsy in Indian population: A preliminary experience

Introduction: Disorders with epilepsy are genetically and phenotypically heterogeneous. The rapid advancement of genetic testing has helped address these complexities and aided definitive diagnosis, precision medicine and genetic counseling in families with these disorders. **Methods:** We recruited 49 families (51 individuals) with neurodevelopmental disorder (NDDs) with epilepsy. Four individuals (four families) with clinically recognizable phenotypes underwent targeted genetic testing and 48 individuals (46 families) with clinically unrecognizable phenotypes and/or undiagnosed by targeted testing underwent genomic testing after detailed clinical evaluation. The implications on genetic counseling and therapy were evaluated in individuals with definitive diagnosis. **Results:** Our cohort comprises of 24 males (47%) and 27 females (53%) from 19 consanguineous (39%) and 30 non-consanguineous (61%) families. A definitive molecular diagnosis was achieved in 32 families with three being diagnosed by targeted testing and 29 by exome sequencing (ES). Twenty-nine monogenic disorders and one imprinting/microdeletion syndrome (Angelman syndrome) were identified. Of these, eight (25%) families had variants in seven genes causing developmental epileptic encephalopathies (*KCNQ2*, *STXBP1 UGDH*, *FGF13*, *AP3B2*, *FGF12*, *CYFIP2*). Seven (23%) families had variants in seven genes causing metabolic disorders (*HEXB, GCDH, GCSH, PNPT1, SHMT2, CARS2, SLC25A10*) of which six had variants in six nuclear encoded mitochondrial genes. Seven (23%) families had variants in 6 genes causing disorders with epilepsy as a core symptom (*SCN1A, KCTD7, NAXD, TRAPPC4, TPP1, KCNJ10*) and nine (29%) had variants in nine genes causing NDDs associated with epilepsy (*KMT2A, AP4S1, DYRK1A, RNASEH2C, DYNC1H1, GALNT2, ARID1B, ANKRD11, MECP2*). Biallelic variants were identified in 17 families (53%), *de novo* in 13 (41%), and heterozygous exonic deletion in one (3%) family. Seventeen (55%) of 31 disease-causing variants were novel. We also report variants in *SHMT2, SLC25A10*, and *FGF13* causing extremely rare disorders with less than 10 patients reported worldwide. Prenatal diagnosis was carried out in 19% (5/26) of families. Notably, ES had therapeutic implications in 50% of individuals (13/26) with a definitive diagnosis. **Conclusion:** The above-mentioned cohort is a part of an ongoing study of disorders with epilepsy. We herein describe the first cohort elucidating the genotypic spectrum and its clinical implications in disorders with epilepsies in Indian population.

PrgmNr 2192 - Identification of *NDEL1* as a novel gene for lissencephaly

View session detail

Author Block: **M-H. TSAI**[1,2], H-C. Ke[3], C-Y. Fong[4], C-C. Ng[4], K-S. Lim[4], J-W. Tsai[3]; [1]Kaohsiung Chang Gung Mem. Hosp., Kaohsiung, Taiwan, [2]Chang Gung Univ., Taoyuan, Taiwan, [3]Natl. Yang-Ming Ciao-Tung Univeristy, Taipei, Taiwan, [4]Univ. of Malaya, Kuala Lumpur, Malaysia
Disclosure Block: **M. Tsai:** None.
Background Lissencephaly (LIS) is a rare neurological disorder caused by abnormal neuronal migration. More than 20 LIS genes have been reported so far, most of them are functionally associated with the cytoskeleton. In a recent large study, more than 80% of patients with lissencephaly can have a pathogenic variant in reported genes. The genetics of lissencephaly in Asian patients is relatively under-explored. In addition, novel genes remain to be identified in unsolved cases. Method We recruited 33 lissencephaly patients and their family members. Candidate gene Sanger sequencing or whole exome sequencing (WES) was performed to search for known genetic causes. Trio WES study was used to study unsolved cases. In utero electrophoresis model was performed to investigate the effect of NDEL1 mutant on neuronal migration. Results In total, 33 patients with lissencephaly were enrolled in this study. 20/33 (60.6%) had a pathogenic variant in reported genes, including 7 DCX, 2 CEP85L, 2 DYNC1H1, 2 MAST1, 2 chromosome 17 deletion, 1 PAFAH1B1, 1 WDR62, 1 TUBA1A, 1 GRIN1, and 1 BICD2. WES Trio study was performed on the remaining 13/33 (39.3%) patients. One patient with a de novo NDEL1 missense variant was identified. NDEL1 is known to interact with LIS1 (PAFAH1B1) and required for microtubule organization and anchoring microtubule to the centrosome. Our preliminary functional study demonstrated that NDEL1 knock down and mutant both impaired neuronal migration. Conclusion The currently known lissencephaly genes are accounted for ~60% of our Asian cohort. We reported that NDEL1 is a novel gene for lissencephaly in human. NDEL1 dysfunction impaired neuronal migration during brain development.

PrgmNr 2193 - LRFN1- a novel candidate gene as a potential cause of autism spectrum disorder

View session detail

Author Block: **J. Shah**[1], D. Jain[2], F. J. Sheth[1], H. Sheth[1]; [1]FRIGE's Inst. of Human Genetics, Ahmedabad, India, [2]Shishu Child Dev. and Early Intervention Ctr., Ahmedabad, India
Disclosure Block: **J. Shah:** None.
Autism spectrum disorder (ASD), a complex neurodevelopmental condition is broadly characterized by impaired social interactions and stereotypy. It has an estimated prevalence of â¥64 per 10,000 people worldwide. Genetic factors have been recently identified which are associated with ASD phenotype, although the genetic etiology is highly variable and explains only 30-40% of the cases. Whole exome sequencing has led to the identification of several novel genes for ASD. Considering 10-15% cases with a confirmed genetic diagnosis have a *de novo* mutation, many novel genes have been identified using a patient-parentsâ trio based approach. We report the utility of this approach in a child that was clinically diagnosed with ASD according to DSM-V criteria. WES in the proband showed a heterozygous, missense variant c.176T>C (p.V59A) in exon 1 of the *LRFN1* gene (ENST00000248668.4). Validation and segregation analysis by Sanger sequencing showed the variant to be *de novo* in origin and classed as likely pathogenic according to the ACMG-AMP classification system. *LRFN1* is predominantly expressed in adult and fetal brain and is involved in the promotion of neurite outgrowth in hippocampal neurons, regulation and maintenance of excitatory synapses and induction of clustering of excitatory postsynaptic proteins, including DLG4, DLGAP1, GRIA1 and GRIN1. Literature has suggested a strong association between synaptic proteins and autism. Furthermore, mutations in genes encoding the aforementioned postsynaptic proteins are known to be associated with ASD. Collectively, the *in-silico* information, gene expression and interaction pathway along with mouse expression studies suggests *LRFN1* gene as a potential novel candidate gene associated with ASD.

PrgmNr 2194 - Metabotropic glutamate receptor subtype 2 (*GRM2*) is a novel disease gene for developmental and epileptic encephalopathy

View session detail

Author Block: **C. W. Lam**; The Univ. of Hong Kong, Hong Kong, China
Disclosure Block: **C.W. Lam:** None.
Introduction: Developmental and epileptic encephalopathy (DEE) is not an uncommon condition and currently 96 genes causing DEE have been reported in the literature. Most of the DEE genes are neuronal channels or receptors. With the advance of whole exome sequencing (WES), the underlying genetic defects in patients with DEE can be demystified. Here, we identified a *de novo* novel missense variant in the *GRM2* gene (metabotropic glutamate receptor subtype 2) in a patient with DEE. **Case:** We report a case of infantile-onset epilepsy in a 6 months old Chinese girl. The patient was first presented at birth with twitching movements and was later referred to us for convulsion of unknown aetiology. EEG showed hypsarrhythmia, generalized slow spike and wave discharges. Biochemical investigations were normal and there was no family history of similar disorders. Developmental delay became apparent only after the onset of seizures. The patient was diagnosed to have DEE. **Method:** Clinical genetic and genomic analyses included conventional PCR and Sanger sequencing and WES. The bioinformatics analysis was performed using in-house pipelines. **Results:** No known pathogenic variant was found in the known disease-causing genes for DEE. A novel heterozygous missense variant, NM_000839: c.2582G>A, p.Gly861Asp was found on the last exon of the *GRM2* gene. The c.2582G>A variant is an unreported variant and not found in population databases (ExAC and GnomAD). The variant was undetected in the parents. According to the American College Medical Genetics Guideline 2015 for the interpretation of sequence variants, the variant c.2582G>A was classified to be likely pathogenic. **Conclusions:** L-glutamate is the major excitatory neurotransmitter in the brain and activates metabotropic glutamate receptors. Though GRM2 is important in glutamatergic neurotransmission, the role of GRM2 in epilepsy and development has not been studied. We envisage metabotropic glutamate receptors may be potential therapeutic targets for epilepsy control.

The ATP binding cassette transporter ABCA2, encoded by the *ABCA2* gene, is an endolysosomal membrane protein and has a critical role for mediating the movement of sphingolipids within cellular compartments and maintaining homeostasis of sterols, sphingolipids and cholesterol. ABCA2 is most highly expressed in brain tissue and knockout mice display neurological defects consistent with aberrant myelination. We collected data from nine patients in eight unrelated families and added four cases from the literature. Five patients had *de novo* heterozygous variants (HTZ) and eight bi-allellic variants [seven homozygous variants (HMZ) and one compound heterozygous variant (cHTZ)] in *ABCA2*. All but one of the patients (with the cHTZ) had delayed psychomotor development. Two patients (one HMZ; one cHTZ) did not develop intellectual disabilities (ID); the remaining 11 had mild to moderate ID. Brain MRI was performed on eight patients - four had normal (two HTZ; two HMZ) results and the remainder had different abnormalities, but none had aberrant myelination as observed in the *ABCA2* knockout mice. Autism spectrum disorder occurred in three HTZ and one HMZ patient. Epilepsy was diagnosed in one patient with HTZ and five patients with HMZ. Different types of movement disorders (e.g. dystonia, ataxia) were diagnosed in five HMZ, two HTZ and one cHTZ. No patients were reported to have abnormal levels of serum cholesterol and/or lipoproteins, except two HMZ brothers with elevated level of low-density lipoprotein. However, untargeted metabolomic analysis performed from plasma revealed low levels of many sphingolipids in a patient with a *de novo* missense variant. The phenotype of the collected patients was variable with the core features of ID and various types of movement disorders in most patients. No clear correlation between the phenotype and the different inheritance patterns was observed. Various variants in the *ABCA2* gene were reported, such as missense variants, deletions or duplications; and they were located in different parts of the gene, with no clear correlation between the location or the type of the variant and clinical features. These findings suggest *ABCA2* to be associated with a spectrum of neurodevelopmental disorders, but highlights the need to further collect and investigate patients with variants in *ABCA2*.

Intellectual disability (ID) is a highly heterogenous disorder, yet analysis of the genetic etiology of ID often focuses on only a single mechanism (e.g. *de novo* or pedigree analysis) and excludes others. In the Northern Finland Intellectual Disability (NFID) study, we analyzed de novo variants in trios, inherited variants in large pedigrees, and the polygenic contribution to ID in 901 families (352 trios). We hypothesized that families with a single case of ID (enriched in our cohort for mild ID) were more likely to be explained by *de novo* variants, and families with multiple cases were more likely to be explained by inherited variants and polygenic burden. In *de novo* analysis, we compared the number of observed loss-of-function (LOF) mutations in known ID-associated genes to that expected by known mutation rates, which is well-powered with small sample sizes. We found that there were significantly more LOF mutations in known ID genes than expected, but only in families with a single case of ID (1.6 expected, 30 observed, p=1.34e-20, n=243, 46.7% mild ID) and not in families with multiple cases of ID (0.5 exp., 1 obs., p=0.398, n=109, 34.7% mild ID). When we examined the proportion of these families with an inherited rare, damaging variant in a known ID-associated gene, we found it was similar between families with a single ID case (43/243, 17.7%) and families with multiple ID cases (15/109, 12.8%, p=0.277). This suggests alternative modes of inheritance or damaging variants in novel genes in these multiply-affected families. When we investigated the polygenic contribution to ID, we saw that all ID cases had a lower polygenic score (PGS) for cognitive performance (CP; mean=-0.098 [95%CI:-0.165, -0.031], p=4.77e-3) and educational attainment (EDU; mean=-0.111 [95%CI:-0.178, -0.044], p=1.54e-3, n=901) compared to population controls, which persisted in ID cases from families with a single affected individual (CP: mean=-0.102 [95%CI:-0.172,-0.032] p=4.71e-3; EDU: mean=-0.118 [95%CI:-0.188,-0.047], p=1.35e-3, n=815, 47.7% mild ID). In ID cases from families with multiple affected individuals we did not see a difference in PGS from population controls (CP: mean=-0.058 [95%CI:-0.270,0.153], p=0.586; EDU: mean=-0.053 [95%CI:-0.265,0.159], p=0.641; n=86, 53.4% mild ID), but considering the small n we interpret this finding with caution. Over all, we begin to paint a picture of genetic architecture in our cohort that hints at possible different genetic etiologies in spontaneously-occurring vs inherited ID. Future work will focus on finding novel ID-associated genes and missing etiology in our large pedigrees.

Background: Single nucleotide variations (SNVs) and copy number variations (CNVs) play a critical role into the pathogenesis of neurodevelopmental disorders (NDDs). In this study, we have applied whole exome sequencing (WES) and chromosomal microarray (CMA) to detect clinically relevant variations/genes in a Bangladeshi NDD cohort.

Methods: We have conducted WES (33.05 Mb human coding regions) and genome-wide CMA (642,824 probes spanning the genome) analysis for 375 NDD patients to identify SNVs and CNVs.

Results: The cohort comprises 68.53% male and 31.47% female, age ranges from 9 days to 31 years where male to female ratio is 2.2:1. Of the total cohort (375 cases), CMA, WES and combined test (CMA and WES) was done on 56.53% (212), 32.00% (120) and 11.47% (43) cases, respectively. The diagnostic yield from CMA, WES and combined test for broader NDD is 12.26% (26/212), 20.00% (24/120) and 32.56% (14/43), respectively. Moreover, we have found 47.17% (100/212), 50.00% (60/120) and 48.84% (21/43) patients carrying variant of uncertain significance (VOUS) in CMA, WES and combined test respectively. An increased diagnostic yield was observed from WES 37.5% (9/24) and combined test 70.00% (7/10) in patients with epilepsy. All the epilepsy patients carrying a pathogenic mutation from our WES analysis are CNV negative in the combined test cohort confirms the utility of WES test for epilepsy cases. In the CMA cohort, we have found a significantly greater head circumference in male compared to female (p=0.0002). Analysis of both pathogenic and VOUS CNVs for â□□critical exonâ□□ genes (CEGs) yielded 153 unique CEGs in pathogenic CNVs and 31 in VUS. Of the unique 184 CEGs, we have considered *PSMC3* gene as a potential candidate gene for the NDD. 95 NDD patients were evaluated for autism spectrum disorders by Autism Diagnostic Observation Schedule-Second Edition (ADOS-2) method. Analyzing the ADOS-2 score, a trend of increased impairment in social communication (p=0.041) was observed in patients carrying duplication CNV compared to patients carrying deletion CNV. Rest of the data analysis of the WES and combined cohort are ongoing.

Conclusions: Our findings demonstrate the utility of WES and CMA as a first-tier diagnostic approach in cases lacking a clear differential diagnosis in a developing country with limited healthcare resources. The results also highlight the utility of WES for precise genetic diagnosis of epilepsy and its integration into the diagnosis therapeutics and management of epilepsy patients. To our knowledge, this is the first genomic research using larger number of NDD patients of Bangladesh.

PrgmNr 2198 - Novel *PCDH19* frameshift variant in a girl with recurrent seizures and phenotype overlapping with *SCN1A* gene dysfunction: a case report and literature review

View session detail

Author Block: **M. Mijovic**[1], J. Ruml Stojanovic[1], A. Miletic[1], B. Bosankic[1], H. Petrovic[1], G. Cuturilo[1,2]; [1]Univ. Children's Hosp., Dept. of Clinical Genetics, Belgrade, Serbia, [2]Faculty of Med., Univ. of Belgrade, Belgrade, Serbia
Disclosure Block: **M. Mijovic:** None.
Case report: We report the case of a 19-month-old girl with recurrent seizures from the nine months of age. Most seizures were provoked by fever and acute illness. Her EEG showed generalized discharges with specific graph elements. Brain MRI was normal. Early psychomotor development in the first year of life was orderly. From the second-year parents noticed a developmental delay, predominantly poor expressive speech development and attention deficit. Prenatal and perinatal anamnesis were unremarkable. Family history regarding seizures and intellectual disability is negative. Clinically, there was a strong suspicion of a disorder from a phenotypic spectrum of *SCN1A* gene dysfunction. Materials and methods: We performed whole exome sequencing and identified causative novel heterozygous *PCDH19* gene variant. In addition, we done a literature research regarding pediatric female cases of *PCDH19* gene dysfunction. Aim of present study was to establish the similarity between phenotypes of *PCDH19* and *SCN1A* gene disfunction. Results: Heterozygous variant identified in the *PCDH19* gene (c.243_246dup, p.Thr83Glyfs7*) creates a shift in the reading frame starting at codon 83, with new reading frame ending in a stop codon 6 positions downstream. It is classified as a likely pathogenic variant according to the ACMG recommendations. Pathogenic variants in the in the *PCDH19* gene, have been associated with developmental and epileptic encephalopathy type 9 (OMIM: 300088), an intriguing X-linked disorder affecting heterozygous females and sparing hemizygous males. Conclusion: Literature data suggests that additional clinical signs, like behavioral difficulties such as autistic spectrum disorders may rather correlate with *PCDH19* than with *SCN1A* gene dysfunction. Nevertheless, there is almost complete overlap in neurodevelopmental and epileptic phenotype in females with *PCDH19* and *SCN1A* gene alteration presented in infancy and early childhood. Distinction between these diseases is important for the proper therapy as well as recurrence risk estimation, since *PCDH19* gene dysfunction can be transmitted through asymptomatic fathers. This suggests the importance of multigene testing based on NGS sequencing in children, especially female, with a clinical diagnosis of Dravet or Dravet-like syndrome.

PrgmNr 2199 - Preliminary studies on apparent Mendelian psychotic disorders in consanguineous families

A psychiatric disorder is a mental condition in which emotions, cognition, behavioral patterns and moods of an individual are disturbed. Multiple psychiatric disorders recur in families, suggesting a role of genetic factors. Genome-wide association studies have identified these complex traits as highly polygenic. We hypothesize that variants, even though very rare, may exist associated with psychiatric disorders following Mendelian inheritance. Some of these causative gene variants can be identified in families with multiple affected individuals born to unaffected consanguineous parents. Here, we focused on the phenotype of psychosis, since the symptom is severe, demands clinical attention, and can occur in several Diagnostic and Statistical Manual of Mental Disorders (DSM) such as schizophrenia, bipolar disorder, substance abuse, and dementia. We visited outpatient departments and psychiatric wards of multiple hospitals in Lahore, Pakistan. We contacted families with individuals apparently inheriting psychosis in an autosomal recessive or X-linked recessive mode. Patients were first diagnosed by psychiatrists at the hospitals. Later, we administered detailed clinical assessments using Diagnostic Interview for Genetic Studies (DIGS), Diagnostic Interview for Psychosis and Affective Disorders (DI-PAD), Positive and Negative Syndrome Scale (PANSS), Hamilton Depression Rating Scale (HAM-D) and Hamilton Anxiety Rating Scale (HAM-A) standardized rating tools to all affected and unaffected participants. These rating tools confirmed rigorously the diagnosis of the patients, as well as the severity of their symptoms. Similarly, these assessments corroborated the unaffected status of the participating relatives of the patients. In total, we identified five families with ten individuals suffering from schizophrenia, three families with six individuals diagnosed with bipolar disorder and one family with two patients exhibiting unspecified psychosis. All affected individuals were born to unaffected consanguineous parents, most of whom were first cousins. We have obtained DNA samples from consenting affected and unaffected individuals of the families for future genetic analyses. We believe our continued research will help in the identification of rare recessively inherited gene variants for psychiatric disorders. These findings could pinpoint underlying biological mechanisms altered in these devastating diseases. This information will be useful in developing targeted therapies in future. Our work is funded by NIMH, NIH USA, 1R21MH120692-01A1 (SN & JVP).

Disclosure Block: **P. Plante:** None.
Combination of loss-of-function *UGDH* alleles have been recently described in autosomal-recessive cases of early infantile epileptic encephalopathies (EIEE). Most of the reported patients presented pharmaco-resistant epilepsy, severe intellectual disability (ID) with absent speech, significant motor delay, and structural abnormalities on cerebral MRI. Here, we report on two new cases of *UGDH* syndrome expanding the phenotype, with one case without any seizure history.
P1 is a 2 y/o boy with known *UGDH* syndrome phenotype, ie pharmacoresistant EIEE, axial hypotonia, pyramidal signs, microcephaly, no development of motor milestones, absent speech, feeding difficulties, abnormal movements without structural abnormalities on cerebral MRI. P2 is an 8 y/o girl presenting with severe global developmental delay (walk at 3), no speech, stereotypic movements, sleep disturbances and scoliosis. She has no feeding difficulties and no seizures history.
Both patients benefited from exome trio sequencing considering their developmental delay. Compound heterozygous variants involving the recurrent and pathogenic variant p.(Arg65*) associated with heterozygous missenses variants in trans were identified in both cases. Two unreported missense variants were detected: p.(Arg102Trp) (P1) and p.(Arg135Trp) (P2) both located in the NAD-binding domain of the protein. Missense variants p.(Arg102Trp) and p.(Arg135Trp) involved highly conserved residues with CADD scores of 26.0 and 24.5, and were respectively predicted to bound C-terminal aspartates in structural modelizations.
In conclusion, we identified two new and close pathogenic arginine to tryptophane missenses in the same domain and in trans of a known pathogenic nonsense, expanding the phenotype of *UGDH* syndrome to a broader presentation from early infantile intractable encephalopathy to severe ID without epilepsy.

PrgmNr 2201 - The Genetic Architecture of Neurological Diseases in Khyber Pakhtunkhwa-Pakistan

View session detail

Author Block: **M. Ilyas**[1], H. Houlden[2]; [1]Ctr. for Omic Sci., Islamia Coll. Univ., Peshawar, Pakistan, [2]Inst. of Neurology, Univ. Coll. London, London, United Kingdom
Disclosure Block: **M. Ilyas:** None.
Neuro-developmental disorders have become a major public health problem in Pakistan in recent years. Its treatment and management strategies are a daunting problem in Pakistan due to lack of funding, poorly developed primary and basic health care facilities and weak political processes. This increasing rate depends upon certain rare, neglected and often difficult to understand neurological conditions. These disorders therefore require special attention, particularly in rural areas where these disorders remains unexplored. Identifying specific genetic markers may provide a useful explanation for disease etiology, molecular characterization and pathogenesis. We used Next generation sequencing to investigate the novel causative gene(s) in hundreds of families and understand the role in order to develop effective treatments for neurological and neuro-developmental disorders. Clinical examination was performed on more than 50 consanguineous families with affected children. Using exome sequencing, the causative genetic variant was clarified in the families, and 25 convincing candidate genes were identified. It is further expected that personal genetic profiling will also become more relevant, with implications for patient care in line with the proposed idea of personalized medicine.

PrgmNr 2202 - A large deletion in *EVER1* gene: Identification and validation through amplicon-based Next Generation Sequencing

View session detail

Author Block: **A. Godfred**, Z. Thomas, L. Ravichandran, A. Joseph, D. Peter, A. A. George, S. A. Pulimood, P. Gaikwad, T. V. Paul, N. Thomas, A. Chapla; Christian Med. Coll., Vellore, India
Disclosure Block: **A. Godfred:** None.
Mutations in *EVER1* and *EVER2* genes are associated with Epidermodysplasia verruciformis (EV), a rare autosomal recessive genodermatosis. Mutation screening in these genes was carried out in an Indian family with clinically diagnosed EV using amplicon-based Next Generation Sequencing (NGS). Novel primer sets were designed to amplify the coding and splice site regions in these genes in healthy controls and two affected probands. This revealed no amplification with primer set for exons 16 to 18 in the *EVER1* gene of both the probands. To evaluate the possibility of a deletion at the site of the missing amplicon, we designed a Long-range PCR spanning the length of exon 15-20 and NGS was carried out to delineate the deleted segment. This Long range amplicon in the probands and controls was sheared, adapter ligated and size selected, followed by clonal amplification with emulsion PCR and sequencing on Ion Torrent PGM. The generated BAM files were analyzed on Integrated Genome Viewer (IGV), showing a homozygous deletion of 2081bp in exon 17 and 18 of this region. The results were also validated with Sanger sequencing.
Screening the family revealed the same homozygous deletion (similar to index cases) in 2 other affected siblings. The parents and two asymptomatic siblings were heterozygous carriers for the deletion, while one healthy sibling was negative. This deletion *EVER1:c.2072_2278*del produces a frameshift and a resultant loss of 68 amino acids in the transmembrane domain of the protein. The truncated protein product then causes a subsequent loss-of-function which can affect zinc homeostasis. Similar clinical presentations associated with several other mutations in the same gene have been described in the past. This mutation is classified as Pathogenic based on ACMG 2015 guidelines but requires further functional validation to confirm its pathogenicity.
These results indicate that a stepwise amplicon-based target enrichment would enable the identification of a homozygous large deletion before sequencing itself. Also, with long-range PCR options, these results can be validated and sequenced with NGS. Utilizing this strategy, we were able to differentiate carriers with this deletion in a heterozygous state from healthy normal. The data obtained now offers an opportunity for genetic counseling for the family and the possibility of early genetic diagnosis and screening of concerned family members. To the best of our knowledge, this is the first large deletion in *EVER1* gene to be identified in an Indian family.

PrgmNr 2203 - A novel deletion causes SLC25A42-associated mitochondrial encephalomyopathy in a Saudi patient: Report of additional founder cases and functional characterization study

View session detail

Author Block: **M. Aldosary**; KFSH&RC, Riyadh, Saudi Arabia
Disclosure Block: **M. Aldosary:** None.

SLC25A42-associated mitochondrial encephalomyopathy is recently described disorder featuring various symptoms such as hypotonia, intellectual disability and developmental delay, epilepsy and, mitochondrial encephalomyopathy. To date, 15 subjects are reported due to one of two, bi-allelic homozygous missense variants and interestingly most of these patients (n=14) are of Saudi origin harboring the same founder variant, c.871A>G:p.Asn291Asp. The remaining affected individuals, a german patient, was identified with a variant at canonical splice site, c.380+2T>A. Here in this study we employed autozygosity detection using affymetrix axiom human mapping assays, whole exome sequencing and confirmatory sanger sequencing on Saudi patients and identified additional six Saudi patients with the disease from four unrelated consanguineous families. While five patients have the very same Saudi founder p.Asn291Asp variant, one subject has a novel deletion. Functional analyses on fibroblasts obtained from this patient revealed that the deletion causes significant decrease in mitochondrial oxygen consumption and ATP production compared to healthy individuals. Moreover, extracellular acidification rate revealed significantly reduced glycolysis, glycolytic capacity, and glycolytic reserve as compared to control individuals. There were no changes in the mitochondrial DNA (mtDNA) content of patient fibroblasts. Immunoblotting experiments revealed significantly diminished protein expression due to the deletion. In summary, our study expands the molecular spectrum of this condition and provides further evidence of mitochondrial dysfunction as a central cause of the disease pathology. This disorder should be included in the differential diagnosis of any patient with unexplained motor and speech delay, recurrent encephalopathy and metabolic acidosis, intermittent or persistent dystonia, lactic acidosis, basal ganglia lesions and Arab ethnicity. Finally, deep brain stimulation should be considered in the management of patients with life altering dystonia.

PrgmNr 2204 - An *MRM2* splicing variant in a complex dystonic syndrome: a second report and incomplete penetrance

View session detail

Author Block: **A. Shafique**[1], B. Arif[1], S. Naz[1], N. Sobreira[2], E. Wohler[2], C. Klein[3], K. Lohmann[3]; [1]Univ. of the Punjab, Lahore, Pakistan, [2]Johns Hopkins Univ., Baltimore, MD, [3]Univ. of LÃ¼ebeck, LÃ¼ebeck, Germany

Disclosure Block: **A. Shafique:** None.

Dystonia involves repetitive movements and muscle contractions leading to abnormal postures. Pathogenic variants of many mitochondrial and nuclear encoded genes cause isolated dystonia or dystonic syndromes. We analyzed a complex dystonic syndrome in a consanguineous family with four affected individuals. The patients and unaffected individuals were investigated by neurologists and doctors at a local hospital. Magnetic Resonance imaging (MRI), Electromyogram (EMG), laboratory tests including ceruloplasmin and copper levels were completed. The dystonic phenotype manifested in all patients in early childhood which worsened with time. Symptoms started in the upper limbs, and progressively involved the lower limbs and the trunk. The patients were wheel chair bound by the age of 10 years. MRI, EMG and other laboratory tests were normal. Genome-wide mapping was performed on DNA of all participants using GeneChipÂ® Human Mapping 250K Nsp Array. No significant homozygous region which was only present in the affected individuals with perfect segregation was found. An 8.1cM region on chromosome 7p22.3-22.1 was identified which was heterozygous in the obligate carriers and homozygous in all affected individuals as well as in their unaffected 25-year old sibling. Exome sequencing was carried out for two patients. A homozygous splice site variant in *MRM2*, located within the candidate region on chromosome 7, was identified. The variant affected all *MRM2* isoforms, was extremely rare (gnomAD allele frequency 0.00002-no homozygotes) and absent in 150 ethnically matched unaffected controls. No other variant was identified which could explain the phenotype of the patients. Sanger sequencing on samples of all participants confirmed that, similar to the linkage results, the variant in *MRM2* was heterozygous in the obligate carriers and homozygous in the samples of the affected individuals and the unaffected older sibling. The *MRM2* encoded methyltransferase catalyzes the formation of 2'-O-methyluridine within the 16S mitochondrial ribosomal RNA. Previously, a homozygous deleterious missense variant c.567G>A;p.(Gly189Arg) in *MRM2* was linked to Mitochondrial DNA depletion syndrome 17 (MIM#618567). The affected child had a complex movement disorder with multi-organ failure and died in early childhood. Muscular weakness, involuntary and repetitive movements were shared symptoms in affected individuals in our family and the reported case. Our work extends the allelic spectrum of *MRM2* variants including reduced penetrance in the unaffected sibling. This study was supported by the BHCMG, USA, the DFG, & HEC, Pakistan.

Five novel mutations in *FKBP10* and *PLOD2* expanding the molecular and phenotypic spectrum in 10 new patients with rare Bruck syndrome

Bruck Syndrome (BS) is an autosomal recessive disorder characterized by osteogenesis imperfecta (OI) associated with congenital contractures and caused by mutations in *FKBP10* and *PLOD2* genes (BS1 and BS2 respectively). *FKBP10* mutations were found also to cause moderately severe recessive OI type XI. BS is very rare with only 49 cases reported in literature from various ethnic groups. Here we describe 11 new patients from 8 unrelated consanguineous Egyptian families with BS. All patients had white sclerae, recurrent fractures, multiple joint contractures, scoliosis and osteoporosis with variable range of severity. Mutational analysis of *FKBP10* and *PLOD2* genes revealed seven pathogenic variants including 5 novel mutations. *FKBP10* mutations were more common and found in 5 families (62.5 %) while *PLOD2* mutations were identified in 3 families (37.5 %). All *FKBP10* mutations were protein truncating except for one new missense mutation (c.698C>T, p.P233L), while the three *PLOD2* mutations were missense including the novel one. All mutations were homozygous in the probands and affected sibs and heterozygous in their respective parents with no clear genotype-phenotype correlation. Interestingly, the two sibs with the *FKBP10* missense mutation had variable phenotypic presentation. The older sister had joint contractures, severe kyphoscoliosis, hydrocephalus and osteoporosis while the younger brother had multiple fractures, severe osteoporosis and no contractures but rather joint laxity. In conclusion, this study describes five novel mutations in *FKBP10* and *PLOD2* thus expanding the mutational spectrum of the rare BS. In addition, our results further confirm the phenotypic overlap between OI and Bruck syndrome raising the concern of considering BS as a variant of OI and not a separate syndrome.

PrgmNr 2206 - Bi-allelic missense variant p.Thr368Ala in DLST is associated with 2-oxoglutarate dehydrogenase complex deficiency related neurometabolic disorder

View session detail

Author Block: **P. Upadhyai**[1], M. do Rosario[2], P. H. Somashekar[1], K. M. Girisha[3], A. Shukla[4]; [1]Kasturba Med. Disclosure Block: **P. Upadhyai:** None.
Introduction: The human 2-oxoglutarate dehydrogenase complex (OGDHC) is a multi-subunit mitochondrial tricarboxylic acid (TCA) cycle enzyme that catalyses the decarboxylation of alpha ketoglutarate to succinyl-CoA, reducing NAD+ to NADH. It is composed of multiple copies of three components: 2-oxoglutarate dehydrogenase (OGDH), dihydrolipoyl succinyltransferase (DLST) and dihydrolipoamide dehydrogenase (DLD). Bi-allelic variants in DLD cause dihydrolipoamide dehydrogenase deficiency (MIM #246900) and defect in OGDH has been proposed to cause alpha-ketoglutarate dehydrogenase deficiency (MIM %203740). **Methods:** Clinical examination and magnetic resonance imaging was performed in the proband followed by whole exome sequencing (WES). Segregation analysis was performed by Sanger sequencing. Metabolic investigations were performed using gas chromatography mass spectrometry in blood and urine from the subject. Molecular evaluation of transcript processing, levels and protein expression were carried out by reverse transcription PCR (RT-PCR), reverse transcription quantitative real-time PCR (RT-qPCR) and immunoblotting, respectively using subject fibroblast cells. **Results:** We ascertained a nine-month old female child born with global developmental delay, microcephaly, episodic decompensation, persistent metabolic and lactic acidosis, hyperammonemia and hyperketonemia. Brain imaging revealed atrophy of caudate and putamen. Her clinical features overlap with those reported previously in OGDH and DLD deficiency. WES revealed a missense variant, c.1102A>G (p.Thr368Ala) in DLST (NM_001933.5) that was present in homozygous state in the subject and her parents were heterozygous carriers. The mutation occurs at a highly conserved residue located within the C-terminal acyltransferase inner core or catalytic domain (ICD) of DLST. *In silico* mutagenesis predicted that the mutant residue caused loss of interaction with Asn299 and abrogation of one of two polar contacts with Asp316, as well as diminished mutant protein stability. *DLST* mRNA levels and processing were unchanged. However, DLST protein levels appeared to be significantly reduced. Further congruent with impaired OGDHC enzymatic activity, the levels of alpha ketoglutaric acid and its derivative 2 hydroxyglutaric acid were also elevated in her. **Conclusion:** Taken together we propose DLST as a novel candidate gene for OGDHC deficiency related neurometabolic disorder. This would be further substantiated with future reports of additional individuals and extended functional studies in cells and model organisms.

PrgmNr 2207 - Drug repurposing based on multi-omics data for osteoporosis

Disclosure Block: **D. Liu:** None.

Osteoporosis is a worldwide public health problem characterized by low bone mineral density (BMD) and a high risk of osteoporotic fracture. The currently available drugs for osteoporosis provide symptomatic benefits, but there is no desirable drug to cure the disease. Repurposing of drugs is a widely used approach to investigate the efficacy of approved drugs for a new indication because of lower overall development costs and shorter development timelines. In the present study, we used driver signaling network identification (DSNI) and drug functional network (DFN) based drug repurposing methods to recommend drug candidates for the treatment of osteoporosis. Osteoporosis driver signaling networks (ODSN, including 1039 genes and 521 subnetworks) were established based on multi-omics data, and drugs functional networks (including 196 drugs and 29 drug functional modules) from the Library of Integrated Network-based Cellular Signatures (LINCS) were determined based on drug similarity. By integrating ODSN and DFN with transcriptome data from LINCS and calculating target effect scores, we found that 8 drugs (including Acebutolol, Amoxapine, Acenocoumarol, Artesunate, Armodafinil, Abacavir, Aminocaproic-acid, and Amiloride.) showed top-ranked scores to display potential for osteoporosis treatment. Furthermore, Mendelian Randomization analysis was used to determine the positive or negative effect on BMD using drug candidates targets cis-eQTL (expression Quantitative Trait Loci) and BMD GWAS data. We found that Acebutolol through inhibiting expression of target ADRB2 (effect = -0.05, P-value = 1.06E-3) and Amiloride through inhibiting expression of target AOC1 (effect = -0.02, P-value = 2.03E-7) showed significant positive association with BMD, while Acebutolol has not previously been proposed as possible treatments for osteoporosis. Besides, Acenocoumarol through inhibiting expression of VKORC1 (effect = 0.01, P-value = 2.92E-48), Aminocaproic-acid through inhibiting expression of PLAT (effect = 0.02, P-value = 3.38E-7), and Armodafinil through inhibiting expression of target SLC6A3 (effect = 0.01, P-value = 1.40E-4), all decreased BMD, which implied that the risks around these drug use for osteoporosis need to be concerned. These findings investigated potential drug candidates in osteoporosis treatment and further warrant bone loss pharmacovigilance with drugs' long-term use.

PrgmNr 2208 - Exome sequencing in 13 families with monogenic forms of rickets

View session detail

Disclosure Block: **K.M. Girisha:** None.
Introduction Rickets is a disorder of growing bone caused by defects in the metabolism of calcium, phosphate and/or vitamin D or from nutritional deficiency of vitamin D. Hereditary forms are very rare, and account for about 13% patients with rickets. Eighteen genes are associated with monogenic forms of rickets. **Methods** Sixteen individuals from 13 families were recruited for the study. Detailed clinical features, radiological findings and family history were recorded. Calcium and vitamin D metabolism was assessed by suitable tests. Exome sequencing was performed in the probands from 13 families. The data were analyzed and the rare variants in genes likely to cause the disease were prioritized using standard protocols. **Results** This cohort consists of 11 females and five males with rickets in the age range of 2-21 years. Molecular diagnoses were established for 10 families: vitamin-D dependent rickets type I due to biallelic pathogenic variants in *CYP27B1* (three families); vitamin D resistant rickets, type IIA due to biallelic pathogenic variants in *VDR* (one family); vitamin-D dependent rickets type IB due to pathogenic compound heterozygous variants in *CYP2R1* (one family); hypophosphatemic rickets in four families (pathogenic variants in *PHEX* causing X-linked dominant hypophosphatemic rickets in three and a homozygous pathogenic variant in *SLC34A3* causing hypophosphatemic rickets with hypercalciuria in a family), and biallelic pathogenic variant in *SLC2A2* causing Fanconi-Bickel syndrome. A total of 12 disease-causing variants were identified, of which six were novel. Three families had no diagnosis after exome sequencing in two sibs each. **Conclusion** Our study helped in elucidation of 12 disease-causing variants in six genes associated with monogenic form of rickets in 10 families. Failure of molecular diagnoses in three families even after exome sequencing suggests yet unknown genetic etiology of these disorders.

PrgmNr 2209 - Further delineation of *RPL13*-related skeletal dysplasia

View session detail

Author Block: **P. Jacob**[1], P. Udupa[1], G. S. Bhavani[2], A. B. Dalal[3], K. M. Girisha[4]; [1]Kasturba Med. Coll., Manipal, Manipal, India

Disclosure Block: **P. Jacob:** None.

Introduction Spondyloepimetaphyseal dysplasia, Isidor-Toutain type (MIM*618728) is a recently elucidated skeletal dysplasia caused by heterozygous variants in *RPL13* (ribosomal protein, required for pre-ribosomal RNA processing). Till date, nine patients have been reported in the literature. **Methods** Two unrelated families were ascertained. Nine patients from two families were ascertained (Family 1 had eight affected members). Detailed clinical features, radiological findings and family history were recorded. Exome sequencing was performed in two affected individuals of family 1 and in the proband of family 2. Data analysis and interpretation was performed using standard procedures. **Results** Family 1 consists of eight affected members with variable levels of phenotypic severity. The proband at age five years had severe short stature, genu varum, wide wrists, delayed carpal bone ossification and joint laxity. Radiographic features included platyspondyly, bowed femora, severe epiphyseal and metaphyseal dysplasia and exaggerated lumbar lordosis. The other family members demonstrated variable clinical and radiological phenotypes including non-penetrance in one individual. The proband from family 2 at age nine years demonstrated short stature, short trunk and mild pectus excavatum, delayed carpal bone ossification, small and irregular epiphysis of radius and ulna, irregular vertebral end plates and sclerotic changes in the metaphysis of proximal femoral metaphysis. Magnetic resonance imaging showed widening of femoral neck with bilateral symmetrical striated area in the metaphyseal region of proximal femur, osteonecrosis of left femoral head and slipped capital femoral epiphysis on right side. Exome sequencing revealed, a pathogenic variant, c.548G>A p.(Arg183His) in heterozygous state in *RPL13* known to cause Spondyloepimetaphyseal dysplasia, Isidor-Toutain type in both the families. This variant was also present in an unaffected member of family 1 suggesting non-penetrance. A novel missense change at the same amino acid residue (p.Arg183Pro) has been reported recently. **Conclusion** We report two more families with *RPL13*-related skeletal dysplasia with variable clinical features and report an instance of non-penetrance. With this study, we expand the phenotypic spectrum of this rare disease entity.

Mitochondrial function is under bigenomic control, meaning pathogenic variants in both the nuclear and mitochondrial genomes (mtDNA) result in clinical mitochondrial disease. The most common pathogenic, heteroplasmic, mtDNA variant m.3243A>G (NC_012920.1), is associated with extensive clinical heterogeneity. Established risk factors (age and m.3243A>G variant level) explain only a small proportion of phenotypic variability, whereas high to moderate estimates of heritability for some m.3243A>G-related phenotypes provide evidence for the influence of unidentified nuclear factors. We aimed to explore the genetic aetiology of this variability and locate these factors using genetic linkage analysis.

We identified 238 deeply-phenotyped individual m.3243A>G carriers within 88 pedigrees recruited from: the UK Mitochondrial Disease Patient Cohort; the German Network for Mitochondrial Diseases (mitoNET); the Nationwide Italian Collaborative Network of Mitochondrial Diseases; and the Exeter Centre of Excellence for Diabetes Research. Using the established risk factors of age and m.3243A>G variant level as predictors, we performed logistic regression to quantify the residual unexplained variation in the risk of developing sixteen recognised m.3243A>G-related phenotypes, defined using the validated Newcastle Mitochondrial Disease Score for Adults. To scan the nuclear genome for regions linked to this residual variation, we performed genome-wide Haseman-Elston regression-based linkage analysis, implemented in Merlin-REGRESS, using ~8000 nuclear SNV markers.

For eight m.3243A>G-related phenotypes (cardiovascular involvement, cognition, dysphonia-dysarthria, gastro-intestinal dysmotility, hearing impairment, migraine, neuropathy and seizures), no regions of interest (LOD>1.8) were identified, indicating that the aetiology of these traits is likely to be highly complex, with no major nuclear loci influencing risk. For seven phenotypes (cerebellar ataxia, chronic progressive external ophthalmoplegia, diabetes, myopathy, psychiatric disturbance, ptosis and stroke-like episodes) we identified at least one region of interest (LOD>1.8). For encephalopathy we detected seven regions of interest, including one (LOD>3.3) on the long arm of

chromosome 5, suggesting that a small number of nuclear genetic factors play a key role in the development of this severe neurological phenotype. Association analysis and whole-genome sequencing studies are being pursued to refine these genomic regions.

PrgmNr 2211 - High prevalence of *DMD* gene mutations in Duchenne muscular dystrophy in South Indian population

View session detail

Author Block: **K. Vaidyanathan**, P. K. Manuprasad, C. K. Reshma, S. Nampoothiri; Amrita Inst. of Med. Sci. & Res. Ctr., Kochi, Kerala, India, Kochi, India
Disclosure Block: **K. Vaidyanathan:** None.
Background Alterations in the DMD gene, encoding the dystrophin protein, are known to be common in Duchenne muscular dystrophy (DMD) and Becker-type dystrophy. The DMD gene is located on the X-chromosome. Many mutations are known to be associated with DMD; the commonest being gene deletions/duplications. The objective of our study was to find the variations in DMD gene in confirmed cases of DMD/Becker-type dystrophies. We have studied DMD gene deletion/duplication by Multiplex Ligation-dependent Probe Amplification (MLPA) technique over a two year period (2018-2019). Methods The subjects in this study presented to the Department of Pediatric Genetics, Amrita Institute of Medical Science, Kochi, India during a two-year period (2018-2019). 48 patients with symptoms suggestive of DMD/Becker-type dystrophy were enrolled into the study. They were studied by the MLPA technique. Results 30 patients were detected to have DMD. The commonest changes detected were exons 44-55 deletions (9 patients). Other changes detected were exons 1-44 deletions (5 patients), duplications (3 patients) and exon 55-79 deletions (1 patient). 12 patients tested negative for DMD gene alterations. Conclusions Alterations in DMD gene were frequently found in patients (18/30, 60%) with DMD/Becker-type dystrophy. The commonest alterations found were deletions in exons 44-55 of the DMD gene.

PrgmNr 2212 - Identification of novel candidate genes and expansion of the phenotypic spectrum in a large skeletal dysplasias cohort

View session detail

Author Block: **D. Uludag Alkaya**[1], K. Bilguvar[2], M. GÃ¼nel[3], B. TÃ¼ysÃ¼z[4]; [1]Dept. of Pediatric Genetics, Istanbul Univ.-Cerrahpasa, Istanbul, Turkey, Istanbul, Turkey, [2]Yale Univ., Dept. of Genetics, New Haven, CT, [3]Yale Univ., Dept. of Neurosurgery, New Haven, CT, [4]Istanbul Univ.-Cerrahpasa, Istanbul, Turkey

Disclosure Block: **D. Uludag Alkaya:** None.

Skeletal dysplasias are a large group of disorders that mostly manifest with disproportionate short stature, in which bone and/or cartilage tissue is affected. To date, more than 450 skeletal dysplasia syndromes have been identified and 437 different genes related to these syndromes have been reported. In patients with rare and/or similar signs of skeletal dysplasia, whole exome sequencing can determine the molecular basis of the present disorder. In this study, we aimed to investigate genes related to skeletal dysplasia in a large cohort of patients using the whole exome sequencing. We focused on patients with skeletal dysplasia that could not be diagnosed clinically or molecularly to identify new candidate genes and to contribute to phenotypic expansion. 102 patients from 78 families were included. Molecular diagnosis was confirmed in 55 families (70.5%). The novel candidate skeletal dysplasia genes, *ADAMTS1, CKAP2, MBOAT1, FBN3* were proposed in four of these families. We expanded the phenotype in very recently discovered skeletal dysplasia syndromes such as *PRKG2, GAD1, RPL13, PRKG2, SLC10A7, SIK3* related disorders. Also, novel findings were described in well-known skeletal dysplasia syndromes such as gonadal mosaicism, recessive inheritance pattern in *COL2A1* related disorders. The advanced diagnostic success rates in our clinic is a result of having access to a large patient cohort, selecting relevant patients carefully for this specific study based on abundant clinical and radiological data and implementing appropriate correlation studies between the clinical data sets and patientsâ genetic information.

PrgmNr 2213 - Long-term prognosis and genetic background of cardiomyopathy in 223 mitochondrial disease children

Disclosure Block: **A. Okazaki:** None.

Background: Cardiomyopathy is a risk factor for poor prognosis in children with mitochondrial disease. However, other risk factors including genetic factors associated with poor prognosis in mitochondrial disease has yet to be elucidated fully.**Methods and Results**: Between January 2004 and September 2019, we enrolled 223 consecutive children with mitochondrial disease aged Conclusion: In children with mitochondrial disease, cardiomyopathy was common (22%) and was associated with increased mortality. LV hypertrophy, neonatal onset and chromosomal aberrations were independent predictors of all-cause mortality. Prognosis is particularly unfavourable if LV hypertrophy is combined with neonatal onset and/or chromosomal aberrations.

PrgmNr 2214 - Lysosomal storage disorders at a tertiary care centre in a developing country

View session detail

Author Block: **I. Panigrahi**, A. Angral, P. Kaur; PGIMER, Chandigarh, India
Disclosure Block: **I. Panigrahi:** None.
Introduction: The diagnosis of lysosomal storage disorders (LSDs) can be challenging because o varied clinical presentations at different ages. Gaucher disease is a prototype disorder for which various forms of therapy are available. Enzyme replacement therapy (ERT) is now available here for MPS I, MPS II, Gaucher disease, Fabry disease and Pompe disease. We report the spectrum of LSDs at a tertiary care center**. Methods:** The families of patients of lysosomal storage disorders visiting the Genetic Clinic, or admitted in the Genetic ward in last 12 years were included in this retrospective analysis. Consent for genetic testing or antenatal testing was as per standard protocols and recommendations of the PNDT Act. Mutations were done only in some families, especially to facilitate prenatal diagnosis. In families in which PND was done, the testing was done by enzyme analysis and/or mutation testing by Sanger sequencing on chorionic villus or amniotic fluid samples. **Results:** In last 12 years, 35 families with Gaucher disease, 27 families with MPS, 10 families with Niemann Pick disease (NPD), 8 families of Pompe disease, 5 families with GM1 gangliosidosis, 4 families with GM2 gangliosidosis and 2 families with Fabry disease were seen, evaluated and counselled in the Genetic Clinic or Genetic ward of the Institute. The patients were from adjoining states. The diagnostic delay varied from 2-10 years. PND was done in 3 Gaucher disease, 2 each for GM1 and GM2 gangliosidosis, 2 NPD, 2 MPS III and 2 Pompe disease families. Most patients with Gaucher disease showed the *GBA*: c.1448T>C(L444P) mutation in homozygous or heterozygous state. Therapy in form of ERT was given in 4 patients with Gaucher disease, 2 patients with MPS II, and one patient with Pompe disease. It could not be given in most eligible patients because of financial constraints. .**Conclusions:** LSDs can present with hepatosplenomegaly, cytopenias, renal disease, cardiomyopathy, neurological and skeletal features. In developing countries, usually the diagnosis is delayed, all patients do not have access to therapy, and prevention by prenatal diagnosis is major preventive option in these families. We could diagnose many patients by enzyme testing, and could plan and perform prenatal diagnosis in some of the families by enzyme or molecular diagnosis. In absence of rare disease model, and government support for therapy for many families; the parents run from pillar to post for ensuring therapy for their children. With the National policy for Rare diseases (NPRD) implementation, and streamlining of the services and prioritisation of therapy in eligible patients, the situation is likely to change in next few years.

PrgmNr 2215 - Mechanism of WRN loss for causing short stature in Werner syndrome

View session detail

Author Block: **H. Cheung**, O. Leung, T. Yiu; The Chinese Univ. of Hong Kong, Shatin, Hong Kong
Disclosure Block: **H. Cheung:** None.
Werner Syndrome is a premature aging disease characterized by early onset of many age-related phenotypes in the adulthood. It is a monogenic disease caused by recessive mutations in the WRN gene, a member of the conserved RECQ DNA helicases. The first phenotype of WS is typically displayed in the skeletal system, with approximately 95% of reported WS cases showed short stature. Individuals diagnosed as WS have an abnormally slow growth rate, and growth usually stops at puberty. As a result, affected individuals develop short stature. The mechanism through which WRN loss causes short stature, and the underlying genetic basis are not clearly elucidated. To determine the cause of short stature in WS, we used human pluripotent stem cell (hPSC) model for identifying deferentially expressed genes in the differentiated mesenchymal cells. Transcriptome analysis revealed that *short stature homeobox* (SHOX) gene was one of the downregulated targets in WS. SHOX is known to play a vital role in chondrogenesis and bone development. As SHOX deficiency is a frequent cause of short stature, we hypothesized that SHOX is downregulated in WRN mutated cells. Knockout of WRN or SHOX in human mesenchymal stem cells and hPSC impaired chondrocyte differentiation, as shown by reduced expression of chondrocyte markers SOX9 and COL2A1. Furthermore, we identified a molecular mechanism that wild-type WRN protein binds to SHOX promoter and resolves the G-quadruplex structure which hinders the transcription of SHOX. The current work suggests a novel mechanism through which SHOX insufficiency in WS is connected with bone development.

PrgmNr 2216 - Molecular diagnostic challenges related to mutations in the low-complexity domain of heterogenous nuclear ribonuclearprotein A1 (HNRNPA1)

Disclosure Block: **M. Johari:** None.

Heterogeneous nuclear ribonucleoproteins are RNA-binding proteins, many of which contain low complexity sequences known as â□□prion-like domainsâ□□ or PrLDs. Mutations in these PrLDs are associated with several diseases such as Multisystem proteinopathies (MSP) and Amyotrophic lateral sclerosis (ALS). These mutations affect the abnormal stress granule (SG) formation and clearance resulting in increased toxicity due to aggregated proteins. Understanding how mutations in heterogenous nuclear ribonuclearprotein A1 (*HNRNPA1*) functionally affect the SGs, holds the key in improving our knowledge of the molecular pathomechanisms of the disease.We identified three different mutations in the PrLD of *HNRNPA1* (NM_031157) associated with dominant myopathy phenotypes in three unrelated families (FAM1-3). In FAM1, the previously reported D314N mutation segregated with a proximal rimmed vacuolar myopathy. The finding was initially missed due to coverage issues in exomes and traditional variant calling on captured regions. In FAM2, published earlier with a distinct distal myopathy phenotype (MPD3), we performed linkage analysis, subsequent Sanger sequencing of candidate genes, exome and genome sequencing (GS), which remained inconclusive. Copy Number Variant analysis of newer high depth GS identified a heterozygous 160 bp deletion in exon 10 of *HNRNPA*1 in the linked region, segregating with the phenotype in this family. The finding again asserted the possible coverage issues plaguing this gene. In FAM3 with severe myopathic atrophy in forearms and hands, we identified a *de novo* heterozygous indel in the same exon 10 causing extension of the HNRNPA1 tail by 3 amino acids. We are currently investigating the effects of these mutations on transcript and protein level. We postulate that different mutations in the PrLD of *HNRNPA1* can give rise to different overlapping phenotypes. Our internal analysis of over 400 exomes and genomes suggests, that due to the genomic complexity of this region some sequencing chemistries do not result in high confidence coverage. The coverage analysis of data from 10638 samples in Solve-RD suggests that exome capture kits have difficulty in covering the GC rich regions of *HNRNPA1* which could lead to cases of â□□missed diagnosisâ□□.

PrgmNr 2217 - Mutations in DNA ligase III cause mitochondrial neurogastrointestinal encephalomyopathy

Abnormal gut motility is a feature of several mitochondrial encephalomyopathies, and mutations in genes such as *TYMP* and *POLG*, have been linked to these rare diseases. The human genome encodes three DNA ligases, of which only one, ligase III (*LIG3*), has a mitochondrial splice variant and is crucial for mitochondrial health. We investigated the effect of reduced LIG3 activity and resulting mitochondrial dysfunction in seven patients from three independent families, who showed the common occurrence of gut dysmotility and neurological manifestations reminiscent of mitochondrial neurogastrointestinal encephalomyopathy. DNA from these patients was subjected to whole exome sequencing. In all patients, compound heterozygous variants in a new disease gene, *LIG3*, were identified. All variants were predicted to have a damaging effect on the protein. The *LIG3* gene encodes the only mitochondrial DNA (mtDNA) ligase and therefore plays a pivotal role in mtDNA repair and replication. *In vitro* assays in patient-derived cells showed a decrease in LIG3 protein levels and ligase activity. We demonstrated that the *LIG3* gene defects affect mtDNA maintenance, leading to mtDNA depletion without the accumulation of multiple deletions as observed in other mitochondrial disorders. This mitochondrial dysfunction is likely to cause the phenotypes observed in these patients. The most prominent and consistent clinical signs were severe gut dysmotility and neurological abnormalities, including leukoencephalopathy, epilepsy, migraine, stroke-like episodes, and neurogenic bladder. A decrease in the number of myenteric neurons, and increased fibrosis and elastin levels were the most prominent changes in the gut. Cytochrome *c* oxidase (COX) deficient fibres in skeletal muscle were also observed. Disruption of *lig3* in zebrafish reproduced the brain alterations and impaired gut transit *in vivo*. In conclusion, we identified variants in the *LIG3* gene that result in a mitochondrial disease characterized by predominant gut dysmotility, encephalopathy, and neuromuscular abnormalities.

PrgmNr 2218 - NTBC efficacy in alkaptonuria

View session detail

Author Block: **H. Alsharhan**[1,2], H. Alharbi[2], S. M. Kallish[3], J. Sharer[4], S. R. Master[2,3], M. Yudkoff[2,3], M. He[5]; [1]Dept. of Pediatrics, Faculty of Med., Kuwait Univ., Kuwait City, Kuwait, [2]Children's Hosp. of Philadelphia, Philadelphia, PA, [3]Univ. of Pennsylvania Perelman Sch. of Med., Philadelphia, PA, [4]Univ. of Alabama at Birmingham, Birmingham, AL, [5]Childrenâ□□s Hosp. of philadelphia, Philadelphia, PA
Disclosure Block: **H. Alsharhan:** None.
Alkaptonuria (AKU) is a rare autosomal recessive disorder in tyrosine degradation pathway, characterized by ochronosis, arthritis and significant urinary homogentisic acid (HGA) excretion. There are no preventive or curative treatment options currently available. Nitisinone (NTBC), a drug that is currently approved for treating AKU by the European Medicines Agency but not by the US Food and Drug Administration (FDA), was found to significantly decrease plasma and urine HGA and benzoquinone acetic acid levels while moderately increasing plasma tyrosine. Individuals with hereditary tyrosinemia type I require immediate treatment with NTBC to avoid acute hepatic failure. This is not the case in patients with AKU, in whom clinicians must balance an anticipated reduction of HGA production against the risk of an elevated tyrosine level. We present here three cases with AKU (one child and two adults) who were managed with NTBC. In the first case, a 47-year-old female, treatment (0.3 mg/kg/day, or a total of 20 mg/day) has normalized HGA excretion but caused a rise in blood tyrosine to 521.2 Âµmol/L (normal: 22 - 102 Âµmol/L). Lowering the dose by half maintained negligible excretion of HGA but plasma tyrosine remained elevated at 567 Âµmol/L. Our second case, a 5-year-old boy who received a low dose of NTBC (0.1 mg/kg/day), manifested continued diminished excretion of HGA (101 mg/gm creatinine), but he developed elevated plasma tyrosine (713.1 Âµmol/L) and corneal crystals after 10 months of treatment. The NTBC was discontinued. Similarly, the third patient, a 70-year-old male, developed blepharitis on a daily NTBC dose of 0.03 mg/kg/day (2 mg/day) with plasma tyrosine at 976 Âµmol/L and 86% reduction in HGA to 181 mg/g creatinine. Reduction of NTBC administration to an every-other-day schedule resulted in continued increase of plasma tyrosine (740-799 Âµmol/L) and a 56% reduction of urinary HGA to 540 mg/g creatinine. Our report indicates that the effect of NTBC in lowering HGA is variable among patients and that even seemingly low drug doses can cause undue increases of plasma tyrosine. Careful monitoring of both plasma tyrosine and urinary HGA are essential in order maximally to inhibit production of HGA without elevating systemic tyrosine concentrations to a toxic level that causes serious ocular side effects. Indeed, even ultra-low doses may favor deposition of tyrosine crystals in the cornea. A need for regular monitoring of blood tyrosine is clear. It may be prudent to defer initiation of treatment in young children, given a theoretical concern for the impact of hypertyrosinemia on cognitive development and our observation of corneal crystal deposition.

PrgmNr 2219 - Outcome of Clinical Genetic Testing in Patients with Features Suggestive for Ehlers Danlos Syndrome

View session detail

Author Block: **N. Damseh**[1], L. Dupuis[2], C. Oâ□□Connor[3], r. Oh[3], D. J. Stavropoulos[4], S. Schwartz[3], R. Mendoza-Londono[2]; [1]Clinical and Metabolic Genetics, Hosp. for Sick Children, TORONTO, ON, Canada, [2]Hosp. for Sick Children, Toronto, ON, Canada, [3]The Hosp. for Sick Children, TORONTO, ON, Canada, [4]Hosp for Sick Children, Toronto, ON, Canada

Disclosure Block: **N. Damseh:** None.

Ehlers Danlos Syndrome (EDS) is a heterogeneous group of connective tissue disorders (CTD). The cardinal features of EDS are hyperextensible skin, hypermobile joints, easy bruisability, and fragility of the connective tissues leading to a wide variety of clinical manifestations. The EDS diagnosis is usually based on clinical assessment and phenotypeâ□□guided genetic testing. All the EDS subtypes can be confirmed by genetic testing except for hypermobile EDS (hEDS). In this retrospective study, we reviewed 72 patients suspected to have EDS who underwent genetic testing. Eighteen patients (25%) met the clinical criteria for one of the EDS subtypes (other than hEDS), 15 patients (83%) of which received confirmatory molecular genetic diagnoses. Fifty-four patients (75%) didnâ□□t meet full clinical criteria however 13 of these patients (26%) also received a confirmatory molecular genetic diagnosis Different molecular genetic tests were performed (CTD panel n=44, microarray n=23, whole exome sequencing (WES) n=9, targeted gene testing n=4, familial variant testing n=12, other genetic panels n=3). The diagnostic outcome of the CTD genetic panel was 41% (82% in patients who met one of the EDS subtype diagnostic criteria and 27% of patients who did not) while WES had a diagnostic outcome of 22%. We observed that generalized joint hypermobility, poor healing, easy bruising, atrophic scars, skin hyperextensibility, and developmental dysplasia of the hip correlate with positive genetic results. This study explores the utility of 2017 EDS classification criteria and molecular genetic testing in establishing an EDS diagnosis in pediatric population. It also provides some guidance in using molecular genetic testing in children presenting with EDS characteristics.

PrgmNr 2220 - Phenotypic Spectrumof DihydrolipoamideDehydrogenase Deficiencyin Saudi Arabia

Disclosure Block: **A. Alfarsi:** None.

BACKGROUND: Dihydrolipoamide Dehydrogenase Deficiency is one of the rare metabolic disease with autosomal recessive inheritance. It is clinically heterogeneous with variable presentations, onsets, and biochemical markers. Yet, it difficult to have a genotype-phenotype correlation.
MATERIALS AND METHODS: We retrospectively review the clinical and molecular diagnosis of 8 cases with DLD from four referral center in Riyadh. **RESULTS:** we found hepatic involvement in half of the patient ranging between acute hepatic failure, encephalopathy and chronic hepatitis. One patient had Recurrent episodic hypoglycemia while neurological involvement seen in form of seizure, developmental delay, ataxia, hypotonia and psychomotor symptoms. In regards to biochemical markers, lactic acid, metabolic acidosis and branched chain amino acid are extremely variable across our cohort. 60% of the cohort patients had homozygous variant p.(Gly229Cys) in the DLD gene.
CONCLUSIONS: We describe the largest reported DLD cohort in Saudi Population. The clinical, biochemical, radiological, and molecular characterization have been reviewed. Genotype-phenotype correlation is still unclear, that related to the complexity of the enzyme.

PrgmNr 2221 - The p.L3P (p.Leu3Pro) variant in GLA is not associated with Fabry disease

View session detail

Author Block: **O. Ailioaie**[1], R. MATESAN[2], M. N. KONAN[3], F. JABBOUR[1], J-P. RABES[4], N. MAROUN[2], D. P. GERMAIN[5]; [1]APHP - Paris Saclay Univ., Garches, France, [2]GHT Yvelines Nord, Poissy, France, [3]CHU de Treichville, Abidjan, CÃ´te D'Ivoire, [4]APHP - Paris Saclay Univ., Boulogne, France, [5]Paris Saclay Univ., Univ. of Versailles, Montigny, France
Disclosure Block: **O. Ailioaie:** None.
Background: Fabry disease (FD, OMIM #301500) is an X-linked genetic disease characterized by the deficient activity of the lysosomal alpha-galactosidase. The functional deficiency of the enzyme leads to pathogenic accumulation of Gb3 and lyso-Gb3 responsible for the development of a multi-systemic disease with onset during childhood (acroparesthesia, angiokeratoma) and subsequent complications (hypertrophic cardiomyopathy, chronic kidney disease, stroke) in adulthood leading to reduced life expectancy. Over 1000 variants have been reported in the *GLA* gene. Among those, a significant number are benign or likely benign and not associated with FD. **Patient and Methods**: A 64-year-old male patient of African ancestry with a medical history of familial cardiomyopathy and end-stage renal disease treated by hemodialysis benefited from a molecular screening on dried blood spot (DBS) funded by the pharmaceutical industry that led to the identification a missense variant (p.L3P or p.Leu3Pro) initially reported as of variant of unknown significance (class 3) leading the treating nephrologist to consider the diagnosis of FD on the basis of both clinical and molecular data. The patient was therefore referred to the French Referral Center for Fabry disease for further investigation. **Results:** Interrogation of the ClinVar database gave conflicting results on pathogenicity. Data obtained from GnomAD database showed that the p.L3P variant, while absent in Caucasian and Hispanic subpopulations, was relatively frequent in the African sub-populations (allelic frequency of 0.00319, higher than 0.000265 derived from 620 variants in *GLA*) emphasizing the value of studying multiple ethnic backgrounds in databases. A complete workup was carried out showing normal (100%) alpha-galactosidase A activity, normal lyso-Gb3 values and skin biopsy with no storage when examined with light microscopy allowing us to definitely rule out the diagnosis of Fabry disease. **Discussion:** This case illustrates how surrogate markers may be of considerable help in elucidating the pathogenicity of a molecular variants in some inborn errors of metabolism. Datasharing data with the medical and genetics community is of utmost importance to avoid undue healthcare expenses in individuals bearing benign variants. In the present case, correct assignment of the variant has avoided the very high costs for the healthcare system associated with specific treatment of FD (170,000 USD /year) and the iatrogenic risks associated with intravenous infusions of enzyme therapy. Moreover, it warrants further diagnostic odyssey since the identified variant cannot explain the observed clinical phenotype.

PrgmNr 2222 - Association analysis of rare variants identified risk genes with neonatal respiratory distress syndrome

View session detail

Author Block: **X. Dong**, H. Chen, X. Chen, W. Zhou; Children's Hosp. of Fudan Univ., shanghai, China
Disclosure Block: **X. Dong:** None.
Abstract Background Neonatal respiratory distress syndrome (NRDS) is considered to be primarily caused by deficiency of pulmonary surfactant (PS) in neonates. Genetic abnormalities were recently identified as the important etiologies. **Methods** The newborns were enrolled from the China Neonatal Genomes Project (CNGP, NCT03931707) from August 2016 to June 2020. All patients underwent clinical exome sequencing but no disease-causing genes were found. Rare-variant association analysis were performed to detect the potential genetic risk factors of NRDS. For exploring their functions, a lung-specific gene regulatory network was constructed and the regulatory activity was calculated to study their role in fetal lung developmental. After focusing on genes with continued increasing pattern, a multivariate logistic regression model was used to extract out the independent NRDS contributed risk genes. **Results** A total of 123 RDS and matched 214 control infants with gestational ageâ¥34 weeks were included. Association analyses found 53 high-confidence NRDS risk genes and 10 genes had continued increasing pattern among three stage of normal fetal lung developmental (P=0.019). Among them, 5 were RDS-independent risk genes (*GRN, SFTPB, IL1RN, TJP2, ADAMTS2*) and only *ADAMTS2* showed âhiddenâ feature (with significantly activity pattern change but not expression level change) in regulating lungâs development. Re-analyze the public transcriptomic dataset showed that glucocorticoids could increase the activity of *ADAMTS2* in mouse lung A549 cell lines (PADAMTS2 variants. **Conclusion** NRDS is probably a multigenetic disease with complex genetic risk factors. Except *SFTPB*, we detected other new novel and potential NRDS risk genes, including *ADAMTS2*. Further investigation is necessary to identify their function in the onset of NRDS.

PrgmNr 2223 - Combined immunodeficiency and increased cellular sensitivity to radiation due to a novel DNA Ligase 1 mutation

View session detail

Author Block: **A. Alazami**[1,2], H. Alajlan[1], R. Mohammed[1], H. Al-Mousa[1,2,3]; [1]King Faisal Specialist Hosp. & Res. Ctr., Riyadh, Saudi Arabia, [2]Saudi Human Genome Program, King Abdulaziz City for Sci. and Technology, Riyadh, Saudi Arabia, [3]Coll. of Med., Alfaisal Univ., Riyadh, Saudi Arabia
Disclosure Block: **A. Alazami:** None.
DNA Ligase 1 (*LIG1*) plays a critical role in the joining of Okazaki fragments during DNA replication, as well as in single- and double-stranded break repair pathways. Only six patients have been reported to date with mutations in this gene, exhibiting a range of phenotypes such as hepatosplenomegaly, sun sensitivity, severe eczema, severe anemia and recurrent infections. Here we report the case of a baby girl who presented with recurrent chest infections, significant erythroid dysplasia, neutropenia and combined immunodeficiency. She underwent successful bone marrow transplantation 3 years ago at the age of 6 months. Whole exome sequencing revealed homozygosity for a novel *LIG1* mutation (A556T), which segregated with the disease state. Immunophenotyping displayed depressed T cell levels along with most CD4+ and CD8+ subsets, but with an increase in CD4+ central memory cells, and with a reduction in the B memory subset. Patient fibroblast cells showed severe reduction in proliferation rates, and exposure to ionizing radiation led to a cell cycle block in the G2/M phase along with significant increase in gamma-H2AX foci as compared to controls. Our findings broaden the phenotypic and allelic heterogeneity associated with this rare autosomal recessive immunodeficiency.

PrgmNr 2224 - Functional characterization of a *Xenopus tropicalis* knockout and a human cellular model of *RCBTB1*-associated inherited retinal disease shows involvement of *RCBTB1* in the cellular response to oxidative stress

View session detail

Author Block: **M. Carron**[1], T. Naert[2], G. Ascari[3], S. Demuynck[2], T. Van Nieuwenhuyzen[2], T. Van Laethem[3], T. Rosseel[3], D. Priem[4], A. Kremer[5], H. Van Landeghem[2], L. Wanneyn[2], S. Hosp.,, Gent, Belgium, [2]Dept. of BioMed. Molecular Biology, Ghent Univ., Gent, Belgium, [3]Ctr. for Med. Genetics, Dept. of Biomolecular Med., Ghent Univ. and Ghent Univ. Hosp., Gent, Belgium, [4]VIB-UGent Ctr. for Inflammation Res., Gent, Belgium, [5]VIB Imaging Core, Gent, Belgium, [6]Ctr. for Med. Genetics, Dept. of Biomolecular Med., Ghent Univ. and Ghent Univ. Hosp., Ghent, Belgium, [7]VIB Bioimaging Core, Gent, Belgium, [8]Dept. of BioMed. Molecular Biology, Ghent Univ., Ghent, Belgium
Disclosure Block: **M. Carron:** None.
We identified *RCBTB1* as a novel disease gene for autosomal recessive inherited retinal disease (IRD), with or without syndromic features, such as primary ovarian insufficiency, goiter, and mild intellectual disability. Patients with biallelic variants in *RCBTB1* display diverse IRD phenotypes such as retinitis pigmentosa, reticular dystrophy and chorioretinal atrophy. Each novel genetic subtype of IRD may shed light on the particularly complex pathways of vision and create opportunities for intervention. So far the function of the ubiquitously expressed *RCBTB1* gene remains unknown. RCBTB1 has been indicated as putative substrate adaptor for the E3 ligase Cullin 3 (CUL3) complex and interactor of UBE2E3, an E2 conjugating enzyme. As both CUL3 and UBE2E3 are associated with regulation of the NRF2/KEAP1/ARE pathway, we hypothesize that *RCBTB1* is involved in NRF2-regulated protection against oxidative stress in the eye, more specifically in the retinal pigment epithelium (RPE). Here, a *Xenopus tropicalis* knockout (KO) animal model was generated using CRISPR/Cas9 gene editing. Histological examination and three-dimensional electron microscopy was performed on retinas of *rcbtb1*$^{-/-}$ frogs. RNA-seq analysis was performed on embryos from the *rcbtb1*$^{-/-}$ animal model treated with $CdCl_2$ and on lymphocytes from cases with biallelic *RCBTB1* variants, treated with H_2O_2. A knockdown (KD) cell line was generated in ARPE-19 cells via viral transduction and in vitro functional assays (flow cytometry, MTT-assay, cell death kinetics) were used to assess the consequences of *RCBTB1* depletion. The *rcbtb1*$^{-/-}$ animals showed changes in the RPE, similar to observations in human cases, including loss of apical-basal cell polarity, loss of cuboidal cell morphology, spreading of the pigment granules and vacuolisation. Via RNA-seq, NRF2 downstream targets and several metallothioneins were found to be differentially expressed, both in the animal and cellular models. The functional assays in ARPE-19 cells revealed that RCBTB1 depletion affects cellular responses to external insults of oxidative stress. We showed that the *Xenopus tropicalis rcbtb1*$^{-/-}$ animal model recapitulates the human IRD phenotype. Both in vivo and in vitro functional data show involvement of *RCBTB1* in the cellular response to oxidative stress. This provides insight into the mechanism underlying *RCBTB1*-associated IRD and uncovers potential future therapeutic opportunities.

PrgmNr 2225 - Genetic and clinical characteristics of inherited retinal dystrophies in Northern Finland

View session detail

Author Block: **L. LÃ¤hteenoja**[1,2], A. Falck[2], E. Rahikkala[1,3]; [1]Dept. of Clinical Genetics, PEDEGO Res. Unit and Med. Res. Ctr. Oulu, Oulu Univ. Hosp. and Univ. of Oulu, Oulu, Finland, [2]Dept. of Ophthalmology, Oulu Univ. Hosp. and Univ. of Oulu, Oulu, Finland, [3]Inst. of Biomedicine, Univ. of Turku, Turku, Finland
Disclosure Block: **L. LÃ¤hteenoja:** None.
Purpose: To describe the genetic and clinical features of patients with genetically confirmed inherited retinal degenerations (IRDs) in the Northern Finnish founder population. **Methods**: A population-based study was conducted in the tertiary catchment area of the Oulu University Hospital between 1996 and 2020. Patients were identified retrospectively by International Classification of Diseases codes in hospital records. The inclusion criterion was genetically confirmed IRD. The pathogenicities of variants were evaluated according to the American College of Medical Genetics and Genomics guidelines (ACMG). The phenotype-genotype correlations were defined. **Results**: 152 patients were diagnosed with a genetically confirmed IRD. The probands were diagnosed most commonly with retinitis pigmentosa, choroideremia, familial exudative vitreoretinopathy or retinoschisis. A total of 225 pathogenic or potentially pathogenic variants in 34 genes were observed, including 98 missense variants, 33 frameshift variants, 41 nonsense variants, 22 canonical splice site variants, 27 deletion variants, three inversion variants, and one duplication variant. The most common genes causing RD were *RPGR*, *CHM*, *FZD4*, *RS1* and *CERKL*. Causal variants were consistent with a recessive mode of inheritance in 49% (33% homozygous, 16% compound heterozygous), dominant in 14%, and X-linked in 35% of cases. 26% had syndromic IRD, including 16 causative genes. 53 patients (35%) with diseases belonging to the Finnish disease heritage were identified. **Conclusion**: IRD is genetically and clinically highly heterogeneous. This study expands the spectrum of disease-causing genes and variants in IRD, which will further facilitate genetic counseling.

PrgmNr 2226 - Genetic variants influencing penetrance to iron overload disorder hereditary haemochromatosis: evidence from UK Biobank

View session detail

Author Block: **L. C. Pilling**, J. L. Atkins, D. Melzer; Univ. of Exeter, Exeter, United Kingdom
Disclosure Block: **L.C. Pilling:** None.

Haemochromatosis is the most common genetic disorder in Northern Europeans, with up to 1 in 150 people homozygous for the *HFE* p.C282Y mutation. p.C282Y increases iron absorption from the diet, resulting in increased morbidity, especially liver disease and cancer, especially in males. Yet penetrance is incomplete and expressivity is heterogeneous, with many homozygous carriers either diagnosed late or not at all, with varying degrees of symptoms. Co-morbidities can include diabetes, arthritis, and osteoporosis, but the factors that modify individual patient trajectories are uncertain. We aimed to identify genetic factors in *HFE* p.C282Y homozygotes affecting likelihood of haemochromatosis diagnosis and co-morbidity status.

In 2,980 *HFE* p.C282Y homozygotes in the UK Biobank cohort we investigated factors that modify penetrance, disease severity, and co-morbidities. Using genetic risk scores (GRS), we found that p.C282Y homozygotes carrying greater numbers of osteoarthritis alleles had increased likelihood of osteoarthritis diagnoses (Odds Ratio per standard deviation of GRS 1.24: 95% Confidence Intervals 1.08 to 1.41, p=0.002), and similarly participants with higher GRS for Rheumatoid arthritis, diabetes, and fracture risk (osteoporosis) had greater risk of the respective co-morbidities. Underlying predisposition to individual diseases may therefore explain part of the phenotypic heterogeneity in haemochromatosis patients.

We also performed genome-wide analysis of haemochromatosis diagnosis in p.C282Y homozygotes and found one locus in the *TMPRSS6* gene (rs9610638) associated with increased likelihood of diagnosis (OR per T allele 1.21: 95% CIs 1.17 to 1.25, $1*10^{-8}$). This locus is known to affect iron levels, including in the brain. In analysis using 11 non-*HFE* iron-associated variants in a GRS, p.C282Y homozygotes with increased iron GRS were substantially more likely to be diagnosed with haemochromatosis (OR for top 20% of GRS 2.36: 95% CIs 1.79 to 3.13, $p=2*10^{-9}$).

Together, these results show that haemochromatosis is a complex disease somewhere between monogenic and polygenic. Patient outcomes could be improved by taking account of more genetic variants, thereby identifying the most at-risk patients.

PrgmNr 2227 - Identification of variants associated with moderate to severe hearing loss

View session detail

Author Block: **S. Naz**[1], M. Ramzan[2], H. Idress[1], R. Faridi[3], Z. Munir[1], F. Muzaffar[1], K. Shabbir[1], A. Imtiaz[1], H. Khan[1], E. Wohler[4], P. Witmer[4], N. L. Sobreira[5], G. Seo[6], R. J. Morell[7], T. B. Disclosure Block: **S. Naz:** None.

Variants of at least 25 genes are associated with nonsyndromic recessively inherited moderate to severe hearing loss in human. We ascertained and studied 36 families with multiple individuals affected with either moderate hearing loss or hearing which progressively worsened to profound deafness. Families segregating variants of *GJB2* and the two non-coding variants of *HGF* (c.482+1986_482+1988delTGA, c.482+1991_482+2000del10) were identified using Sanger sequencing. Selected samples from affected and unaffected individuals in the remaining 33 families were exome sequenced. Altogether, we identified 12 novel and 25 reported variants in genes associated with either moderate-to-severe hearing loss or profound deafness. Variants of *SLC26A4* were associated with hearing loss in members of nine families. Variants of *CDH23* and *MYO15A* were each identified in three families. Additional likely pathogenic variants were observed in two families each (*ESPN*, *GJB2*, *MYO7A*, *OTOF*) or one family (*ELMOD3, EPS8*, *ESRRB*, *GIPC3*, *HGF*, *LHFPL5*, *MARVELD2*, *MY06*, *PCDH15*, *POU3F4*, *TECTA*, *TMPRSS3* and *TPRN*). Thirteen of the pathogenic alleles were missense variants, three were in-frame deletions and one was the reported three base pair non-coding deletion in *HGF*. Twenty of the identified variants affected splice sites or introduced frameshifts and stop codons in the reading frames of the respective genes. Thus, more than half of the alleles are predicted to affect gene expression or exon splicing. Currently, we are designing experiments to examine the pathogenic effects of some of these variants. Our research corroborates the contribution to moderate to severe hearing loss of variants of many previously studied â□□deafness genesâ□□ and for the first time implicates *LHFPL5*, *MY06* and *PCDH15* in the etiology of a moderate to severe hearing loss phenotype. This study was supported by the Baylor-Hopkins Center for Mendelian Genomics, 3billion inc., Higher Education Commission, Pakistan 3288 (SN) and funded (in part) by the National Institute on Deafness and Other Communication Disorders Intramural Research Program DC000086 to R.J.M., DC000039 to T.B.F.

PrgmNr 2228 - Inborn errors of immunity: Novel insights from four unrelated Indian families

View session detail

Author Block: **R. Lakshmi Priya**[1], P. H. Somashekar[1], D. L. Narayanan[1], A. Shrikiran[2], D. Rangaswami[3], A. Shukla[1]; [1]Med. Genetics, Kasturba Med. Disclosure Block: **R. Lakshmi Priya:** None.

Inborn errors of immunity are monogenic disorders of the immune system, which can present with recurrent infections, increased susceptibility to allergy, autoimmunity, autoinflammation, and malignancy. We present four Indian families with inborn errors of immunity, evaluated by exome sequencing. The proband in family 1, is a one-year-old male born to a second-degree consanguineous couple. He presented with failure to thrive, recurrent infections, and irritability. Laboratory investigations revealed macrocytic anemia, pancytopenia, and neutropenia. He had low IgG, IgA, IgM, CD3+ T cells and CD4+ T cells, indicating combined immunodeficiency. Singleton exome sequencing revealed a novel variant, c.1003C>T p.(Gln335Ter) in *TCN2* in the homozygous state, causing transcobalamin II deficiency (MIM#275350). The one-year-old proband in family 2 is the firstborn of second-degree consanguineous parents. He had recurrent infections and agammaglobulinemia. Singleton exome sequencing revealed a novel missense variant, c.374T>G p.(Val125Gln) in *CD79A* causing agammaglobulinemia 3 (MIM#613501). The thirteen-year-old female proband in family 3, was born to non-consanguineous parents and was evaluated for steroid-responsive membranous nephropathy. She also had short stature, hyperpigmentation of the skin, and a history of autoimmune hemolytic anemia and recurrent oral candidiasis. Her IgA and IgM levels were low. Mendeliome sequencing revealed a novel homozygous variant, c.520C>T p.(Arg124Ter) in *CARMIL2,* causing immunodeficiency 58 (MIM#618131). This is the first report of a subject with CARMIL2 deficiency presenting with membranous nephropathy. The proband in family 4, is a three-month-old child who presented with recurrent infections, sparse hair and eyebrows, hypopigmented skin, and small finger and toenails. Trio exome sequencing revealed a *de novo* heterozygous missense variant c.962A>G p.(His321Arg) in *FOXN1* causing T-cell lymphopenia, infantile, with or without nail dystrophy, autosomal dominant (MIM#618806). We herein add to the existing genotypic and phenotypic spectrum of the above-mentioned rare inborn errors of immunity. We also emphasize the role of next-generation sequencing in the rapid and efficient diagnosis of these disorders thus guiding treatment, genetic counseling, and prenatal diagnosis.

PrgmNr 2229 - Progressive familial intrahepatic cholestasis type3: two novel pathogenic variants in a cohort of Egyptian children with cholestatic disorders of infancy

View session detail

Author Block: **S. A. Sharaf**, N. N. Abbass, M. El-Sharkawy, M. S. El-Raziky, L. Hussein, H. Baz, M. H. Kamel, J. M. Medhat, H. El-Karaksy; Faculty of Med. Cairo Univ., cairo, Egypt
Disclosure Block: **S.A. Sharaf:** None.
Introduction: Progressive familial intrahepatic cholestasis (PFIC) is a heterogenous group of disorders in canalicular hepatobiliary transport results in progressive cholestasis and liver injury. Patients with PFIC type 3 have elevated gamma glutamyl transpeptidase and a variable degree of cholestasis that presents later in infancy or in early childhood. We aimed to identify mutations in the *ABCB4* gene responsible for PFIC3 in a group of infants and children presenting with high GGT chronic cholestasis. **Methodology:** This study was conducted at the Pediatric Hepatology Unit, Cairo University Hospital, Egypt over a 3 year period. Sixteen patients from both sexes presenting in the first year of life with cholestasis with high GGT were included. Patients were subjected to full history taking, detailed examination. Genetic analysis sanger sequencing of the coding exons and intronic boundaries of *ABCB4* gene was performed. Sequencing could be completed in nine patients only due to financial limitation. Allelic discrimination of *ABCB4:* p.(A1066D), rs31668 and rs31653 were done using Real-time PCR assay for all patients and 100 healthy controls. **Results** The age of disease onset ranged from birth till 12 months of age (median [IQR]: 0.6 (7) months). Positive consanguinity of the patients was 56.25%. Positive family history of similar conditions was 43.75%. The main presenting symptom was jaundice in 13 patients. GGT levels were elevated in all patients ranging from 112-792 U/L; 1 patient had mild elevation less than double the upper limit of normal and 10 patients were above five folds of the upper limit of normal. Nine patients had hypoalbuminemia and 5 had coagulopathy. Liver biopsy was performed in our entire study group. Their results varied from neonatal hepatitis, chronic hepatitis with variable degrees of fibrosis, bile duct proliferation suggestive of major bile duct obstruction and paucity of interlobular bile ducts. Two patients had novel pathogenic variant in homozygous pattern in exon 25 and a third patient in exon 27**.** One missense novel variant *ABCB4:* p.(A1066D) and the second novel variant is a single base substitution causes nonsense mutation and premature stop codon on the protein level which results in truncated protein in exon 27 *ABCB4*: p.(Q1181X) both classified as class 5 (pathogenic) according to the ACMG guidelines. **CONCLUSION:** The nonsense mutation is likely to present the symptoms of PFIC3 early in life. 2 Novel disease causing variants in exon 25 and 27 were detected in the Egyptian patients.

PrgmNr 2230 - Targeted exome sequencing identifies novel variants associated with non-syndromic hearing loss in an Indian family

View session detail

Author Block: **D. Kumari**, I. Panigrahi; Post Graduate Inst. of Med. Ed. and Res., Chandigarh, India
Disclosure Block: **D. Kumari:** None.
Introduction: Non -syndromic hearing loss (NSHL) is the most common sensory disorder worldwide and highly heterogeneous .Genetic factors account for approximately 50% congenital hearing loss cases. Multiple gene variants are associated with similar phenotype in case of non-syndromic hearing loss. Targeted exome sequencing has the advantage of studying multiple genes by massive parallel sequencing. Hence, it is advantageous for disorders in which multiple genes are involved in causation of similar clinical presentation.**Method**: The index case 10 years old, born of a non-consanguineous marriage with clinical indications of congenital profound sensorineural hearing loss. His ultrasound abdomen, thyroid profile and CMV serology were negative. His elder brother and maternal cousin are similarly affected and also undergone cochlear implant. Targeted next generation sequencing was performed covering for possible target genes of hearing loss using capture system as per the manufacturer's standard protocols. The libraries were sequenced to mean >80-100X coverage on Illumina sequencing platform. Sanger sequencing was performed to validate the identified variants in the index case and affected family members. Segregation analysis of the parents was done for identifying carrier state. **Result**: Molecular diagnosis confirmed by targeted exome sequencing revealed novel variants in the *TMC1* and *MYO7A* genes respectively. Two heterozygous variants NM_138691.3(*TMC1*):c.624C>A:p.Ser208Argand NM_(*MYO7A*):c.3856G>A:p.Ala1286Thr were identified in the brothers and homozygous variant NM_138691.3(*TMC1*):c.624C>A:p.Ser208Arg identified in the maternal cousin. On segregation analysis, parents of maternal cousin were confirmed carriers of the same variant. The *in silico* predictions of the variants were damaging by LRT and Mutation Taster 2.The identified variants were not reported in population databases 1000genome, gnomAD and ClinVar.**Conclusion**: Targeted NGS enabled the identification of novel variants in the multiply-affected family. Early diagnosis for congenital deafness helps in appropriate genetic counseling. High risk family members are better informed about the risk of their offspring being hearing impaired and can decide regarding further reproductive options. It also facilitates planning proper interventions for improving the hearing outcomes.

PrgmNr 2231 - A Novel Variant in RAP1GDS1 gene in a child with developmental

View session detail

Author Block: **H. Ahmed**[1], W. Eyaid[1], P. Bauer[2]; [1]KASCH Hosp., Riyadh, Saudi Arabia, [2]Centogene GmbH, Rostock, Germany
Disclosure Block: **H. Ahmed:** None.
ABSTRACT Background: 1-2% of children are affected with developmental delay all over the word. In more than half of them there is no clear cause. However genetic defect has been responsible for a quarter to one-half of identified cases. **Case presentation**: Here in our case we have found a 4yrs. Old child who presented with developmental delay, repetitive hand movements and dysmorphic features . Using whole exome sequencing we detected a homozygous variant in RAP1GDS1 gene in c.83del (p.LeuTrpfs*32), causing frame shift, likely affecting protein function (class 2P). Both parents are heterozygous carriers of the same variant. **Conclusion**: This gene has been shown to be expressed in several tissues including brain. Loss of function variants in the RAP1GDS1 are extremely rare in controls, and to our knowledge, not observed in homozygous state in any individual so we consider this c.83del (p.LeuTrpfs*32) variant in RAP1GDS1 gene as novel variant .

PrgmNr 2232 - Beta-Ketothiolase deficiency in a patient with coexistence of homozygous *ACAT1* gene mutation and homologous constitutional translocation t(4;11)(q13;q23) and father with XYY syndrome

View session detail

Author Block: **M. Albalwi**[1,2,3], E. AlOnazi[1], B. AlAwad[1], Y. AlThubati[1], A. AlKhaldi[1], W. Eyaid[1]; [1]King Abdulaziz Med. City, MNGHA, Riyadh, Saudi Arabia, [2]King Abdullah Intl., Med. Res. Ctr., King Saud bin Abdulaziz Univ. for Hlth.Sci., Riyadh, Saudi Arabia, [3]Coll. of Med., King Saud bin Abdulaziz Univ. for Hlth.Sci., Riyadh, Saudi Arabia

Disclosure Block: **M. Albalwi:** None.

Beta-ketothiolase deficiency is a rare metabolic disorder that is inherited in an autosomal recessive manner. Homologous constitutional chromosomal rearrangements is an extremely rarely reported chromosomal aberration. Here, we report on a 14 year-old boy whose parents are first degree consanguineous cousins. He has dysmorphic features, growth retardation, global developmental delay, bronchial asthma,and an Attention-Deficit/Hyperactivity disorder. Biochemical and molecular analysis *showed the presence of* homozygous c.410_418delinsT (p.Ser137Phrfs*37) *ACAT1* mutation. Both parents were heterozygous for the *ACAT1* gene mutation. *The chromosomal analysis showed* chromosomal homologous translocation t(4;11)(q13;q23) respectively. Besides that, the fatherâ□□s chromosomal analysis showed that he is a carrier for the translocation, also he has an XYY syndrome with 47,XYY,t(4;11)(q13;23). The motherâ□□s chromosomal analysis was 46,XX,t(4;11)(q13;23). Having a genetic disorder that is inconsistent with its usual clinical presentation should alert clinicians to the possibility of having another disorder, particularly in a highly consanguineous population. Proper clinical evaluation, and laboratory investigations are important for a proper genetic counseling.

PrgmNr 2233 - Biallelic *VPS35L* pathogenic variants cause 3C/Ritscher-Scinzel-like syndrome: Description of two novel cases confirming the pathogenicity and clinical diversity

View session detail

Author Block: **S. Otsuji**[1,2], K. Kato[1,2,3], C. HUBER LEQUESNE[4], S. Mizuno[2], M. RIO[4], S. Miyatake[5], Y. Nishio[1,3], N. Matsumoto[5], V. CORMIER-DAIRE[4], S. Saitoh[1]; [1]Dept. of Pediatrics and Neonatology, Nagoya City Univ. Graduate Sch. of Med. Sci., Nagoya, Japan, [2]Pediatrics and Clinical Genetics, Central Hosp., Aichi Dev.al Disability Ctr., Kasugai, Aichi, Japan, [3]Dept. of Pediatrics, Nagoya Univ. Graduate Sch. of Med., Nagoya, Japan, [4]DÃ©partement de GÃ©nÃ©tique MÃ©dicale (C.H.-L., V.C.-D.), Inst. Natl. de la SantÃ© et de la Recherche MÃ©dicale UnitÃ© 781, UniversitÃ© Paris Descartes-Sorbonne Paris CitÃ©, Inst. Imagine, HÃ´pital Necker Enfants Malades, Paris, France, [5]Dept. of Human Genetics, Yokohama City Univ., Graduate Sch. of Med., Yokohama, Japan

Disclosure Block: **S. Otsuji:** None.

Background VPS35L forms a retriever heterotrimer protein complex with VPS29 and DSCR3, which plays a pivotal role in the endosomal cargo recycling system, interacting with the WASH and CCC complex. Retriever complex promotes selective cell surface protein entry into the recycling pathway instead of degradation in lysosomes, and disruption of its function decreases expression level of numerous kinds of membrane proteins. We previously reported that *VPS35L* could be a novel cause for 3C-like syndrome, since a sibling with biallelic *VPS35L* loss-of-function variants showed overlapping symptoms of 3C syndrome. *CCDC22* and *WASHC5*, a member of CCC and WASHC complex respectively, were known to be the responsible genes for 3C syndrome. However, the association between VPS35L dysfunction and 3C-like syndrome remained unconfirmed because of the lack of other cases. **Methods** Exome sequencing was performed to identify pathogenic variants. Cellular biological analyses were carried out to prove the pathogenicity of the identified variants. **Results** We identified two novel cases with compound heterozygous loss-of-function variants in *VPS35L* (NM_020314.5), c.1650+2T>A; c.2982_2984del, p.Asn995del in the first case, and c.1577del; p.Ala526Valfs*14, c.3057del; p.Met1020Trpfs*2 in the other case. c.1650+2T>A and c.1557del frameshift variants were considered to induce nonsense mediated mRNA decay (NMD). In addition, although VPS35L-M1020-frameshift mutant was considered to escape NMD as it located C-terminal end, immunoprecipitation analysis of the VPS35L-M1020-frameshift mutant, as well as VPS35L-N995del, showed loss of binding ability to the endogenous VPS29, confirming that both cases have the biallelic loss of function variants in VPS35L. As with the case of previously reported sibling, both cases showed brachydactyly, skeletal complication, macrodontia, dysmorphic facial features, proteinuria, intellectual disability, and short stature. In addition, former case suffered from protein-losing-gastroenteropathy, and latter case showed hyperlipidemia, anterior ocular lesions and vascular malformations. **Conclusions** Biallelic *VPS35L* loss-of-function variants cause the 3C-like syndrome, with multisystem complications including what were not described in the conventional 3C syndrome.

PrgmNr 2234 - First reanalysis highlighting the increasing role of multiple molecular diagnoses in the field of rare diseases

Background: The etiological work-up of congenital abnormalities and intellectual disability (CA/ID) benefited from the implementation of next-generation sequencing technologies, which has opened the possibility of identifying multiple molecular diagnoses (MMD), ranging from 1.8% to 7.1% of positive cases in the literature. We aim to highlight the increasing role of MMD and their main characteristics and consequences in this field. Methods: We included patients referred to our diagnostic laboratory by local and Orphanomix reference centers for the etiological work-up of CA and/or ID, via exome sequencing (ES). The cohort was divided in two: a prospective cohort for ES data (re)analyzed from 01/2019 to 06/2021, and a retrospective cohort for local ES data (allowing easy access to clinical update & retro-phenotyping) analyzed prior to 2019; cut-off was based on preliminary encouraging results of prospective study of MMD from 01/2017 to 12/2020 combined with reanalysis of positive ES data rendered prior to 2017. Preliminary results: Out of the 604 positive ES data of the prospective cohort, 21 (3.5%) turned out being MMD and 20 (3.3%) included a variant of unknown significance (VUS) with a high probability of being reclassified (overall diagnostic rate of 6.8%). After reanalysis, 2 out of the 85 local positive ES data of the retrospective cohort, led to a MMD rate of 2.4%, and 5 VUS were deemed relevant, rising the overall diagnostic rate to 8.2%. Modes of transmission, types of variants, copy-number variants proportion, inheritance, contribution of VUS, temporality of MMD, and attributes of the patients will be discussed. Preliminary discussion: Rates of MMD, respectively 3.5% (6.8% including VUS) and 2.4% (8.2%) for the prospective and retrospective cohorts, are consistent with the literature and can be based on awareness of the interpretating team on this concept, up-to-date clinical data, knowledge enhancement on genes linked to human diseases, and bioinformatics tools improvement. The limits of our study are the potential missed MMD (by non-informative clinical updates, genes not yet known, VUS not yet reclassified, and ES limits). MMD appear to be underestimated and would benefit from greater insights since not only they have a

significant impact for patients and their families for genetic counselling, prenatal testing, and personalized follow-up, but also participate in better delineation of genesâ phenotypic spectra. This also raises the question whether positive ES data should benefit from reanalysis on request or systematically. Reanalysis of local positive ES data rendered in 2017/2018 and prospective study of 2021 first semester data are ongoing.

PrgmNr 2235 - Helsmoortel-van der Aa syndrome in a 14-year-old girl demonstrates intellectual impairment, facial dysmorphism and morbid obesity

View session detail

Author Block: **E. AL-Enezi**[1], W. Eyaid[2], K. Al-Anazi[3]; [1]Clinical Genetic and Metabolic Fellow, Dept. of Genetics, King Abdulaziz Med. City, Riyadh, Saudi Arabia, [2]Consultant Genetic and Endocrinology, Dept. of Genetics, King Abdulaziz Med. City, Riyadh, Saudi Arabia, [3]Pediatric Cardiology Fellow, Dept. of Pediatric Cardiology, King Abdulaziz Med. City, Riyadh, Saudi Arabia
Disclosure Block: **E. AL-Enezi:** None.
Helsmoortel-Van der Aa syndrome (HVDAS) (OMIM# 615873), is a recently discovered neurodevelopmental disorder, caused by pathogenic mutations in the ADNP gene (OMIM#611386), characterized by impaired intellectual development, motor delay, facial dysmorphism, autism spectrum disorder, visual difficulties, congenital heart diseases, gastrointestinal disorders, attention deficit/hyperactivity disorder (ADHD) and obsessive-compulsive behaviour. We report here a patient demonstrates the clinical features of Helsmoortel-van der Aa syndrome, molecularly confirmed, in addition to morbid obesity, short stature, bilateral ovarian cysts, solitary right kidney, distinctive dysmorphic features like highly arched eyebrows, proptosis and crowded teeth.

PrgmNr 2236 - Importance of genetic diagnosis on the PICU: case series during COVID-19 pandemic

View session detail

Author Block: **V. Plaiasu**, I. Apostol, A. Caia-Hoanas, A. Dobre, O. Farkas, A. Cochino, T. Ciomartan; INSMC Alessandrescu-Rusescu, Bucharest, Romania
Disclosure Block: **V. Plaiasu:** None.
Introduction: Congenital anomalies and genetic disorders are the most frequent cause of death in infancy. Children in intensive care frequently have a rare underlying genetic condition, often with atypical clinical presentation, unusual and puzzling symptoms, such as intractable seizures, acidosis or dysmorphic conditions with multiple congenital anomalies. It is critical to find the diagnosis of these children to reduce mortality and unessential intensive care and to decrease the anxiety of patient families. **Patients:** This study represents a retrospective evaluation for 30 unrelated children with age at recruiting ranged from 2 weeks to 3 years admitted to the PICU who were nominated between March 2020 and April 2021 during 14 months of COVID-19 pandemic. Data of the patients were obtained from their medical records from our paediatric tertiary care institution - PICU and genetics department. **Methods:** A molecular diagnosis was made by NGS technology: WGS (Whole Genome Sequencing) or WES (Whole Exome Sequencing) +/- CNV (Copy Number Variants) or targeted exome sequencing (TES) panels. Parental samples were not available to complete familial genetic investigation. **Results:** The diagnoses reported included pathogenic, likely pathogenic or uncertain (VUS) variants or incidental genetic findings of the genes such as ***TRAPPC4***, ***RYR1, MT-TS1, HEXB***, ***DOLK, ASL, UFM1, SLC4A1, ABCB11, TTC37, RAG1*** in a broad range of rare disorders including neurodegenerative conditions, myopathies, inherited metabolic disorders, congenital immunodeficiency and other syndromes. All positive results provided a valuable etiological explanation for the management of the cases and for the genetic counselling of the families. Changed specific clinical management of diagnosed patients was applied: avoiding morbidity from symptomatic monitor, avoiding severe infection, uncontrolled seizures, avoiding another accessory lab test, identifying unnecessary procedures for examination, furthering life-saving procedures. The molecular diagnosis of deceased infants was important due to implications for recurrence risk counselling. Also substantial challenges from medical and administrative point of view have been registered during pandemic period. **Conclusion**: The use of comprehensive genomic testing by NGS in intensively ill children facilitated diagnoses and assisted acute and long-term clinical decisions. Geneticists and critical care specialists should collaborate to get more accurate diagnoses for the patients with suspected monogenic disorders. Inborn errors of metabolism and neonatal encephalopathy represented the top diagnoses in intensive care setting.

PrgmNr 2237 - MLPA mediated molecular characterization of associated syndromes with orofacial cleft patients

View session detail

Author Block: **K. Avasthi**; Sanjay Gandhi Post Graduate Inst. of Med. Sci., Lucknow, India
Disclosure Block: **K. Avasthi:** None.
Introduction Orofacial clefts, also categorized as either Cleft Lip/Palate or Cleft Palate, are second most common congenital deformity. A worldwide birth prevalence orofacial clefts are 2.62 per 1000 live births. It can occur as part of mendelian syndromes or isolated/non-syndromic clefts. It is heterogeneous group of disorders, and Varies with ethnicity, gender and cleft type. It can arise through singleâ□□gene mutations, chromosomal abnormalities and effect of teratogens. The syndromic clefting designation refer to the presence of additional other physical and/or cognitive abnormalities, along with CL/P. **Materials and Methods** The present study was conducted on 25 syndromic orofacial cleft patients present with different clinical features. Genomic DNA was extracted from peripheral blood and multiplex ligation dependent probe amplification was performed for two probe sets, one for common microdeletions or second for Di-George syndrome. Sequence type electrophoresis was performed using ABI prism 310 genetic analyser. Later, fragment and comparative analysis part was carried out by coffalyser software. **Results** We detected 3 patients were with 22q11.2 deletion and shown that association of Di-George syndrome. No cases were detected for the other common microdeletion syndromes. **Conclusions** Our work demonstrated that Di-George Syndrome (22q11.2 deletion) is most common syndrome associated with orofacial cleft patients and it can be used as primary screening through the MLPA in orofacial cleft patients.

PrgmNr 2238 - Pulmonary valvular stenosis missed Rasopathies in two asymptomatic adults

View session detail

Author Block: **R. Louati**; FMS, Sfax, Tunisia
Disclosure Block: **R. Louati:** None.
Pulmonary stenosis (PS), rare among adults, develops usually before birth as a congenital heart defect (7-10%). PS ranges from a mild form to moderate severe forms valvular PS (VPS) is the most common type. Adults with PS may be asymptomatic regardless of the severity of their obstruction. Here, we report two adults diagnosed with a syndromic PS following the detection of a Noonan syndrome (NS) in their children. Material and methods: We analyzed by bidirectional sequencing all exons introns-exons boundaries of PTPN11 gene in two children suspected to have NS on the basis of facial dysmorphism, chest deformity congenital heart defect. They were affected respectively by an isolated VPS an associated VPS to an atrial septal defect. Results: The diagnosis of VPS associated to NS was confirmed. The first child had a c.923 A>G (p.N308S) mutation of PTPN11 exon 8 the second had a c.188 A>G (p.T63C) of PTPN11 exon 3. Familial investigation showed the presence of these mutations in the father of the first child the mother of the second. Clinical counselling showed a NS dysmorphism indicated cardiac echography which showed the presence of a silent VPS for the two 37-year-old parents. Conclusion: PS is often diagnosed in childhood, but sometimes it is not detected until later in life. This heart defect is commonly associated with congenital structural cardiac defect as tetralogy of Fallot Rasopathies like syndromes. It is primordial to look for to identify silent PVS missed Rasopathies in parents when a NS or other related Rasopathies are confirmed in their offsprings.

PrgmNr 2239 - The identification of microduplications in 17q21.31 locus that might disrupt the *KANSL1* gene

View session detail

Author Block: **A. Alaqeel**[1], A. Aladwani[2], A. Alahmad[2], A. Alhouly[2], H. AL-Balool[3]; [1]Kuwait Med. Genetic Ctr. (KMGC); Neurocare / 60 Degree Clinic, Sulaibikhat, Sabah Health Area, Kuwait, [2]Kuwait Med. Genetic Ctr. (KMGC), Sulaibikhat, Sabah Health Area, Kuwait, [3]Kuwait Med. Genetic Ctr. (KMGC), Sulaibikhat, Sabah Health Area, Kuwait
Disclosure Block: **A. Alaqeel:** None.
Background: 17q21.31 microdeletion syndrome, also known as Koolen-De Vries syndrome (KDVS), is a multisystem genetic disorder genetically recognized by the loss of function of the *KANSL1* gene and characterized by intellectual disability, hypotonia, failure to thrive, characteristic facial features, and other neurologic and cardiovascular defects. Point mutations in the *KANSL1* gene and microdeletions including the same gene cause KDVS.
Method: Copy number analysis using Affymetrix Cytoscan HD Microarray assay to analyse patients with unclear clinical diagnosis. It is to identify genetic aberrations in these cases. Results: The oligonucleotide array analysis detected a gain in 17q21.31 region (approximately chr17:44187491-44784639) in 5 unrelated patients; which are approximately 570-600 kb in size and includes 8 genes. Although this type of aberration has not been reported as causative for a any known microduplication syndrome; it partially overlaps with the *KANSL1* gene and may potentially compromise its function. Due to high sensitivity of Affymetrix Cytoscan HD Array platform; it is possible to detect the duplication that might cause disruption in the structure of *KANSL1* gene. As a result, it may lead to loss-of-function of *KANSL1* gene. Moreno-Igoa *et al* (2015) reported a patient with balance *de novo* translocation between chromosome 1 and 17 (46, XX,t(1;17)(q12;q21) that includes duplicated segment that disrupts the *KANSL1* gene. Two out of the five cases also harbor a pathogenic aberration, the first one with 22q11.21 deletion (DiGeorge syndrome), and the second with 7q11.23 deletion (Williams Syndrome). Although both cases do exhibit clinical features related to their syndromes, other features however were detected that overlap with 17q21.31 microdeletion syndrome. Microduplication in 17p21.31 region that includes the first three exons of *KANSL1* gene reported to be with associated with 22q11.2 deletion and was found to significantly influence the patients clinical phenotype (Leon *et al* 2016). Conclusion: The investigation of the human genome of undiagnosed clinical genomic cases using microarray has identified microduplication located in 17q21.31 that overlap partially with the *KANSL1* gene in 5 unrelated individuals. Although there is some evidence supporting the pathogenicity of a microduplication disrupting the *KANSL1* gene function; however, more evidence is needed to re-classify this aberration. Therefore, further testing is required to investigate this aberration. Thus, our laboratory classifies this type of aberration as variant of unknown significance according to *American College of Medical Genetics* guidelines.

PrgmNr 2240 - Clinical whole genome sequencing as an efficient first-tier diagnostic test for patients withrare diseasesfrom a resource-limited setting in the Democratic Republic of Congo

View session detail

Author Block: **A. Lumaka Zola**[1,2], G. Mubungu[1], A. Malhotra[3], S. Sajan[3], P. Lukusa[1], P. Makay[1], M. Ngole[1], D. Tshika[1], .. ILS Interpretation, Reporting, and Bioinformatics[3], D. L. Perry[3], J. W. Belmont[3], J. Ortega[3], R. J. Taft[4]; [1]UniversitÃ© de KINSHASA, KINSHASA, Congo, Democratic Republic of the, [2]UniversitÃ©de LiÃ¨ge, LiÃ¨ge, Belgium, [3]Illumina Inc., San Diego, CA, [4]Illumina Inc, San Diego, CA
Disclosure Block: **A. Lumaka Zola:** None.
There is increasing utilization of clinical whole genome sequencing (cWGS) as a first-tier diagnostic test for rare and undiagnosed diseases in Western countries. Thus far, this approach has not been evaluated in Africa. The Illumina iHope Program is a philanthropic initiative that aims to provide cWGS to individuals with a suspected rare genetic disease who have limited access to molecular testing. Recently, this program expanded to provide cWGS to a resource-limited and underserved population from the Democratic Republic of Congo through an ongoing partnership with the University of Kinshasa. The initial cohort includes 40 patients ranging in age from 10 months to 78 years from 35 unrelated families. Following cWGS, variants were reported in 24 of the 35 families (68.6%). Fifteen of the 35 families (42.9%) carried at least one likely pathogenic or pathogenic variant identified in a gene associated with a disease that was consistent with the phenotype. An additional nine individuals (25.7%) carried variants of uncertain significance due to currently limited evidence, but showed some clinical congruence to the reported phenotype. Clinically significant variants included single nucleotide variants (SNV) and small indels (n=12), aneuploidy (n=1), copy number variants (CNV; n=4), and one repeat expansion. Five individuals had multiple variant types reported, most often a compound heterozygous pair with a CNV and SNV. Of note, two individuals with thrombocytopenia-absent radius syndrome had an ~448 kb deletion of 1q21.1 in trans with a recently described hypomorphic variant in the 3â□□ UTR of *RBM8A* that is common in the African population. In addition, variants were identified that were informative to multiple affected family members including three siblings with suspected retinitis pigmentosa who all carried biallelic variants in *ADAM9* (associated with cone rod dystrophy). Similarly, three siblings with spinocerebellar ataxia all had a pathogenic repeat expansion in the *ATXN7* gene. The cWGS results also provided information on potential change in clinical management in two individuals: monitoring for gastric cancer in an individual with a *CDH1* variant and possible treatment with levothyroxine in an individual with a *THRA* variant, based on literature evidence showing beneficial outcomes of treatment in individuals with the variant. These data demonstrate the comprehensive diagnostic advantage of cWGS as a first-tier test in individuals with a suspected genetic disease in resource-limited African populations. Gene and variant information from this unique and under-represented population will be shared with the community through ClinGen and ClinVar.

PrgmNr 2241 - Current status of genetic diagnosis laboratories and frequency of genetic variants associated with cystic fibrosis through a newborn-screening program in Turkey

View session detail

Author Block: **S. Tug Bozdogan**[1,2], C. Mujde[2], I. Boga[1,2], O. Sonmezler[2], A. Hanta[2], C. Rencuzogullari[2], D. Ozcan[3], D. Ufuk Altintas[3], A. Bisgin[1,2]; [1]Cukurova Univ., Faculty of Med., Dept. of Med. Genetics, Adana, Turkey, [2]Cukurova Univ., AGENTEM (Adana Genetic Diseases Diagnosis and Treatment Ctr.), Adana, Turkey, [3]Cukurova Univ., Faculty of Med., Dept. of Pediatric Allergy and Immunology, Adana, Turkey
Disclosure Block: **S. Tug Bozdogan:** None.
Background: Cystic fibrosis (CF) is the most common worldwide, life-shortening multisystem hereditary disease, with an autosomal recessive inheritance pattern caused by mutations in the cystic fibrosis transmembrane conductance regulator (CFTR) gene. The national newborn screening (NBS) program for CF has been initiated in Turkey since 2015. If the immunoreactive trypsinogen (IRT) is elevated (higher than 70 Î¼g/L in the second control) and confirmed by sweat test or clinical findings, genetic testing is performed. The aims of this study are to emphasize the effect of NBS on the status of genetic diagnosis centers with the increasing numbers of molecular testing methods, and to determine the numbers and types of CFTR mutations in Turkey. **Methods:** The next-generation sequencing (NGS) and multiplex ligation-dependent probe amplification (MLPA) results of 1595 newborns, who were referred to Cukurova University Adana Genetic Diseases Diagnosis and Treatment Center (AGENTEM) for molecular genetic testing, were evaluated with positive CF NBS program results since 2017. **Results:** According to the results; 560 (35.1%) of the 1595 patients carried at least 1 (one) CF-related variant, while 1035 patients (64.9%) had no mutation. Compound heterozygosity for two mutations was the most common in patients, while two detected variants were homozygote in 14 patients. A total of 161 variants were detected in 561 patients with mutations. Fifteen novel variants that have not been previously reported were found. Moreover, p.L997F was identified as the most frequent pathogenic mutation that might affect the IRT measurements used for the NBS. The distribution of mutation frequencies in our study showed a difference from those previously reported; for example, the well-known p.F508del was the third most common (n = 42 alleles), rather than the first. The most striking finding is that 313 cases had a pathogenic variant together with the V470M variant, which might have a cumulative effect on CF perpetuation. **Conclusion:** This study is the first to determine the mutational spectrum of CFTR in correlation with the NBS program in the Turkish population. NBS for CF raises issues regarding screening in diverse populations, both medical and non-medical benefits, and carrier identification. Through the lens of NBS, we focused on the integrated diagnostic algorithms and their effect on the results of genetic testing.

PrgmNr 2242 - Detection of pathogenic CNVs in isolated and non-isolated congenital heart defects (CHD) by MLPA and CMA (retrospective cohort study)

View session detail

Author Block: **P. Capkova**[1,2], Z. Capkova[1,2], J. Srovnal[3], S. Travnickova[2], V. Curtisova[1,2], A. Stefekova[1], J. Petrkova[1,2], E. Klaskova[4,2]; [1]Dept. of Med. Genetics, Univ. Hosp. Olomouc, Olomouc, Czech Republic, [2]Faculty of Med. and Dentistry, Palacky Univ. Olomouc, Olomouc, Czech Republic, [3]Inst. of Molecular and Translational Med., Palacky Univ. Olomouc, Olomouc, Czech Republic, [4]Dept. of Paediatrics, Univ. Hosp. Olomouc, Olomouc, Czech Republic
Disclosure Block: **P. Capkova:** None.
CHDs are among the commonest birth defects. Pathogenic CNVs are frequent causes of CHD. The aim of the study was to determine the detection rate of pathogenic CNVs in prenatal and postnatal cohorts of isolated and non-isolated CHD cases after exclusion of aneuploidies by MLPA and CMA. **Method:** 129 samples (peripheral blood, amniotic fluid, chorionic villi) of patients with CHD were tested by MLPA and/or aCGH. **Results**: We detected 6 (13.33 %) and 12 (14.29 %) pathogenic CNVs in prenatal (45) and postnatal (84) cohort respectively. The most frequent were CNVs of 22q11.2 locus: they were present in one third of the prenatal as well postnatal samples and segregated with various types of CHD, including minor abnormalities (FOA etc.). Only one pathogenic CNV (1.92 %) and 5 VOUS CNVs (9.62 %) were detected in the cohort with isolated CHD (52) compared to 17 (22.08 %) pathogenic and 3 (3.9 %) VOUS CNVs in the group where CHD was present together with other congenital malformations or comorbidities (77). In addition to the recurrent microdeletions which are a known cause of CHD (1p36.33, 1q21.1, 4p16.3p16.2, 5p15.33, 7q11.2, 8p23.1, 9p34.3) we also detected two large regions of homozygosity - one resulting from upd(20)mat and one on chromosome 10 as a consequence of parental consanguinity. This finding suggests a possible role of AR condition or imprinting in CHD. Incidentally we also detected a point mutation in *BMP4 (*rs897543876) in a family with bicuspid aortic valve and aortic dilatation by MLPA testing and Sanger sequencing. **Conclusion**: Targeted (MLPA) and whole-genome (CMA) investigation of pathogenic CNVs is beneficial especially where other co-morbidities/malformations accompany CHD. The rate of detection of pathogenic CNVs is modest in isolated CHD cases where polygenic aetiology is assumed. High frequency of microdeletion 22q11.2 in both cohorts and its highly variable phenotype (wide spectrum of CHD, some of them undetectable by prenatal US examination, absence of CHD) suggests that it might be helpful to perform screening for the microdeletion routinely in prenatal diagnosis. Supported by MH CZ-DRO(FNOl,00098892), IGA_LF_2021_019.

PrgmNr 2243 - Genetic determinants of mosaic loss of the X chromosome in peripheral leukocytes of 395,036 women from 3 biobanks

View session detail

Author Block: **A. Liu**[1], G. Genovese[2,3], Y. Zhao[4], FinnGen, P-R. Loh[5,3], A. Ganna[1,3,6], J. R. Perry[4], M. J. Machiela[7]; [1]Inst. for Molecular Med. Disclosure Block: **A. Liu:** None.

Mosaic loss of the X chromosome (mLOX) is the most frequently occurring age-related somatic chromosomal alteration detected in peripheral leukocyte DNA of females, with a prevalence of 3.9% in women younger than 50 and reaching 33.3% after age 70. However, little is known about the genetic causes of mLOX and its epidemiological consequences. Building on success from prior genome-wide association studies (GWAS) of mosaic Y loss (mLOY) in males, we performed a GWAS meta-analysis of mLOX in 395,036 women of European ancestry (36,178 with mLOX) from UK Biobank, FinnGen, and Mass General Brigham Biobank to characterize germline genetic architecture of mLOX.

We identified 8 autosomal germline susceptibility loci, including one locus in the MHC region and multiple loci located near genes associated with blood cell counts (*SP140L*, *SCML4*, *MSC-AS1*, *CTD-2207O23.3* and *KRI1*), blood protein level (*ADAMTS5*), and chronic lymphocytic leukemia (*SP110*). Rare variant analyses in UK Biobank exome sequencing data (N=101,027) identified additional rare variation in the *BUB1B* cancer predisposition gene (a mitotic checkpoint kinase) associated with increased risk of mLOX ($P=5.4x10^{-7}$). Only one of the genome-wide significant signals for mLOX (MHC locus) was associated with mLOY ($P=1.7x10^{-6}$) suggesting distinct molecular drivers for mLOX relative to mLOY. However, the genetic correlation between mLOX and mLOY was 0.25 (95% CI 0.08 to 0.42), indicating some shared genetic architecture from common variants.

Allelic shift analyses were performed on X chromosome data to identify germline variants for which one allele was preferentially lost in mLOX cases with heterozygous genotypes. Multiple such variants were identified over a large region spanning the centromere (P-250) as well as near chromosome X genes associated with skewed X-inactivation (*PLS3* and *ITM2A*) and cancer risk/progression (*FAM9C*, *CT45A1* and *SAGE1*). Furthermore, many of these allelic shift variants were near genes that modulate blood cell counts (*P2RY8*, *WAS*, *PJA1*, *PLS3*, *ITM2A* and *TMEM255A*). As mLOX preferentially involves the inactive X chromosome, such associations hint towards some form of competitive advantage for clonal growth or selection among the two populations of cells inactivating different X chromosomes. Leveraging genotype data from 400k females, we detected multiple germline variants associated with mLOX suggesting susceptibility to mLOX exhibits relationships with skewed X inactivation, blood cell traits, and cancer predisposition genes. Allelic shift analyses further demonstrate the strong cis selection of specific X variants providing novel insights into the genetic etiology of mLOX.

PrgmNr 2244 - Low-pass genome sequencing-based detection of absence of heterozygosity: validation in clinical cytogenetics

Introduction: Absence of heterozygosity (AOH) is a genetic characteristic known to cause human genetic disorders through autosomal recessive or imprinting mechanisms. However, the analysis of AOH via low-pass genome sequencing (GS) is not yet clinically available. **Materials and Methods:** Low-pass GS (fourfold) with different types of GS libraries was performed on 17 clinical samples with previously ascertained AOH by chromosomal microarray analysis (CMA). In addition, AOH detection was performed with low-pass GS data in 1,639 cases that had both GS and high-probe density CMA data available from the 1000 Genomes Project. Cases with multiple AOHs (coefficient of inbreeding F â¥ 1/32) or terminal AOHs â¥5 Mb (suspected uniparental disomy [UPD]) were reported based on the guidelines of the American College of Medical Genetics and Genomics. **Results: We first demonstrated the optimal read-depth for AOH analysis to be fourfold regardless of sequencing modes (paired-end or single-end) and library types (small-insert or large-insert). In addition,** low-pass GS revealed suspected segmental UPD and multiple AOHs (F â¥ 1/32) in nine and eight clinical cases, respectively, consistent with CMA. Lastly, among the 1,639 samples with CMA and GS available in the 1000 Genomes Project, low-pass GS not only consistently detected multiple AOHs (F â¥ 1/32) in 18 cases, but also reported 60 terminal AOHs in 44 cases including four mosaic AOHs at a level ranging from 50% to 75%. **Conclusion:** Overall, our study demonstrates the feasibility of AOH analysis (â¥5 Mb) with low-pass GS data and shows high concordance compared with CMA.

PrgmNr 2245 - Multilocus disease-causing genomic variations for Mendelian disorders: role of systematic phenotyping and implications on genetic counselling

Multilocus disease-causing genomic variations (MGVs) and multiple genetic diagnoses (MGDs) are increasingly being recognised in individuals and families with Mendelian disorders. This can be mainly attributed to widespread use of genomic tests for evaluation of these disorders. We conducted a retrospective study of families evaluated over the last 6 years at our centre to identify families with MGVs and MGDs. MGVs were observed in fourteen families. We observed five different consequences: (i) Individuals with MGVs presenting as blended phenotypes (ii) Individuals with MGVs presenting with distinct phenotypes (iii) Individuals with MGVs with age-dependent penetrance (iv) Individuals with MGVs with one phenotype obscured by another more predominant phenotype (v) Two distinct phenotypes in different individuals in families with MGVs. Consanguinity was present in eight (8/14, 57.1%) of them. Thirteen families had two Mendelian disorders and one had three Mendelian disorders. The risk of recurrence of one or more conditions in these families ranged from 25% to 75%. Our findings underline the importance of the role of a clinical geneticist in systematic phenotyping, challenges in genetic counselling and risk estimation in families with MGVs and MGDs, especially in highly inbred populations.

PrgmNr 2246 - The high-risk phenotypes of genetic disease in a Neonatal Intensive Care Unit population from the China neonatal genomes project

It is difficult to determine when neonates required genetic testing, especially for the neonates without special facial features or multiple congenital anomalies. Therefore, we conducted an observational study to systematically analyze the phenotypes of the genetic disease in a Neonatal Intensive Care Unit population between June 1, 2016 and June 30, 2020. We systematically investigated the phenotypes of the neonates with the Auto-Neo-HPO pipeline assistance and compared the phenotypes between the neonates with or without positive genetic diagnosis. Of 2,600 enrolled neonates, 248 neonates (9.5%) were diagnosed with a positive genetic diagnosis. The most common phenotypes in neonates with positive genetic diagnosis was abnormal heart morphology (HP: 0001627) (50.8%, 126/248), followed by sepsis (HP:0100806) (34.2%, 85/248), jaundice (HP:0000952) (31.8%, 79/248), encephalopathy (HP:0001298) (24.6%, 61/248), seizure (HP:0001250) (23.8%, 59/248). Compared to the neonates with negative genetic diagnosis, the risk phenotypes included muscular hypotonia (HP:0001252) (p

PrgmNr 2247 - A novel splice site variant causes SLC13A5-related developmental and epileptic encephalopathy in large consanguineous family

Disclosure Block: **H. Aldhalaan:** None.
SLC13A5 (solute carrier family 13, member 5) encodes Na+ coupled citrate (NaCT) transporter protein which can carry dicarboxylates in addition to tricarboxylates substrates. Mutant *SLC13A5* proteins can lose the ability to bind to Na molecules, therefore failing to transport citrate, an essential compound for brain function, to from extracellular matrix to cytosol. Lack of cellular citrate results in energy deficit in the brain, thus contributes to pathogenesis of epilepsy and delayed brain development. Biallelic mutations in *SLC13A5* (homozygous or compound heterozygous) are associated with different phenotypic features such as seizures, intellectual disability, global developmental delay, and tooth dysplasia. Up to date 36 different disease-causing variants have been reported in the literature. Here, we present a novel splice site variant in three Saudi patients from a large consanguineous family. Patients experienced epileptic encephalopathy, microcephaly, motor difficulties, and intellectual disability. Most treatment regimen of such cases consists of group of traditional antiepileptic drugs (e.g. diazepam, topiramate, and depakine) to control their seizures. *SLC13A5* related epilepsy can be treated with Stiripentol (second-generation antiepileptic drug) not only to control seizures but also to enhance cellular citrate levels. Our study expands genetic spectrum of the disease and presents alternative approach to the suffering family to seek healthy siblings though pre-implementation genetic diagnosis.

PrgmNr 2248 - Apolipoprotein E4 and meningeal lymphatics in Alzheimer disease: a conceptual framework

View session detail

Author Block: **A-F. Mentis**, G. Chrousos; Univ. Res. Inst. of Child and Maternal Hlth.& Precision Med., Athens, Greece
Disclosure Block: **A. Mentis:** None.
The potential existence and roles of the meningeal lymphatic system in normal and pathological brain function have been a long-standing enigma. Recent evidence suggests that meningeal lymphatic vessels are present in both the mouse and human brain; in mice, they seem to play a role in clearing toxic amyloid-beta peptides, which have been connected with Alzheimer disease (AD). Here, we review the evidence linking the meningeal lymphatic system with human AD. Novel findings suggest that the recently described meningeal lymphatic vessels could be linked to, and possibly drain, the efferent paravascular glial lymphatic (glymphatic) system carrying cerebrospinal fluid, after solute and immune cell exchange with brain interstitial fluid. In so doing, the glymphatic system could contribute to the export of toxic solutes and immune cells from the brain (an exported fluid we wish to describe as glymph, similarly to lymph) to the meningeal lymphatic system; the latter, by being connected with downstream anatomic regions, carries the glymph to the conventional cervical lymphatic vessels and nodes. Thus, abnormal function in the meningeal lymphatic system could, in theory, lead to the accumulation, in the brain, of amyloid-beta, cellular debris, and inflammatory mediators, as well as immune cells, resulting in damage of the brain parenchyma and, in turn, cognitive and other neurologic dysfunctions. In addition, we provide novel insights into APOE4-the leading genetic risk factor for AD-and its relation to the meningeal lymphatic system. In this regard, we have reanalyzed previously published RNA-Seq data to show that induced pluripotent stem cells (iPSCs) carrying the APOE4 allele (either as APOE4 knock-in or stemming from APOE4 patients) express lower levels of (a) genes associated with lymphatic markers, and (b) genes for which well-characterized missense mutations have been linked to peripheral lymphedema. Taking into account this evidence, we propose a new conceptual framework, according to which APOE4 could play a novel role in the premature shrinkage of meningeal lymphatic vessels (meningeal lymphosclerosis), leading to abnormal meningeal lymphatic functions (meningeal lymphedema), and, in turn, reduction in the clearance of amyloid-beta and other macromolecules and inflammatory mediators, as well as immune cells, from the brain, exacerbation of AD manifestations, and progression of the disease. Altogether, these findings and their potential interpretations may herald novel diagnostic tools and therapeutic approaches in patients with AD.

PrgmNr 2249 - ÂÂÂÂASL deficiency in ALDH1A1^{+}- neurons in the substantia nigra metabolically promotes neurodegenerative phenotypes

View session detail

Author Block: **A. Erez**[1], S. Lerner[2], S. Nagamani[3], J. Baruteau[4]; [1]Weizmann Institue of Sci., Rehovot, Israel, [2]Weizmann, Rehovot, Israel, [3]Baylor Coll. of medicine, Houston, TX, [4]Great Ormond Street Inst. of Child Hlth., London, United Kingdom

Disclosure Block: **A. Erez:** None.

Argininosuccinate lyase (ASL) is essential for the NO-dependent regulation of tyrosine hydroxylase (TH) and thus for catecholamine production. Using a conditional mouse model with loss of ASL in catecholamine neurons, we demonstrate that ASL is uniquely expressed in ALDH1A1^{+} subpopulation of dopaminergic neurons in the substantia nigra pars compacta, that are pivotal for the pathogenesis of Parkinson disease (PD). Neuronal loss of ASL results in catecholamine deficiency, in accumulation and formation of tyrosine aggregates, in elevation of Î±-synuclein, and phenotypically in motor and cognitive deficits. NO supplementation rescues the formation of aggregates as well as motor deficiencies. Our data point to a potential metabolic link between accumulations of tyrosine and the seeding of pathological aggregates in neurons as initiators for the pathological processes involved in neurodegeneration. Hence, interventions in tyrosine metabolism *via* regulation of NO levels may be therapeutic benefits for the treatment of catecholamine-related neurodegenerative disorders.

PrgmNr 2250 - Compound heterozygous *ATM* variants cause late onset cerebellar and extrapyramidal disease in the absence of telangiectasia in a consanguineous Pakistani family

View session detail

Disclosure Block: **F. Aslam:** None.

Ataxia-telangiectasia (A-T) is a heterogeneous genetic disorder with a recessive mode of inheritance resulting from homozygous or compound heterozygous variants in the A-T mutated gene (*ATM)*. ATM is a serine-threonine kinase that is activated by DNA double strand breaks and then initiates a number of signaling cascades modulating a variety of processes including cell cycle, DNA repair, and cell death. Dysfunctional ATM leads to A-T, which is marked by compromised immunity, chromosomal instability and increased risk of malignancies. We present a consanguineous Pakistani family with multiple individuals having late-onset ataxia. Affected individuals manifested gait and limb ataxia, postural instability and generalized dystonia. Whole exome sequencing identified a known pathogenic nonsense *ATM* variant c.2413C>T, p.(Arg805Ter) in trans with a previously unreported missense variant c.8708C>T p.(Pro2903Leu). Sanger sequencing of DNA from all participants revealed that the variants segregated with the disease in this family. A few cardinal features of A-T were absent that include telangiectasia of the eyes and skin, which led to the initial misdiagnosis of the disease as cerebellar ataxia. There were no reports of malignancies in the family and affected individuals were alive in their third and fourth decades of life, which is uncommon for A-T. Thus, molecular analysis of affected individuals resulted in reclassification of the disease as A-T, an example of reverse phenotyping. We suspect that this novel missense variant likely has residual kinase activity, thus causing a milder form of late-onset A-T with the absence of telangiectasia. Our findings extend the allelic spectrum of *ATM* variants and expand phenotypic heterogeneity of A-T. This study was funded by Higher Education Commission (HEC) of Pakistan with the award of IRSIP scholarship to F.A. and research grant HEC 2877 to S.N. and by a Yale New Haven Hospital research grant to S.A.L.

PrgmNr 2251 - Dysregulated expression levels of *APH1B* in peripheral blood are associated with brain atrophy and amyloid-Î² deposition in Alzheimerâ□□s disease

Sch. of Med., Indianapolis, IN

Disclosure Block: **Y. Park:** None.

The interaction between brain and periphery might play a crucial role in the development of Alzheimer's disease (AD). Using blood transcriptomic profile data from two independent AD cohorts, we performed expression quantitative trait locus (*cis*-eQTL) analysis of 29 significant genetic loci from a recent large-scale genome-wide association study to investigate the effects of the AD genetic variants on gene expression levels and identify their potential target genes. We then performed differential gene expression analysis of identified AD target genes and linear regression analysis to evaluate association of differentially expressed genes with neuroimaging biomarkers. *cis*-eQTL analysis identified and replicated significant associations in seven genes. *APH1B* expression levels in blood increased in AD and were associated with entorhinal cortical thickness and global cortical amyloid-Î² deposition. An integrative analysis of genetics, blood-based transcriptomic profiles, and imaging biomarkers suggests that *APH1B* expression levels in blood might play a role in the pathogenesis of AD.

PrgmNr 2252 - IMMP2L gene and Gilles de la Tourette syndrome a new case & review of the literature

View session detail

Author Block: **N. Almobadel**, H. Elghezal, I. Ben Abdallah, a. el onazi, A. Alhashem, O. Al Suhaibani; Prince Sultan military Med. city, Riyadh, Saudi Arabia
Disclosure Block: **N. Almobadel:** None.
Gilles de la Touretteâ□□s syndrome (GTS) is an inherited neuropsychiatric disorder characterized by the presence of chronic multiple motor and vocal tics affecting up to 1% of schoolchildren with a wide range of severity. The etiology of GTS is complex, combined with multiple genes and environmental factors. Family and twin studies have conï¬□rmed that the majority of GTS cases are inherited, although the exact mode of inheritance is not yet known. In recent years, several new candidate genes, in particular SLITRK1, IMMP2L, CNTNAP2, and NLGN4 genes, were identiï¬□ed through linkage studies and structural genomic aberrations, as major candidate genes in GTS. 7q31 Chromosomal aberrations studies have identiï¬□ed rare structural aberrations associated with GTS in particular in a case were the Inner mitochondrial membrane protein 2L (IMMP2L) gene was disrupted by a deletion of exons 1-3 in a male patient with GTS. We report here a 3 years old male, of a first degree cousins unaffected parents with no family history, presenting a neonatal form of GTS with recurrent abnormal movements diagnosed since the age of 40 days. Array CGH analysis showed a pathogenic abnormal result with a 331 Kb heterozygote intragenic deletion into IMMP2L gene. IMMP2L intragenic deletions were detected in 7 cases among 188 unrelated patients with GTS as reported in a previous Danish cohort and one of them present a similar 331 Kb deletion indicating a possible recurrent genomic instability in this region. However, partial deletions of this gene have been observed in 0.9% of the control population in the Danish cohort and in 2 other cases among 2150 CGH array analyses performed in our laboratory and presenting an unrelated phenotype. These data suggest that IMMP2L gene deletions are recurrent finding with variable pathogenic effect and high recurrence of GTS condition.

PrgmNr 2253 - Lipid transporter TMEM24/C2CD2L plays critical roles in ensuring the survival of retinal rod cells

View session detail

Author Block: **Y. Yang**[1,2], X. Zhu[2]; [1]Sch. of Med., Univ. of Electronic Sci. and Technology of China, Chengdu, China, [2]Sichuan Provincial Key Lab. for Human Disease Gene Study, Sichuan Provincial Peopleâ□□s Hosp., Chengdu, China
Disclosure Block: **Y. Yang:** None.

C2CD2L/TMEM24, an endoplasmic reticulum (ER)-localized phospholipid transporter, maintains lipid transport between ER and plasma membrane (PM). The lipid transport function of TMEM24 is essential for sustaining the intracellular Ca^{2+} oscillations, supporting a key role of TMEM24 in the coordination of Ca^{2+} and phosphoinositide signaling. C2CD2L is enriched in neuroendocrine cells and previously suggested to be required for a normal secretory response. However, little is known about the roles of this protein in retina. To this end, we investigated the effect of genetic deletion of *C2cd2l* in retinal rods on the visual function and on pathological changes in mouse. Rho-Cre mice was crossed with *C2cd2l* transgenic mice to yield *C2cd2l* Rod-KO (RKO) progenies. ERG recordings manifested a reduction in the amplitudes of a- and b-waves in RKO mice. Both H&E staining and immunohistochemistry of retinas sections from 4-month-old mice revealed the loss of rod cells and shortened photoreceptor outer segments in RKO retina. Besides, activated astrocytes detected in RKO retinas by immunostaining with GFAP suggested severe glial reaction. Mechanistically, RNA-seq results indicated that the expression levels of several key genes were reduced in RKO retinas, which were involved in multiple biological process, such as voltage-gated calcium channel activity (*Cacna1f, Cacng7, Cacna2d2*), postsynaptic membrane regulation (*Dlg4, Ptprs, Adnp, Cux2, Dnm1*) and visual perception (*Reep6, Rho, Aipl1, Rpgrip1, Fam161a*). These results were further verified by qPCR. Thus, in retinal rods, C2CD2L should participate in these processes to maintain normal visual function. Our data demonstrated novel essential roles of C2CD2L in the retina.

PrgmNr 2254 - Novel variants in *UBE3B* lead marfonoid body habitus of blepharophimosis ptosis intellectual disability syndrome

View session detail

Author Block: **A. Albakheet**, R. Al-Mass, H. AlQudairy, A. Qari, R. Huma1, H. Ghebeh, A-O. Mohammad, D. Colak, N. Kaya, M. Al-Sayed; King Faisal Specialist Hosp. & Res. Ctr., Riyadh, Saudi Arabia

UBE3B, an E3 class ligase, is involved in ubiquitination of short-lived proteins and targets them for protein degradation pathway. Recently, defects in this gene are reported to cause Kaufman oculocerebrofacial syndrome. We employed comprehensive genetic analyses including homozygosity mapping, candidate gene sequencing, exome sequencing, and confirmatory Sanger sequencing on a cohort of 139 neurodevelopmental cases and screened the cohort for putative mutations. Here, we report three consanguineous families with 8 patients harboring three novel variants, a missense substitution on HECT-domain in family 1 and a three basepair deletion within exon 14 (leading to removal of a serine) in family 2 and family 3 has a splice site mutation in *UBE3B.* The variants were fully segregated with the phenotype in the tested families members. Iterative filtering of exome sequencing did not reveal any other candidate genes. Further screening on the 500 ethnically matching controls as well as a comprehensive search on local (inclusive of more than 2000 samples), international (public) and commercially available databases confirmed the novelty of three variants. Unlike several other features, blepherophimosis, telecanthus, ptosis and low serum lipid profile were similar to those of previously reported cases having pathogenic *UBE3B* variants. Longitudinal follow up of the selected patients in both families revealed rather tall marfanoid body habitus of our patients. Our study expands phenotypic spectrum of the disease.

PrgmNr 2255 - Phenotypic variability of MEGF10 variants in a consanguineous population

Disclosure Block: **H. AlQudairy:** None.
Congenital myopathies are group of inherited neuromuscular disorders with neonatal or infancy onset. Their most common symptoms are hypotonia, muscle weakness and dysmorphic features. One of the rare autosomal recessive congenital myopathy is early onset myopathy, areflexia, respiratory distress, and dysphagia (EMARDD, OMIM: 614399, MIM: 612453). It is caused by biallelic mutations (homozygous or compound heterozygous) in *MEGF10* gene (multiple epidermal growth factor-like domains protein family). There are only five cases reported in the literature to date. Saudi Arabia is a highly consanguineous population and harbor significant number of autosomal recessive rare disorders. Interestingly, no *MEGF10* associated EMARDD has been reported up to date. In this study, we took the initiative and searched our neurology clinics and local databases to identify individuals with this disease. We determined two unrelated consanguineous families with patients having novel *MEGF10* mutations. Our study provides insight into clinical details of the patients and expands phenotypic spectrum of the disease

PrgmNr 2256 - Second report of *SHMT2* related neurodevelopmental disorder with cardiomyopathy, spasticity, and brain abnormalities

View session detail

Author Block: **V. Bhat**[1], P. Majethia[1], B. L. Yatheesha[2], A. Shukla[1]; [1]Kasturba Med. Coll., Manipal, India, [2]Dheemahi Child Neurology and Dev. center, Shimoga, India
Disclosure Block: **V. Bhat:** None.
Mitochondrial one carbon metabolism enzyme serine hydroxymethyltransferase, encoded by *SHMT2* (MIM 138450), plays a crucial role in amino acid and folate metabolism. Biallelic variants in *SHMT2* has been recently described to cause a novel neurodevelopmental disorder with cardiomyopathy, spasticity, and brain abnormalities (NEDCASB; MIM# 619121) in five subjects from four unrelated families. A six-month-old male, first born to third-degree consanguineous parents, presented with developmental delay and occasional jerky movements. On examination at six months of age, his weight was 6kg (-2.5 SD), length was 58cm (-4.9 SD) and head circumference was 37cm (-6.5 SD). He had shallow orbits, anteverted nares, thin vermillion borders, spasticity and exaggerated deep tendon reflexes. Biochemical investigations showed mildly elevated lactate (21mg/dL; ref: 4.5 - 19.8mg/dL). Electroencephalogram showed multifocal epileptiform abnormalities. A magnetic resonance imaging (MRI) of the brain showed thinning of the corpus callosum, particularly at the splenium and hypomyelination. Exome sequencing identified a likely pathogenic novel missense variant c.1133A>G, p.(Asp378Gly) in exon 10 of *SHMT2* (NM_005412.6) in a homozygous state. On segregation, the variant was seen in heterozygous state in the parents. The clinical findings in the reported individuals are subtle dysmorphism, cardiac abnormalities, intellectual disability, peripheral neuropathy, and motor dysfunction in the form of spasticity and ataxia. Cardiac anomalies included hypertrophic cardiomyopathy in four and atrial septal defect in one individual. Clinically, cardiovascular examination of our subject was normal, however complete cardiac evaluation by echocardiography is planned on follow-up visit. Hypertrophic cardiomyopathy has been seen as early as 3 years of age earlier. MRI findings in all previously reported individuals have thin corpus callosum and perisylvian polymicrogyria. The present proband showed thin corpus callosum, particularly at the splenium and delayed myelination. No cortical abnormalities were seen. The electroencephalogram was abnormal in the present subject similar to one of the reported individuals, in absence of clinical seizures. Peripheral neuropathy has not been evaluated in the present subject. Mild lactic acidosis was seen in present proband, however, previously reported individuals have not been evaluated for the same. Till now, a total of seven variants including six missense and one deletion-insertion have been reported in *SHMT2*

PrgmNr 2257 - Simultaneous screening for SMN copy numbers and 2+0 silent carrier genotypes for Spinal Muscular Atrophy

View session detail

Author Block: **P-S. Lai**, G. Y. Chia, C. Liu, P. S. Low, S. K. Tay; Natl. Univ. of Singapore, Singapore, Singapore, Singapore
Disclosure Block: **P. Lai:** None.
Spinal muscular atrophy (SMA) is an autosomal recessive neuromuscular disorder that affects the lower motor neuron cells. It is the most common genetic cause of infant mortality and is caused by homozygous deletions of the *SMN1* gene in ~94% of patients, with remaining cases carrying a heterozygous deletion and a pathogenic variant on each allele. The reported carrier frequency varies between 1 in 35 to 1 in 60 individuals among different populations. Determination of *SMN1* copy number is important for molecular diagnosis and carrier identification. Due to the high incidence and severity of the disease, population-wide SMA screening can identify couples-at-risk and facilitate appropriate genetic counselling. Since carriers are asymptomatic, they can only be detected through *SMN1* copy number screening. However, carrier screening using dosage analysis can present false negative risks for silent carriers with the 2+0 genotype who are not picked up due to having one chromosome carrying two copies of *SMN1* and the other chromosome having 0 copy of *SMN1*. In this study, we analyzed 100 individuals from SMA affected families using the CarrierMaxâ□¢ *SMN1/SMN2* (Thermo Fisher Scientific Inc.) assays to investigate both SMN1/2 copy numbers and 2 SNPs (g.27134T>G and g.27706-27707delAT) associated with the 2+0 genotype. Multiplex qPCR was performed and the amplicons were separated via capillary electrophoresis on the SeqStudioâ□¢ Genetic Analyzer (Applied Biosystems) and analysed on GeneMapper 6.0 and CarrierMax software. A total 12 patients with 0 copy of *SMN1* was observed while family members carrying 1 to 2 or more copy numbers of *SMN1* and *SMN2* were detected. There were 55 carriers with 1 copy of *SMN1*. Validation of the copy numbers was performed by other gene dosage comparisons (MLPA and qPCR). In addition, putative silent carriers were detected (3 with g.27706-27707delAT and 1 with g.27134T>G). No gene conversion event was detected among this cohort. We found this screening approach to be convenient and rapid as diagnosis of copy number and detection of carriers, including silent carriers could be done simultaneously.

PrgmNr 2258 - The suppressive role for the splicing regulator, PTBP1, in the production of neuron-specific Agrin isoform

View session detail

Author Block: **S. Bushra**, Y. Lin, A. Masuda, A. Joudaki, K. Ohno; Nagoya Univ., NAGOYA, Japan
Disclosure Block: **S. Bushra:** None.
Agrin is a ubiquitously expressed proteoglycan, which has diverse functions by tissue-specific isoform expression. The neuron-specific isoforms (neural agrin), but not other isoforms, specifically induce acetylcholine receptor clustering, which is indispensable for the formation of neuromuscular junctions. Neural agrin is generated by the inclusion of three alternative exons called â□□exon Yâ□□, â□□exon Z8â□□ and â□□exon Z11â□□, although the underlying mechanism is not well understood. Here, we investigated splicing *cis*-elements and trans-factors involved in the splicing of exons Y/Zs, and explored their roles in the production of neural agrin. Publicly available CLIP-seq data analysis revealed several trans-factors, such as MATR3, RBFOX, and Polypyrimidine Tract Binding Protein (PTBP) 1, which bind extensively around exons Y/Zs of AGRN pre-mRNA. The knockdown experiments revealed that PTBP1 but not others suppressed the inclusion of exons Y/Zs in the SH-SY5Y neuroblastoma cell line. Consistently, RT-PCR analysis showed that the differentiation of SH-SY5Y cells downregulated PTBP1 expression and increased the inclusion of exons Y/Zs. The bindings of PTBP1 were prominent in the flaking introns of exon Y, which contains 5 polypyrimidine-rich sites. The analysis of AGRN minigenes with mutations of these sites identified two crucial sites, designated PM2 and PM1, responsible for splicing exon Y and exon Zs, respectively. We confirmed that the tethering of PTBP1 to PM2 specifically promoted the inclusion of exon Y. We propose that the neuron-specific splicing of exon Y and Zs in the AGRN gene is facilitated by the suppression of PTBP1 expression.

PrgmNr 2259 - Transcriptomic profiling of chromatin-related neurodevelopmental disorders in human induced pluripotent stem cell -based models

Neurodevelopmental disorders (NDDs) are characterized by abnormalities of brain development, most commonly manifesting as intellectual disability or autism spectrum disorders. The genetic architechture of NDDs comprises of highly penetrant de novo mutations in protein-coding genes, which account for up to half of genetically determined NDDs, and frequently affect genes that encode for chromatin-modifying and remodelling proteins. Given their central role in gene regulation, loss-of-function of chromatin-related genes are likely to have widespread effects on the transcriptome, but it is currently not known which cell types during neurodevelopment are most affected by such mutations and when, and whether such effects could be therapeutically reversed. Here, we have applied single-cell gene expression profiling (scRNA-seq) of cortical neuron differentiation in induced pluripotent stem cell (iPSC) models of NDD patients and controls. To model the NDD mutations, we have used both patient-derived iPSCs as well as CRISPR-Cas9-engineered knock-outs (KO) of the corresponding disease genes, and carried out pooled differentiations in order to achieve better comparability of samples through reduced heterogeneity. To identify and characterize the cell types, developmental lineages, and cellular processes most affected in NDDs, the cells were profiled at two timepoints during differentiation: cortical neuron precursors (NPC) and mature cortical neurons. The findings from the single-cell experiments will be compared to bulk transcriptomic data from NPCs derived from a larger number of isogenic iPSC lines with engineered KOs of ~30 known NDD genes, as well as further perturbation experiments with existing chromatin-targeting drugs and a KO screen of 500 chromatin-associated genes, also in NPCs. The aim of the study is to identify novel therapeutic targets for NDDs by comparing transcriptomic and other cellular responses to different types of perturbations across known NDD genes.

PrgmNr 2260 - Ultra rare truncating mutations of GRIK family genes associated with schizophrenia disrupt the interaction with PSD95 protein

View session detail

Author Block: **M-C. Cheng**, T-M. Hu, Y-Y. Wang, C-L. Wu, S-H. Hsu, H-Y. Tsai; Yuli Branch, Taipei Veterans Gen. Hosp., Hualien county, Taiwan
Disclosure Block: **M. Cheng:** None.
Schizophrenia is a complex mental disorder with a high genetic component in its etiology. Identification of the genetic underpinnings of schizophrenia is the key to decipher the pathogenesis of schizophrenia. The ionotropic glutamate receptor kainate type plays a critical role in regulating the synaptic transmission and the functions of various synaptic receptors. GRIK gene family encoding the ionotropic glutamate receptors of kainate subtypes can be considered the candidate genes of schizophrenia. We screened for the rare and pathogenic mutations at the protein-coding sequences of 5 genes (*GRIK1*, *GRIK2*, *GRIK3*, *GRIK4*, and *GRIK5*) in 516 unrelated patients with schizophrenia using the ion semiconductor sequencing method. We conducted the functional assay using immunoblot, immunocytochemistry, and NanoBRETâ□¢ bioluminescent resonance energy transfer (BRET) assay. We identified 44 protein-altering variants, including 12 in *GRIK1*, 5 in *GRIK2*, 7 in *GRIK3*, 13 in *GRIK4*, and 7 in *GRIK5* in patients with schizophrenia and *in silico* analysis showed that some of these mutations were damaging or pathological to the protein function. Notably, we identified two frameshift deletion mutations (GRIK1^{Phe24fs} and GRIK1^{Thr882fs}) in two unrelated patients with schizophrenia and two nonsense mutations (GRIK2^{Arg300Ter} and GRIK4^{Gln342Ter}) in two unrelated patients with schizophrenia. These four truncating mutations have minor allele frequency (MAF) of less than 0.01% from the public database or were absent in 1517 healthy controls from Taiwan BioBank. Functional analysis with immunoblot and immunocytochemistry identified these four truncating mutants as the loss-of-function mutants in HEK-293 cells. BRET assay showed that three truncating mutations (GRIK1^{Phe24fs}, GRIK1^{Thr882fs}, and GRIK2^{Arg300Ter}) weaken the interaction with PSD95 protein. The study suggests that the GRIK genes harbor ultra-rare truncating mutations in certain patients with schizophrenia, supporting that rare coding variants contribute to the genetic architecture of schizophrenia. Future studies using transgenic mouse models carrying these truncating mutations are necessary to understand the functional consequence of the GRIK gene family mutants *in vivo* and, most importantly, to elucidate whether and how they contribute to the etiology of schizophrenia.

PrgmNr 2261 - Whole-genome sequencing analysis identifies rare Alzheimerâ□□s disease risk variants among Chinese individuals

View session detail

Author Block: **J. Cao**[1], Y. Li[1], C-Y. Lo[1], Q. Guo[2], Zhangjiang Internaitional Brain Bank, J. Chen[1], X-M. Zhao[1]; [1]Inst. of Sci. and Technology for Brain-inspired Intelligence, Fudan Univ., Shanghai, China, [2]Dept. of Gerontology, Shanghai Jiao Tong Univ. Affiliated Sixth People's Hosp., Shanghai, China
Disclosure Block: **J. Cao:** None.
Genome-wide association studies (GWAS) have identified more than 30 loci implicated for Alzheimerâ□□s disease (AD), but there is still a substantial proportion of missing heritability which may be explained by rare variants. Here, we performed a whole-genome sequencing analysis on 198 elderly Chinese including 28 individuals with AD, 66 cognitive normal controls and other 104 cognitive declined individuals. Through a pipeline integratively considering allele frequency, functional impact, and pathogenicity, we found 33 rare pathogenic variants exclusively existing in 22 AD individuals but not in normal controls, which affected 29 high confidence AD-associated genes involved in endocytosis, immune response, and amyloid precursor protein (APP) metabolism. Among genes proposed by previous GWAS projects, we discovered 4 variants presenting exclusively in 2 AD samples, including a homozygous missense variant (rs756786529) in *CHRNE* gene, emphasizing the applicability of the cholinergic hypothesis in Alzheimerâ□□s disease. Furthermore, we focused on rare pathogenic variants enriched in AD group (OR > 5), and identified 4 variants that were successfully replicated in 10,913 unrelated case/control samples. We particularly noticed a rare missense variant rs139437968 in *SAMD11* gene. *SAMD11* had a significantly lower expression level in hippocampus from AD brains compared with control brains, and showed a strong negative correlation between its expression and AD pathology in AÎ² line AD mouse models, indicating it can be a possible new biomarker for AD. In summary, our analysis screened multiple rare variants and possible new genes related to AD pathogenesis, highlighting the role of rare variants in AD genetic architecture and their possible indications for diagnostic and therapeutic uses.

PrgmNr 2262 - Microtubule-Associated Serine/Threonine Kinases family genes (MAST) involved in the pathogenesis of seborrheic dermatitis may be related to Parkinson disease

View session detail

Author Block: **A. KARRA**, B. Abdelmoula, N. Bouayed Abdelmoula, Genomics of signalopathies at the service of medicine UR17ES36; Med. Univ. of Sfax, Sfax, Tunisia
Disclosure Block: **A. Karra:** None.
There is a growing body of evidence indicating the implication of abnormal protein kinase function in various aspects of Parkinsonâ□□s disease (PD) etiology and the possible association of microtubule defects and PD pathogenesis. In fact, LRRK2 gene, through deregulation of microtubule assembly, has been demonstrated as the most commonly mutated gene in the clinically typical, late-onset PD as well as both familial and sporadic forms. On the other hand, PD is an entity with a highly increased prevalence of seborrheic dermatitis (SD), which can be seen in approximately 60% of PD patients. SD is a common chronic inflammatory skin disorder affecting 1 to 3 percent of the general population, but even more commonly found in PD patients with a prevalence of 52 to 59 percent. The exact mechanism underlying the association of PD and SD is not fully clear. The increased sebum production associated to the increased reproduction of Malassezia yeasts with a nonspecific immune response are the two major factors believed to contribute to the development of SD. A direct involvement of Malassezia as the common denominator in the pathogenesis of both SD and PD is recently suggested. Moreover, the strong association between SD and PD is supposed to be due to genetic pathways link. Here we present a novel hypothesis concerning a potential molecular mechanism underlying the association of PD and SD that can be associated to the immune-mediated inflammatory process and endorsing the known skin-brain axis theory. In fact, a recent pilot genome-wide association study conducted to identify genetic variants associated with SD, showed two significant SNPs mapped to the MAST4 gene at chromosome 5 and to an intergenic region at chromosome 17p12, between the genes PIRT and SHISAQ. Through a literure review and databases analysis we concluded that microtubule-associated serine/threonine kinases family genes (MAST) involved in the pathogenesis of SD may be related to PD. MAST genes encode proteins members of the microtubule-associated serine/threonine protein kinases family. These proteins contain a domain that gives the kinase the ability to determine its own scaffold to control the effects of their kinase activities. Alternative splicing results in multiple transcript variants encoding different isoforms. MAST kinases named MAST1 to MAST4 are characterised by containing a serine/threonine kinase domain and a postsynaptic density protein-95/discs large/zona occludens-1(PDZ) domain. MAST4 gene is associated with spinocerebellar ataxia 27 and epilepsy with generalized tonic-clonic seizures. It has a ubiquitous expression including the brain and the skin.

PrgmNr 2263 - RNAseq characterization of the effect of titin truncating variants

View session detail

Author Block: **M. Savarese**[1], M. Johari[1], A. Vihola[1], H. Luque[1], M. Iacomino[2], P. Hackman[1], B. Udd[1]; [1]FolkhÃ¤lsan Res. Ctr., Univ. of Helsinki, Helsinki, Finland, [2]IRCCS Istituto Giannina Gaslini, Genoa, Italy

Disclosure Block: **M. Savarese:** None.

Titin related diseases include dominant cardiomyopathies and, mainly recessive, skeletal muscle diseases. Due the sheer size of the *TTN* transcripts, the interpretation of titin variants is challenging. Titin truncating variants (TTNtv) have been associated with a dominant cardiomyopathy with a reduced, age dependent, penetrance. On the other hand, TTNtv carriers do not show any skeletal muscle disease. Congenital skeletal muscle titinopathies are mainly due to bi-allelic TTNtv, with a large proportion of patients having variants affecting the splicing. The ACMG/AMP guidelines for variant interpretation underline that splicing defects are an important mechanism of pathogenicity. To estimate the clinical impact of variants potentially impacting the splicing, we re-evaluated by SpliceAI all the possible single nucleotide changes in the titin coding sequence, identifying 9,732 variants predicted to alter the splicing (threshold 0.5). Of these, 2,078 are synonymous or missense variants and 317 are nonsense variants. Few previously reported causative â□□missenseâ□□ variants are predicted to impact the splicing. In order to characterize the effect of titin truncating variants on skeletal muscle transcripts, we analysed by RNA sequencing 44 skeletal muscle samples from patients with a confirmed or a suspected titinopathy. Our study suggests that variants causing a premature stop codon, located in exons out of the M-band, result in a nonsense mediated decay of titin transcripts. Vice versa, the in-depth characterization of 15 variants affecting canonical splice sites demonstrates that most of them cause in-frame losses or gains, still resulting in a near-full length protein. A direct analysis of RNA, cDNA and protein is crucial to characterize the effect of splice variants. However, further studies are still needed to support the variant classification of DNA changes causing in-frame losses or gains.

PrgmNr 2264 - Automated prediction of the clinical impact of copy number variants: The power of combining expert and machine learning approach

Introduction: Copy number variants (CNVs) play an important role in many biological processes, including the development of genetic diseases, making them attractive targets for genetic analyses. The interpretation of the effect of structural variants is a challenging problem due to highly variable numbers of gene, regulatory or other genomic elements affected by the CNV. The state-of-the-art scoring scheme proposed by the American Academy of Medical Genetics (ACMG) is a well-respected guideline for the interpretation. The proper evaluation of the scheme is however challenging even for experts skilled in clinical genetics.

Materials and Methods: We automated several steps of the ACMG scoring scheme, proposing clinicians the recommended choices along with enclosed explanatory genomic annotations. In addition, we implemented a novel method based on machine learning that uses its own modeling beyond the ACMG scheme to predict the clinical impact of CNVs.

Results: We demonstrate the high accuracy of the automated scoring of the ACMG scheme and compare it with the accuracy of the machine learning approach. We show that the combination of these two complementary methods accurately predicts the impact of the majority of CNVs extracted from the ClinVar database.

Conclusions: Prediction of the clinical impact of CNVs can be automated, relieving highly valued clinical professionals of tedious annotation and interpretation processes.

PrgmNr 2265 - Coding DNA numbering errors occurring in multiple pipelines

View session detail

Author Block: **S. Seo**, S. Hwang, K. Park; Seoul Natl. Univ. Bundang Hosp., Seongnam, Korea, Republic of
Disclosure Block: **S. Seo:** None.
Introduction: Accurate variant calling in NGS data is critical in clinical sequencing. Herein we report a nucleotide numbering issue that arises from the errors in coding positions of the exons in a specific gene. Methods: A patient with progressive hearing loss underwent a targeted sequencing by using a multigene panel consisted of the genes related to hearing loss. The library was prepared and sequenced on Ion Torrent S5 XL (Thermo Fischer Scientific, USA). Reads were aligned to hg19 and variant calls were made by three different pipelines. Results: All three pipelines detected two variants in *PTPRQ*, chr12:81004405G>A and chr12:81043449G>A, which seemed to be the genetic cause for the patientâ□□s condition. However, all three pipelines showed different cDNA numbering in these two variants (c.4402+1G>A, c.4462+1G>A and c.4464+1G>A for chr12:81004405G>A; c.5508+1G>A, c.5568+1G>A and c.5570+1G>A for chr12:81043449G>A). Accurate nomenclature for these two splice site variants was confirmed as c.4918+1G>A and c.6024+1G>A. The difference were found in coding positions of *PTPRQ* exons defined in each pipeline, which seemed to result in this cDNA numbering error. Conclusions: The coding DNA reference sequences may be updated or replaced by another record regularly, which might result in numbering errors in particular genes. Since accurate nomenclature of a pathogenic variant is critical in a clinical laboratory setting, additional use of a validating tool for variant nomenclature can be of help for the clinical sequencing report.

PrgmNr 2266 - Copy number variation analysis with targeted next generation sequencing in patients with inherited metabolic disorders

View session detail

Author Block: **M. Reboun**, R. Svacinova, V. Todorovova, M. Novakova, D. Musalkova, H. Vlaskova, G. Storkanova, K. Peskova, T. Honzik, L. Dvorakova; Dept. of Paediatrics and Inherited Metabolic Disorders, First Faculty of Med., Charles Univ. and Gen. Univ. Hosp., Prague, Czech Republic
Disclosure Block: **M. Reboun:** None.
Introduction: We implemented a targeted NGS for the diagnosis of patients with a suspicion for various groups of inherited metabolic disorders including glycogen storage diseases, disorders of amino acid/organic acid metabolism and fatty-acid oxidation disorders. **Methods**: A total of 237 genes were analyzed using a custom-designed oligo capture probe set (Roche NimbleGen) and Illumina MiSeq system. Inhouse bioinformatic pipeline was used for of SNPs, small deletions/duplications and copy number variants analysis. Using a CNVkit, copy number variation (CNV) analysis was performed on 24 samples (one sequencing run) with variable sizes of resolution of the deleted/multiplicated regions - â□□binsâ□□: 50bp, 100bp and 150bp. **Results**: In a cohort of 99 patients, in whom the diagnosis was genetically confirmed, ten large deletions were identified. Extensive duplication has not been found yet. Deletions detected in four patients involved only one exon (i.e. deletions of exon 17 in *PYGM*, exon 16 in *HADHB*, exon 1 in *DBT* were present in heterozygous state while exon 33 in *PHKA2* was identified in hemizygous state). Deletions detected in five patients contained two to ten exons of one gene, none of them encompassed the neighboring genes. Thus, deletions including exons 2-3 in *SLC3A1*, 1-10 in *HADHA*, 2-13 in *PHKB*, 12-17 in *CBS*, 10 -12 in *IVD* were detected. The presence of identified CNVs was confirmed by qPCR and/or by Sanger sequencing of PCR products overlapping the deletion boundaries. In the last presented female patient CNV analysis suggested monosomy of X chromosome. This result was confirmed by cytogenetic methods. **Conclusions**: Our results show, that CNV analysis for small panels (i.e. hundreds of genes) and small numbers of samples (i.e. 24) is possible. Analysis of variable bin size showed comparable results, however, 50bp resolution showed a lot of poorly predicted CNVs at the ends of the investigated regions. Resolution of 100-150bp analysis exhibited more precise results and revealed variants at the range of the only one exon to the entire chromosome. In our cohort CNV was detected in 10 (10%) out of 99 diagnosed patients. The presented data indicate, that CNV detection is an important part of mutation analysis. Support: MZ_CR - RVO_VFN64165, SVV260367

PrgmNr 2267 - Evaluating RNA-seq gene expression profiles for disease prediction using machine learning

View session detail

Author Block: **V. Lanke**, R. Srinivasan, S. Datta; Tata Consultancy Services, Hyderabad, India
Disclosure Block: **V. Lanke:** None.
The use of individual genotypes in screening and diagnosis of inherited Mendelian rare disorders is becoming prevalent. While the use of polygenic risk scores to evaluate the likelihood of multigenic disorders is gaining currency, it is understood that augmenting genotypes with intermediary phenotypes such as gene expression and methylation status can lead to improved risk assessment models. Unlike with genotypes, where the presence or absence of a variant required to evaluate risk can be readily reckoned from a reference genome, the lack of an accepted standard reference for gene expression leads to challenges in interpreting individual gene expression profiles. Since there are public repositories of gene expression (SRA, GTEx, TCGA for example) that include a number of healthy controls we hypothesized that we may be able to use these data to create disease specific models by integrating data from these resources with gene expression data from samples with the disease. In this study, we collected data from recount2 - a repository of uniformly processed RNA-Seq samples from multiple resources. Using feature importance metric for iterative feature elimination, we built random forest based disease specific models to distinguish disease and healthy state given an expression profile. Using a test set of four diseases - Chronic Obstructive Pulmonary Disease(COPD), Dilated Cardiomyopathy(DCM), Systemic Lupus Erythematosus(SLE) and Breast Cancer(BC), we demonstrate that we can achieve reliably high classification performance using disease specific models. Although the approach holds promise, the performance of a disease model in the presence of other diseases from the same tissue remains a challenge to be explored.

PrgmNr 2268 - Human Genome Topology for Selected Trios from the 1000 Genomes Project

View session detail

Disclosure Block: **D.M. Plewczynski:** None.
In this work, we present ***a comprehensive analysis of human genome topological changes due to the genomic variability at the population and single family scale*** [Sadowski et al, Genome Biology 2019]. In recent years the number of personal genomes has increased substantially allowing the identification of single nucleotide polymorphisms and structural variants common for the human population. A major challenge is to understand which of these changes have structural or functional implications [Chaisson et al, Nature Comm 2019]. The goal of this work is to understand the link between changes in the DNA sequence, the 3D structure of the genome, and gene expression. In detail the lymphoblastoid cell lines from 9 individuals have been chosen for this study. The samples represent 3 families originating from three geographical locations - China, West Africa, and Puerto Rico.

First, we have used 1000 Genomes public data from Oxford Nanopore sequencing technology along with short-read Illumina, focusing on the detection of the structural variants (SVs) improvement. We improved the quality of the Structural Variants identification from the whole genome sequencing (WGS) experiments by using the consensus approach. Fifteen gold-standard silico callers were used for obtaining the polished list of Structural Variants for each family. The results of the SV callings were merged using our novel ConsensuSV algorithm, which integrates the SV sets using machine learning by combining decision trees and neural networks trained and benchmarked on the high-quality SVs from the Human Genome Structural Variation Consortium. We provide the validated sets of high-confidence Structural Variants identified for each of the analyzed daughters from Trios.

Having identified the SVs dataset from both short-read and long-read techniques, we studied the influence of SNPs and SVs on the genome 3D structure and explored the heritability of genome organization. We performed the differential peak analysis for the Yoruban trio using CTCF ChIA-PET data and identified more than 18 000 unique loci with CTCF binding peak. For 10 336 loci, CTCF peaks were present in all the samples. More than 90% of all loci were also involved in the formation of DNA loops. Next, we incorporated the RNA-seq data to select only regions characterized by an altered gene expression between family members. We presented the mechanism that by changing the specific 3D interactions can increase gene expression, likely by joining promoter and enhancer. We also compare the experimental CTCF ChIA-PET results obtained for the selected trio with our in silico prediction algorithm [Wlasnowolski et. al., NAR 2020].

PrgmNr 2269 - Mining risk regulatory variants of Tetralogy of Fallot using deep learning models

Tetralogy of Fallot (TOF) is the most common form of cyanotic congenital heart defects with a disease prevalence of ~1 in 3,000 newborns. Over the past decade, studies on the human genome and transcriptome have revealed that non-coding variations contribute significantly to human disorders through dysregulating gene expression. However, most of the rare disease-causing non-coding variants were explored using transcriptomic data due to the complexities of gene regulation on the genome level. Recent development of deep learning models has largely improved the performance of alternative splicing and regulatory effect prediction based on sequence context and epigenomic data. Here, we aim to explore if rare noncoding variants contribute to the genetic etiology of TOF through applying deep learning models on whole genome sequencing (WGS) data of 148 TOF trios (patient and unaffected parents) of Chinese ancestry. From the WGS data, we first detected non-coding *de novo* variants (DNVs) and applied SpliceAI and MMSplice to identify those DNVs that are likely to result in alternative splicing and hence loss of function of the genes. Secondly, we applied HeartENN, a neural network-based model trained with 184 human and mouse heart epigenomic features, to predict the regulatory potential of the non-coding DNVs in TOF patients. We observed an increased burden of likely damaging non-coding DNVs (HeartENN scores â¥ 0.1) in TOF patients compared to controls (*P*

PrgmNr 2270 - Reanalysis of population cohort WGS revealed considerable minor allele frequency differences

View session detail

Author Block: **J. Hsu**[1], P-L. Chen[1], C-Y. Chen[1], D-C. Wu[1], S-H. Shih[1], Y-C. Tsai[1], W-A. Chen[2]; [1]Natl. Taiwan Univ., Taipei City, Taiwan, [2]Natl. Taiwan Univ. Hosp., Taipei City, Taiwan

Population cohort whole-genome sequence represents the overall genetic variation profile as a strong foundation of implementing precision medicine in the national healthcare system. A comprehensive variants discovery framework is crucial to ensure the accuracy and reproducibility in detail. For a large-scale sequencing project, the systematic noise from the analytic pipeline can introduce a large number of false-positive calls, which will heavily impact the cohort minor allele frequencies, leading the type 1 errors for concluding false associations between genotype and phenotypic trait. Therefore, it is highly recommended to adopt a compatible analytic pipeline for case and control studies, especially compare the cohort allele frequency with the Genome Aggregation Database (gnomAD). We applied and reanalyzed 1,496 Taiwan Biobank (TWB) whole-genome sequence data to represent the comprehensive genetic variation profile of the Taiwanese population. Combining a standard material (NA12878) from Genome In A Bottle Consortium (GIAB) with the corresponding validated results, we benchmarked the variant discovery pipeline for single nucleotide variation (SNV) and small insertion and deletion (INDEL). Variant quality score recalibration (VQSR) suggested by GATK best practice has been used to stratify all variants based on each variant-level quality score. We found more than 4.7% of nonsynonymous variants in the TWB cohort have substantial minor allele frequency (MAF) differences (> 0.05) compared to the East Asian (EAS) population data in gnomAD v2.1. MAF differences may influence a significant proportion of the corresponding phenotypic traits to be considered differently in healthcare settings. Furthermore, there were 0.58% of population-specific variants between TWB and EAS, suggesting the importance of Taiwanese population cohort data for clinical disease diagnosis in Taiwan. As our analysis pipeline has been benchmarked by comparing to GIAB data, the MAF inconsistency should be due to population stratification or small sample size. More population WGS data and a reproducible analysis framework to reanalyze the biobank cohort periodically are necessary to achieve compatible MAF information with other populations.

PrgmNr 2271 - VulExMap: Detection of exons which are vulnerable to exonic splicing mutations

View session detail

Author Block: **L. L. Holm**[1], K. K. Flugt[1], T. K. Doktor[2], M. B. Hansen[1], B. S. Andresen[2]; [1]Univ. of Southern Denmark, Odense M, Denmark, [2]Univ Southern Denmark, Odense M, Denmark
Disclosure Block: **L.L. Holm:** None.
It is now well established that exonic mutations may cause aberrant splicing by altering splicing regulatory elements (SREs) located outside the splice sites. Consequently, software for predicting mutation effects on individual SREs is now widely used in precision medicine. Unfortunately, it is typically presumed that all exons are equally dependent on SREs and that predicted effects of mutations on SREs have the same effect in all exons. However, exonic splicing mutations (ESMs) tend to cluster in particular exons of a gene and similar mutations in SREs located in different exons do not always have identical effects. Furthermore, the existing tools for predicting splicing mutations are predominantly focused on detecting mutations in the splice sites, where a mutation typically may cause aberrant splicing simply by directly affecting splice site strength. We have defined a new subgroup of constitutive exons that are more likely to be affected by ESMs because they have an inherent suboptimal splicing efficiency and therefore are more dependent on the balance between positive and negative SREs. We coin these exons as vulnerable and have created a tool, VulExMap, which uses large RNA-seq datasets to assign exon vulnerability, based on small but significant levels of constitutive exon skipping. We show that approx. 25 % of all constitutive exons are vulnerable, and that vulnerable exons as a group displays characteristics of a suboptimal splicing context, such as weaker splice site strengths, lower density of positive SREs and higher density of negative SREs. VulExMap currently uses 5 different datasets to categorize exon vulnerability and allows the user to upload their own mutations to analyze if they are located in a vulnerable exon. Furthermore, we have generated a database of 202 validated ESMs, and we show by analysis with VulExMap that ESMs are several fold more frequent in vulnerable exons. Moreover, we demonstrate that ESMs that reside in vulnerable exons generally produce smaller changes to the splicing code, whereas ESMs in more resilient exons result in a more severe change to the splicing code. Our goal is that VulExMap will be used as a tool to determine exon vulnerability as a pre-requisite before assessing the potential effects of exonic mutations on splicing. VulExMap is available at https://vulexmap.compbio.sdu.dk

PrgmNr 2272 - A metagenome-wide association study revealed disease-specific landscape of the gut microbiome of systemic lupus erythematosus in Japanese

View session detail

Author Block: **Y. Tomofuji**[1], Y. Maeda[1], E. Oguro-Igashira[1], T. Kishikawa[1], K. Yamamoto[1], K. Sonehara[1], D. Motooka[2], Y. Matsumoto[3], H. Matsuoka[4], M. Yagita[4], N. Takuro[1], S. Oshima[4], S. Nakamura[3], H. Inohara[1], K. Takeda[1], A. Kumanogoh[1], Y. Okada[5]; [1]Osaka Univ. Graduate Sch. of Med., Suita, Japan, [2]Res. Disclosure Block: **Y. Tomofuji:** None.
Alteration of the gut microbiome has been linked to the pathogenesis of systemic lupus erythematosus (SLE). However, a comprehensive view of the gut microbiome in SLE and its interaction with the host remains to be revealed. Whole metagenome shotgun sequencing technology is useful for evaluating the human gut microbiome and has many advantages over conventional 16S ribosomal RNA (rRNA) sequencing such as higher taxonomic resolution and applicability for functional analysis. However, evaluation of the microbiome-disease association based on shotgun sequencing is still incomplete for SLE, hindering us from understanding the link between the gut microbiome and the etiology of SLE. Furthermore, the insufficient number of shotgun sequencing studies in the non-European population is problematic given the significant impact of ethnicity and lifestyle on the microbial landscape. Here we performed a metagenome-wide association study (MWAS) of SLE based on shotgun sequencing of the gut microbial DNA from 250 Japanese individuals, composed of 47 SLE patients and 203 healthy controls. Our MWAS consisted of three major bioinformatic analytic pipelines (phylogenetic analysis, functional gene analysis, and pathway analysis). Additionally, we integrated the result of the MWAS with the genome-wide association study (GWAS) data and plasma metabolite data for revealing the interaction between the gut microbiome and the host. Via species level phylogenetic analysis, we identified and validated increases of *Streptococcus intermedius* and *Streptococcus anginosus* in the SLE patients. Microbial gene analysis revealed increases of *Streptococcus* derived genes including one involved in the redox reaction. Additionally, microbial pathways related to sulfur metabolism and flagella assembly were altered in the SLE patients. We identified a pathway level SLE-specific link between the metagenome and the germline genome by comparing the result of the current MWAS and GWAS of SLE (i.e., MWAS-GWAS interaction). Î±- and Î²-diversity analyses provided evidence of dysbiosis in the metagenome of the SLE patients. Microbiome-metabolome association analysis identified a positive dosage correlation of acylcarnitine with *Streptococcus intermedius*, an SLE-associated taxon. Thus, our MWAS followed by integrative analysis with the GWAS and the metabolite data revealed SLE-associated changes in the gut microbiome and its interaction with the host. Our analysis provided novel insights into the pathogenesis of SLE and could be a key step toward the implementation of more appropriate therapeutic frameworks.

PrgmNr 2273 - A multi-disciplinary approach to solving undiagnosed patients - Unsolved Cases Unit Groningen

View session detail

Author Block: **D. Bos**[1], C. M. A. Van Ravenswaaij-Arts[1], T. Dijkhuizen[1], A. H. van der Hout[1], K. Kok[1], K. Van Dijk-Bos[1], L. Zijlstra[1], D. S. Verbeek[1], F. De Andrade[1], R. Pfundt[2], N. Corsten-Janssen[1], B. Sikkema-Raddatz[1], M. Van Gijn[1], K. M. Abbott[1]; [1]Univ. Med. Ctr. Groningen, Groningen, Netherlands, [2]Radboud Univ. Nijmegen Med. Ctr., Nijmegen, Gelderland, Netherlands
Disclosure Block: **D. Bos:** None.
Introduction: After solving 30-40% of all patients submitted for clinical genetic testing, the possible avenues for follow-up testing are diagnostically limited. Experimental diagnostics can help to bridge the gap between the clinic and research, providing the next step after diagnostic genetics has been exhausted. At the UMCG, we have implemented a multi-disciplinary team focused on solving well-phenotyped unsolved cases using an experimental diagnostic approach.
Methods: A team of clinicians, researchers, laboratory geneticists and a patient representative was established. A secure portal was created for registering unsolved cases. A trial-run of the unit was initiated to assess its inclusion criteria, accessibility, feasibility, as well as its added value. Subsequent tests included mRNA and WGS, novel bioinformatics tools for prioritizing variants and functional testing. The progress was tightly monitored; biweekly meetings were organized to monitor progress and regular updates were shared with clinicians to avoid endless experimental diagnostic tracks. Over a six month period, 10 out of 17 patients registered were chosen for inclusion. The phenotypic spectrum included developmental delay, MCA, skin ailments and suspected hereditary cancer. Five patients required further functional testing to enable re-classification for VUS. The remaining five were chosen for whole genome sequencing.
Results: To date, a homozygous missense variant in *PLAA* was found to initiate alternative splicing using mRNA techniques, resulting in truncation of the gene. With this result the phenotype of the patient, who has brain anomalies, hypotonia, edema of the hands, episodes with bradycardia and saturation loss, epilepsy and feeding difficulties, is explained. A VUS in *TBCK* (compound heterozygous with pathogenic variant) in a patient with muscular hypotonia, seizures, motor delay, severe intellectual disability was not found to have an effect on splicing (using a mini-gene assay technique). Further mRNA testing is being performed in connection with another study. A VUS missense variant in *EDA* in family members with ectodermal dysplasia is currently being tested. Using RT-PCR and Western blot techniques we will compare *EDA* function in one healthy/VUS-neg family member with two affected/VUS-pos family members. Testing for the remaining patients is ongoing.
Conclusions: With the invaluable support of the department, the assistance of a patient representative and an enthusiastic team, the Unsolved Cases Unit - Groningen was piloted. Preliminary results indicate the added value of such a unit in genome diagnostics to assist in solving the unsolved cases.

PrgmNr 2274 - An atlas of genetic scores to predict multi-omic biomolecular traits in blood

View session detail

Pirastu[5], D. Paul[1], C. Yau[6], J. F. Wilson[7], C. Langenberg[1], A. MÃ¤larstig[8], J. Danesh[1], A. S. Butterworth[1], M. Inouye[1]; [1]Univ. of Cambridge, Cambridge, United Kingdom, [2]Univ. of Edinburgh, Edinburgh, United Kingdom, [3]Baker Heart and Diabetes Inst., Melbourne, Australia, [4]Uppsala Univ., Uppsala, Sweden, [5]Univ. of Edinburgh, Edinburgh, Midlothian, United Kingdom, [6]Univ. of Manchester, Manchester, United Kingdom, [7]Univ Edinburgh, Edinburgh, United Kingdom, [8]Karolinska Inst.t, Stockholm, Sweden
Disclosure Block: **Y. Xu:** None.
Introduction: Genetically predicted levels of biomolecular traits have been shown to be a useful tool for investigating the molecular underpinnings of complex phenotypes. However, existing studies mainly focus on molecular traits of a single or a small number of biological domains (e.g. gene and protein expression) sourced from a variety of different studies. There is currently a lack of resources that leverage the large-scale multi-modal data of single cohorts, thus facilitating well-powered and cross-modality analyses in cohorts where multi-omic data are unavailable but genotype data are.
Objective: Develop an open resource of genetic scores for transcriptomic, proteomic and metabolomic traits, to enable any genotyped cohort to generate accurate and comparable predictions of multi-modal omics data.
Method: We utilized the INTERVAL study, a 50,000-participant cohort of blood donors with extensive multi-omic profiling, including genome-wide genotypes and biomolecular traits for plasma proteomics (SomaScan, and Olink), serum metabolomics (Nightingale), plasma metabolomics (Metabolon), and gene expression (whole-blood RNA sequencing). We trained genetic score models for these >24,000 biomolecular traits on the INTERVAL cohort utilizing a machine learning method and evaluated the performances of the genetic scores within the cohort and externally in four other cohorts. Furthermore, we applied the genetic scores to impute biomolecular traits into UK Biobank and subsequently performed a phenome-wide association scan (PheWAS) for predicted biomolecular trait associations.
Results: First, we illustrate the consistent performance of the constructed genetic score models between the internal and external validation, and that many traits have highly predictive scores (e.g. 98 SomaScan proteins, 21 Olink proteins and 6 Metabolon metabolites had an $r^2 > 0.3$ in both validations). We also illustrate the utility of our scores in a PheWAS, where we replicate well-known blood proteins/metabolites to disease associations, e.g. blood C-reactive protein and total cholesterol with coronary artery disease (CAD), and discover new associations where no previous molecular data was available.
Conclusions: We present a resource for genetic imputation of biomolecular traits that can boost cross-cohort, cross-domain analyses, and enable large-scale data integration for greater powered studies to identify biomarkers, therapeutic targets and pathways.

PrgmNr 2275 - Enzymatic DNA synthesis (EDS) enables rapid and broad-based access to synthetic oligos needed for the genetic analysis and functional characterization of the SARS-CoV-2 virus

View session detail

Author Block: **B. Derrien**, S. Romero; DNA Script, SAS, Le Kremlin-BicÃªtre,, France
Disclosure Block: **B. Derrien:** None.
The COVID-19 pandemic sparked a global scientific effort to study the epidemiology, genetics, biochemistry and evolution of the SARS-CoV-2 virus. One unforeseen effect of this work was a worldwide bottleneck in the supply of synthetic DNA (primers, probes, assay controls, and gene fragments), which currently relies on highly centralized phosphoramidite-based production and third-party logistics.
We have developed a novel enzymatic DNA synthesis (EDS) technology that enables decentralized, same-day, on-demand oligo production in a standard molecular biology lab. Here we report the use of EDS primers in (i) amplicon sequencing and phylogenetic analysis of clinical SARS-CoV-2 samples and (ii) site-directed mutagenesis of the SARS-CoV-2 spike (S) gene.
For SARS-CoV-2 amplicon sequencing, the ARTIC v3 panel (218 primers) was produced by EDS. Libraries generated from two synthetic RNA controls and five Mexican isolates yielded coverage uniformity and variant calling data similar to that obtained with commercial primers. Phylogenetic analysis of clinical samples showed no correlation with isolates from countries where patients had travelled prior to testing positive.
In another study, the unique ability of EDS to extend existing ssDNA was used to produce a custom version of the ARTIC v3 panel, with 5â□□-overhangs to add Illumina adaptors in a second PCR. By eliminating ligation-based library prep, the sample-to-sequencing turnaround time was reduced to a single day. This simplified protocol enabled high-throughput monitoring of SARS-CoV-2 variants in Finland.
EDS primers were also used to produce an expression plasmid encoding the spike SARS-CoV-2 Alpha/B.1.1.7 variant for functional studies. Oligos were designed to introduce ten mutations into a cloned copy of the 3.8-kb S gene using a multi-site approach. Sanger sequencing primers produced by EDS were used to confirm individual mutations in picked clones and tiled sequencing of the entire S gene. EDS primers showed high success rates in a multi-site mutagenesis strategy and yielded high-quality Sanger sequencing data. In-house oligo synthesis enabled a fast, iterative process that needs only a few days per mutagenesis/sequencing cycle.
Data generated in collaboration with The Jackson Laboratory for Genomic Medicine, USA; the University of Zacatecas Molecular Medicine Laboratory and Zacatecas Public Health Laboratory, Mexico; the Institute for Molecular Medicine, Finland; and the Pasteur Institute, France.

PrgmNr 2276 - Impaired type I interferon activity of subjective cognitive decline in preclinical Alzheimerâ□□s disease

View session detail

Author Block: **L. Song**[1], J. Chen[1], C-Y. Lo[1], Q. Guo[2], Zhangjiang Internaitional Brain Bank, X-M. Zhao[1]; [1]Fudan Univ., Shanghai, China, [2]Shanghai Jiao Tong Univ. Affiliated Sixth People's Hosp., Shanghai, China

Disclosure Block: **L. Song:** None.

Subjective cognitive decline (SCD) is considered to be the preclinical syndrome of Alzheimerâ□□s disease (AD), which is a potentially crucial window for preventing or delaying the progression of this disease. No previous study has evaluated the transcriptomic profilings on SCD in preclinical AD. To explore the etiology of AD and identify candidate biomarkers, we comprehensively assessed the peripheral blood transcriptomic disruption for SCD, including lncRNA, mRNA, and miRNA. Dysregulated protein-coding mRNA at gene and isoform-level and integrative coexpression network consistently implicated an impaired type I interferon signaling pathway in SCD. The pathway was regulated by differential splicing of interferon genes, *NRIR*, and *has-miR-146a-5*, hub genes, and transcription factors. Normal cognition individuals with lower expression of hub genes *STAT1* and *TRIM22* exhibited a higher MCI and AD conversion rate in the ADNI cohort, indicating that *STAT1* and *TRIM22* might serve as candidate biomarkers for disease progression. Our findings demonstrate a down-regulation of type I interferon activity in preclinical AD, which would increase the risk of disease progression.

PrgmNr 2277 - Molecular Cartography: a multiplexed high resolution transcriptomics approach to spatially analyze rare events demonstrated in an infection model of SARS-CoV-2

View session detail

Author Block: **S. Groiss**[1], D. Pabst[1], C. Faber[2], A. Meier[2], A. Bogdoll[2], C. Unger[2], B. Nilges[2], E. FÃ¶derl-HÃ¶benreich[1], M. Hardt[1], A. Geipel[2], F. Reinecke[2], C. Korfhage[2], K. Zatloukal[1]; [1]Med. Univ. of Graz, Graz, Austria, [2]Resolve BioSci.s GmbH, Monheim am Rhein, Germany
Disclosure Block: **S. Groiss:** None.
COVID-19, the clinical manifestation of the SARS-CoV-2 infection, exhibits severe heterogeneity in infection rates and cellular responses in different cell types. Such heterogeneity necessitates the molecular analysis of single cell gene expression in a highly multiplexed manner. Many regulatory genes responsible for these processes are expressed in low copy numbers and the cellular and subcellular location impacts their function. Single-cell spatial transcriptomics technologies allow investigations of intricate processes in cells such as host-to-pathogen responses, antiviral defense pathways and mapping the response dynamics in different infection sites. The methods and technologies available thus far lack a direct comparison of multiple samples and are limited in detecting rare events due to reduced sensitivity, specificity, or resolution. To gain a thorough comparative understanding of the infection rate of various cell lines by SARS-CoV-2 and their molecular response, we used a multiplexed single-cell mRNA in-situ hybridization technique developed by Resolve Biosciences called Molecular Cartographyâ¢ (MC) that allows for the detection and quantification of rare transcripts at a subcellular level. In this study, we demonstrate that MC detects single mRNA species at a specificity of > 99 % and a sensitivity comparable to single-molecule FISH that is considered the gold standard of spatial in-situ methods. We illustrate the utility of MC in a SARS-CoV-2 infection model using cell lines of pulmonary, colorectal, and hepatocellular origin. Using MC, we localized transcripts of the SARS-CoV-2 nucleocapsid protein majorly vicinal to the cell nuclei, highlighted cell-to-cell variances in expression levels of the key viral entry factors *ACE2*, *TMPRSS2* and *FURIN*, and revealed virus-induced dysregulation of major primary and secondary antiviral genes. By spatially tracking antiviral responses emanating from the primary infected cell, we elucidate differences in individual, temporal divergent infection sites and trace individual regulatory signatures in pathways hijacked by SARS-CoV-2. Overall, MC is demonstrated to be a novel, multiplexed single-molecule spatial technology to explore complex cellular responses at unprecedented specificity, sensitivity, and resolution.

PrgmNr 2278 - Translational diagnostics program -TDP-, an innovative intramural approach for hospital-based functional genomics of undiagnosed and rare diseases

Author Block: **F. Palau**[1,2,3,4], J. Pijuan[2], M. Rodriguez-Sanz[2], A. Altisent-Huguet[2], M. Roldan[1], J. Armstrong[1], D. Yubero[1], J. Maynou[1], L. Cantarero[3], G. Fernandez[1], J. Hoenicka[2]; [1]Hosp. Sant Joan de DÃ©u, Barcelona, Spain, [2]Inst. de Recerca Sant Joan de DÃ©u, Barcelona, Spain, [3]CIBER de Enfermedades Raras (CIBERER), ISCIII, Barcelona, Spain, [4]Hosp. ClÃnic and Univ. of Barcelona, Barcelona, Spain

Disclosure Block: **F. Palau:** None.

INTRODUCTION: For the best management and treatment of patients with undiagnosed and rare diseases (URDs), it is necessary to innovate in the diagnostic process. In a significant number of patients, genome sequencing has increased the rate of diagnosis of URDs, but it also detects genetic variants of unknown clinical significance (VUS) or inconsistent with the phenotype. To assist physicians in the variant classification concerning patient's phenotype we have developed the in-house Translational Diagnostics Program (TDP)[1]. OBJECTIVES: To validate for diagnosis variants that are classified as a VUS or novel phenotype-genotype correlation using the holistic approach â□□precision phenotyping - clinical genomics - functional genomics - team decision-makingâ□□. RESULTS: Between 2017 and 2020, we conducted 4,149 clinical exome sequencing studies at the Department of Genetic Medicine at SJD Children's Hospital. The genetic diagnosis was achieved in 1,360 patients (33%) and in 717 (17%) we detected genetic variants classified as VUS following the ACMG/AMP standards and guidelines. To address functional studies of a VUS or a phenotype-genotype incongruity we applied the TDP pipeline that includes: (1) a comprehensive evaluation of the phenotype, including HPOs; (2) *in silico* analysis of the pathogenicity of the candidate genetic variant/s; (3) functional validation of the variant by examine the encoded protein using molecular and cellular assays, and comparative computational analysis of confocal microscopy images; (4) diagnostic decision-making with referring physicians. Currently, 51 patients have been included in the TDP for biological validation of the candidate genetic variant/s. Most patients are affected by neurological diseases such as neuromuscular, neurodevelopmental (mainly syndromic), or epileptic disorders. We confirmed in 27 out of 51 patients a deleterious impact of the VUS upon the location/function of the encoded protein. Of the remaining patients, in 5 cases the variant had no functional impact on the coded product, 13 are under study, and 5 are still under discussion. CONCLUSIONS: The genetic diagnosis of URD patients requires the promotion and implementation of intramural functional genomics/diagnostics programs to support and resolve medical problems when the patient's variant is uncertain or inconsistent with the phenotype. The TDP is a strong in-house tool to fill the gap between clinical phenotype and genotype. [1]Pijuan et al. J Mol Diagn 2021, doi:10.1016/j.jmoldx.2020.10.006. Automation solutions can significantly improve sample processing efficiency and can be of particular help in core facility settings. Centralized core facilities are being established world-wide with the aim at strengthening institutionsâ clinical and research enterprises and at addressing the need to process large volumes of samples on expensive cutting-edge technologies in a limited time. High-throughput qPCR profiling is a service offered by most genomics facilities. Several platforms have been developed to process large numbers of samples in a short time, including the Fluidigm Biomark HD. Several automation systems are currently available to miniaturise volumes and improve bioanalytical workflows, including the SPT Labtech Mosquito HV system. Here we applied the Mosquito HV platform for the automation of the sample preparation of the Fluidigm gene expression workflow. We successfully automated the pre-amplification and exonuclease cleanup steps with the aim at reducing manual error and sample processing time. We show consistency in the expression of house-keeping genes when assessing pooled RNA control samples for the manual and automated workflow of Fluidigm gene expression profiling.

PrgmNr 2280 - An integrated pipeline for genome analysis and phenotype-based gene prioritization with GenDiseak

Genetic examination through next-generation sequencing has been integrated into routine clinical practice in the modern era. However, to interpret the most relevant genetic variations through whole genome or exome sequencing remains a significant challenge for most clinical utilities in terms of bioinformatics analysis capacity. To accelerate the process of molecular diagnostics and reduce the turnaround time, we developed GenDiseak, a cloud-based genetic disease diagnosis platform. GenDiseak provides an end-to-end (from fastq to causative variants) solution for the application of clinical genetics on a single sample and family-based samples. GenDiseak has built multiple variant analysis and interpretation strategies for diseases with a comprehensive phenotype-gene association from different resources. First, we curated the widely-used databases, including ClinVar and PanelAPP, which help rapidly identify causal genes associated with particular phenotypes. Second, we employed state-of-the-art deep learning techniques in natural language processing to annotate the associations between phenotypes and genes on the same sentences from the full text of medical literature using a Transformer model automatically. We further used dNorm to normalize phenotype entities into the Medical Subject Headings (MeSH) ID in order to match the gene-phenotype pairs. Therefore, users could also input free text of phenotypic descriptions for patients without diagnosed diseases to prioritize a gene list based on their genome sequencing data. In summary, GenDiseak is an innovative tool for the automatic genome analysis and prioritization of phenotype-based gene panels. It thus facilitates and accelerates the variant interpretation in clinical genetics practices.

PrgmNr 2281 - Implementation of heart disease-associated cellular heterogeneity in vivo with Gene-Disease Integrative Systems Transgenesis (GENISYST) and Molecular Cartography

View session detail

Author Block: **N. Kashikar**[1], B. Nilges[1], J. Maxeiner[2], D. Stefanoska[2], J. Kaur[3], A. Bogdoll[1], J. Krishnan[3,2]; [1]Resolve BioSci. GmbH, Monheim am Rhein, Germany, [2]Genome Biologics, Kronberg im Taunus, Germany, [3]Inst. for Cardiovascular Regeneration, Ctr. for Molecular Med., Goethe Univ., Frankfurt am Main, Germany
Disclosure Block: **N. Kashikar:** Salary/Employment; Resolve BioSciences GmbH.
Spatial tissue population heterogeneity in disease arises due to cellular evolution culminating in the establishment of cellular subpopulations with molecular and phenotypic variations - leading to differential drug and therapeutic responses. Although best established in the cancer paradigm, the impact of disease heterogeneity in non-neoplastic disease has similarly been observed in cardiovascular, metabolic and neurodegenerative indications. However, current transgenic methodologies are not able to facilitate the establishment of complex heterogeneity patterns in vivo. This inability to mimic human disease heterogeneity in animal models is a stumbling block for precision pre-clinical disease modeling in target and therapeutics validation. To overcome these limitations, we have developed a novel methodology enabling the implementation of complex disease heterogeneity patterns through combinatorial transduction of modular genetic units to drive gene-specific loss-of-function (LOF). In analyzing heterogeneity patterns in human diseased myocardium, we identified LOF of Hif1a, Atp5a1, Syt17, Smg1, Mthfd1 and Mthfd1l in distinct subpopulations of cardiomyocytes. We utilized GENISYST to implement these heterogeneity patterns in mouse myocardium and validated them with Molecular Cartography (MC) technology. MC is a novel imaging-based combinatorial single-molecule fluorescent in situ hybridization technology. We detected and quantified the expression of 100 mRNA species at subcellular resolution at high sensitivity and specificity in different layers of the mouse heart with MC. Analysis of hundreds of single mRNA molecules per cell yielded detailed information on the spatial distribution of cardiomyocyte subtypes and their transcriptomic states in the context of their location in the tissue and relative to other cell types. The high sensitivity allowed for the detection of underrepresented transcripts and their cell specificity; potentially serving them as useful drug targets for cell-specific therapeutics. In summary, MC accurately defined the spatial heterogeneity patterning imposed on cardiac subpopulations by GENISYST in native myocardium for the first time.

PrgmNr 2282 - scDetect: A rank-based ensemble learning algorithm for cell type identification of single-cell RNA sequencing in cancer

View session detail

Author Block: **Y. Shen**; Zhejiang Univ., Hangzhou, China
Disclosure Block: **Y. Shen:** None.
Motivation Single-cell RNA sequencing (scRNA-seq) has enabled the characterization of different cell types in many tissues and tumor samples. Cell type identification is essential for single-cell RNA profiling, currently transforming the life sciences. Often, this is achieved by searching for combinations of genes that have previously been implicated as being cell-type specific, an approach that is not quantitative and does not explicitly take advantage of other scRNA-seq studies. Batch effects and different data platforms greatly decrease the predictive performance in inter-laboratory and different data type validation. **Results** Here, we present a new ensemble learning method named as â□□scDetectâ□□ that combines gene expression rank-based analysis and a majority vote ensemble machine-learning probability-based prediction method capable of highly accurate classification of cells based on scRNA-seq data by different sequencing platforms. Because of tumor heterogeneity, in order to accurately predict tumor cells in the single cell RNA-seq data, we have also incorporated cell copy number variation consensus clustering and epithelial score in the classification. We applied scDetect to scRNA-seq data from pancreatic tissue, mononuclear cells, and tumor biopsies cells and show that scDetect classified individual cells with high accuracy and better than other publicly available tools. **Availability** scDetect is an open source software. Source code and test data is freely available from Github (https://github.com/IVDgenomicslab/scDetect/) and Zenodo (https://zenodo.org/record/4764132#.YKCOlrH5AYN). The examples and tutorial page is at https://ivdgenomicslab.github.io/scDetect-Introduction/.

PrgmNr 2283 - Allelic and genotypic frequencies of *CYP2C19*2, CYP2C19*3,* and *CYP2C19*17* alleles in the healthy South Indian population and their phenotypic prediction

View session detail

Author Block: **A. Prashant**, A. Yadav, A. Kodakkat, A. Helna, P. Vishwanath, S. Nataraj; Ctr. of Excellence in Molecular Biology & Regenerative Med., Dept. of Biochemistry, JSS Med. Coll., JSS Academy of Higher Ed. and Res., Mysuru, India
Disclosure Block: **A. Prashant:** None.
Introduction: Pharmacogenomics and pharmacogenetics of *CYP2C19* help to select appropriate medication to avoid toxicity and to determine proper drug dosage regimen based on an individual's genotype. The allelic study of *CYP2C19* plays a vital role in drug therapy and research and it is important to investigate the implications of various alleles on drug metabolism to avoid adverse drug reactions. This study measures the allelic frequencies of *CYP2C19* (*2, *3 and *17) alleles in the general population. Methodology: The study involved 300 healthy subjects between the age group of 15-85 years recruited by simple random sampling from areas in and around Mysuru, South India. Allele-specific touch-down PCR was employed for genotyping. The allelic and genotypic frequencies were calculated and were checked for Hardy-Weinberg equilibrium, the phenotypic prediction of ultra-rapid metabolizer (UM = *17/*17), extensive metabolizer (EM = *1/*17, *1/*1), intermediate metabolizer (IM = *1/*2, *1/*3, *2/*17) and poor metabolizer (PM = *2/*2, *2/*3, *3/*3) was made based on their genotype. Results: The allele frequency of *CYP2C19*2, CYP2C19*3,* and *CYP2C19*17* was 0.365, 0.0033, and 0.18 respectively. The IM phenotype predominated with an overall frequency of 46.67% including 101 subjects with *1/*1, 2 subjects with *1/*3, and 37 subjects with *2/*17 genotype. This was followed by EM phenotype with an overall frequency of 35% including 35 subjects with *1/*17 and 70 subjects with *1/*1 genotype. PM phenotype had an overall frequency of 12.67% including 38 subjects with *2/*2 genotype and UM phenotype had an overall frequency of 5.67% including 17 subjects with *17/*17 genotype. Conclusion: In view of the high frequency of PM in the South Indian population a pre-treatment test to identify the genotype of the individual may be recommended to decide on the dosage and monitor the drug response and avoid adverse drug reactions.

PrgmNr 2284 - Assessment of cytochrome P450 polymorphism for personalized therapy in acute coronary syndrome

View session detail

Author Block: **R. Frikha**, H. Ghozzi; Univ. Hosp., Sfax, Tunisia
Disclosure Block: **R. Frikha:** None.
The cytochrome P450 (CYP) 2C19 isoenzyme plays an important role in clopidogrel metabolization. CYP2C19*17, the c.C806T, is a recently reported variant causing ultra-rapid metabolism of CYP2C19 substrates, which may lead to an enhanced platelet response to clopidogrel treatment with an increased risk of bleeding. Molecular diagnostic testing for this polymorphism is widespread and needs to be standardized. 13 patients with acute coronary syndrome undergoing coronary intervention after pretreatment with clopidogrel were enrolled in this study. Genotyping was performed with a specific PCR-RFLP. 2 patients were heterozygous (CT806) and 1 patient was homozygous (CC806) for variant C806T of CYP2C19*17 with an overall frequency of 23%. A particular history of bleeding risk and high on-treatment reactivity to clopidogrel were recorded in these patients. Genotyping of CYP2C19*17 variant, the c.C806T, prior to clopidogrel treatment is likely to be useful in order to personalize therapy.

PrgmNr 2285 - Association between HLA-DRB1*15:01 and DQA1*01:02 frequencies and Lumiracoxib-induced DILI in healthy Thai Population

View session detail

Author Block: **P. Chokpitakkul**[1], P. Satapornpong[2]; [1]Shrewsbury Intl. Sch. Riverside Bangkok, Bangkok, Thailand, [2]The division of general pharmacy practice, Dept. of pharmaceutical care, Coll. of Pharmacy, Rangsit Univ., Pathum Thani, Thailand
Disclosure Block: **P. Chokpitakkul:** None.
Introduction:Lumiracoxib is used mainly for symptomatic treatment of osteoarthritis and acute pain in patients. However, lumiracoxib is responsible for drug induced liver injury (DILI) and can cause serious life threatening outcomes. We found the genetic markers predictive of lumiracoxib-related hepatotoxicity in Europeans, consisting of HLA-DRB1*15:01 (P=6.8x10-25, OR 7.5 and 95% CI = 5.0-11.3) and HLA-DQA1*01:02 from genome-wide studies. Objectives: The aim of this study was to evaluate the distribution of HLA-DRB1*15:01 and HLA-DQA1*01:02 associated with pharmacogenetics markers of lumiracoxib-induced DILI for screening in Thai population.Materials and Methods:200 participants were recruited from a healthy Thai population. HLA class II alleles were genotyped using sequence-specific oligonucleotides. Results:Our data revealed 41 alleles of the HLA-DRB1*15:01 (10.25%) and 98 alleles of the HLA-DQA1*01:02 (24.50%) in the Thai population. We founded the most allele frequencies are HLA-DRB1*15:02 (15.25%), -12:02 (14.25%), -15:01 (10.25%), -09:01 (8.75%), and -16:02 (7.50%). Furthermore, HLA-DQA1*01:01 (27.75%), -01:02 (24.50%), -03:02 (13.00%), -06:01 (10.25%), and -02:01 (4.50%) in Thais. Conclusion:To conclude, instead of completely withdrawing Lumiracoxib from treatments, it is advisory to screen for the pharmacogenetics markers of HLA-DRB1*15:01 and HLA-DQA1*01:02 alleles in Thai patients for the purpose of avoiding DILI.

PrgmNr 2286 - Association of a single nucleotide polymorphism rs12496846 in the *C3orf20* gene region, identified to be associated with postoperative analgesia after mandibular sagittal split ramus osteotomy, with postoperative analgesia after major abdominal surgery

View session detail

Author Block: **D. Nishizawa**[1], M. Nagashima[2], S. Kasai[1], J. Hasegawa[1], K. Nakayama[1], Y. Ebata[1], M. Hayashida[1,3,4], K. Ikeda[1]; [1]Tokyo Metropolitan Inst. of Med. Sci., Tokyo, Japan, [2]Toho Univ. Sakura Med. Ctr., Sakura, Japan, [3]Saitama Med. Univ. Intl. Med. Ctr., Saitama, Japan, [4]Juntendo Univ. Sch. of Med., Tokyo, Japan
Disclosure Block: **D. Nishizawa:** None.
Purpose: Opioids are commonly used as effective analgesics for the treatment of acute and chronic pain. However, considerable individual differences have been widely observed in sensitivity to opioids. To explore polymorphisms responsible for the inter-subject difference in the opiate sensitivity, we performed an association analysis focusing on rs12496846 single-nucleotide polymorphism (SNP) in the *C3orf20* gene region, which was identified to be associated with postoperative analgesia after mandibular sagittal split ramus osteotomy, to investigate an association of this SNP with postoperative analgesia after major abdominal surgery. **Methods**: The subjects in the association study were a total of 112 patients with written informed consent who underwent major open abdominal surgery in hospitals and were treated with analgesics including opioids after surgery. The study protocol was approved by the Institutional Review Board at each related institute. Total genomic DNA was extracted from peripheral blood or oral mucosa samples by standard procedures and used for genotyping. TaqMan(R) SNP Genotyping Assays was conducted for genotyping the rs12496846 SNP. Further, effect of the SNP on the *C3orf20* gene expression was investigated with RNA and DNA samples offered by Stanley Foundation Brain Bank. **Results**: In an association study in patients undergoing major open abdominal surgery, carrying G alleles in the rs12496846 SNP was found to be significantly associated with increased postoperative 24-h analgesic requirements, as was observed in the previous study in patients undergoing mandibular sagittal split ramus osteotomy (pC3orf20 gene (pConclusions: The results indicate that this SNP could serve as a marker that predict increased analgesic requirements. Our findings will provide valuable information for achieving satisfactory pain control and open new avenues for personalized pain treatment.

PrgmNr 2287 - Comprehensive analysis of the genetics of clozapine-induced adverse effects

View session detail

Author Block: **J. Partanen**[1], M. LÃ¤hteenvuo[2], H. Taipale[2,3], A. Hellsten[4], M. J. Daly[5,1], A. Palotie[5,1], S. Ripatti[1], J. Koskela[1], FinnGen; [1]Inst. for Molecular Med. Finland FIMM, Helsinki, Finland, [2]Dept. of Forensic Psychiatry, Univ. of Eastern Finland, Niuvanniemi Hosp., Kuopio, Finland, [3]Dept. of Clinical NeuroSci., Div. of Insurance Med., Karolinska Inst.t, Stockholm, Sweden, [4]Univ. of Helsinki, Helsinki, Finland, [5]Massachusetts Gen. Hosp., Boston, MA
Disclosure Block: **J. Partanen:** None.
Clozapine is the most effective antipsychotic drug and the only drug available for treatment-resistant schizophrenia (SCZ). Clozapine discontinuation is avoided because of the lack of effective alternatives and potential attenuation of effect at reinitiation. Several adverse effects, some of which are life-threatening, substantially hinder clozapine use, as around 20% of patients discontinue treatment due to them. The genetics of these adverse effects remain largely undiscovered as only agranulocytosis and myocarditis have been studied genome-wide.

We studied the genetics of clozapine-induced adverse effects at scale in the FinnGen biobank study (n = 321,300), including the SUPER cohort of 8,833 patients diagnosed with psychotic illnesses. First, we identified adverse effects by exploring which of 4,131 endpoints were enriched in 2,659 SCZ patients with clozapine purchases compared to 3,628 SCZ patients without, using logistic regression adjusting for age and sex and limiting to incident cases after clozapine initiation or SCZ diagnosis. Second, we studied the genetics of these adverse effects using GWAS comparing incident cases in clozapine users to controls in long-term clozapine users using SAIGE adjusting for age, sex and ten first principal components.

Enriched endpoints (FDR-adjusted p Preliminary GWAS suggested a genome-wide significant association for pneumonia after clozapine initiation at chr13 (intergenic rs1925750(A>G), AF = 66%, p = 4.6E-8, OR = 0.68) in proximity to *PCDH9* previously associated with drug response and a number of psychiatric phenotypes. Further, at chr4 intergenic rs11727255(C>T) (AF = 19%, p = 7.5E-7, OR = 0.66) was associated with adverse drug events and drug allergies in the UKBB (p = 2.6E-4, OR = 0.79).

While GWAS in other endpoints analyzed did not reach genome-wide significance, they included a number of suggestive signals in high LD with Finnish enriched coding variants, in genes involved in drug metabolism, and near previously reported drug-related phenotype associations. All GWAS will be updated to the newest data release.

Our study elucidates trajectories of clozapine treatment and aims to identify genetic determinants of adverse effects related to clozapine, facilitating the progress toward safer use of the most effective antipsychotic in the future.

PrgmNr 2288 - CYP2D6 genetic variants and their metabolic efficacy - insight from Molecular Dynamics Simulations

View session detail

Author Block: **D. Kotzampasi**[1], A. Kanterakis[2], V. Daskalakis[3], G. Potamias[2]; [1]Sch. of Med., Univ. of Crete, Heraklion Crete, Greece, [2]Fndn. for Res. and Technology - Hellas, Heraklion Crete, Greece, [3]Cyprus Univ. of Technology, Limassol, Cyprus
Disclosure Block: **D. Kotzampasi:** None.
Cytochrome P450s is an enzyme superfamily of hemoglobin, responsible for metabolizing more than 90% of clinical drugs. One of the most significant enzymes in this family, Cytochrome P450 2D6 (CYP2D6), metabolizes approximately 25% of the clinically used drugs including crucial and commonly administered drugs such as antidepressants, chemotherapeutics, beta-blockers and opioids. Variations in CYP2D6, a highly polymorphic loci in the genome, could alter its activity influencing the efficacy and toxicity of numerous drugs. More than 100 haplotypes (star alleles) of the drug metabolizing enzyme CYP2D6 have been reported in the Pharmacogene Variation Consortium (PharmVar, www.pharmvar.org), resulting in wide intraindividual variability in drug metabolism activity and changes of the drug plasma concentration. The complete connecting link between the genetic variants and the metabolizer phenotype is still an open and challenging question. Our main objective was to investigate the key factors that determine the metabolizer phenotype by exploiting and appropriately employing molecular dynamics (MD) methods. MD is an elaborate computational method that enables the prediction of the time evolution of atomic positions within interacting systems of molecules. To this end, we have probed the dynamics of numerous CYP2D6 variants, as enzyme models with normal and no function, at an all-atom resolution. With this approach we aimed at filling-in the gaps of missing information and provide a series of analyses, crucial for the prediction of the metabolizer phenotype of CYP2D6. Results are of great importance for areas like Personalized Medicine, Adverse Drug Reaction (ADR) prediction and drug discovery.

PrgmNr 2289 - Distribution of *HLA-B*13:01* allele related with dapsone-induced severe cutaneous adverse reaction in Thai and Asian population

View session detail

Author Block: **M. Leelakajonjit**[1], A. Srisodsai[2], P. Satapornpong[3]; [1]Satit Pattana secondary school, Bangkok, Thailand, [2]MedCoach Inst., Bangkok, Thailand, Bangkok, Thailand, [3]The division of general pharmacy practice, Dept. of pharmaceutical care, Coll. of Pharmacy, Rangsit Univ., Pathum thani, Thailand

Disclosure Block: **M. Leelakajonjit:** None.

Background:Dapsone is antibiotic and anti-inflammatory which is widely used for treatment such as leprosy. However, dapsone cause severe cutaneous adverse reactions (SCARs) include Stevens-Johnson syndrome (SJS), toxic epidermal necrolysis (TEN) and drug rash with eosinophilia and systemic symptoms (DRESS), approximately 0.5-3.6% of patients treated with dapsone and 9.9% mortality rate. From the previous studies, only *HLA-B*13:01* allele has a strongly association with dapsone-induced SCARs in Asian population. Moreover, the distribution of *HLA* alleles that play important roles in predicting adverse drug reactions in each population.Objective:Thus, this study was to investigate the distribution of *HLA-B*13:01* allele in Thai and Asian population and importance of this pharmacogenetics marker.Materials and Methods:We recruited 200 unrelated healthy Thai individuals in this study. *HLA-B* were genotyped using sequence-specific oligonucleotides (PCR-SSOs).Results:We found *HLA-B* alleles frequencies in Thai population consist of *HLA-B*46:01* (11.75%), *HLA-B*15:02* (9.25%), *HLA-B*13:01* (6.25%), *HLA-B*4001* (6.25%), and *HLA-B*38:02* (5.50%). For *HLA-B*, *HLA-B*46:01* was the predominant allele commonly found in Thais. This study showed that the frequency of *HLA-B*13:01* allele was similar to the previous study in Thai population. Many publications presented varying distributions of *HLA-B*13:01* in Asians including 9.15% of Han Chinese, 6.67% of Japanese and 5.94% of Vietnamese.Conclusion:Therefore, database of pharmacogenomics containing distribution of *HLA-B*13:01* alleles will support the screening of dapsone-induced SCARs in Thai and Asian population.

PrgmNr 2290 - Distribution of *HLA-B*58:01* allele associated with allopurinol-induced SCARs in healthy Thai population

View session detail

Author Block: **S. Jaroenjiengchai**[1], A. Srisodsai[2], P. Satapornpong[3]; [1]Bodindecha (Sing Singheseni), Bangkok, Thailand, [2]MedCoach Inst., Bangkok, Thailand, [3]The division of general pharmacy practice, Dept. of pharmaceutical care, Coll. of Pharmacy, Rangsit Univ., Pathum Thani, Thailand
Disclosure Block: **S. Jaroenjiengchai:** None.
Background: Allopurinol is the most commonly used for treatment in patients with gouty arthritis, hyperuricemia and cancer patients undergoing chemotherapy. However, allopurinol is a major cause of severe cutaneous adverse reactions (SCARs) in Europeans, Asians, and Thais. We found that the *HLA-B*58:01* is associated with allopurinol-induced SCARs including Stevens-Johnson syndrome (SJS), toxic epidermal necrolysis (TEN), and drug reaction with eosinophilia and systemic symptoms (DRESS) in many populations. Furthermore, the frequency of *HLA-B*58:01* allele has interested for the screening among different ethnicities before initiation of treatment.Objective: To study the frequency of *HLA-B*58:01* with Allopurinol-induced SCARs in Thai population.Materials and Methods: 200 general Thai population who had no history of drug-induced SCARs were included in this study. *HLA-B* alleles were genotyped using polymerase chain reaction-sequence-specific oligonucleotides (PCR-SSOs).Results: Among all 200 subjects in Thais, the top five of *HLA-B* alleles consisted of *HLA-B*46:01* (16.00%), *HLA-B*40:01* (8.00%), *HLA-B*15:02* (7.25%), *HLA-B*13:01* (6.50%), and *HLA-B*58:01* (6.25%). Moreover, *HLA-B*58:01* allele was the highest allele in the Asian population approximately 7.38%. On the contrary, we found this allele approximately 1.13% of Caucasians, 1.07% of Hispanics, and 0.80% of North American. Interestingly, *HLA-B*58:01* was the main allele in Thailand and there was found more common in African Americans (6.37%).Conclusion: Our pharmacogenomics database could be used as a screening test for other populations before treatment with allopurinol.

PrgmNr 2291 - Experience and expectations of pharmacogenetic tests in France

Although French genomic medicine is reaching a turning point in its history and the implementation of genome sequencing in routine will be possible by the France genomic medicine 2025 plan (PFMG), many questions remain unanswered. The management of secondary pharmacogenetic information is one of them. Therefore, it is necessary to ascertain the opinion of French healthcare stakeholders on the subject.
We created a 29-question questionnaire on the experiences, attitudes, expectations and knowledge of French-speaking physicians and pharmacists towards pharmacogenetics. We compared the responses in different groups and also determined a knowledge score. We created a prediction model for this score and we determined which factors may influence. All differences between these groups were evaluated using Ï□2 and all factors using multivariate logistic regression.
In our study, 90.4% (n=314) of responders thought PGx tests could be a tool to optimize a patient's drug therapy in the future. Therefore, a large majority of responders (90.4%, n=262) were favorable to the incorporation of PGx recommendations into health computerized systems. Moreover, 63.0% (n=335) thought that pharmacogenetic data should be communicated along with the results of the primary analysis on PFMG results when a pharmacogenetic result could influence a therapeutic prescription. Only 9.7% of responders reached the maximum score on the knowlege test. In our regression model, physicians have a lower chance to have a high score (odd ratio: 0.081, pDuring this work we were able to compare the results of a French study with work carried out in other countries. American, Dutch, Canadian and Flemish studies also show similar results. Similarly, Flemish pharmacists achieve higher knowledge scores compared to Flemish physicians.[1] Education is requested by physicians on the topic.
1. Edris A, Vanoverschelde A, Bushaj P, Van Nieuwerburgh F, Lahousse L. Pharmacogenetics in clinical practice: current level of knowledge among Flemish physicians and pharmacists. Pharmacogenomics J. fÃ©vr 2021;21(1):78-84.

PrgmNr 2292 - Integration of genetically regulated gene expression and pharmacological library provides therapeutic drug candidates

Author Block: **T. Konuma**[1], K. Ogawa[2], Y. Okada[3]; [1]Central Pharmaceutical Res. Inst., JAPAN TOBACCO INC., Takatsuki, Osaka, Japan, [2]Osaka Univ. Graduate Sch. of Med., Suita, Japan, [3]Dept. of Statistical Genetics, Osaka Univ. Graduate Sch. of Med., Suita, Osaka, Japan
Disclosure Block: **T. Konuma:** None.
Since recent studies have shown that drug development projects whose drug targets were supported by human genome information improved these success probability, human genomics-led approaches for drug development have been anticipated. Genomic loci associated with human complex diseases identified by genome-wide association studies (GWASs) are promising genomic information for insights of new therapeutics. Transcriptome-wide association study (TWAS), which predict genetically-regulated gene expression (GREx) by integrating GWAS and expression quantitative trait loci, is one of powerful methods for yielding functional insights into disease susceptibility. We have hypothesized that compounds which have inverse effects in gene expression profiles when compared to GREx from common diseases could be detected as potential drug candidates effective for disease treatment. Here, we constructed the GWAS-TWAS-compound library integration pipeline software (Trans-Phar; integration of Transcriptome-wide association study and pharmacological database) (Konuma T. et al., *Human Molelucar Genetics* 2021). This software conducts *in silico* screening of the compounds from a large-scale pharmacological database, the CMap L1000 library, which have an inverse correlation with GREx estimated from the inputted GWAS summary statistics. Trans-Phar incorporates thirteen tissue or cell-type categories, which we assigned based on the 29 Genotype-Tissue Expression (GTEx) tissues used in TWAS and 77 cell types from the CMap L1000 library database, so that Trans-Phar can detect compounds on a broad scale that affect tissue or cell-type category-specific manners. We applied Trans-Phar to GWAS summary statistics of large-scale European meta-analysis (17 traits; $n_{average}$ = 201,849). As top-associated compounds, anisomycin (FDR-q = 0.056), followed by proscillaridin (Na^+/K^+-ATPase inhibitor) (FDR-q = 0.138) and digoxin (Na^+/K^+-ATPase inhibitor) (FDR-q = 0.138) in central nervous system category in schizophrenia were detected and mechanism of actions of these compounds are likely involved in pathophysiology of schizophrenia. In summary, Trans-Phar successfully identified promising drug target candidates with implications on cell-type-specific pathophysiology of the diseases.

PrgmNr 2293 - Pharmacogenomics Marker of *HLA-A*33:01* Allele Frequency in Healthy Thais

View session detail

Author Block: **N. Chitthiang**[1], A. Srisodsai[2], P. Satapornpong[3]; [1]Singapore Intl. Sch. of Bangkok, Bangkok, Thailand, [2]MedCoach Inst., Bangkok, Thailand, [3]Div. of general pharmacy practice, Dept. of pharmaceutical care, Coll. of Pharmacy, Rangsit Univ., Pathum Thani, Thailand
Disclosure Block: **N. Chitthiang:** None.
IntroductionTerbinafine is an antifungal medication. However, terbinafine has been associated with drug induced liver injury (DILI). Genome-wide association study had shown significant correlations between terbinafine-induced DILI, and HLA-A*33:01 gene (OR=2.6, 95% CI=1.8-3.7, and p-value = 7.0Ã□10â□□8) in Europeans. Interestingly, the distribution of pharmacogenetics markers in each population might differ. ObjectiveThis study aims to investigate the distribution of HLA-A*33:01 gene related to terbinafine-induced DILI in the healthy Thai population. Materials and Methods200 healthy Thais were enrolled in this study who have lived in the area for more than three generations. HLA class I alleles were genotyped by using polymerase chain reaction-sequence specific oligonucleotides (PCR-SSOs). ResultsA total of 33 *HLA-A* alleles were found. Ranked by their frequencies, top 10 were HLA-A*11:01 (27.50%), HLA-A*24:02 (11.50%), HLA-A*02:03 (11.00%), HLA-A*33:03 (10.75%), HLA-A*02:07 (7.50%), HLA-A*02:01 (4.75%), HLA-A*24:07 (4.50%), HLA-A*01:01 and HLA-A*30:01 (2.75%), HLA-A*11:02 and HLA-A*24:10 (2.00%), and HLA-A*02:06 (1.75%). HLA-A*33:01â□□s frequency was 0.25% in the healthy Thai population, while it was 2.95% of Israel, 1.92% of Han Chinese, 1.8% of Brazil, 1.7% of Columbia, 1.1% of Germany, and 0.6% of India. ConclusionThe frequency of HLA-A*33:01 could be used for pharmacogenetics screening before initiation of terbinafine treatment, in order to avoid terbinafine-induced DILI.

Efficient screening of novel therapeutic targets is an essential process of drug discovery. Disease risk genes by GWAS are promising resources for *in silico* screening. Disease risk genes are known to be enriched in the targets of the drugs approved for the treatment of the diseases themselves, which motivates genomics-driven drug repositioning. However, there does not exist practical guidelines of how to conduct genomics-driven drug discovery, especially for the large-scale GWAS meta-analysis of multiple ancestries. Here, we introduce practical guidelines, as lessons from cross-population GWAS meta-analysis results of a set of common diseases from Global Biobank Meta-analysis Initiative (GBMI). Our framework consists of two parts. (i) Overlap enrichment of disease risk genes with targets of existing drugs. We translate variant-based GWAS p-values into gene-based p-values (e.g., MAGMA). After functional prioritization of biological genes (e.g., DEPICT & Pi), we quantified enrichment of disease risk genes with drug targets, according to disease classification such as WHO ATC and ICD10 codes, using GREP (Sakaue S. *Bioinformatics* 2019). (ii) Integrative approach to screen negative correlations between genetically-determined and compound-regulated case-control gene expression profiles (e.g., tissue-specific TWAS results and the CMAP L1000 database, respectively), using Trans-Phar (Konuma T. *Hum Mol Genet* 2021). We applied our framework to the GBMI GWAS results of 14 phenotypes, which provided a list of candidate drugs for repositioning. In particular, we observed drug target enrichment in asthma, gout, venous thromboembolism (VTE) GWAS. Biological gene prioritization can improve tissue-specificity enrichment and overlap with drug targets, while the choice of prioritization methodologies can induce trends not equally among tissue and drug indication categories. Per-variant effective sample sizes vary strikingly among genome-wide variants in cross-population meta-analysis (only 21.3% of the variants satisfied >50% of effective sample sizes compared to the total ones). We found that this issue can confound biological gene prioritizations, and recommend to restrict the variants to those with more effective sample sizes than the pre-defined threshold. Our work provides the best practices for genomics-driven drug discovery in the era of global biobank collaboration.

PrgmNr 2295 - The frequency of *HLA-B*57:01* allele in healthy Thai population

View session detail

Author Block: **P. Samphatcharoen**[1], A. Srisodsai[2], P. Satapornpong[3]; [1]Chiangmai Univ. Demonstration Sch., Chiangmai, Thailand, [2]MedCoach Inst., Bangkok, Thailand, [3]3.The division of general pharmacy practice, Dept. of pharmaceutical care, Coll. of Pharmacy, Rangsit Univ., Pathum Thani, Thailand

Disclosure Block: **P. Samphatcharoen:** None.

IntroductionsAbacavir hypersensitivity reactions (AHR) are a life-threatening drug reaction and develop in approximately 5-8% of patients receiving abacavir and usually occur between the 6 weeks after initiation treatment. Previous studies showed that the *HLA-B*57:01* allele is strongly associated with abacavir hypersensitivity reactions. Objective This study aimed to investigate the frequency of *HLA-B*57:01* in the healthy Thai population. MethodsWe enrolled 200 healthy Thais and *HLA-B* alleles were genotyped with sequence-specific oligonucleotides (PCR-SSOs).ResultsThis study we found a total of 53 alleles for *HLA-B* genotyping. The most of *HLA-B* alleles in Thais including of HLA-B*46:01 (14.25%), HLA-B*58:01 (6.5%), HLA-B*40:01 (6.25%), *HLA-B*13:01* (5.5%), *HLA-B*44:03* (4.5%), *HLA-B*15:02* (4.5%), *HLA-B*38:02* (4.5%), *HLA-B*44:06* (3.75%), *HLA-B*51:01* (3.75%) and *HLA-B*52:01* (3.25%). Additionally, the allele distribution of *HLA-B*57:01* was 1.75% in Thai population. On the contrary, *HLA-B*57:01* allele was found more commonly in 5.00% of Costa Rica, 4.70% of Chile, 3.15% of East Croatia and 3.30% of China.ConclusionTherefore, the distribution of *HLA-B*57:01* was pharmacogenomics marker, which could be used a screening AHR for all ethnicities.

PrgmNr 2296 - Association between relative telomere length in umbilical cord tissue and PCB congeners in maternal blood and cord blood in a birth cohort in Chiba, Japan

View session detail

Author Block: **T. Takahashi**[1], A. Eguchi[2], M. Watanabe[2], E. Todaka[3], K. Sakurai[4], C. Mori[2,5]; [1]Dept. of Environmental Preventive Med. According to the Developmental Origins of Health and Disease hypothesis, fetal exposure to environmental pollutants during pregnancy increases the risk of non-communicable diseases such as obesity, diabetes, and mental disorder in later life. Environmental exposure to persistent organic pollutants such as polychlorinated biphenyls (PCBs) during pregnancy has been reported to affect the health of the fetuses adversely. Telomere is a highly conserved repetitive DNA sequence. It is currently considered a biomarker for aging. As the telomere has been reported to be affected by exposure to chemical substances, stress, and diseases, it is possible to be used as a biomarker to evaluate health risks by fetal exposure to environmental pollutants. To elucidate the effects of fetal exposure to PCBs, we examined the relationship between maternal and cord blood PCB levels and the umbilical cord telomere length (TL). Our study participants comprised 114 mother-child pairs who had participated in the Chiba Study of Mother and Child Health birth cohort. Maternal blood during pregnancy, cord blood, and umbilical cords at birth were collected at a hospital in Chiba Prefecture, Japan. We extracted genomic DNA from the umbilical cord tissue to measure the TL. Quantitative PCR was used to assess the TL for quantitatively measure the repeat sequence. TL is defined as the ratio of the quantity of the amplicon for the telomere region to the single-copy region of the human Î²-globin (hbg) gene, and is expressed by the formula TL=Telomere / hbg. Serum concentrations of PCB congeners were analyzed using gas chromatography-quadrupole mass spectrometry. We detected 16 and 5 PCB congeners in maternal and cord serum, respectively. We found an association between cord serum PCB levels and TL in the cord tissues of the male fetuses, and the association was significant than between maternal serum PCB levels and TL in the cord tissues. It was also found that among the five congeners detected in cord serum, only PCB74 showed a significant positive association with TL in the cord tissues of the male fetuses. These associations were not found in the female fetuses. As TL could be a biomarker to screen PCB74 exposed male fetuses, further investigation regarding the relationship between PCBs and TL, health effects of PCB74, and the mechanism of the effect difference between the two sexes should be studied.

PrgmNr 2297 - Distinct roles of ADAM10 and ADAM17 for testicular germ cell apoptosis

View session detail

Disclosure Block: **O. Aydos:** None.
Introduction: Germ cells apoptosis during spermatogenesis is a key process to control germ cell maturation and eliminate damaged or unwanted cells. An increase or decrease in the rate of apoptosis can cause defective consequences and lead to azoospermia. The ADAMs, family of transmembrane proteins play an important role in different processes such as cell death, differentiation and migration. ADAM17 and ADAM10 are two members of this family, involved in germ cell apoptosis during spermatogenesis. In this study, our aim was to investigate the role of *ADAM10* and *ADAM17* genes in non-obstructive azoospermia (NOA) etiology. **Materials and methods:** Fold changes in expression levels of *ADAM10* and *ADAM17* were determined by quantitative PCR in NOA (n = 10) patients and obstructive azoospermia (OA) (n = 2) as control cases. Testicular tissue samples were taken during microTESE attempt and testicular biopsy was performed for histopathological evaluation. **Results:** Quantitative PCR results showed a significant decrease and increase in mRNA levels of *ADAM10* and *ADAM17* by 0.23Â± 0.11 (pConclusion: Activation of *ADAM10* could release the extracellular domain of FasL and hinders its binding to Fas in germ cells. Shedding of the extracellular domain of c-kit by *ADAM17* inhibits survival signals of germ cells, leading them to apoptosis. In our study, low expression of *ADAM10* and high expression of *ADAM17* suggest that the germ cells may be directed to apoptosis. This is important for understanding the etiology of NOA. Further studies in larger groups, including protein analysis, are required to clarify the role of *ADAM10* and *ADAM17* in male fertility.

Background: Despite frequent updates in guidelines, classification of copy number variants (CNVs) by different clinical laboratories is inconsistent. Studies exploring the factors affecting clinical decision making are rare, especially in the prenatal setting. The objective of our study was to shed light on these factors, using a 'virtual fetus' model. Methods: Ten prenatally diagnosed CNVs of unknown significance larger than 1 Mb, encompassing OMIM-morbid genes and inherited from a healthy parent (five duplications and five deletions), were independently classified by 15 medical geneticists from five genetic centers. In each referral center, three senior MD specialists were selected, all experienced in CNV classification, representing clinical laboratory, prenatal medicine, and preimplantation genetic testing (PGT) units. Specific points addressed included independent CNV classification, the obligation to report to the parents, recommendation for invasive testing or PGT in future pregnancies, and the relevance of various clinical factors (phenotype and gender of family members carrying CNV, patient request to report any finding, ethnic background, obstetric history, and maternal age) for classification and reporting. Results: The agreement upon classification of various CNVs ranged between 57% to 100%; and was higher for duplications vs. deletions (87% vs. 72%, p=0.013). 84% of the geneticists would report the findings to the parents (92% vs. 76% for deletions and duplications, respectively, p

PrgmNr 2299 - Genome-wide association analysis implicates dysregulation of Wnt signaling pathway in biliary atresia

View session detail

Author Block: **C. S. Tang**[1,2], W. Y. Lam[1,2], Q. Lin[1], M. M. Garcia-BarcelÃ³[1], P. K. H. Biliary Atresia (BA) is a severe, complex hepatobiliary disorder and is a major cause of neonatal cholestasis. It is characterized by progressive fibrosclerosing and inflammatory obliteration of the biliary system in response to unknown insult during the first few weeks of life. Recent genetic researches revealed several BA-susceptibility loci with common risk alleles predisposing to BA; however, the genetic basis of BA and its underlying disease mechanisms remain largely unexplored. With the aim of identifying novel BA-associated variants, we conducted a meta-analysis of genome-wide association studies (GWAS), including 489 non-syndromic BA cases and 1044 controls of East Asian ancestry. We uncovered two BA-associated loci with low frequency variants marginally associated with BA (*USP34*: $P=2.9x10^{-7}$; OR=3.02 [95% confidence interval(CI): 1.98-4.60] and *PTPRZ1*: $P=7.8x10^{-7}$; OR=2.12 [95% CI: 1.57-2.86]). Both *USP34* and *PTPRZ1* play important roles in Wnt/Î²-catenin signalling and were reported to be dysregulated upon liver injury. Specially, BA patients with liver transplant have three times higher risk allele frequency for the top variant at *USP34* (~11.7%) than controls and the frequency is also higher than those BA patients without transplant. Our results showed that Wnt/Î²-catenin signalling may underlie both the aetiology and progression of BA.

PrgmNr 2300 - Genomic sequencing in critically ill newborn infants shows high diagnostic rate in neurometabolic phenotypes and positive impact on clinical management

Disclosure Block: **H. Suzuki:** None.

Among critically ill newborn infants who are admitted to neonatal intensive care unit, 5-10% have underlying genetic etiologies. Recently, genomic sequencing is increasingly recognized as a powerful diagnostic tool in critical care settings. We performed genomic analysis in critically ill neonates and infants to delineate the diagnostic efficacy of genomic sequencing by primary symptoms that prompted genomic testing and impact on the clinical management.

The study was conducted for 2 years between April 2019 and March 2021. A total of 85 patients were enrolled in this study. The final molecular diagnosis was provided in 41 of 85 subjects (48%). Four subjects had structural variations that were detectable by whole genome analysis. Based on the primary symptoms, metabolic phenotypes yielded the highest diagnostic rate of 67% (4/6 subjects), followed by renal (60%, 3/5 subjects) and neurological phenotypes (58%, 14/24 subjects). In the 41 subjects who were given final molecular diagnosis, 21/41 (51%) had change in the clinical management. New treatment options were identified in 6 subjects. Invasive testing (e.g., muscle biopsy and skin biopsy) were cancelled in 6 patients. Two subjects had critical changes in treatment plan; one had cancellation of organ transplantation and the other started preparation for organ transplantation.

Genomic analysis in critically ill neonates and infants showed high diagnostic rates for metabolic, renal, and neurological phenotypes. At least half of such infants would receive more optimal clinical care if the molecular diagnosis is made. For those who have neurometabolic phenotypes, genomic sequencing is recommended as the first tier of testing because of its high diagnostic yield and positive impact on clinical management.

PrgmNr 2302 - Residual risk for clinically significant copy number variants in pregnancies with normal NIPS

View session detail

Author Block: **L. Sagi-Dain**[1], I. Maya[2], D. Brabbing-Goldstein[2], L. Basel-Salmon[2], L. Salzer[2]; [1]Carmel Med. Ctr., Haifa, Israel, [2]Rabin Med. Ctr., Petach Tikva, Israel
Disclosure Block: **L. Sagi-Dain:** None.
Background: Chromosomal microarray analysis (CMA) is the recommended first-tier in pregnancies with sonographic anomalies, while in low-risk pregnancies this test detects clinically significant copy number variants (CNVs) in about 1%. As the constantly growing wide use of non-invasive prenatal screening (NIPS) facilitates the detection of chromosomal aberrations, defining the residual risk for abnormal CMA following normal NIPS is of importance for informed decisions regarding prenatal testing and screening options. The objective of our study was to shed light on this issue. **Methods:** CMA results of all pregnancies undergoing amniocentesis between the years 2013-2021 in large hospital-based laboratory were collected. Pregnancies with major sonographic anomalies or multiple fetuses were excluded. Clinically significant (pathogenic and likely pathogenic) CNVs were divided into: 3-NIPS-detectable (trisomies 13, 18 and 21), 5-NIPS-detectable (including sex chromosome aberrations), 5-NIPS and common microdeletion-detectable (including 1p36.3-1p36.2, 4p16.3-4p16.2, 5p15.3-5p15.1, 15q11.2-15q13.1, and 22q11.2 deletions), and genome-wide NIPS-detectable (including variants >7Mb). The theoretical residual risk for clinically significant CNVs was calculated following exclusion of NIPS-detectable findings. **Results:** Of the 8,099 pregnancies, clinically significant CNVs were demonstrated in 70 pregnancies (1.4%). The residual risk following theoretically normal NIPS was 1.2% (1/85) for 3-NIPS, 0.92% (1/109) for 5-NIPS, 0.88% (1/113) for 5-NIPS including common microdeletions, and 0.82% (1/122) for genome wide NIPS. In the subgroup of 4,048 pregnancies with advanced maternal age, the residual risk for clinically significant CNVs following theoretically normal NIPS ranged from 1.3% (1/75) for 3-NIPS to 0.8% (1/122) for genome wide NIPS. In 3,187 pregnancies of women younger than 35 years, this residual risk ranged from 0.7% (1/145) for 3-NIPS to 0.5% (1/198) for genome wide NIPS. The residual risk was highest for the 559 pregnancies with abnormal serum screening and 305 pregnancies with soft markers - about 2.2% (1/45) for 3-NIPS and 2.0% (1/50) for genome wide NIPS. **Conclusions:** The residual risk of clinically significant CNVs in pregnancies without structural sonographic anomalies is appreciable, and depends on NIPS extent, maternal age, the results of biochemical screening and presence of soft markers. This knowledge is important for the patients, the obstetricians and the genetic counselors, in order to facilitate informed decisions regarding prenatal testing and screening options.

PrgmNr 2303 - The potential of RNAsequencing for fetal malformation syndromes

View session detail

Author Block: **S. Aggarwal**[1,2], A. BHATTACHERJEE[3], I. Rungsung[2], V. S. Vineeth[2], V. S. Venkatapuram[1], A. Dalal[2]; [1]Nizam's Inst. of Med. Sci., Hyderabad, India, [2]Ctr. for DNA Fingerprinting and Diagnostics, Hyderabad, India, [3]The Ctr. for DNA Fingerprinting and Diagnostics (CDFD), Hyderabad, India

Disclosure Block: **S. Aggarwal:** None.

Objective: To assess the performance of RNA sequencing from cultured amniocytes as an investigative approach to study fetal malformation syndromes. Methods: Four fetuses with prenatal presentation of a fetal malformation syndrome underwent amniocentesis followed by establishment of amniocyte culture. Total RNA was extracted and converted into cDNA libraries further subjected to whole transcriptome sequencing. Paired end RNA-Seq data with 25X coverage was generated using Illumina HiSeq2500 sequencing platform. Good quality reads were processed to aligned to the human reference genome (GRCh37/hg19) using STAR RNA-Seq aligner (version 2.4.0.1). GATK was used to process the bam files to generate the variant call files and these were annotated using ANNOVAR, followed by standard variant filtering protocols. For quantification of transcripts and identification of alternative transcripts, data was analysed using Tuxedo pipeline. In one case, Gfold tool was used to estimate the differential gene expression with respect to a control sample. Standard log2foldchange cut-off was applied to screen the significantly differentially expressed genes in the data set, which was then used for various functional enrichment analysis.Results: The causative pathogenic variants were identified in all four cases from the RNAseq data. These were a homozygous nonsense variant in *NEK1* in a fetus with Short rib thoracic dysplasia type 6, a homozygous nonsense variant in *PLOD2* in a fetus with Bruck syndrome type 2, a homozygous missense variant in *ESCO2* in a fetus with Roberts syndrome and a de-novo heterozygous variant in *COL1A1* in a fetus with Osteogenesis imperfecta type II. The transcript analysis of the respective genes revealed nonsense mediated decay and alternative splicing events in the cases with *NEK1* and *PLOD2* variants, and no transcript abnormality with missense *ESCO2* and *COL1A1* variants. In the case with *NEK1* variant differential gene expression analysis as compared to control revealed insights into the possible downstream effects of the variant on overall transcriptome. Conclusions: RNAsequencing from cultured amniocytes is feasible, contains transcripts from multiple fetal tissues, and can be used to interrogate Mendelian phenotypes. This approach has the potential to identify the underlying putative variant, study the pathogenic potential of the variant as well as the transcriptome wide effect of the variant, thereby providing a window to study pathophysiology of various developmental Mendelian phenotypes.

PrgmNr 2304 - 3DeepMHC : 3D structure based Deep learning model for MHC-peptide binding prediction

View session detail

Author Block: **S. Jang**[1], B. Han*[2]; [1]Seoul Natl. Univ. Coll. of Med., SEOUL, Korea, Republic of, [2]Seoul Natl. Univ. Coll. of Med., Seoul, Korea, Republic of

Disclosure Block: **S. Jang:** None.

Cancer immunotherapy is a new method of treatment that helps the immune system recognize and attack the cancer cells with its own natural defense system. In fact, very few patients respond to this treatment. For immunotherapy to work, the patientâ□□s Major Histocompatibility Complex (MHC) should have the characteristics of combining with neoantigen of cancer. Lately, there have been many deep learning approaches to predicting MHC peptide binding affinity. However, previous methods only take into account the sequences or physicochemical properties, which suggests that they do not reflect the 3D genomic features. We developed the model called 3DeepMHC, which uses the information from the 3D structure of protein binding. Then we compared this 3DeepMHC with traditional deep learning-based methods. Our prediction model suggests the potential of clinical benefit for personalized neoantigen-based cancer immunotherapies more accurately.

PrgmNr 2305 - A 100,000 Genome Project haplotype reference panel of 156,390 haplotypes and the improved imputation of UK Biobank

View session detail

Author Block: **S. Shi**[1], S. Rubinacci[2], S. Hu[3], L. Moutsianas[4], A. Stuckey[4], C. Cabrera[5,6], V. Cipriani[5,6], D. P. Smedley[5,6], M. J. Caulfield[7], S. R. Myers[1], J. L. Marchini[8]; [1]Univ. of Oxford, Oxford, United Kingdom, [2]Univ. of Lausanne, Ecublens, Switzerland, [3]Novo Nordisk Res. Ctr., Oxford, United Kingdom, [4]Genomics England, London, United Kingdom, [5]William Harvey Res. Inst., London, United Kingdom, [6]Queen Mary Univ. of London, London, United Kingdom, [7]Genomics England, Queen Mary, London, United Kingdom, [8]Regeneron Genetics Ctr., Tarrytown, NY
Disclosure Block: **S. Shi:** None.
The Genomics England (GEL) 100,000 genome project has sequenced over 85,000 genomes across England. By using high coverage whole-genome sequencing (WGS), this constitutes the largest human genetic variation resource ever collected in the UK, and represents a near-complete characterization of genetic variation in the population. We generated a GEL haplotype reference panel, comprising 341 million autosomal variants and 156,390 haplotypes from diverse ancestries. We exploit both the sample size and relatedness structure among individuals, 61.3% of whom possess at least one sequenced first-degree relative, to allow high-precision haplotypic phasing.
We used 1000 Genomes WGS data to assess the imputation performance across ancestries, and observe improvements in some populations. In samples of British origin the mean imputation r2 at 0.01% allele frequency is 0.45, 0.67 and 0.74 when using the HRC, TOPMed and GEL reference panel. In samples of South Asian origin the mean imputation r2 at 0.01% allele frequency is 0.04, 0.24 and 0.61 when using the HRC, TOPMed and GEL reference panel.
We used the GEL reference panel to impute the UK Biobank dataset, that was previously imputed at 39 million autosomal variants, using an HRC+UK10K reference panel. It results in a ~6 fold increase in the number of imputed variants. Mean information scores at imputed SNPs, from the GEL and HRC-UK10K reference panels, were 0.65 and 0.61 respectively. At low allele frequencies the differences were larger. For example, for SNPs with allele frequency between 0.01% to 0.1% mean information scores were 0.88 and 0.66 for the GEL and HRC-UK10K reference panels respectively. This translates into an appreciable boost in power to detect associations. The GEL-imputed UK Biobank dataset is being made available to all approved researchers of the UK Biobank.
We will also report results of experiments of examine the implications for fine mapping and burden association tests in the context of imputed GWAS for blood pressure and other traits.

PrgmNr 2306 - A weighted selection probability to locate rare variants associated with highly correlated multiple phenotypes

View session detail

Author Block: **X. Liang**, H. Sun; Dept. of Statistics, Pusan Natl. Univ., Busan, Korea, Republic of
Disclosure Block: **X. Liang:** None.
In the past few decades, many statistical methods have been developed to identify rare variants associated with a complex trait or a disease. Recently, rare variant association studies with multiple phenotypes have drawn a lot of attentions because association signals can be boosted when rare variants truly associated with more than one phenotype. Most of existing statistical methods to identify rare variants associated with multiple phenotypes are based on a group test, where a gene or a genetic region is tested one at a time. However, these methods are not designed to locate individual rare variants within a gene or a genetic region. In this article, we propose a weighted selection probability to locate rare variants associated with highly correlated multiple phenotypes. Once a group-based test identifies the significant association of a group, the proposed method then computes selection probabilities of individual rare variants within the group to prioritize the rare variants. Selection probability represents selection frequency of nonzero regression coefficient in a regularization model using bootstrap sampling. Since the strength of an association vary in phenotypes for susceptible rare variants, selection probability weights can be computed based on a distribution of selection frequency of variants each phenotype. In our simulation study, we demonstrated that the weighted selection probability method outperforms unweighted selection methods in terms of true positive selection, when phenotype outcomes are highly correlated with each other. We also applied the proposed method to our genomic data set consisting of 10,783 rare variants and 13 correlated phenotypes. We identified some potentially susceptible rare variants which were missed by an association test with a single phenotype.

PrgmNr 2307 - Accurate imputation of human leukocyte antigens with CookHLA

View session detail

Author Block: **W. Choi**; Seoul Natl. Univ., Seoul, Korea, Republic of
Disclosure Block: **W. Choi:** None.
The recent development of imputation methods enabled the prediction of human leukocyte antigen (HLA) alleles from intergenic SNP data, allowing studies to fine-map HLA for immune phenotypes. Here we report an accurate HLA imputation method, CookHLA, which has superior imputation accuracy compared to previous methods. CookHLA differs from other approaches in that it locally embeds prediction markers into highly polymorphic exons to account for exonic variability, and in that it adaptively learns the genetic map within MHC from the data to facilitate imputation. Our benchmarking with real datasets shows that our method achieves high imputation accuracy in a wide range of scenarios, including situations where the reference panel is small or ethnically unmatched.

PrgmNr 2308 - An explainable machine learning method for polygenic scores using whole UK biobank genotype dataset

View session detail

Author Block: **R. Ota**, S. Morishita; The Univ. of Tokyo, Tokyo, Japan
Disclosure Block: **R. Ota:** None.

For studying polygenic diseases, GWAS has been largely contributing to identifying associated single nucleotide variants (SNVs); however, SNVs for polygenic diseases often have low odds ratio (1.1-1.3) and only explain a small proportion of heritability, which is called 'missing heritability.' To solve this problem, a number of statistical methods to estimate polygenic scores have been proposed. Khera et al. demonstrated that LDpred can identify a part of the population with a large odds ratio. However, these statistical methods typically use more than 10 thousand SNVs in P+T or more than 7 million SNVs in LDpred, making it hard to interpret the result to understand the mechanism of the disease. Several machine learning methods have been designed to select a limited number of relevant variables, such as SNVs, to output predictions that are easy to interpret while retaining high accuracy, and are therefore expected to be useful for the analysis of polygenic diseases. Indeed, there have been attempts to employ machine learning-based methods for risk prediction (Xu et al., 2020), though they output uninformative predictors that are either hard to interpret, almost as accurate as traditional statistical methods, or incapable of handling all SNVs in UK Biobank dataset due to large computational time. One promising machine learning method is Adaboost that adopts a linear model of a limited number of informative SNVs for better interpretation of the prediction model and is known to be infrequent to be overfitting. However, we found that Adaboost failed to capture low-frequent SNVs.

We developed an improved boosting method, Genoboost to capture low-frequent SNVs. Genoboost demands no information on LD beforehand but can implicitly exclude the effect of LD, which is the unique nature of boosting algorithm. We also developed a program that can process very large GWAS data such as the entire UK Biobank data, which contains about 300 thousand samples each of which has more than 7 million SNVs, in a reasonable amount of time (2.5 days).

For the Type 2 Diabetes data, letting methods use 50 SNVs, Genoboost identified 2.0% and 0.7% of the population whose respective odds ratios are 2 and 2.5 while P+T prediction did 1.2% and none and LDpred and Lassosum did less. The result demonstrates the merit of Genoboost for capturing a smaller number of SNVs relevant to the disease that applies to the wider population.

In conclusion, we propose the first machine learning method that can fully exploit the whole UK Biobank genotype dataset as far as we know, and can output better predictions than the state-of-the-art statistical methods, LDpred, P+T and Lassosum in terms of odds ratios and applicable population.

PrgmNr 2309 - Association tests of gene-environment interactions for time-to-event traits in family studies

View session detail

Complex disease often involves both genetic and environmental factors. Investigating gene by environment (G-E) interactions is therefore an essential step to dissect disease etiology. Analysis of gene-environment (G-E) interactions for rare variants for survival traits is challenging due to lack of statistical power. Family-based study designs help improve statistical power as functional variants are likely to be aggregated in family studies enriched with affected member. Previously, we developed novel pedigree-based burden and kernel association tests for time-to-event outcomes with right censoring for pedigree data, referred to FamRATS (**Fam**ily-based **R**are variant **A**ssociation **T**ests for **S**urvival traits). In the present study, we extended our developed tests for survival outcomes to jointly test for genetic main effects and G-E interactions between a set of rare variants and environmental factors. Cox proportional hazard models were employed to relate a time-to-event trait with interactions between rare variants and environmental factors. The proposed tests do not require for estimating individual effects of rare variants and their G-E interactions. Adjustments were made for the fixed effects of confounding factors. Comprehensive simulation studies were conducted to evaluate the proposed tests in terms of type I error rates and statistical power. Application to a real data example for time-to-event traits was used for an illustration.

PrgmNr 2311 - Correction for sample overlap, winner's curse and weak instruments bias in two-sample Mendelian Randomization

View session detail

Author Block: **N. Mounier**[1,2], Z. Kutalik[1,2,3]; [1]Univ. Ctr. for Primary Care and Publ. Hlth., Lausanne, Switzerland, [2]Swiss Inst. of Bioinformatics, Lausanne, Switzerland, [3]Dept. of Computational Biology, University of Lausanne, Switzerland
Disclosure Block: **N. Mounier:** None.

Introduction:
Inverse-variance weighting (IVW) two-sample Mendelian Randomization (MR) is the most widely used method to estimate the causal effect of an exposure on an outcome. However, the resulting causal effect estimates may suffer from different biases due to sample overlap, winnerâ□□s curse and weak instruments.

Methods:
Assuming a spike-and-slab genomic architecture, we analytically derived the bias of such estimate, which can be quantified using only summary statistics. Hence, we propose a correction of the IVW-MR estimate and compared it against its uncorrected counterpart under a wide range of simulations settings. Finally, we performed IVW-MR based on summary statistics for body mass index (BMI) and systolic blood pressure (SBP) obtained from overlapping samples(N_{BMI}=686,128, N_{SBP}=340,159, $N_{overlap}$= 340,159) and corrected the obtained causal effect estimates using our method.

Results:
Using simulated data, we observed that when the confounder and the causal effect are acting in the same direction, IVW-MR effects are overestimated for fully-overlapping samples and underestimated for non-overlapping samples. When they are acting in opposite directions, observed effects are underestimated for all overlaps because the three sources of biases are towards the null. In all the explored scenarios, our correction reduced bias (up to 30 folds). Using summary statistics for real data, our method revealed that IVW-MR causal effects of BMI on SBP and of SBP on BMI were both significantly overestimated (by 15% and 10% respectively).

Conclusions:
We developed a method to correct causal effect estimates for sample overlap, weak instrument bias and winnerâ□□s curse simultaneously using only summary statistics.

PrgmNr 2313 - Genome-wide classification of epigenetic signal reveals regions of enriched heritability in complex immune traits

View session detail

Author Block: **M. Stricker**[1], W-Y. Cheng[2], S. Nahkuri[3], P. Palamara[1]; [1]Univ. of Oxford, Oxford, United Kingdom, [2]Roche Pharma Res. & Early Dev. Informatics, Roche Innovation Ctr., New York, NY, [3]Roche Pharma Res. & Early Dev. Informatics, Roche Innovation Ctr., Zurich, Switzerland

Epigenetics is known to play a key role in the regulation of adaptive and innate immune-system (AIIS) relevant genes that dictate the therapeutic course for many diseases such as cancer and COVID-19. We built a model that leverages epigenetic data to perform supervised gene classification, with the goal of detecting AIIS genes. We leveraged known similarities between epigenetic states to encode high-dimensional epigenetic data (Epigenome Roadmap, Kundaje et al 2015; ChromHMM, Ernst & Kellis 2012) for different human tissues into images. We then trained a convolutional neural network from a handcrafted list of 477 known AIIS genes to perform image recognition, achieving a testing accuracy of 0.93 (SE 0.03). We used the trained model to scan the human genome for new AIIS regions and detected 1964 putative loci, of which 1129 do not have an associated Gene Ontology (GO) term. Some of these predicted novel AIIS regions harbour immune-cell specific alternative transcription variants, suggesting underlying biological mechanisms.
To evaluate the role played by these predicted AIIS regions in the genetic architecture of complex immune-related traits, we built a genome-wide annotation that reflects our modelâ□□s confidence of AIIS relevance at each locus. Regions with high predicted AIIS relevance (score > 0.5) were found to be enriched for GO terms related to immune-related function (p = 7e-21). We used linkage disequilibrium score regression (LDSC) coupled with genome-wide association summary statistics for 176 traits (average N = 262k) to test whether our AIIS annotation is predictive of regional heritability for these traits. We detected a significant heritability enrichment (LDSC |Ï□*| p To confirm the specificity of the detected enrichments for immune-related phenotypes, we performed a meta-analysis of 64 independent traits, including 4 autoimmune diseases. For all autoimmune diseases, the heritability enrichment remained strong (|Ï□*| > 0.5; p These results underscore the promise of leveraging machine learning algorithms and large epigenetic datasets to detect genomic regions implicated in specific classes of heritable traits and diseases.

PrgmNr 2314 - Integrating facial and genomic data for subtyping individuals in the presence of confounders via individual-specific network analysis

With the collection of vast amounts of heterogeneous data, an increasing number of individuals can be featured by multiple data types, giving richer and complementary information than single data views. This is particularly useful in the context of precision medicine in which the individual plays a central role and benefits can be gained from grouping individuals by âsimilarityâ. Such similarity assessments in sample collections is typically part of latent class analyses, in particular multi-view clustering efforts. The issue of confounded clustering is dealt with a posteriori, if at all. In more recent efforts, individual-specific networks (here, referring to networks with subject-specific edge weights) are constructed and processed, usually focussing on a single data source. In this work, we propose a novel analysis workflow for data integrative subtyping of individuals from two data modalities, in the presence of confounders. Clustering is performed at two possible levels: 1) multi-view components that are extracted from each data view by (sparse) Canonical Correlation Analysis (CCA), and 2) individual-specific (sub-)networks (ISNs) that are derived from the feature similarity matrix following CCA on the entire dataset. ISN nodes (features) represent both data views; edges represent perturbations of an individual to the entire sample network. Special attention is given to optimize the selection of subnetworks when clustering (sub-)ISNs; the latter via hierarchical arguments and similarity measures between graphs (e.g. shortest path kernel distance). The number of subgroups is derived via a recursive strategy, relying on an adaption of distance-based ANOVA and permutation testing. In the presence of known confounders, the workflow consists of 1) quantifying the impact on subtyping (e.g. comparing final clusterings when CCA was informed versus uninformed by confounders), and 2) adjusting for the undesired effects (e.g. via Partial Least Squares regression directly on the original input data, via Kernel Conditional Clustering at the clustering stage itself).For illustrative purposes, we apply the outlined workflow on real-life data from a US cohort of 4680 individuals, assuming age as confounder: facial images are hierarchically grouped into 63 segments and represented by principal components; genetic markers are mapped to genes by genomic positions. All obtained clusterings are compared (f.i. Variation of Information metric). Our work shows the importance of eliminating undesired factors driving individual subtyping and offers unprecedented approaches via multi-view individual-specific networks.

PrgmNr 2315 - Mendelian Randomization with repeated measurement using Taiwan Biobank

View session detail

Author Block: **J-J. Sie**[1], C. S. Fann[2], L. Ie-Bin[3]; [1]Dept. of Mathematics, Natl. Changhua Univ. of Ed., Changhua County, Taiwan, [2]Inst Biomed Sci, Acad Sinica, Taipei, Taiwan, [3]Graduate Inst. of Statistics and Information Sci., Natl. Changhua Univ. of Ed., Changhua County, Taiwan
Disclosure Block: **J. Sie:** None.
Mendelian randomization (MR) controls for the confounding and reversed causality problem in observational studies. Genetic variants as instrumental variables (IV) are utilized to mimic the randomization of exposure. Many modified MR methods have been developed to cope with a variety of study designs and scenarios, e.g., multivariable MR methods, MR methods controlling for pleiotropy, etc. As common practice is to use the mean as a representation for repeated measures, to our knowledge, no MR as of yet has been developed to effectively manage repeated measurements or longitudinal data. In this study, we propose an MR method incorporating Generalized Estimation Equation (GEE) for data with repeated measurements, and compare its performance with conventional MR approaches. We applied this method using data from Taiwan Biobank, which contains more than 120,000 genotyped individuals (March 2021). Among them, more than 22,000 have one follow-up measurements. The range of follow up is between 3 to 6 years (mean = 3.84); age between 30-70 years old with about 64% female. In order to prove our concept, the well known causality between BMI and T2D was chosen. For the baseline data, the mean and standard deviation of BMI were (24.1, 3.59) and the T2D prevalence was 5.13%. For the follow up data, they were (24.3, 3.72) for BMI mean and standard deviation and T2D prevalence was 7.5%. If mean was used as a proxy for two measurements of BMI, OR from MR was 1.549 with se = 0.161 and p = 0.0066. The obtained IVs from this model were used for the subsequent analyses. When using the baseline BMI, OR = 1.316 with se = 0.135 and p = 0.0413; OR = 1.575 with se = 0.152 and p= 0. 0027 when follow up BMI was used. By using MR-GEE model, OR = 1.52 with se = 0.132 and p= 0. 00146.In comparison of these MR results from different models, the causality between BMI and T2D was all significant. The estimated OR were very similar; however, standard error and p value from MR-GEE were smallest. MR-GEE utilizes the longitudinal measurements of both exposure and disease status by taking into account of their correlation, which may make it a more powerful approach than using mean as a proxy, in terms of producing smaller standard error. The causality between other phenotypes are being tested using our proposed MR-GEE model. The limitation of Taiwan Biobank data is that there is only one follow up data available. Simulated follow up data will be used in future studies.

PrgmNr 2316 - Significance in individual-specific networks: assessment, methods and characteristics

Individual-specific networks (ISNs) are graphical structures for which at least one element type (node, edge) has individual-specific labels or weights. In this work, we assume ISNs to be undirected networks with subject-specific edge weights and node values, with edges as a major information source (as in Kuijjer et al., 2019). ISNs are valuable tools to understand individual-to-individual heterogeneity, a key component in Precision Medicine. One of the shortcomings of edge-oriented ISNs, hampering valorization, is that these are usually not encapsulated in a framework that assesses whether it is worthwhile to continue working with an individual-specific network. In other words, it is of interest to know when an ISN is â significantâ. The notion of significance depends on the context but often reduces to how significantly different a leave-one-out-individual network is from the full network (i.e. no individuals left out). Most approaches deal with the significance of an individualâs perturbation, edge by edge, often not considering proper standard errors for test statistics that contrast two strongly dependent samples. Moreover, it defeats the effort of deriving a graphical structure for each individual that can later serve as input to predictive or descriptive models. In an extensive simulation study, we investigate the impact of distributional assumptions of edge weights in a full network from which ISNs are derived, on ISN significance. Deviations from normality are emphasized to cover networks built via more general association than âcorrelationsâ. We explore multiple ISN significance assessment methods, including a newly proposed method ISN-LOO, that involves frequent resampling from a multivariate normal distribution, with covariance structure templated on the observed full network. We consider both edge or module driven significance assessment, relying on appropriate distance measures between an edge (respectively, a module) via subtraction of edge weights for the full and LOO model (respectively, via graph kernels). The novel approach is compared to outlier detection approaches (e.g., proximity-based algorithms and influence analyses). Testing for multiple edges (respectively multiple modules) is controlled at 5%. Our results show the added value of ISN-LOO when deviations from normally distributed full edge weights are limited. Also, modular significance assessment is most powerful for more complex network structures. We furthermore use real-life data from 16S microbiome profiles of 69 newborns from the Dutch LucKi cohort, and illustrate the utility of ISN significance testing to highlight individuals of interest.

PrgmNr 2317 - SNPs tagging structural variations help to reveal widespread role of CNVs in complex traits and gene expression

View session detail

Author Block: **M. Lepamets**[1], K. Alasoo[2], M. Kals[1,3], U. VÃµsa[1], R. MÃ¤gi[1]; [1]Estonian Genome Ctr., Inst. of Genomics, Univ. of Tartu, Tartu, Estonia, [2]Univ. of Tartu, Tartu, Estonia, [3]Inst. for Molecular Med. Finland, FIMM, HiLIFE, Univ. of Helsinki, Helsinki, Finland
Disclosure Block: **M. Lepamets:** None.
Genome-wide association studies (GWAS) have been successful at identifying links between single nucleotide polymorphisms (SNPs) and complex traits. Pinpointing true causal markers, however, has been challenging, and can be even more so in loci where SNP effects reflect the underlying structural variation. In order to recognise such loci, we identify copy number variable (CNV) regions that are tagged by SNPs (tagSNPs) and evaluate the abundance of those tagSNPs among known GWAS and expression quantitative trait loci (eQTLs).
We detected CNVs using Genome STRiP pipeline from ~2,300 Estonian Biobank (EstBB) whole-genome sequencing samples. After initial quality control, ~9M SNPs (MAF>0.01) and 3,631 common CNV regions were included in the tagSNP identification process. We discovered that 52.2% (N=1,895) of CNVs had tagSNPs (R^2>0.8) in their 1Mb radius.
First, we overlapped the tagSNPs with known associations from GWAS Catalog and found that for 285 CNVs the tagSNPs were in high LD (R^2>0.8) with a GWAS top hit. These make up about 1.6% of all GWAS Catalog associations that passed our filtering criteria, 3.6 times more than expected by chance (P-300). The most frequent associations were with BMI (18 CNVs) and different cognitive ability traits (in total 24 CNVs). Second, we analysed the overlap of tagSNPs and 95% credible sets (CS) for eQTLs from eQTL Catalogue. We discovered 309 unique CNV regions for which the tagSNPs covered over 90% of a single CS in at least one dataset/tissue. In 122 (39.5%) cases the CNV physically overlapped with the corresponding gene. Furthermore, we conducted genetic fine-mapping analysis on ~500 EstBB samples with: a) SNPs only and b) SNPs and CNVs combined. We found that in 28.2% (N=50) of CS that originally contained tagSNPs (N=177), the CNVs were chosen over or in addition to the tagSNPs in the second run as potentially causal.
Altogether, we found that 471 (24.9%) CNV regions which were tagged by SNPs showed evidence of being an underlying variant behind either GWAS or eQTL SNP associations. Considering the pronounced impact on gene function and dosage that CNVs can have, they are strong candidates for causal variants. Therefore, tagSNP information is essential when designing functional follow-up experiments based on SNP results.

PrgmNr 2318 - Statistical selection method to identify pleiotropic variants associated with both quantitative and qualitative traits

View session detail

Author Block: **K. Kim**, H. Sun; Pusan Natl. Univ., Busan, Korea, Republic of
Disclosure Block: **K. Kim:** None.

In recent genetic association studies, statistical methods to identify pleiotropic variants associated with multiple phenotypic traits have been developed, since susceptible variants with small or moderate effects are rarely detected by association methods based on a single trait. However, most of the existing methods to identify pleiotropic variants are designed for only quantitative traits even though pleiotropic variants are often associated with both quantitative and qualitative traits. This is a statistically challenging problem because there does not exist an appropriate multivariate distribution to model both quantitative and qualitative data. There are some meta-analysis methods which basically integrate summary statistics of individual variants associated with either a quantitative or qualitative trait. However, these methods cannot account for correlations between genetic variants. In this article, we propose new selection method to prioritize individual variants associated with both quantitative and qualitative traits. For individual traits, regression coefficients of elastic-net regularization are first estimated and then they are additively combined to compute selection probability of individual variants. In our extensive simulation studies where either homogeneous or heterogeneous variant effects on both quantitative and qualitative traits were considered, we demonstrated that the proposed method outperforms the existing meta-analysis methods in terms of true positive selection. We also applied the proposed method to real genomic data with both quantitative and qualitative traits.

PrgmNr 2319 - The Alpha variant: A comparison for risk for hospitalization and case-mortality rate for younger and older patients

View session detail

Author Block: **S. Cetin**[1,2], A. Ulgen[3]; [1]Ã¼nv, Tokat, Turkey, [2]Tokat GaziosmanPasa Univ., Biostatistics, Faculty of Med., Tokat, Turkey, [3]Faculty of Med., Girne American Univ., Karaman, Cyprus
Disclosure Block: **S. Cetin:** None.

Knowing the risks for hospitalization and case-fatality-rate for emerging SARS-CoV-2 variants for different age groups is necessary for hospital management and vaccination planning. It is therefore important to collect and analyze health data related to the variants. We have obtained more than 3700 COVID-19 patients (3100 outpatients and 600 inpatients) where about 30% are infected by Alpha variant. Both logistic regression and cause-specific Cox survival analysis of competing-risk is run on inpatients to examine the impact of the Alpha variant on hospitalization and on mortality, conditional on other factors. Descriptive statistics is used to characterize different subgroups. We observed that the Alpha variant is over-represented in inpatients than outpatients so carrying the Alpha variant increases the chance for hospitalization. The impact of the Alpha variant on mortality seems to depend on the patientâ□□s age. For age *70 group, the case-fatality-rate is 0.84% (5.3%) for patients without (with) the Alpha variant (Fisherâ□□s test P-value = 2.4 Ã□10â□□10). For age â□¥ 70 group, the trend is opposite: the case-fatality-rate is 31.5% (13.6%) for patients without (with) Alpha variant (Fisherâ□□s test P-value = 0.0016). The two opposite trends would cancel each other, making other analyses such as cause-specific Cox regression and logistic regression non-significant. The Alpha variant increases the risk for hospitalization, increases the case-fatality-rate for lower age group, and decreases the case-fatality-rate for the upper age group. It is therefore imperative to vaccinate young, middle-aged, and early senior population to counter the impact of wave of the Alpha variant.*

PrgmNr 2320 - Time to mortality and time to discharge from the hospital in Covid-19 data: A Turkish study

View session detail

Author Block: **A. Ulgen**; Dept. of Biostatistics, Faculty of Med., Girne American Univ., Karmi, Cyprus
Disclosure Block: **A. Ulgen:** None.
COVID-19 survival data presents a special situation where not only the time-to-event period is short, but also the two events or outcome types, death and release from hospital, are mutually exclusive, leading to two cause-specific hazard ratios ($csHR_d$ and $csHR_r$). The eventual mortality/release outcome is also analyzed by logistic regression to obtain odds-ratio (OR). We have the following three empirical observations: (1) The magnitude of OR value is an upper limit of the $csHR_d$ value: |log(OR) | â¥ | log($csHR_d$)|. This relationship between OR and HR could be understood from the definition of the two quantities in an approximation; (2) $csHR_d$ and $csHR_r$ point in opposite directions: log($csHR_d$) . log($csHR_r$) d and $csHR_r$: $csHR_d$ ~ 1/$csHR_r$. Though an approximate reciprocal trend between the two hazard ratios is an indication that the same factor causing faster death also lead to slow recovery by a similar mechanism, and vice versa, a quantitative relation between $csHR_d$ and $csHR_r$ in this context is not obvious. These observations will help future analyses of COVID-19 data, as well as other data of similar nature, in particular if the deceased samples are lacking. In particular, if the death rate is moving towards zero with future life-saving drugs, it is still possible to obtain $csHR_r$ using large number of surviving patients; then inferring $csHR_d$ from $csHR_r$.

PrgmNr 2321 - TransformerPRS: a deep learning-based polygenic risk model using bidirectional transformers derived from a language model

View session detail

Disclosure Block: **J. Kim:** None.

Polygenic risk score (PRS) is the cumulative, mathematical aggregation of risk derived from the contributions of many DNA variants across the genome. Recent studies have demonstrated the utility of PRS on identifying individuals who are at high risk of disease and could benefit from early preventative intervention. However, there are several limitations of PRS; 1) only capturing the marginal effect of variants, 2) only reflecting linear effects of variants, and 3) no consideration and interpretation of any interactions between genes. In this study, we propose *TransformerPRS*, a deep learning-based model using a transformer module derived from a language model, which combines the concepts of PRS and interactions between genes to overcome the limitations of PRS. In our approach, we first introduce a monogenic risk score (MRS) by aggregating risks of variants in a gene and transform the MRSs into a sequence of risky genes and a sequence of protective genes. *TransformerPRS* takes these as input and learns the optimal representation of genes to predict disease risk by incorporating the interaction between input tokens. We also propose *TransformerPRS with pre-trained gene embeddings* using biological knowledge provided by *HiG2Vec* which is based on gene embedding. For the experiments, we used whole genome-sequencing data from ADNI-WGS-2 with ADSP Follow-Up Study (n=1,566) and the AD GWAS summary statistics data from an independent IGAP cohort (with ADNI-ADSP samples removed). As a result, conventional PRS (with p-value threshold=1E-04) showed an area under the receiver operating characteristics curve (AUC) of 0.658 Â± 0.034 (mean Â± std) to classify patients with Alzheimerâ□□s disease and cognitively normal participants. Both *TransformerPRS* and *TransformerPRS with pre-trained gene embeddings* outperformed it by AUC of 0.680 Â± 0.033 and 0.691 Â± 0.034, respectively. In addition, the self-attention module in a transformer block identified important features and their interactions. Our models can improve disease risk prediction by providing information on which genes and interactions between genes have an important impact on disease prediction, which are missed by conventional PRS.

PrgmNr 2322 - Using a digital health tool to analyse UK primary care electronic health records to identify potential cases of undiagnosed Marfan syndrome

View session detail

Author Block: **P. Ravichandran**, O. Buendia, W. Evans, L. Menzies; Mendelian, London, United Kingdom
Disclosure Block: **P. Ravichandran:** None.
Background: Marfan syndrome (MS) is a genetic disorder that affects connective tissue. It is caused by mutations in the fibrillin-1 gene. Aortic dissection is a significant cause of premature mortality. Early identification enables monitoring, risk factor modification and timely surgery. We used a digital health case-finding tool, MendelScan, to identify potential cases of MS in UK primary care electronic health records (EHR). Method: Firstly, we identified MS as a suitable rare disease to digitalise using our internal disease scoring metrics. We digitised a criterion based on the 2010 revised Ghent nosology to create a digital algorithm, refining the algorithm using common coded clinical features identified in the EHR of patients with established diagnoses. Each identified case underwent a manual internal clinical review, assessing the full structured (no free text) information held in the EHR for each case and evaluating whether there was a strong enough suspicion of MS to recommend further investigation. Results: Using a sample of 501,188 EHR, our algorithm identified 39 potential cases (including 3 previously diagnosed cases); internal clinical review refined the number of potential previously undiagnosed cases to 10.There were 47 previously diagnosed cases within our sample, of which our digital health tool identified 3. Our algorithm flagged 2 of these cases in advance of their diagnosis being recorded in their EHR; by 1 year and 2 years. Conclusion: We have demonstrated that using a digital health case-finding tool, with an algorithm developed from the Ghent nosology, we can identify credible cases with possible undiagnosed MS for further investigation.

PrgmNr 2323 - A machine-learning-based prediction of disease endpoints from administrative health data accounts for misclassification and disease liability in GWAS

View session detail

Author Block: **L. Eick**[1], S. Jukarainen[1], M. Cordioli[1], T. T. Kiiskinen[1,2], FinnGen, A. Ganna[3,1]; [1]FIMM, Inst. for Molecular Medicin Finland, Helsinki, Finland, [2]Broad Inst. of MIT and Harvard, Cambridge, MA, [3]Harvard Med. Sch. and Massachusetts Gen. Hosp., Boston, MA
Disclosure Block: **L. Eick:** None.
Genome wide association studies (GWAS) assume there is a correct classification of subjects into cases and controls. Nonetheless, misclassification is expected, especially in biobanks that rely on administrative health data. Additionally, the genetic liability to a disease might best be viewed as a continuous value rather than a binary one. In order to address potential misclassification and increase the statistical power of GWAS, we implement an XGBoost based classifier. Instead of binary disease labels, it outputs a continuous liability measure based on diagnoses and medication usage and takes the result to perform a GWAS.
We analyzed data from the FinnGen study (n=253,072) based on Finnish registries with a follow-up of up to 50 years. We used 4003 diseases and 445 different medication classes as predictors for the classifier. Our method can be used for any disease present in FinnGen, and we demonstrate the method using ischemic stroke. We performed a GWAS over all individuals of FinnGen and defined as cases those individuals that were at high stroke risk according to our machine-learning-based prediction. We identified three GW-significant loci that were not found in GWAS that used the original case control classification. All three loci are known to be associated with stroke based on results from the largest stroke GWAS meta-analysis to date.
Our method expand GWAS possibilities accounting for potential misclassification and leveraging disease liability in individuals that are not yet diagnosed.

PrgmNr 2324 - Characterization of the human *ABO* genotypes and their association to inflammatory and cardiovascular disease

View session detail

Author Block: **J. R. HÃ¶glund**, T. Karlsson, T. Johansson, W. E. Ek, Ã. Johansson; Uppsala Univ., Uppsala, Sweden
Disclosure Block: **J.R. HÃ¶glund:** None.
The *ABO* gene contains three major alleles that encodes different antigens; A, B, and O, which determine an individualâs blood group. Previous studies have primarily focused on identifying associations between ABO blood groups and diseases risk. Here, we sought to test for association between *ABO* genotypes (OO, OA, AA; OB, BB, and AB) and a large set of diseases and disease-related protein biomarkers. We conducted association studies in two European cohorts; UK Biobank and NSPHS. We first tested for association by conducting a likelihood ratio test, testing whether ABO contributed significantly to the risk for 24 diseases, and 438 plasma proteins. For phenotypes with FDR ABO genotypes using logistic or linear regression. Our study confirmed previous findings of a strong association between *ABO* and cardiovascular disease, and provide additional evidence of significant differences between heterozygous and homozygous allele carriers for pulmonary embolism, deep vein thrombosis, but also for von Willebrand factor levels. Additionally, we found that *ABO* contributed significantly to 39 plasma proteins, of which 24 have never been linked to the *ABO* locus before. These results show the need of incorporating *ABO* genotype information in the consultation and management of patients at risk, rather than classifying patients into blood groups. Furthermore, the results indicated an additive effect between genotypes.

PrgmNr 2325 - Effects of *GLP1R* coding variation on random glucose levels and functional responses to GLP-1R agonists using whole exome sequencing data

View session detail

Genetic imputation has been useful in enlarging the number of testable variants for genome-wide association studies (GWAS). However, imputation and genotyping accuracy for rare variants (minor allele frequency, MAF5%). The usefulness of both array genotyping and imputation in establishing the role of rare variants in complex diseases is therefore thought to be limited. In this study, we compared the estimated effects of glucagon-like peptide-1 receptor (*GLP1R*) gene missense single nucleotide polymorphisms (SNPs), derived from imputed/array genotype or whole exome sequencing (WES) UK Biobank data, on random glucose (RG). We performed functional and structural studies to explain these effects and identify how patients with type 2 diabetes might respond differently to GLP-1R agonist drugs. We used the latest WES data release from the UK Biobank to test for association between *GLP1R* coding variants and natural log transformed RG adjusted for age, sex and time since last meal under an additive model of genetic effects in 165,818 unrelated European individuals. Further, we ran the same RG GWAS model in the UK Biobank (n=401,810) using the Haplotype Reference Consortium (HRC) imputed panel. For selected coding missense *GLP1R* variants we experimentally assessed G protein coupling and endocytosis in response to endogenous and FDA-approved therapeutic GLP-1R agonists, and performed molecular dynamics simulations of the oxyntomodulin-bound human GLP-1R using a recently described cryo-EM structure. 853 *GLP1R* coding variants were detected in WES data while 18 variants were detected in the HRC-imputed GWAS data. RG effects estimated in the larger imputed dataset were directionally consistent with the WES dataset, but effect size consistency was highest for commoner variants (e.g., rs10305492; protein coding consequence A316T, MAF = 1.5%, $BETA_{WES}$ = -0.011, SE_{WES} = 0.001; $BETA_{Genotyped}$ = -0.011, $SE_{Genotyped}$ = 0.002). The RG-lowering A316T variant showed increased agonist-induced coupling to stimulatory G proteins and endocytosis, which was explained by a structural alteration in the nearby hydrogen bond network. Experimentally determined gain-of-function for A316T applied more to certain GLP-1R agonists (e.g., tirzepatide) than to others (e.g., exenatide). Sensitivity analysis using WES data confirmed imputed data for common variants on RG effect. Our observation of ligand-specific responses to *GLP1R* variants such as A316T provides a mechanism that can explain why some individuals respond better or worse to particular GLP-1R-targeting drugs and a possible framework for T2D treatment stratification.

PrgmNr 2326 - Genetic and environmental determinants of drug adherence and drug purchasing behaviour

View session detail

Author Block: **M. Cordioli**[1], S. Jukarainen[1], T. T. Kiiskinen[1], FinnGen Study, S. Ripatti[1], A. Ganna[2,1]; [1]Inst. for Molecular Med. Finland, Univ. of Helsinki, Helsinki, Finland, [2]Harvard Med. Sch. and Massachusetts Gen. Hosp., Boston, MA
Disclosure Block: **M. Cordioli:** None.
One of the major factors behind the efficacy of pharmacological treatments is patients adherence to the prescribed therapy regimen. While demographic and socioeconomic factors may play a role in determining adherence, there have been few investigations on the potential effects of genetic variation on drug adherence. Drug adherence is difficult to measure because, unlike prescriptions, drug purchases are often not recorded in a centralized database. The Finnish drug purchase registry offers a unique resource towards this aim, covering a time span of more than 20 years and including the dose and quantity of every reimbursable prescription medication purchased at a pharmacy.
By leveraging genetic data from the FinnGen study (N=309,154) and data from the Finnish drug purchase registry (63,084,035 total purchases), we provide a systematic investigation of adherence determinants across multiple diseases and medications.
For each drug class of interest, we reconstructed individual drug trajectories and defined adherence as the ratio between the total purchased quantity and the length of the trajectory. We then ran a GWAS of adherence to each medication.
Here we report the results for statins (2,821,628 purchases, N=90,617) and blood pressure (BP) medications (4,512,383 purchases, N=99,793). We replicated the analysis for statins using prescription data from the UK Biobank as a proxy for adherence (N=37,783) and meta-analyzed with FinnGen results. For both medications, we estimated the genetic correlation (r_g) between adherence and 27 publicly available traits.
Overall, the results suggest adherence pertains to general behavioural aspects rather than to biological factors. For example, higher adherence to statins resulted to be genetically associated with higher educational attainment (r_g=0.22, P=3.3x10^{-4}) a lower risk tolerance (r_g=-0.36, P=6.6x10^{-5}) and lower openness to experiences (r_g=-0.3, P=6.8x10^{-4}). Psychiatric traits such as schizophrenia, bipolar disorder and depression also showed a negative genetic correlation with adherence. Furthermore, in both UK Biobank and FinnGen, well-known variants in statins pharmacogenetics (*ABCG2, HMGCR, SLCO1B1*) showed no effect on adherence.
By extending this approach to multiple long-lasting drug treatments, this study provides better insights into the factors affecting adherence and allows for a better identification of patients at high risk of non-adherence in drug taking.

PrgmNr 2327 - Higher adisposity, depression and wellbeing: causal inference using Mendelian randomization

View session detail

Author Block: **F. Casanova**[1], J. O'Loughlin[1], S. Martin[1], R. N. Beaumont[1], A. R. Wood[1], E. Watkins[2], R. Freathy[1], H. Saskia[3], T. Frayling[4], H. Yaghootkar[5], J. Tyrrell[4]; [1]Coll. of Med. and Hlth., Univ. of Exeter, Exeter, United Kingdom, [2]Sch. of Psychology, Univ. of Exeter, Exeter, United Kingdom, [3]Social, Genetic and Dev.al Psychiatry Ctr., Inst. of Psychiatry, Psychology and NeuroSci., King's Coll. London, London, United Kingdom, [4]Univ. of Exeter, Exeter, Devon, United Kingdom, [5]Univ. of Exeter Med. Sch., Exeter, Devon, United Kingdom

Disclosure Block: **F. Casanova:** None.

Higher adiposity is associated with higher odds of psychiatric diseases, including depression. These associations may be explained by the metabolic consequences and/or by the psychosocial impact of higher adiposity. Genetic variants associated with higher adiposity and with a favourable (lower triglycerides, higher HDL and lower type 2 diabetes risk) and unfavourable (higher triglycerides, lower HDL and higher type 2 diabetes risk) metabolic profile have been identified and can be used to understand which component of higher adiposity causes the highest risk.

We performed two-sample Mendelian Randomisation (MR) in up to 145,668 participants of European descent from the UK Biobank to test for a causal effect of higher adiposity on depression and wellbeing outcomes from the Mental Health Questionnaire (MHQ). We used three sets of adiposity genetic instruments: a) a set of 72 BMI genetic variants, b) a set of 36 favourable adiposity variants and c) a set of 38 unfavourable adiposity variants. We additionally tested causal relationships in a subset of individuals not taking antidepressants and using non-linear MR models.

Two-sample MR provided evidence that a genetically determined one standard deviation (1-SD) higher BMI (4.6â□□kg/m2) was associated with higher odds of depression [OR:1.50, 95%CI: 1.15, 1.95] and lower wellbeing [beta:-0.15, 95%CI:-0.26, -0.04]. When using the favourable and unfavourable adiposity variants higher adiposity was consistently associated with higher odds of depression (favourable adiposity OR:2.85, 95% CI:1.38, 5.89; unfavourable adiposity OR: 2.59, 95% CI:1.60, 4.21) and lower wellbeing scores (favourable adiposity beta:-0.20, 95%CI:-0.40, -0.01; unfavourable adiposity beta:-0.19, 95%CI:-0.39, 0.00). Excluding individuals on antidepressants had no effect on our results. A non-linear relationship was found between BMI and wellbeing: for individuals in the lowest BMI decile (32.5 kg/m2) a unit higher BMI was associated with lower wellbeing [Ã□:-0.12, 95%CI:-0.19, -0.05].

Our study provides further evidence that higher BMI is causally associated with higher odds of depression and lowers wellbeing. Using genetics to separate out metabolic and psychosocial effects, our study suggests that in the absence of adverse metabolic effects higher adiposity remains causal to depression and lowers wellbeing, highlighting the importance of psychosocial factors in this relationship. Our results showed evidence of non-linear causal association between adiposity and wellbeing.

PrgmNr 2328 - HLA Fine Mapping and Genetic Risk Factors in Tuberculosis

View session detail

Author Block: **A. Tervi**[1], N. Junna[1], M. Broberg[1], S. E. Jones[1], F. FinnGen[2], S. Strausz[1], C. A. Heckman[3], H. M. Ollila[1,4]; [1]Inst. for Molecular Med. Flagship, Univ. of Helsinki, Helsinki, Finland, [4]Broad Inst. of Harvard and MIT, Cambridge, MA

Disclosure Block: **A. Tervi:** None.

Background: Tuberculosis is a significant public health concern resulting in the death of over 1 million individuals each year worldwide. Smoking, BMI, HIV, diabetes and COPD have been suggested as risk factors. While treatment options and vaccines exist, a substantial number of infections still remain untreated or are caused by treatment resistant strains. Therefore, it is important to identify mechanisms that contribute to risk and prognosis of tuberculosis as this may provide tools to first understand disease mechanisms and provide novel treatment options for those with severe infection.
Aim: Our goal is to identify genetic risk factors that contribute to tuberculosis and to understand biological mechanisms and causality behind tuberculosis progression.
Results: A total of 1,895 individuals in FinnGen had ICD-based tuberculosis diagnosis. GWAS analysis identified three genetic variants with statistically significant association with tuberculosis at the Human leukocyte antigen (HLA) region (pINPP5A. Fine mapping the HLA-association provided evidence for one protective haplotype tagged by *DQB1*05:01* (p=1.82e-06, OR = 0.81 [CI 95% 0.74-0.88]), and predisposing alleles tagged by *HLA DQB1*06:04* (p=0.00030, OR = 1.34 [CI 95% 1.15-1.56]). Furthermore, genetic correlation analysis shows association with earlier reported risk factors including smoking and low BMI (pConclusions: Our findings indicate that genetic variants at the HLA region and *INPP5A* associate with the risk of tuberculosis. These findings suggest that the risk for tuberculosis is mediated by individual genetic variants and differences in the immune system. In addition, lifestyle risk factors such as smoking contribute to the risk of developing tuberculosis.

PrgmNr 2329 - Secondary findings from exome sequencing of 15,000 South Asians

Author Block: **W. McLaren**[1], N. Sarkar Roy[2], Z. Nagda[2], N. Shaikh[2], S. Tuna[1], N. England[1], A. Shah[3], Regeneron Genetics Center, M. Kapoor[4], Y. Turpaz[5], J. D. Picker[6], A. R. Shuldiner[4], S. S. Jamuar[5]; [1]Global Gene Corp Pvt Ltd, Cambridge, United Kingdom, [2]Global Gene Corp Pvt Ltd, Mumbai, India, [3]Global Gene Corp Pvt Ltd, Ahmedabad, India, [4]Regeneron Genetics Ctr., Tarrytown, NY, [5]Global Gene Corp Pvt Ltd, Singapore, Singapore, [6]Global Gene Corp Pvt Ltd, Boston, MA
Disclosure Block: **W. McLaren:** None.
Background: In Western cohorts, the prevalence of secondary findings (SFs), referring to disease-causing variants in genes unrelated to a patient's primary condition or in healthy population-based sequencing programs, is between 0.86% and 8.8%. However, data on prevalence and type of SFs in South Asian (SA) populations is lacking. Moreover, genomic data from SA populations is underrepresented in public databases.
Methods: As part of our ongoing Indian biobank project we have collected and performed exome sequencing (ES) on leukocyte derived DNA from 15,185 individuals of SA origin. The GGC biobank includes both healthy individuals and a wide spectrum of disease cohorts, from diabetes, cardiovascular, neurodegenerative, oncology and others, and serves to build a longitudinal cohort for each disease area. We extracted and annotated variants from ES data in 59 ACMG-recommended genes (ACMG SF2.0) and filtered them to identify disease-causing variants based on ACMG-AMP criteria: pathogenic (P) or likely pathogenic (LP). We analyzed the distribution of SFs, class of gene, related medical conditions, and potential clinical impact.
Results: We found a total of 15,388 variants (14,762 SNVs, 576 in/dels) in the 59 genes in our cohort. Of these, 54% (8,326) are observed in only one individual and 38% (5,836) are novel variants not previously observed in public datasets (1000 Genomes, gnomAD). Among the novel variants, 194 (3.3%) are predicted to be loss-of-function. Filtering for rare and coding variants, we identified 253 potential disease causing variants present in 577 (3.8%) individuals. After reviewing family history and the ClinVar database, 148 (58.5%) of 253 variants were classified to be pathogenic, while an additional 105 (41.5%) variants were classified as LP. The overall cumulative prevalence of SFs (P and LP in ClinVar) in our cohort was 3.8% and could be as high as 5.1% including novel loss-of-functions.
Conclusion: The cumulative prevalence of SFs in our data was marginally higher than previously reported in Caucasian and South East Asian studies. Our ability to recontact individuals and use personal and/or family history to assess significance of the genomic findings demonstrates the value of longitudinal data collection in our biobank. More importantly, across 15,185 unrelated SA individuals, we identified 38% novel variants across the 59 genes, supporting the case for sequencing underrepresented populations to support precision medicine efforts globally.

PrgmNr 2330 - Separating the effects of cardiometabolic risk factors from type 2 diabetes on coronary and peripheral artery disease

View session detail

Author Block: **V. Walker**[1], M. Vujkovic[2], A. Carter[1], N. Davies[1], M. S. Udler[3], G. Davey Smith[4], B. F. Voight[2], T. Gaunt[1], S. M. Damrauer[5]; [1]Univ. of Bristol, Bristol, United Kingdom, [2]Univ. of Pennsylvania, Philadelphia, PA, [3]Broad Inst., Cambridge, MA, [4]Bristol Univ., Bristol, United Kingdom, [5]Hosp. of the Univ. of Pennsylvania, Philadelphia, PA
Disclosure Block: **V. Walker:** None.
Background: Type 2 diabetes and atherosclerotic cardiovascular disease share several risk factors. Yet, it is not fully understood if the effect of these risk factors on liability to atherosclerotic cardiovascular disease is mediated by liability to type 2 diabetes.
Methods: We performed univariate Mendelian randomization to quantify the effects of 57 continuous risk factors, selected for their clinical relevance to type 2 diabetes, on three outcomes: liability to type 2 diabetes, liability to coronary artery disease, and liability to peripheral artery disease. Next, we performed univariate Mendelian randomization to determine the effects of liability to type 2 diabetes on the risk factors, excluding risk factors with bidirectional relationship with liability to type 2 diabetes as they are unsuitable for mediation analyses. Finally, we performed two-step Mendelian randomization for mediation to estimate the mediating pathways between the risk factors, liability to type 2 diabetes, and liability to the atherosclerotic cardiovascular disease outcomes.
Results: Among the 57 risk factors, five were causes of liability to type 2 diabetes, 22 were causes of liability to coronary artery disease, and 22 were causes of liability to peripheral artery disease. A further 14 risk factors were consequences of liability to type 2 diabetes. We removed 16 risk factors, which had a bidirectional relationship with liability to type 2 diabetes, prior to conducting the mediation analyses. The effects of total cholesterol, diastolic blood pressure, hip circumference were likely to have direct effects on liability to both atherosclerotic cardiovascular disease outcomes. Height was also likely to have a direct effect on liability to coronary artery disease. These effects were unlikely to be mediated via liability to type 2 diabetes.
Conclusions: Separating the effects of risk factors from liability to type 2 diabetes can aid understanding of their relationships with liability to atherosclerotic cardiovascular disease. Our analysis suggests that the effects of these risk factors on liability to atherosclerotic cardiovascular disease are unlikely to be mediated by liability to type 2 diabetes. Therefore, control of the modifiable risk factors remains important for reducing atherosclerotic cardiovascular disease risk regardless of patient liability to type 2 diabetes.

PrgmNr 2331 - Transcriptome and GWAS identified rs2238678 as a critical SNP for eosinophilia in primary biliary cholangitis

Disclosure Block: **K. Ueno:** None.
Primary biliary cholangitis (PBC) is a chronic cholestatic liver disease characterized by the destruction of biliary epithelial cells, presumably by autoimmune mechanism. Our recent transcriptome analysis of the diseased liver has identified that mRNA expression associated with eosinophilia is specifically increased in PBC as compared to chronic hepatitis C (CHC). The aim of this study is to investigate the molecular mechanisms of eosinophilia in PBC using GWAS and transcriptome datasets. By mRNA-microarray analysis of liver-biopsy samples (PBC: n=43, CHC: n=15), we firstly identified 256 genes that are significantly increased (Fold change>2, P

PrgmNr 2332 - Development of a novel, instrument-free, single-cell RNA sequencing technology (PIPseq) and its application to drug pathway discovery in lung cancer

View session detail

Author Block: **K. Fontanez**[1], I. Clark[2], C. Dâ□□Amato[1], A. Osman[1], S. Pandey[1], Y. Xue[1], A. May-Zhang[1], R. Meltzer[1], S. Kiani[1], A. Abate[3]; [1]Fluent BioSci., Watertown, MA, [2]Berkeley, Berkeley, CA, [3]Univ. of California, San Francisco, San Francisco, CA
Disclosure Block: **K. Fontanez:** Salary/Employment; Fluent BioSciences.
Single-cell RNA sequencing (scRNA-Seq) has enabled unprecedented insight into the biology of individual cells across a broad range of discovery and disease-relevant applications. Traditional scRNA-Seq workflows have included single cell sorting into wells, co-capture of cells with barcoded beads using microfluidics, or in-cell combinatorial indexing. Fluent BioSciences has developed Pre-templated Instant Partitions (PIPs) to simultaneously segregate complex cell mixtures into partitions with barcoded template particles that can be easily processed for scRNA-seq (PIPseq) without the need for complex instrumentation or microfluidic consumables. Here, we used PIPseq to bioinformatically discriminate the transcriptomes of Gefitinib resistant and sensitive cell lines after drug treatment. To evaluate tyrosine kinase inhibitor effects on adenocarcinoma cellular transcriptomics, PC9 cells, H1975 cells, or a mixed population (9:1) of PC9 and H1975, cells were treated with Gefitinib and processed with PIPseq. UMAP analyses of the transcriptome were performed and overlapped for each experiment. We demonstrate drug-treatment dependent gene expression changes in lung adenocarcinoma cells treated with the tyrosine kinase inhibitor Gefitinib. The resulting cell expression profiles clearly segregate by treatment condition in UMAP projections indicating PIPseqâ□□s ability to faithfully detect responses to drug exposure. These studies establish the efficacy of PIPseq for single-cell transcriptomic analysis across multiple drug treatment conditions. The simple PIPseq workflow is optimized for comparing multiple sample treatment conditions in a single controlled experiment. With minimal upfront cost of implementation, PIPseq can be easily implemented in any molecular research lab.

PrgmNr 2333 - Diversity of germline mutations in a cohort of unselected Brazilian pancreatic carcinoma patients

View session detail

Author Block: **L. Rodrigues**[1], S. Maistro[2], L. S. Leite[2], U. Ribeiro Jr[1], R. S. C. Guindalini[3], M. A. K. Folgueira[1]; [1]Faculdade de Med. da Univ.e de SÃ£o Paulo, SÃ£o Paulo, Brazil, [2]Inst. do CÃ¢ncer do Estado de SÃ£o Paulo, SÃ£o Paulo, Brazil, [3]Oncologia D'Or, SÃ£o Paulo, Brazil
Disclosure Block: **L. Rodrigues:** None.
Background: Only a limited number of pancreatic carcinoma patients have been tested for germline mutations in a large panel of genes, particularly outside the North Hemisphere. Therefore, we evaluated a cohort of unselected Brazilian pancreatic carcinoma patients, that represents a multiethnic population, to detect the spectrum and frequency of germline mutations in cancer predisposing genes. **Methods**: Patients from Instituto do CÃ¢ncer do Estado de SÃ£o Paulo, SÃ£o Paulo, Brazil, with histopathological diagnosis of non-endocrine pancreatic carcinoma were included, regardless of the family history of cancer. Genomic DNA was obtained from peripheral blood for Next Generation Sequencing (NextSeq platform) using the TruSight Hereditary Cancer panel, comprising 113 cancer predisposing genes. Variant analysis was performed with the VarStation, a Brazilian tool, that offers post-sequencing computational support. Reported variants are exonic, had coverage â¥150x, allelic frequency â¥0.3 and respect Clinvar deposits. **Results**: A total of 82 patients were evaluated, with mean age 61 years (34-87), among whom, 18% with young age (â¤50 years) and 48 women (57%). Forty-eight patients (57%) reported cases of any cancer in first-degree relatives. Regarding risk factors, 46 patients (55%) reported smoking, 18 alcohol abuse, 52 (62%) self-declared white and 28 were previously obese. Forty-five patients (54%) were diagnosed with T4 or metastatic disease. Sixteen out of 82 (19%) patients presented pathogenic/likely pathogenic variants in the following genes: *ATM, BRCA1, BRIP1, MTIF, MUTYH* (two patients in each gene) and *CDKN2A, CHEK2, FANCE, FANCL, MSH2, RAD51C, SDHA* and *SPINK1* (one patient in each gene), among these, two patients had two variants. **Conclusions**: In this unselected and multiethnic group of pancreatic carcinoma patients, 60% reported family history of cancer and 20% were carriers of pathogenic variants in cancer predisposing genes, mainly genes related with the homologous recombination DNA repair. Future analyzes in a greater number of patients will allow a better understanding of the mutational profile of the pancreatic carcinoma, especially in different populations.

PrgmNr 2334 - Effect of return of unknown significance on surgical variant of decision making in women with invasive breast cancer

Background While clinical management should not be influenced by a return of a variant of uncertain significance (VUS), uncertainty may influence surgical decision making of women with invasive breast cancer. We thus evaluated whether surgical choices differed between women with pathogenic, VUS and benign genetic test results. Methods Germline test results and all surgical procedures were extracted for women who had clinical testing within one year of diagnosis (n=620). Results were classified as pathogenic/likely pathogenic (15.8%), VUS (18.4%) or benign/likely benign (65.8%). Data were analyzed using chi-square tests with p

PrgmNr 2335 - Exome sequencing of 500 Brazilian patients with rare diseases: what we have learned

View session detail

Author Block: **C. D. Quaio**[1], C. Chung[2], S. Perazzio[2], A. Dutra[2], C. Moreira[2], C. Kim[3]; [1]Genetics Unit, Faculdade de Med. da universidade de Sao Paulo, Sao Paulo, Brazil, [2]Fleury Med. e Saude, Sao Paulo, Brazil, [3]Genetics Unit, Faculdade de Med. da Univ.e de Sao Paulo, Sao Paulo, Brazil
Disclosure Block: **C.D. Quaio:** Salary/Employment; Fleury Medicina e Saude.
Literature regarding genomic studies for rare diseases is limited in Latin America. We describe the variable spectrum of primary findings, secondary findings, carrier status for recessive diseases and clinical impact of exome sequencing (ES) in a cohort of 500 Brazilian patients with rare diseases. In total, 164 primary findings were reported in 158 patients (six patients presented dual diagnoses), representing an overall diagnostic yield of 31.6%. Most of the findings (61.6%) corresponded to autosomal dominant conditions, followed by autosomal recessive (25.6%) and X-linked (12.8%) conditions. The 158 patients found with primary findings had on their ES report 195 variants in total, among which 43.6% are novel in the literature. The rate of molecular diagnosis was considerably higher for prenatal samples (67%; 4/6), younger children (44%; 24/55), individuals with consanguinity (50%; 3/6), gastrointestinal/liver disease (44%; 16/36) and syndromic/malformative conditions (41%; 72/175). We observed a potential impact on the clinical care of the patients molecularly diagnosed in our study through the use of targeted therapy, early tumor screening, medication adjustment and monitoring for disease-specific complications in 15.6% of the patients in our cohort. Secondary findings were reported in 37 patients (7.4%). Based on cost-effectiveness studies in the literature, we speculate that the reports of secondary findings may influence an increase of 123.2 years in the life expectancy for our cohort, or 0.246 years/cohort patient. Additionally, carrier status for autosomal recessive diseases was studied in 320 patients: a total of 425 occurrences of 351 rare variants were reported in 278 different genes in 230 patients (71.9%); almost half (48.8%) of these 320 patients were carriers of at least one heterozygous pathogenic/likely pathogenic variant for rare metabolic disorders, while 25.9% of epilepsy, 18.1% of intellectual disabilities, 15.6% of skeletal disorders, 10.9% immune disorders, and 9.1% of hearing loss. In one of the largest cohorts of rare diseases in Latin America, we observed that ES is a powerful method to identify the molecular bases of monogenic disorders and redirect clinical care.
