

ASHG 2022 Poster Abstracts

As of September 30, 2022

Instructions:

1. View the Table of Contents on the next page.
 - a. The Table of Contents is sorted chronologically by Poster Board Number.
2. Click on the Poster Board Number/Abstract Title of the abstract you would like to view and you will be taken to the page the abstract is on.
3. Details included with each abstract are: the poster session name, session date, abstract title, author block, and abstract body.

Table of Contents

PB1001. 3D genomics with Arima Hi-C sequencing enables detection of clinically relevant gene fusions in pediatric cancer samples.....	117
PB1002*. 4C guided cis- and trans-interaction networks associated with the RCCD1 gene at the 15p26.1 breast and ovarian cancer risk locus.....	118
PB1003. A B-ALL pediatric patient with IGH rearrangement	119
PB1004. A Case of A Hyperdiploid Complex Karyotype in a Patient with a Myelodysplastic Syndrome	120
PB1005. A cross-ancestry meta-analysis identifies 451 susceptibility loci for prostate cancer and yields a genetic risk score effective in multiple populations.....	121
PB1006. A genome-wide association study to identify predictive markers for the risk of nivolumab-induced immune-related adverse events	122
PB1007. A genome-wide gene expression signature of Breast cancer in the Moroccan women	123
PB1008. A novel immunohistochemical marker helps in the diagnosis of Lynch syndrome: detection of deficient DNA mismatch repair pathway proteins crypts within non-tumor colonic mucosa.	124
PB1009. A polygenic risk score for prostate cancer risk prediction.....	125
PB1010. A ten-year-long experience of <i>BAP1</i> -Tumor Predisposition Syndrome diagnostics	126
PB1011. Accelerated Tumor Only Variant Analysis Utilizing a GPU Framework.....	127
PB1012. AmpliconClassifier detects the mechanisms of focal genome amplifications in cancer.....	128
PB1013. Amplification of <i>RUNX1</i> in a patient with AML.....	129
PB1014. An active learning framework improves tumor variant interpretation.....	130
PB1015. An AML patient showing an abnormal hyperdiploid karyotype.	131
PB1016. An integrative genomic transcriptomic and proteomic investigation to characterize differences between isogenic radioresistant prostate cancer cell lines.	132
PB1017. Analysis of second-hit events in Tuberous Sclerosis Complex normal tissues and lesions...	133
PB1018. Analysis of the spatial transcriptomic profiles in tumor and tumor microenvironment of colorectal cancer in Alaska Native patients.	134
PB1019. ArCCH: Improving the Performance of Clonal Hematopoiesis Variant Calling and Interpretation using a Consensus Based Approach.....	135
PB1020. Artemis disease-associated variants and their effect on VDJ recombination and genome instability.....	136
PB1021. Assessing the relationship between coding variation and cancer risk in known cancer GWAS susceptibility regions	137
PB1022*. Assessment of genomic instability in aggressive forms of breast cancer in Mali.....	138
PB1023. Association of the rs12587 variant in the KRAS gene in patients with breast cancer and control group of the Mexican population.....	139

ASHG 2022 Annual Meeting Poster Abstracts

PB1024*. Associations of genetic ancestry to the somatic mutational landscape from tumor profiling data of 100,000 cancer patients.....	140
PB1025. B cell repertoire analysis in prostate cancer identifies gene expression pattern differences in FC gamma receptors.	141
PB1026. Breast cancer genetics in non-Ashkenazi breast cancer patients - carrier rates and variant classification in a genetically diverse population.....	142
PB1027*. Breast cancer polygenic risk score as a tool to risk stratify participants in the Healthy Nevada Project.	143
PB1028. Can impairment of kidney function cause kidney cancer? A bidirectional Mendelian randomization study.....	144
PB1030. Cancer subclone detection based on DNA copy number in single cell and spatial omic sequencing data.....	145
PB1031. Cancer-driving mutations are enriched in genic regions intolerant to germline variation.....	146
PB1032. Case report: Olaparib use in metastatic lung adenocarcinoma with <i>BRCA2</i> pathogenic variant	147
PB1033. Case-control likelihood ratio calculation for clinical classification of <i>BRCA1</i> and <i>BRCA2</i> variants of uncertain significance	148
PB1034. Cell-free DNA fragmentation patterns predict the response to immunotherapy in head and neck squamous cell carcinomas	149
PB1035. Cell-intrinsic metabolism and cofactor balancing define the metabolomic impact of NAD ⁺ supplementation in pancreatic cancer cell metabolism	150
PB1036. Characterization of molecular differences between normal weight and overweight/obese cancer patients.....	151
PB1037. Characterization of nucleosome positions and chromatin interactions of regulatory elements comparing Hi-C, Micro-C, and promoter capture Micro-C.....	152
PB1038. Characterization of the <i>2q22</i> renal cancer susceptibility locus	153
PB1039*. Chromatin accessibility of primary human cancers ties regional mutational processes and signatures with tissues of origin.....	154
PB1040. Chromosomal alteration profiling of lymph node metastases in non-small cell lung cancer	155
PB1041. Chromosome Arm Copy Number Profiling using a Clinical, Targeted NGS Panel.....	156
PB1042. Circulating miRNA signature for diagnostic prediction in breast cancer.	157
PB1043*. <i>Cis</i> - and <i>trans</i> -eQTL TWAS of breast and ovarian cancer identify more than 100 risk genes in the BCAC and OCAC consortia.	158
PB1044. Classification of Central Nervous System Tumors with DNA methylation - The Brazilian Experience.....	159
PB1045. Clinical and genetic features of patients with multiple endocrine neoplasia type 1 in Korea	160
PB1046. Clinical utility of genomic sequencing for hereditary cancer syndromes: A retrospective chart review.....	161

ASHG 2022 Annual Meeting Poster Abstracts

PB1047*. Clinicogenomic Neural Networks with Real World Evidence: Predicting Outcomes and Targeting Interventions at a Comprehensive Cancer Center.	162
PB1048. CML with a typical BCR-ABL1 fusion in a 15-year-old male patient presenting with marked leukocytosis, thrombocytosis, left-shifted granulocyte maturation in the peripheral blood	163
PB1049*. Co-delineating genomic and transcriptomic modes of resistance to MEK inhibition in individual triple negative breast cancer cells.	164
PB1050. Combined FISH and cytogenetic testing increases the accuracy of classification and risk stratification of multiple myeloma samples.	165
PB1051. Comprehensive Characterization of Functional Cancer Susceptibility at the 5p15.33 TERT/CLPTM1L Pan-Cancer Risk Locus	166
PB1052. Comprehensive CRISPR-based dissection of a complex common and familial melanoma risk locus on chromosome band 9p21.....	168
PB1053. Comprehensive study of gene expression outliers and their regulation mechanisms in pan-cancer.	169
PB1054. Computational method for the detection of microsatellite instability in tumor tissue samples	170
PB1055. Concurrent Core-binding factor beta subunit (CBFB) gene rearrangement/inv(16)(p13.1q22) in p210 BCR-ABL1 positive chronic myelogenous leukemia.....	171
PB1056. Confirmation of pathogenic germline variants identified by tumour testing in British Columbia.....	172
PB1057. Congenital uterine abnormalities and the risk of gynecological cancers	173
PB1058*. Copy number variation at <i>ATF7IP</i> is associated with increased risk for testicular germ cell tumors.	174
PB1059. Cost-utility of universal screening for common BRCA1 and BRCA2 variants among Ashkenazi Jewish women: a real-life analysis.....	175
PB1060. <i>CRLF2</i> Rearrangements in a Patient with B-ALL.	176
PB1061. Cross disorder genetic analysis identifies autoimmune disease loci inversely associated with diverse cancer types	177
PB1062. Deciphering a prognostic DNA methylation signature in tubo-ovarian high-grade serous cancer.	178
PB1063. Deep and error corrected sequencing via the low-cost Ultima Genomics platform enables ultra-sensitive circulating tumor DNA cancer monitoring.....	179
PB1064. Deep learning identifies gene expression and DNA methylation as highly predictive of lung cancer histologic subtype.....	180
PB1065. Deep learning morphology profiling identifies and enriches carcinoma cells from effusion samples in real-time for cytological and molecular analysis	181
PB1066. Detecting pleiotropic breast cancer susceptibility variants from genome-wide association studies.	182
PB1067. Detection of androgen receptor splice variants from clinical sequencing.....	183

ASHG 2022 Annual Meeting Poster Abstracts

PB1068. Detection of APC and MUTYH germline mutations in two south Indian families with hereditary colorectal cancer. 184

PB1069*. Detection of circulating tumor DNA in resectable pancreatic ductal adenocarcinoma 185

PB1070. Detection of *EGFR* exon skipping variants using clinical sequencing and its application.... 186

PB1071. Detection of somatic copy number alterations using paired DNA and RNA sequencing..... 187

PB1072. Determining the mechanisms of radioresistance in breast cancer..... 188

PB1073. Developing a high-quality, sample-to-result Hereditary Breast and Ovarian Cancer Panel Assay Pipeline for using a novel sequencing platform. 189

PB1074. Development and Clinical Validation of a Bioinformatics Pipeline for Cancer Transcriptome Sequencing..... 190

PB1075*. Development and Clinical Validation of a Liquid Biopsy Assay for Neurofibromatosis 1. 191

PB1076. Development of a breast cancer risk prediction model with carrier status, a polygenic risk score, and epidemiologic risk score. 192

PB1077. DHGAN, Digital Histology Generative Adversarial Networks Used in Creating Synthetic Genitourinary Tissue Slides 193

PB1078. Diagnostic gene fusion detection in cancer by adaptation of short-read CHOP Fusion Panel to Oxford Nanopore long-read sequencing. 194

PB1079. Dietary factors and endometrial cancer risk: A Mendelian randomization study..... 195

PB1080*. Differentially expressed serum RNAs as potential early markers for primary sclerosing cholangitis-associated cholangiocarcinoma. 196

PB1081. Discovery of novel predisposing coding and noncoding variants in familial Hodgkin lymphoma 197

PB1082. Discovery of transcriptomic predictors of colorectal cancer mortality by race and ethnicity 198

PB1083. Dissecting admixture effects on a 313-variant polygenic risk score model for breast cancer in a census-based cohort of Brazilians. 199

PB1084. Does non-coding variation in known breast cancer susceptibility genes contribute to breast cancer risk? 200

PB1085. Dosing-specific modes of resistance to quizartinib in individual acute myeloid leukemia cells exposed by ResolveOME combined genomics and transcriptomics chemistry..... 201

PB1086. Dynamic play between human N a-acetyltransferase D and H4-mutant histones: Molecular dynamic study 202

PB1087. EagleC: A deep-learning framework for detecting a full range of structural variations from bulk and single-cell contact maps. 203

PB1088. Efficacy of universal testing for hereditary cancer syndromes: A community based cancer center (CBCC) experience. 204

PB1089. EG VEGF in ovarian cancer and preeclampsia as an early diagnostic marker: toward a targeted therapy in the treatment of tumors, especially those resistant to chemotherapy. 205

PB1090. Eligibility, uptake and response to germline genetic testing in women with DCIS..... 206

PB1091. Elongin C (*ELOC/TCEB1*) gene: a novel cause of von Hippel-Lindau disease 207

ASHG 2022 Annual Meeting Poster Abstracts

PB1092*. Enhanced expression of mutant alleles of cancer driving genes in pan-adenocarcinoma....	208
PB1093. Estimating total tumor-specific microRNA content in human tissues using computational deconvolution.....	209
PB1094. Evaluating biomarker potential of germline genomic factors for predicting clinical outcomes in prostate cancer.	210
PB1095. Evaluation of miR-21 and miR-938 expression in the progression of gastric cancer in the Magellanic Chilean cohort - MAGIC.	211
PB1096. Evaluation of non-coding regulatory variants in susceptibility of Chordoma	212
PB1097. Evidences for polygenic inheritance in familial cancer	213
PB1098. Exome-wide discovery of the contribution of coding variants identifies novel genes associated with breast cancer risk.	214
PB1099. Expanding the clinical and molecular spectrum of hereditary <i>TINF2</i> cancer predisposition syndrome reporting a family with Hodgkin Lymphoma.....	216
PB1100. Exploring the non-invasive potential of miRNA 145 and miRNA 363 in Prostate Cancer...	217
PB1101. Family History-Based Risk of BRCA Mutations in the Malian Populations.....	218
PB1102. Filling gaps in whole genome analysis in hematology: A chance for optical mapping and long-read NGS.	219
PB1103. Finding Therapeutic Targets in Cancer Cells Using Essential Genes.....	220
PB1104. Frequently mutated TOP2B binding sites reveal candidate structural and regulatory cancer drivers of hepatocellular carcinoma.....	221
PB1105. Functional characterization of the 1p36.33 pancreatic cancer GWAS locus	222
PB1106*. Functional screens implicate candidate breast cancer risk genes in T cell-mediated immune-surveillance	223
PB1107. Functionalizing methylation-derived gene panels in the UK Biobank, TCGA, and HCA datasets.....	224
PB1108. Gene fusion detection and characterization in long-read cancer transcriptomes with FusionSeeker.....	225
PB1109. Gene-environment interaction of antioxidant genes and a healthy lifestyle index (HeLiX) on breast cancer risk reduction.....	226
PB1110. Genetic ancestry correlates with somatic mutations in endometrial cancer.....	227
PB1111*. Genetic ancestry differences in tumor mutation between early and average onset colorectal cancer	228
PB1112. Genetic Modifiers of <i>KRAS</i> -Mutant Colorectal Cancer.....	229
PB1113. Genetically Predicted Telomere Length and Risk of Multiple Primary Cancers in the Prostate, Lung, Colorectal and Ovarian Cancer Screening Trial.	230
PB1114. Genome and transcriptome landscape of familial pancreatic cancer and implications for altered glucose metabolism in moderate-penetrance cancer susceptibility.....	231
PB1115*. Genome-wide Analysis of Rare Haplotypes Associated with Breast Cancer Risk: Discovery, Replication, and Generalizability Evaluation	232

ASHG 2022 Annual Meeting Poster Abstracts

PB1116. Genome-wide association study identifies 4 novel risk loci including a missense variant in <i>LGR5</i> for small intestinal neuroendocrine tumors.....	233
PB1117*. Genome-wide association study of intracranial germ cell tumors: a common deletion at <i>BAK1</i> attenuates the enhancer activity and confers risk for the rare disease.	234
PB1118. Genome-wide profiling of DNA N6methylation from a breast cancer and a matched normal cell lines	236
PB1119*. Genomic landscape of malignant peripheral nerve sheath tumor (MPNST) reveals novel pathways of tumor evolution that correlate with tumor behavior.	237
PB1120. Germline functional non-coding variants associated with ovarian cancer predisposition	239
PB1121. Germline genetics of venous thromboembolism (VTE): Non-cancer polygenic risk scores improve risk stratification in cancer patients	240
PB1122. Germline sequencing in Brazilian pancreatic carcinoma patients.....	241
PB1123. Germline sequencing of DNA damage repair genes in two hereditary prostate cancer cohorts reveals rare risk-associated variants.....	242
PB1124. Germline variants in the Ah Receptor in Colombian smoker patients with squamous cell carcinoma of the head and neck.....	243
PB1125. GLUT10 is a biomarker for poor prognosis and a predictor of vitamin C combination therapy in breast cancer	244
PB1126. Going beyond the atlas: Mapping the tumor landscape with complete genomic signatures..	245
PB1127*. HDM2 differentially modulates the molecular phenotype of lung tumor cells of varying p53 genotypes	246
PB1128. Hemophagocytosis related to acute promyelocytic leukemia is also positive for the <i>PML::RARA</i> gene fusion.....	247
PB1129. Hereditary Cancer Variants & Homologous Recombination Repair Deficiency in Biliary Tract Cancer	248
PB1130*. Heterozygous loss of <i>AURKB</i> in the germline associates with protection from metastasis and death from cancer.....	249
PB1131. High tumor mutational burden by whole-genome sequencing in resected non-small cell lung cancer in never smokers is associated with worse prognosis.....	250
PB1132*. High-throughput functional screening of candidate causal variants from lung cancer susceptibility loci	251
PB1133. Identification of key molecular mechanisms in IDH mutant brain tumors to enable precise risk stratification	252
PB1134. Identification of target genes and pathways involved in triple-negative breast cancer proliferation and stemness using genome-wide CRISPR screens.....	253
PB1135. Identification of <i>USP9X</i> as a leukemia susceptibility gene.....	254
PB1136*. Identifying molecular markers of early stage ovarian cancer pathogenesis through whole genome CRISPR screening of mutant <i>BRCA1</i> fallopian tube cells.	255

ASHG 2022 Annual Meeting Poster Abstracts

PB1137. Identifying strong instrumental variables for pleiotropic assessment in Mendelian randomization: CALGB/SWOG 80405 (Alliance)..... 256

PB1138. Impact of polygenic risk, pathogenic variants, and family history on detection of breast cancers within and outside the national mammography screening programme on 117,252 women over 1992-2019 258

PB1139. Implementation of new ClinGen/CGC/VICC recommendations for classification of oncogenicity of somatic variants using AI..... 259

PB1140. Implementation, utilization, and diagnostic outcomes of a technology-enabled telehealth-based program for individuals to access multi-cancer early detection testing 260

PB1141. Inference on the genetic architecture of breast cancer risk 261

PB1142*. Integrating GWAS and 3D chromatin interactome data to identify multi-cancer risk genes in hormone-related cancers. 262

PB1143. Integrative data analysis to uncover genes and pathways underlying the aggressiveness of lung cancer brain metastasis and the overall prognosis 263

PB1144. Investigating the link between cholesterol-lowering genes and risk of skin cancers 264

PB1145. Isolated multinodular goiter in a family with DICER1 heterozygous germline variant 265

PB1146. Large-scale whole genome sequencing reveals that APOBEC mutagenesis is a common process in normal human small intestine 266

PB1147. Leveraging network architecture and transfer learning for precision oncology..... 268

PB1148. Leveraging somatic cancer mutation data to predict the pathogenicity of germline missense variants..... 269

PB1149. Liquid biopsy for the detection of actionable human variants in the blood of cancer-diagnosed dogs: Opening the door to comparative oncology and therapeutic development. 270

PB1150. Loss of function of *neurofibromin* affects *afadin* -6 in neurofibromatosis type-1..... 271

PB1151. Low CD2 expression in sentinel lymph nodes of early breast cancer patients is associated with postoperative tumor recurrence or metastasis 272

PB1152. Massively parallel sequencing-based panel strategy for microsatellite instability testing..... 273

PB1153. Mechanistic insight into HIF1 α -Notch1 axis in chronic myeloid leukemia patients and its diagnostic implications 274

PB1154. Metabolic Profiling of Primary and Metastatic Breast Cancer Cells and New Treatment Approaches. 275

PB1155. Metagenomics and metabolomics of persistent high-risk Human Papillomavirus (hrHPV) infections and cervical cancer 276

PB1156*. Methylation-sensitive restriction enzyme sequencing (MRE-seq)-based early detection of cancer using deep neural network..... 277

PB1157. Mitonuclear genotype remodels the metabolic and microenvironmental landscape of Hürthle cell carcinoma 278

PB1158. Modulating the immune system not to reject an allograft..... 279

ASHG 2022 Annual Meeting Poster Abstracts

PB1160. Molecular signature predicts immunotherapy resistance in gynecologic cancer patients treated with immune checkpoint inhibition.	280
PB1161. Mosaic chromosomal alterations detected in HIV infected men and its relationship to non-Hodgkin lymphoma.	281
PB1162. Multigene deregulation 12q12 renal cancer-susceptibility locus.	282
PB1163. Multi-modal characterization of ultra-rare germline genetic variants driving breast cancer risk in the indigenous Arab population.	283
PB1164. Multiomic sequencing analysis with whole genome association study at chromosome 16 of wilms tumor patients.	284
PB1165. Multi-omic single-cell profiling of endogenous and engineered T cells in patients undergoing CAR T cell therapy for high-grade glioma.	285
PB1166. Multiplex ligation dependent probe amplification versus fluorescent in situ hybridization for screening RB1 copy number variations in Egyptian patients with retinoblastoma.	286
PB1167. Multi-population GWAS analysis identified functional variants in ever- and never-smoking lung cancer.	287
PB1168*. Multi-stage germline exome sequencing study of 17,546 men with aggressive or non-aggressive prostate cancer identifies genes that may inform clinical gene panel testing.	288
PB1169. Next Generation SP DNA Sample Prep and DLS Labeling Readies Optical Genome Mapping Workflows for Adoption at Scale.	290
PB1170. No evidence of association between clonal hematopoiesis and risk of prostate cancer in large samples of European ancestry men.	291
PB1171. Novel Germline Pathogenic Variants of <i>APC</i> and <i>BMPRIA</i> genes in Algerian patients with Hereditary Polyposis Syndromes.	292
PB1172. Nucleotide resolution of large tandem duplications in cancer genomes.	293
PB1173. OM2BFB: Detecting and elucidating Breakage Fusion Bridge structures in cancer genomes using Optical Mapping data.	294
PB1174. Oncological biomarkers identified by NGS: characterization of the colombian population tumors from 2019 to 2022.	295
PB1175. Online implementation of combined polygenetic protein prediction algorithm for oncology (C3PO): Tumor mutation contributions to cancer hallmarks based on proteomics.	296
PB1176. Ovarian sex cord stromal tumor is a likely additional phenotype of <i>BAP1</i> -Tumor Predisposition Syndrome.	297
PB1177. <i>PALB2</i> -mutated human mammary cells display a broad spectrum of morphological and functional abnormalities beyond defective DNA damage response.	298
PB1178. Pan-Cancer Analysis introduces HLF as a tumor suppressor gene and a promising biomarker for prognosis and targeted therapy in human tumors.	299
PB1179. Pan-cancer polygenic risk distinctly contributes to prediction of heterogeneous subsequent malignancies across treatment profiles in survivors of childhood cancer.	300
PB1180. Parent-of-origin-aware genomic analysis in the management of patients and families with genetic disease.	301

ASHG 2022 Annual Meeting Poster Abstracts

PB1181. Pathogenic genetic variants from highly connected cancer susceptibility genes confer the loss of structural stability and further link with diabetes 302

PB1182. Pathogenic Variants in Adult-Onset Cancer Predisposition Genes Identified by Pediatric Tumor Genomic Testing: Prevalence, Tumor Features, and Germline Testing Outcomes 303

PB1183. Phylogeny-aware detection of single-nucleotide variants and mode of evolution from cancer single-cell DNA sequencing data..... 304

PB1184. Potential misrepresentation of inherited breast cancer risk by common germline alleles..... 305

PB1185. Potential subtype-informative genetic risk variants and genes identified from a case-case analysis for breast cancer 306

PB1187. Prevalence of mutations in hereditary cancers of Czech patients. 307

PB1188*. Prevalence of suspected pathogenic or likely pathogenic germline *TP53* variants in population sequencing databases: A genotype-first analysis. 308

PB1189. Primary myelofibrosis and progression to acute myeloid leukemia in a young patient with variant in *CARL*..... 309

PB1190. Prognostic Value of Bile Acid Transporter SLC10A1 Expression in Hepatocellular Carcinoma 310

PB1191*. Proteome studies of breast, prostate, ovarian, and endometrial cancers implicate plasma protein regulation in cancer susceptibility. 311

PB1192. Rare germline variants in Deubiquitylating enzymes (DUBs) in young women with breast cancer 312

PB1193. Rare variant association study in lymphoid cancers 313

PB1194. Relative involvement of human papillomavirus constitutional genomic instability: Cellular sequela syndromes. 314

PB1195. Resolving clone-and haplotype-specific copy number variation and DNA methylation in heterogeneous tumors with nanopore sequencing..... 315

PB1196. Revisiting tumor evolution in multifocal hepatocellular carcinoma with different clonal origins 316

PB1197. Rewired phospho-signaling networks by genetic variants in Clear Cell Renal Cell Carcinoma 317

PB1198. Risk of cancer in persons with a single Fanconi anemia gene variant: A population-based study of MyCode Cohort 318

PB1199. Serum biomarkers are altered in UK Biobank participants with mosaic chromosomal alterations..... 319

PB1200. Sex differences in the Lung Adenocarcinoma transcriptome: Analysis of TCGA LUAD and GTEx lung tissue..... 320

PB1201. Shared predisposition to cancer and metabolic disorders using large-scale genomic data 321

PB1202. Single cell RNA sequencing reveals global cellular landscape of appendiceal cancer..... 322

PB1203. Single cell transcriptomics of Pituitary Neuroendocrine Tumors (PitNETs)..... 323

ASHG 2022 Annual Meeting Poster Abstracts

PB1204. Single Sample Gene Set Enrichment Analysis (ssGSEA) to Identify Dysregulated Pathways in a Biomarker Matched Pilot Study of Mantle Cell Lymphoma.	324
PB1205. Single-cell identity and state coupled with genome-wide SNV and CNV in primary breast cancer with ResolveOME profiling.	325
PB1206. Single-cell methylation and 3C sequencing in prostate tumors shows substantial epigenome reprogramming.....	326
PB1207. Single-cell multi-omic characterization of MPAL phenotypes reveals patient heterogeneity associated with poor treatment outcomes	327
PB1208. Single-cell sequencing of genomic DNA: Assessing clonal populations of tumor cells in endometrial cancer	328
PB1209. <i>SMARCA4</i> Schwannomatosis: a known cancer susceptibility gene, a new phenotype.....	329
PB1210. Splicing analysis of endometrial cancer GWAS risk loci: splicing-associated variants reveal <i>NFI</i> and <i>SKAPI</i> as candidate susceptibility genes.	330
PB1211. t(6;9)(p22;q34) translocation with DEK-NUP214 fusion identified in one patient with chronic myeloid leukemia.....	331
PB1212. Targeting mutant HLA-bound cancer peptide demonstrated in vivo efficacy in delaying tumour growth in a low mutational burden aggressive ovarian cancer.....	332
PB1213. Telomeric nuclear organization of urinary circulating cells in bladder cancer (BC): A new method uncovers unreported markers.	333
PB1215. The effect of weight-loss on the colorectal transcriptome and its relation to colorectal cancer risk.	334
PB1217. The role of senescent tumor cells in cancer progression.....	336
PB1218. The Role of Tumor Microenvironment and Tumor-Active Pathways in the Progression of Glioma	337
PB1219. The use of <i>TNF</i> - <i>α</i> polymorphic forms as a possible risk assessment tool for the management of breast cancer among Nigerian women.	338
PB1220. Transcriptome Wide Association Study identifies novel candidate risk genes for testicular germ cell tumors	339
PB1221. Transcriptome-wide association study identifies new breast cancer susceptibility genes in Latinas.....	341
PB1222*. Transcriptome-wide association study identifies novel susceptibility genes for childhood acute lymphoblastic leukemia in Latinos.....	342
PB1223*. Uncovering gene fusions with 3D genomics: from clinical validation to actionable insights for undiagnosable solid tumors	343
PB1224*. UNISON: a software toolkit for streamlined detection of clonal hematopoiesis of indeterminate potential in large-scale sequencing studies	344
PB1225. Unraveling the mechanisms behind the malignant behavior of mast cell tumors using laser capture microdissection mediated RNA sequencing on canine models.....	345
PB1226. Unravelling RecQ helicase function in genome stability using Strand-seq	346

ASHG 2022 Annual Meeting Poster Abstracts

PB1227. Using human genetics to evaluate the causal role of circulating inflammatory markers in risk of adult cancer.....	347
PB1228. Utility of hereditary cancer panel testing in individuals with a known familial variant.	348
PB1229*. Utilizing Electronic Health Records (EHR) and Tumor Panel Sequencing to Demystify Prognosis of Cancer of Unknown Primary (CUP) patients	349
PB1230. Variants in <i>FANCM</i> confer risk to estrogen receptor-negative breast cancer among Latinas	350
PB1231. Whole genome CpG-resolution DNA methylation profiling of HNSCC reveals previously ignored heterogeneity among HPV(+)tumors and clinical implications.....	351
PB1232. A catalog of genetic predictors impacting lifelong medication use patterns in hyperlipidemia, hypertension and type 2 diabetes	352
PB1233. A comparative PRS-PheWA of 14 autoimmune disorders, and their genetic relationship....	353
PB1234. A comprehensive coronary artery disease risk prediction framework incorporating genetic and nongenetic risk factors.	354
PB1235*. A comprehensive genetic map of cytokine responses to pathogens in 1063 Lyme patients reveals novel regulatory mechanisms underlying diseases.	355
PB1236. A <i>Drosophila</i> platform to validate and assess pathogenicity of LMNA variants identified from dilated cardiomyopathy patients.	356
PB1237. A genome wide association study of chronic spontaneous urticaria risk and heterogeneity.	357
PB1238. A genome-wide association study in Peruvians suggests new risk loci for Alzheimer disease	358
PB1239. A genome-wide association study of lifetime estrogen exposure in Korean postmenopausal women.....	359
PB1240. A genome-wide association study of mammographic density phenotypes among pre-menopausal women of European ancestry.....	360
PB1241. A Haptoglobin (HP) Exon Deletion Polymorphism Alters the Effect of <i>APOE</i> Alleles on Alzheimer's Disease in Individuals of European Ancestry with <i>APOEε4</i>	362
PB1242. A large-scale genome-wide association meta-analysis of polycystic ovary syndrome in over 540,000 women provides insights into biological mechanisms.....	363
PB1243. A Mendelian randomization study of genetic liability to Post-traumatic stress disorder and risk of Ischemic Stroke.	364
PB1244. A multi-ancestry genome-wide association study identifies two novel loci associated with increased risk of diabetic macular edema.	365
PB1245. A multi-ethnic genome-wide association study in type 1 diabetes.	366
PB1246. A nationwide approach to understand the role of health, socioeconomic and genetic information in predicting COVID-19 vaccination uptake	367
PB1247. A novel missense variant in melanopsin associated with delayed sleep phenotype: A whole genome sequencing study.	368
PB1248. A pan cancer immunogenomic atlas and its applications for immune checkpoint blockade immunotherapy	369

ASHG 2022 Annual Meeting Poster Abstracts

PB1249. A polygenic score-based approach improves discrimination between familial, idiopathic, and pathologic short stature in a cohort of pediatric patients presenting for evaluation.....	370
PB1250. A second wave SARS-CoV-2 variant in Quebec is associated with persistent infection.	371
PB1251. A single nucleus transcriptomics study of alcohol use disorder in postmortem brain tissue.	372
PB1252. A Systematic Multi-omics Approach Identifies miRNA and Proteomic Dysregulation in Human Post-traumatic Stress Disorder	373
PB1253. A trans ancestry genomics based approach to study the interplay between the immune system, infectious type, and HLA type, ancestry and sepsis outcome.....	374
PB1254. Accurate identification of causal variants of intracellular LDL uptake via Bayesian modeling of base editor reporter screens	375
PB1255. Activity-dependent transcriptional program in glutamatergic neurons enriched for genetic risk for schizophrenia.....	376
PB1256. Advancing rare disease research through web-based recruitment: the 23andMe Systemic Sclerosis Research Study	377
PB1257. Age differences in preadipocyte proportions and expression profiles link to obesity and insulin resistance.....	378
PB1258. Altered expression levels of <i>TASIR1</i> , <i>TASIR3</i> genes among SARS-CoV-2 variants	379
PB1259. Alzheimer Disease plasma biomarker pTau-181 in individuals of diverse admixed ancestral backgrounds	380
PB1260. Alzheimer's disease genetic risk and plasma biomarker profiles in the Midwestern Amish.	381
PB1261*. Alzheimer's disease pathology drives distinct homeostatic and active microglia phenotypes revealing clues to early pathogenic transcriptional switches	382
PB1262. An emirati cohort of autism spectrum disorders.	383
PB1263. An integrated genomic and phenotypic analysis of sleep traits in autism spectrum disorder	384
PB1264. An unprecedented level of complexity in the schizophrenia-associated 3q29 region of the human genome with unique segments that increase the risk for non-allelic homologous recombination.	385
PB1265. Analysis of 3,273 undiagnosed neurodevelopmental disorder trios reveals over-transmission of polygenic risk and a female protective effect	386
PB1266. Analysis of adipose and liver expression profiles from dual-tissue transcriptomic cohort discovers 10 serum biomarker candidates for NAFLD.....	387
PB1267. Analysis of both shared and specific associations among various autoimmune disorders greatly helps the identification of the causal gene(s) and the functional mechanisms.....	389
PB1268. Analysis of MRI-derived spleen iron in the UK Biobank identifies genetic variation linked to iron homeostasis and hemolysis.....	390
PB1269. Analysis of nascent RNA reveals distinct gene signatures for acute inflammation in cytokine stimulated keratinocytes.....	391
PB1270. Analysis of poison exons caused by splice donor variants in genes associated with developmental brain disorders	392

ASHG 2022 Annual Meeting Poster Abstracts

PB1271. Analysis of Relationship between Metabolic Syndrome and Genome-Wide Association Study (GWAS) of Vitamin D in Koreans: Community-Based Cohort.	393
PB1272. <i>APOE</i> genotype and rare variants of APP processing complex in autopsy-confirmed rapidly progressive Alzheimer disease.	394
PB1273*. Assessing T-Cell Receptor Diversity and Genetic Variation in Complex Phenotypes.	395
PB1274. Association analysis of <i>LHCGR</i> gene polymorphisms with Polycystic Ovary Syndrome in Punjabi population.	396
PB1275. Association analysis of structural variants in whole-genome sequencing of 150K UK Biobank participants.	397
PB1276. Association between a type 2 diabetes polygenic risk score and type 2 diabetes-related risk factors and complications.	398
PB1277. Association between Blood Pressure-related Polygenic Risk Scores and Hypertension among White and Black Individuals Across the Life Course.	399
PB1278. Association between genomic runs of homozygosity and complex traits in the Taiwan Biobank.	400
PB1279. Association between polymorphisms in <i>CD32</i> , <i>CD36</i> , <i>CD40</i> , <i>CD54</i> and Malaria phenotypes among under-fives in Ibadan South-west Nigeria.	401
PB1280. Association of a genetic risk score with incident coronary heart disease in the Hispanic Community Health Study/Study of Latinos (HCHS/SOL) cohort.	402
PB1281. Association of African Ancestry with risk for fibroproliferative diseases is consistent with selection for a Th2 favored genome in African derived populations.	403
PB1282. Association of genetic predisposition and physical activity with risk of gestational diabetes mellitus in nulliparous women.	405
PB1283. Association of Genetically-Predicted Placental Gene Expression and Diseases of the Cardiovascular System.	406
PB1285. Association of Structural Variants with Coronary Artery Disease.	407
PB1286. Associations between polygenic risk scores and gene expression identify core genes for bipolar disorder.	408
PB1287. Associations between polygenic risk scores, alcohol use, and differences in brain measures in the UK Biobank.	409
PB1288. Autism and Cognitive Ability CNV- Genome Wide Association study (CNV-GWAS).	410
PB1289. Autism Spectrum Disorder (ASD) in Qatar: Whole genome sequencing of 100 affected families highlights Dominant and Recessive risk genes of ASD.	411
PB1290. Automated identification, GWAS, and ExWAS of enlarged perivascular space burden in human brain MRI in the UK Biobank.	412
PB1291. Burden of functional variants in epilepsy patients using a deep learning approach.	413
PB1292. Causal effects of gut-related metabolites on human psychiatric disorders.	414
PB1293. Cell-type-specific activity-dependent multiomic profiling in single hiPSC-derived neurons for neuropsychiatric disorders.	415

ASHG 2022 Annual Meeting Poster Abstracts

PB1294*. Cellular context-specific gene regulation of neuropsychiatric disorders in single human neurons..... 416

PB1295. Characterization of a diverse Frontotemporal Dementia cohort, enriched for Caribbean Hispanic patients..... 417

PB1296. Characterization of gene expression profile and molecular pathways involved in type 2 diabetes among self-identified Hispanic American individuals..... 418

PB1297. Characterization of sequencing-based HLA alleles in a Quebec COVID-19 biobank 419

PB1298. Characterizing 31 cardiometabolic candidate genes for a role in early vascular inflammation and foam cell formation using CRISPR-Cas9, *in vivo* imaging and deep learning 420

PB1299. Cholesterol and LDL-C levels are elevated prior to symptom onset in Alzheimer’s disease independent of APOE-4..... 421

PB1300. Choroidal thickness as a biomarker for age-related macular degeneration progression: Genome-wide Association Study in Amish 422

PB1301. Classical HLA Alleles are Associated with Fasting Glucose and Type 2 Diabetes in Multiple Populations..... 423

PB1302. CLEC16A regulates the adipogenic and lipolytic capacity of adipocytes 424

PB1303*. Clinical utility of polygenic scores for cardiometabolic disease in Arabs 425

PB1304. Clonal behavior across multiple timepoints in clonal hematopoiesis 426

PB1305. Collagen gene cluster expressions role on liver fibrosis in biliary atresia patients..... 427

PB1306. Colocalization and variant-to-gene mapping nominates pleiotropic bone mineral density effector genes 428

PB1307. Combining genetic risk with machine learning derived biological age improves prediction of type 2 diabetes..... 429

PB1308. Combining polygenic and monogenic causes for improved osteoporotic fracture risk prediction. 430

PB1309. Common and rare variant associations with spinal stenosis in 29,488 cases..... 431

PB1310. Comparison of clinical characteristics among survivor and non-survivor of covid-19 infected patients: Scoping review and meta-analysis. 432

PB1311. Concordance of directional effects between sexes suggests pervasive epistasis and omnigenic regulation of complex metabolic traits in mice..... 433

PB1312. Considerations in developing a framework for defining clinical actionability of polygenic risk scores 434

PB1313. Construction of clinically significant mutation map and their spatio-temporal single cell transcriptomics trajectories in congenital heart disease 435

PB1314. Construction of mutational landscape and characterization of associated genes in a Bangladeshi cohort of neurodevelopmental disorders 436

PB1315. Copy number variants and mental health in a community pediatric sample..... 438

PB1316. Coronary artery disease risk assessment in Asian Indian Punjabis using a genome wide polygenic risk score 439

ASHG 2022 Annual Meeting Poster Abstracts

PB1317. Cross-tissue single-nucleus RNA-sequencing reveals distinct tissue-specific expression profiles of adipocytes, depending on their residency in human adipose tissue or heart	440
PB1318. Curation burden mitigation: strategies for empowering high throughput gene panel analysis using whole genome sequencing.....	441
PB1319*. Cytokine treatment increases <i>APOEε4</i> expression in reactive astrocytes in European local ancestry but not in African local ancestry.....	442
PB1320. Data-driven Clustering of Human Cardiovascular Disease (CVD) Related Variables	443
PB1321. Data-driven genome-wide association study of longitudinal pain and mobility trajectories among cases of Parkinson’s disease from the Fox Insight Data Exploration Network	444
PB1322. <i>De novo</i> CNVs impacting constraint overlapping genes in neurodevelopmental disorders and congenital anomalies.....	445
PB1323. <i>De novo</i> germline and somatic variants as modifiers of cleft lip/palate severity in mice	446
PB1324. <i>De novo</i> variant analysis of childhood-onset obsessive-compulsive disorder in the French-Canadian population.	447
PB1325. Deciphering the causal relationship between blood pressure and white matter integrity: a Mendelian Randomization study in the UK Biobank	448
PB1326. Deep embedded clustering by phenotype and genome-wide association study in autism from SPARK individuals.....	449
PB1327. Deep learning models of gene regulation in Alzheimer’s disease improve functional fine-mapping and thereby cross-ancestry PRS portability	450
PB1328. Deep venous thrombosis: genotyping and whole-exome sequencing data to improve genetic risk prediction	451
PB1329. Differential gene expression analysis of alcohol use disorder across postmortem human brain tissues.....	452
PB1330. Differential splicing occurs in individuals with disseminated coccidioidomycosis infections.	453
PB1331. Differentiating Mesenchymal Stem Cells from iPSCs for Analysis of Type 2 Diabetes and Related Trait GWAS Loci	454
PB1332. Direct participation of individuals scales the development of cardiometabolic polygenic risk score models.....	455
PB1333. Discovering disease context eQTLs in a patient cohort with active psoriatic arthritis	456
PB1334*. Discovering the early molecular markers of lipid dysregulation using deep phenotyping and adipose tissue gene expression.....	457
PB1335. Discovery of rare variants in 219 genes associated with adult human height via burden analysis in exomes of 785,210 individuals	458
PB1336. Discovery of Type 2 Diabetes genes using an accessible tissue.	459
PB1337. Discrepancy between genetically-predicted and actual body mass index is a significant predictor of incident cardiovascular disease	460

ASHG 2022 Annual Meeting Poster Abstracts

PB1338. Dissecting autism heterogeneity by genotype phenotype analysis among autism risk gene carriers in SPARK.....	461
PB1339. Dissecting single cell splicing isoforms in human hearts using single cell nanopore sequencing.....	462
PB1340. Dissecting the relationship between recurrent pregnancy loss and type 1 and type 2 diabetes in Western Ukrainian population	463
PB1341. Dissecting the role of pleiotropy in the genetic adaptation of Tibetans to high altitudes.	464
PB1342. Dose-responsive mRNA biomarkers of alcohol consumption and placebo response: A transcriptome-wide gene expression analysis.	465
PB1343. Drug repurposing for osteoporosis in men by integrating multi-omics and pharmacogenomics	466
PB1344. Effect of artificial light on metabolic disorders and circadian gene expression.....	467
PB1345*. Effect of cortisol on cortical organoids: Building a "stress in a dish" model system.....	468
PB1346. Effects of epigenetic age acceleration on kidney function: a mendelian randomization study.	469
PB1347. Effects of the Tau Haplotype on Cognition in Childhood	470
PB1348. Elevated levels of CXCL16 in severe COVID-19 patients: Effects on mortality.....	471
PB1349*. Enriching genetic hypotheses of schizophrenia through neuroimaging transcriptomics.	472
PB1350. Enrichment of Patients with Ehlers Danlos Syndrome in Idiopathic Gastroparesis - A Gene Set Enrichment Analysis.....	473
PB1351. Epstein-Barr virus- and genotype- dependent transcriptional regulation in B cells from patients with multiple sclerosis.....	474
PB1352. ERAP1, ERAP2, and two copies of HLA-Aw19 alleles increase the risk for Birdshot Chorioretinopathy in HLA-A29 carriers.....	475
PB1353. Essential hypertension genomic regions from linkage analysis studies.....	476
PB1354*. Estimating the causal influence of body mass index on gut microbiome variation	477
PB1355. Ethnicity- and sex-specific genome-wide association study on Parkinson's disease	478
PB1356. Evaluating the causal effect of tobacco smoking on whitematter brain aging: a Mendelian randomization analysis in UK Biobank	479
PB1357. Evaluating the frequency and impact of structural variation in amyotrophic lateral sclerosis.	480
PB1358. Evaluation of genetic support for targeting the IL-23 pathway: current and future therapeutic opportunities	481
PB1359. Evaluation of mitochondrial DNA variation in autism and neurodevelopmental disorders ..	482
PB1360. Evaluation of polygenic risk scores to differentiate between type 1 and type 2 diabetes.	483
PB1361. Evidence of allelic series with fine-mapped protein quantitative trait loci across 1,470 protein abundance measurements and 30 biochemistry measurements in UK Biobank participants.	484

ASHG 2022 Annual Meeting Poster Abstracts

PB1362. Examination of PTSD symptoms in older veterans as a function of AD risk genes and combat implicates <i>CLU</i> as a stress-response gene.....	485
PB1363. Exome analysis reveals plausible glaucoma causing mutations in novel genes in dominant JOAG families of Pakistani origin	486
PB1364. Exome sequencing of six singlet Qatar families identified nine neurodevelopmental candidate genes	487
PB1365. Exome-wide association study of DSM-5 antisocial personality disorder in a nationally representative sample.....	488
PB1366. Exploring disease-course trajectories using genomic scores in the Finnish SUPER study - a cohort of 10,407 psychotic individuals.	489
PB1367. Exploring genome-wide association results for neuroticism as a proxy for mental health disorders in individuals of African ancestry	490
PB1368. Exploring the complexity of scleroderma etiology by trio whole genome sequencing	491
PB1369. Expression of adipokine genes associated with gestational diabetes mellitus	492
PB1370. Expression profiling of small bowel tissue from Crohn's disease patients reveals alterations of immune functions and dampening of epithelial response.	493
PB1371. Extensive Transcriptional Complexity of Autism Associated <i>SHANK</i> Family Genes by Capture Based and Long Read sequencing Method	494
PB1372. Findings at both known and novel loci in genome wide linkage and association study of a depression endophenotype, major depressive disorder with chronic pain.	495
PB1373. Fine-mapping 110 migraine risk loci using 98,375 migraine cases	496
PB1374. Fine-mapping 56 lipidomics loci identified by univariate and multivariate genome-wide association analyses	497
PB1375. Fine-mapping and genomic analyses identify causal variants and genes for hypertension ...	498
PB1376. Fine-mapping and signal co-localization of asthma and white blood cell traits within the chr17q12-21 locus across diverse ancestries.....	499
PB1377*. Fine-mapping the association of <i>CYP2A6</i> with nicotine metabolism in African ancestry smokers.	500
PB1378. Fine-mapping to find differences in effect sizes across ancestries for skeletal phenotypes...	501
PB1379*. Functional analysis of rare copy number variations across psychiatric disorders.....	502
PB1380. Functional validation of rs7132908 as the causal variant at the childhood obesity locus on chr12q13.	503
PB1381. Gene-based association studies of rare variants identify novel genes for asthma-associated quantitative traits in African-American children.	504
PB1382. Gene-based tests for early and late onset Alzheimer Disease: common and non-overlapping factors.....	505
PB1383. Gene-by-stress interaction in Alzheimer's disease risks.	507
PB1384. Gene-environment interaction of coffee with body mass index in multiple populations.....	508

ASHG 2022 Annual Meeting Poster Abstracts

PB1385. Gene-level GWAS fine-mapping combined with single cell RNA-seq yields insight into neurodegenerative disease biology	509
PB1386. Genes at asthma-associated GWAS loci are induced in activated CD4 tissue resident memory T cell	510
PB1387. Genes causing significant effects on the dynamics of peroxisomes.....	511
PB1388. Genetic analysis of bruxism and its associations to sleep, psychiatric and behavioural traits.	512
PB1389. Genetic analysis using large biobank controls validates known genes and discover novel genes in Hirschsprung disease.	513
PB1390. Genetic and environmental regulation of caudate nucleus transcriptome in schizophrenia ..	514
PB1391. Genetic architecture of asthma in African American Patients	515
PB1392*. Genetic architecture of insulin-stimulated glucose uptake reveals novel regulators of post-prandial glucose metabolism.....	516
PB1393. Genetic associations of rare variants in alcohol and tobacco use in up-to 526,400 individuals	517
PB1394. Genetic characterization of central serous chorioretinopathy and pleiotropic effects with age-related macular degeneration	518
PB1395. Genetic colocalization between Covid-19 and diseases of the immune system.	519
PB1396. Genetic epidemiology of carotid intima-media thickness in Sub-Saharan African populations contributes to atherosclerosis biology.....	520
PB1397. Genetic Exploration of Military Sudden Cardiac Arrest (GEMini): Genome Sequencing Results from the First 24 Participants.	521
PB1398. Genetic Interactions Implicate Disruption in Ciliogenesis in the Etiology of Non-syndromic Orofacial Clefts.....	522
PB1399. Genetic Mechanisms of Supraventricular Tachycardias	523
PB1400. Genetic Overlap among Alzheimer's Disease and Five Psychiatric Disorders: Genetic Convergence and Specificity.	525
PB1401. Genetic overlap of idiopathic pulmonary fibrosis and hypertension.	526
PB1402. Genetic pleiotropy effects on kidney function and soluble receptor for advanced glycation end-products: The Long Life Family Study (LLFS).....	527
PB1403. Genetic prediction of weight and waist circumference regain after weight loss with Intensive Lifestyle Intervention: A secondary analysis of the Look AHEAD trial.	528
PB1404. Genetic Predictors of Memory Performance in Older Adults	529
PB1405. Genetic profiling and improved predictive capability with protein-based risk scores for IBD and disease progression using UK Biobank data.	530
PB1406. Genetic Regulation of Gene Expression in HIV+ T Cells Associated With Control of HIV spVL in African Populations.....	531
PB1407. Genetic regulation of gene expression in the frontal cortex across the human lifespan	532
PB1408. Genetic susceptibility for autoimmune diseases and white blood cell count variability.....	533

ASHG 2022 Annual Meeting Poster Abstracts

PB1409. Genetic Variability of <i>CYP2B6</i> Polymorphisms (785A>G, 64>CT and 516G>T) in Southwest Nigerian Population: Implications for Malaria Treatment.....	534
PB1410. Genetic variants in Olfactory Response Genes associated with Osteoarthritis progression to Hip or Knee Replacement among African and Hispanic American Veterans.	535
PB1411. Genetic variation in fatty acid amide hydrolase (<i>FAAH</i>) influences early drinking and smoking behaviors.	536
PB1412. Genetically Informed Prediction of Short Term Parkinson’s Disease Progression	537
PB1413. Genetically-associated body-mass index, vitamin D levels, and age at puberty are not associated with Parkinson’s Disease related phenotypes.....	538
PB1414. Genetics determinants of Renin-Angiotensin-Aldosterone System (RAAS) in the Cooperative Health Research In South Tyrol study	539
PB1415. Genetics of Gulf War illness, a genome wide association study.....	540
PB1416. <i>Genetics of ventricular septal defects: A novel genetic interaction between Sox7 and Wnt4 is associated with abnormal endocardial cushion morphogenesis.....</i>	541
PB1417. Genome scans of early childhood caries implicate bitter taste receptors.....	542
PB1418. Genome sequencing in brain samples from the ROSMAP cohort to examine the relationship between telomere length, mitochondrial copy number, and β -amyloid.....	543
PB1419. Genome wide association study of clinically predicted suicide liability.	544
PB1420. Genome-wide analysis in over 1 million individuals reveals over 2,000 independent genetic signals for blood pressure	545
PB1421*. Genome-wide association analyses of sepsis and septic shock in a large practice-based biobank.....	546
PB1422. Genome-wide association analysis of composite sleep scores in 413,904 individuals.....	547
PB1423. Genome-wide association meta-analysis and burden of rare coding variants in African American patients with Acne.....	548
PB1424. Genome-wide association meta-analysis reveals 99 risk loci for pain susceptibility and pleiotropic relationships with psychiatric, metabolic, and immunological traits.....	549
PB1425. Genome-wide association of Copy Number Variation for Cleft Lip with or without Cleft Palate in families from a multi-ethnic study sample.....	550
PB1426*. Genome-wide association of NASH and Mendelian randomization with plasma protein levels identifies putative protein changes resulting from disease.	551
PB1427. Genome-wide association studies identify genetic variants associated with comorbidities in atopic dermatitis.....	552
PB1428. Genome-wide association studies of human and ratbody mass converge on a conserved molecular network.	553
PB1429. Genome-wide association study analysis of glucose response in oral glucose tolerance test (OGTT).	554
PB1430*. Genome-wide association study for 233 circulating metabolic traits in 136,000 participants reveals extensive pleiotropy and novel associations.....	555

ASHG 2022 Annual Meeting Poster Abstracts

PB1431. Genome-Wide Association Study in a Rat Model of Temperament Identifies Multiple Loci for Exploratory Locomotion and Anxiety-Like Traits.	556
PB1432. Genome-wide association study in mesial temporal lobe epilepsy with hippocampal sclerosis	557
PB1433. Genome-wide association study of diabetic retinopathy in the Million Veteran Program identifies four significant loci	558
PB1434. Genome-wide association study of longitudinal changes in motor symptomology in Parkinson's Disease	559
PB1435. Genome-wide association study of nephrotic syndrome replicates <i>APOLI</i> and MHC loci, while predicted gene expression analysis identifies <i>C4A</i>	560
PB1437. Genome-wide association study of plasma amyloid β levels in older adults	561
PB1438. Genome-wide association study of venous thromboembolism in women using combined oral contraceptives	562
PB1439. Genome-wide association study on skin tags.....	563
PB1440. Genome-wide association study to identify genetic variants for obesity in Korean population	564
PB1441. Genome-wide Interaction Study with Smoking Identifies <i>FHIT</i> and <i>SLC22A23</i> Associated with Alzheimer's Disease.	565
PB1442. Genome-wide meta-analysis identifies a potential therapeutic targets for new loci and functional pathways influencing Alzheimer's disease risk.....	566
PB1443. Genome-wide meta-analysis identifies novel susceptibility loci for acne vulgaris	567
PB1444. Genome-wide metabolite quantitative trait loci analysis in red blood cells from routine blood donors.....	568
PB1445. Genome-wide Polygenic Risk Scores in Diabetes Risk Prediction: Results from the Asian Indian Diabetic Heart Study/Sikh Diabetes Study	569
PB1446. Genome-Wide SNP Interaction Tests with Polygenic Risk Score for Ischemic Stroke Identifies Associations with Alzheimer Disease at <i>VCPKMT</i> and <i>KNDC1</i> by Age-Stratified Analysis	570
PB1447*. Genomic architecture of Autism Spectrum Disorder from comprehensive whole-genome sequence annotation.	571
PB1448. Genomic discovery with functional annotation of <i>CNTNAP5</i> in the phenotypic extremes of primary angle closure glaucoma	572
PB1449. Genomic structural equation modeling to unravel kidney-specific variants from multiple biomarkers.....	573
PB1450. GenoPipeR: An Automated Pipeline for Predictive Modelling of Complex Phenotypes using Genome-wide Data	574
PB1451. Genotypic and Phenotypic Heterogeneity in Prader-Willi Syndrome: A Bangladeshi cohort study.....	575
PB1452. Global analysis of RNA editing in Alzheimer's disease across multiple brain regions.	576

ASHG 2022 Annual Meeting Poster Abstracts

PB1453. Global Long COVID Host Genetics Initiative identifies <i>FOXP4</i> locus as the first genetic risk factor associated to Long COVID.....	577
PB1454. GWAS and Polygenic prediction of anthropometric traits in sub-Saharan African populations	578
PB1455. GWAS of the age-of-onset of type 1 diabetes reveals HTATIP2 as a novel T cell regulator.	579
PB1456. Heterozygous loss-of-function mutation in <i>SORL1</i> causes neuronal dysregulation of endosomal trafficking and processing of APP.	580
PB1457. Heterozygous <i>RYR2</i> , <i>ABCG8</i> , <i>PIK3C2G</i> , and <i>RASSF9</i> variants as the cause of premature coronary artery disease in five Iranian families.	581
PB1458. HLA Haplotype Analysis and Genome Wide Association Study of Nephrotic Syndrome in the Million Veteran Program	582
PB1459. HLA in autoimmune encephalitis.	583
PB1460. HLA types are associated with hundreds of complex traits and diseases in an ancestry-dependent manner	584
PB1461. HLA typing and COVID-19 disease outcome associations: GENCOV Study Canada.	585
PB1462. <i>HLA</i> associations with autoantibody-defined subgroups in idiopathic inflammatory myopathies	587
PB1463. <i>HLA-DRB1*15:01</i> modifies sphingolipid levels in multiple sclerosis	588
PB1464. Host Genetics in Resistance to COVID-19: Hints from recovered Brazilian superelderly ...	589
PB1465. How are <i>APOE4</i> , changes in weight/BMI, and longevity related? Insights from a Causal Mediation Analysis.	590
PB1466*. Hypermethylation of <i>PM20D1</i> promoter is associated with atherosclerosis in Dominican Families.....	591
PB1467. Hypertension Prediction From Metabolomics For Two Cardiovascular Disease Cohorts and Transfer Learning of Resultant Models	592
PB1468. Identification of a locus associated with major depressive disorder in a Colombian population	593
PB1469. Identification of genetic loci associated with peanut specific IgG4 in high risk children from the LEAP study	594
PB1470. Identification of genetic loci with divergent effects between Crohn's disease and ulcerative colitis.....	595
PB1471. Identification of novel genetic variants for association with rheumatoid arthritis susceptibility in Pakistani population.....	596
PB1472. Identification of platelet aggregation genetic determinants: Results from a cross-ancestry GWAS meta-analysis.....	597
PB1473. Identification of shared genes and pathways between psychiatric GWAS and monogenic neurodevelopmental disorders	598

ASHG 2022 Annual Meeting Poster Abstracts

PB1474. Identifying compounds to treat opiate use disorder by leveraging multi-omic data integration and multiple drug repurposing databases.....	599
PB1475. Identifying Developmental Stuttering comorbidities using Electronic Health Records.	600
PB1476. Identifying genetic variations that connect iron homeostasis to metabolic disease.	601
PB1477. Identifying Metabolomic Signatures of Genetic Liability to Type 2 Diabetes in East Asian Adolescents.....	602
PB1478. Identifying novel gene dysregulation associated with opioid overdose death: a meta-analysis of differential gene expression in human prefrontal cortex.	603
PB1479*. Identifying phenotypic signatures of circulatory microRNAs.....	604
PB1480. Identifying Rare Variants Associated with Type 2 Diabetes Mellitus in GENNID: a Multiplex, Multiethnic, Family Study.	605
PB1481. Identifying shared genetic architecture across eye diseases using electronic health records.	606
PB1482. Identifying the genetically dysregulated risk and preventative pathways in Alzheimer's disease.....	607
PB1483. Impact of Interleukin-4, Interleukin-13 Gene Polymorphisms and HLA-DQ Alleles on Genetic Susceptibility of Type-1 Diabetes Mellitus (T1DM) in Kuwaiti Children.....	608
PB1484. Improving Common Disease Risk Prediction with Clinical Risk Factors using Polygenic Scores in a Primary Care Physician Network of 35,000 Patients Followed for 16 years.	609
PB1485. Improving model predictivity and explainability by combining genotypes and immunophenotypes in SARS-CoV-2 infected people.	610
PB1486. Improving the selection of variants included in polygenic risk scoring models.....	611
PB1487. In silico analysis to examine COPD genetic associations using scRNA-seq-based CRISPRi approach in iPSC derived alveolar type 2 (iPSC-AT2) cells.....	612
PB1488. Increased burden of pathogenic variants in known aortopathy genes in individuals with early onset thoracic aortic dissection.....	613
PB1490. Increased frequency of predicted loss of function variants in <i>PKP2</i> in African ancestry individuals.....	614
PB1491. Individuals with GCK-MODY are not at increased risk for common complications associated with T2D as measured by the Diabetes Complications Severity Index (DCSI).....	615
PB1492. Insights from HostSeq :Canada's National Whole Genome Sequencing Cohort of 10,000 Canadians Infected with SARS-CoV-2.....	616
PB1493. Insights into pediatric inflammatory bowel disease subtypes using single-cell RNA-sequencing.....	617
PB1494. Integrating common and rare variants into a genetic risk score for Alzheimer's disease risk prediction.	618
PB1495. Integrating Genomic Risk into Absolute Risk Estimates for Coronary Heart Disease.	619
PB1496. Integration Analysis of Multi-Omics Data for Osteoporosis Biomarker Discovery Identification.....	620

ASHG 2022 Annual Meeting Poster Abstracts

PB1497. Integration network-based analyses and Mendelian Randomization to screen drug repurposing candidates for osteoporosis	621
PB1498. Integration of proteomics quantitative trait loci into genetic association analysis of stroke in the African American population.....	622
PB1499*. Integrative analyses to identify plausible target genes on Alzheimer’s Disease genes with genetic evidence.....	623
PB1500*. Integrative analysis of large-scale multi-ancestry genome-wide association study and single-cell omics data provides high-resolution insight of cell-types in the pathogenesis of type 2 diabetes.	624
PB1501. Integrative genomic and transcriptomic analyses revealed new driver variants associated with progression of the non-alcoholic fatty liver disease.....	626
PB1502. Interactions between Valley Fever and genetic ancestry: does genetic ancestry affect risk of developing disseminated coccidioidomycosis?.....	627
PB1504. Interplay of age and Alzheimer’s disease diagnosis in estimating heritability	628
PB1505. Interrogation of shared genetic architecture of infectious disease traits and Alzheimer’s disease	629
PB1506. Intragenic loci within <i>TOMM40</i> modulate <i>APOE</i> expression in human microglia	630
PB1507. Investigating the cellular and molecular response to hyperglycemia in iPSC-derived cardiomyocytes	631
PB1508*. Investigating the influence of genetic ancestry on gene-environment interactions on polygenic risk score and acculturation: Results from the Hispanic Community Health Study/Study of Latinos.	632
PB1509. Irina St. Louis.....	633
PB1510. Is Whole-Blood Cell Mitochondrial Copy Number Lower in Chronic Obstructive Pulmonary Disease in the NHLBI trans-omics for precision medicine (TOPMED) Program?.....	634
PB1511. Isoform usage differences in schizophrenia.	635
PB1512*. Key discoveries of the genetic basis of stuttering.	636
PB1513. Known Alzheimer disease candidate variants influence the severity of neuropathologic lesions underlying Alzheimer disease and related dementias.	637
PB1514*. Large scale genome-wide association study highlights the causality of vasospastic angina	638
PB1515. Large-scale chromatin accessibility fine-mapping of blood lipids GWAS loci in human liver cell types.	639
PB1516. Large-scale exome sequencing identifies common and rare coding variants contributing to tinnitus	640
PB1517. Leveraging aggregation of juvenile idiopathic arthritis in large pedigrees to investigate susceptibility genes.	641
PB1518. Leveraging genetic variation to evaluate risk factors and therapeutic opportunities for aortic valve stenosis: a mendelian randomization analysis.....	642
PB1519. Leveraging spatial patterns in the distribution of dental caries to resolve genetic heterogeneity.	643

ASHG 2022 Annual Meeting Poster Abstracts

PB1520. Leveraging the nutritional geometry framework to dissect the impact of macronutrient composition on metabolic function and gene regulation in fat tissue	644
PB1521. Limited effect of Y chromosome variation on coronary artery disease and mortality in UK Biobank	645
PB1522. Longitudinal transcriptomic profiling of IBD patients reveals therapeutic decision-making determinants of drug response.	646
PB1523. Loss of chromosome Y in leukocytes as a risk factor for critical COVID-19 in men.	647
PB1524*. Loss-of-function variants association study highlights potential new causal genes implicated in blood pressure regulation.....	648
PB1525. Lung-specific alternative splicing is a shared etiological risk for COVID-19 severity and chronic respiratory diseases.	649
PB1526. Machine learning in COVID-19 phenotype prediction.....	650
PB1527*. Machine learning-based classification of Age-related Macular Degeneration using gene expression profiles	651
PB1528. Mapping Autism Spectrum Disorder Endophenotypes to Genomic Regions in Thousands of Families.....	652
PB1529. Metabolomic signatures of body mass index in the Hispanic Community Health Study/ Study of Latinos (HCHS/SOL)	653
PB1530. Metabolomics profiling upranks the role of natural steroids and phenylalanine metabolism over oxidative stress in insulin resistance amongst lean subjects.	654
PB1531. Metagenomic analysis of the gut resistome in dyslipidemia and healthy individuals.	655
PB1532. Mitochondrial and Nuclear genetic variants demonstrate mitochondrial function determines severity but not risk of amyotrophic lateral sclerosis.....	656
PB1533. Mitochondrial <i>TXNRD2</i> and <i>ME3</i> genetic risk scores are associated with specific primary open-angle glaucoma phenotypes	657
PB1534. Modeling cardiac cell developmental trajectories at high temporal resolution.....	658
PB1535. Modeling gene by environment interactions in post-traumatic stress disorder using hiPSC-derived neurons.....	659
PB1536. Modification of coronary artery disease clinical risk factors by coronary artery disease polygenic risk score	660
PB1537. Molecular and clinical characterisation of Polish Temple syndrome patients with 14q32 alterations.....	661
PB1539. Molecular epidemiologic and family history evidence suggests that myalgic encephalomyelitis (ME)/chronic fatigue syndrome (CFS) may be an autoimmune disorder.	662
PB1540. Molecular states during acute COVID-19 reveal distinct etiologies of long-term sequelae. .	663
PB1542*. Multi-ancestry HLA allele calling using whole-exome sequencing in the UK Biobank reveals 353 novel genome-wide significant HLA alleles associated with 11 auto-immune phenotypes	664

ASHG 2022 Annual Meeting Poster Abstracts

PB1543. Multi-ancestry meta-analysis of asthma improves polygenic risk prediction across populations	665
PB1544. Multi-ancestry meta-analysis of X chromosome-wide associations for height.....	666
PB1545. Multiple HLA haplotypes and a variant altering immunogenicity of minor histocompatibility antigen epitopes encoded by <i>CTSH</i> are associated with age at type 1 diabetes diagnosis.....	667
PB1546. Multi-tissue splicing transcriptome-wide association study identifies 25 new candidate susceptibility genes and a new risk region for Alzheimer’s disease	668
PB1547*. Multi-tissue transcriptome-wide association study (TWAS) uncovers 10 novel genes associated with multiple ageing outcomes.....	669
PB1548. Multitrait analysis genome-wide association study of atherosclerosis phenotypes	670
PB1549. Multi-trait rare variant analysis of cardiometabolic traits	671
PB1550. Multivariate GWAS of 3D cranial vault shape in multi-ethnic and admixed children	672
PB1551. Natural language processing and modelling of clinical brain disease trajectories.....	673
PB1552. Neurobiological pathways underlying opioid addiction identified by systems biology multi-omic gene integration.....	674
PB1553. Neuroimmunogenic architecture in brains of Alzheimer's disease at single-cell resolution..	675
PB1554. Neuronal Assay for Investigating Circadian Rhythm Defects in Prader-Willi and Schaaf-Yang Syndrome	676
PB1555. NGS testing and risk stratification of malignant cardiac arrhythmias	677
PB1556. Non-desmosomal genes in Arrhythmogenic Cardiomyopathy: genetic variants rating.....	678
PB1557. Non-Mendelian inheritance patterns and extreme deviation rates of CGG repeats in autism	679
PB1558. Not one and done: A rare finding of two deleterious variants contributing to the onset of rhabdomyolysis.	680
PB1559. Novel Insights into Pediatric Scoliosis Revealed by Genome-wide Association Study and Whole Exome Sequencing	681
PB1560. Obesity genomic loci are heterogeneously associated with lipid profiles in ancestrally diverse <i>Population Architecture using Genomics and Epidemiology (PAGE)</i> study.	682
PB1561. Opportunities in national SARS-CoV-2 genomic surveillance programs for accelerating study on human genetic determinants of differential COVID-19 severity	683
PB1562. Osteoarthritis has high genetic heritability in 488,421 multi-ancestry participants from MVP and the UK Biobank.....	684
PB1563. Overexpression screen of chromosome 21 genes reveals modulators of Sonic hedgehog signaling relevant to Down syndrome.	685
PB1564*. Parsing Transcriptomic and Variant Signatures in Tetrapartite Brain Regions Uncover a Collection of Novel Genes in the Neuropeptide-Neurotransmitter Axis Conferring Addiction Risk ..	686
PB1565. Partitioned polygenic risk scores of adipocyte marker genes and sex-specific GWAS variants explain sex-specific differences in abdominal obesity	687
PB1566. Patterns of human germline hypermutability identified with whole-genome sequencing	688

ASHG 2022 Annual Meeting Poster Abstracts

PB1567. Pediatric Manifestations of Genetic Risk Factors for Polycystic Ovary Syndrome	689
PB1568. Perceived benefits and barriers to implementing polygenic risk scores in primary care: results of a national physician survey.....	690
PB1569. Performance of externally developed polygenic risk scores in the All of Us Research Program Database.....	691
PB1570. Phenome-wide analyses with nonsynonymous variants in SOS2 demonstrate remarkable pleiotropic associations in the UK Biobank.....	692
PB1571*. Phenome-wide association studies of deleterious variants in the Han Taiwanese people ...	693
PB1572. Phenome-Wide Association Study (PheWAS) investigates the role of long-read discovered structural variants in cardiovascular disease risk in the UK Biobank using an imputation framework	694
PB1573*. Phenome-wide perspective into the role of Finnish Y chromosome variation in complex diseases	695
PB1574. Phenome-wide PGS portability in the Colorado Center for Personalized Medicine biobank suggests overlooked challenges in diverse populations	696
PB1575. PLA2G6 associated late onset Parkinson's disease in a Sudanese family: A case report.....	697
PB1576. Polycystic Ovarian Syndrome Physiologic Pathways Implicated Through Clustering of Genetic Loci.....	698
PB1577*. Polygenic burden of major depressive disorder and suicidality in children of diverse ancestries: a US-population-based study	699
PB1578. Polygenic risk and complex trait prediction for East Asians using the Taiwan Precision Medicine Initiative and Taiwan Biobank datasets (N = 500k).	700
PB1579. Polygenic risk burden is associated with early psychosis and endophenotypes of psychotic disorders.....	701
PB1580. Polygenic risk for body mass index is associated with atypical antipsychotic induced weight gain.....	702
PB1581. Polygenic Risk score based phenome wide association study for Tourette Syndrome.....	703
PB1582. Polygenic risk scores affected by different strategies of selection of relevant genomic positions and equations used for calculations	704
PB1583. Polygenic risk scores for quantitative estimation of complex vitamin intake needs to lower homocysteine in the adult population: from population based to personalized dietary intake recommendations.	705
PB1584. Polygenic risk scores identify heterogeneity in disease diagnosis and treatment in asthma and COPD.....	706
PB1585. Polygenic score for height influences adolescent growth spurt in Southwestern Indigenous Americans.	707
PB1586. Polygenic score prediction of atrial fibrillation following cardiac surgery: a retrospective hospital biobank study.	708
PB1587. Population level genetic screening for coronary artery disease with polygenic risk scores and rare variants in a diverse electronic health record linked biobank.....	709

ASHG 2022 Annual Meeting Poster Abstracts

PB1588*. Population-scale proteo-genomic analysis reveals novel loci associated with Parkinson's disease	710
PB1589. Portability of a multiethnic polygenic risk score for low-density lipoprotein cholesterol in a Samoan population.....	711
PB1590. Potential effects of SORBS1 variants on serum immunoglobulin E levels specific to milk intake in relation to prevalence of atopic dermatitis in Korean children	712
PB1591. Predicted loss-of-function variants for blood lipids in over a million individuals.....	713
PB1592*. Predicted polygenic transcriptional risk score supports the inference of canalization of polygenic risk of common diseases and traits in the UKBiobank.....	714
PB1593. Prediction of Alzheimer's disease conversion using polygenic risk scores grouped by transcriptome profiles from blood and brain.....	715
PB1594. Pre-infection antiviral innate immunity attenuate SARS-CoV-2 infection and viral load in iPSC derived alveolar epithelial cells type-2.	716
PB1595*. Prioritization of causal genes at Parkinson's disease associated loci using machine learning.	717
PB1596*. Prioritizing genes and gene programs for disease by integrating genetic and perturbation data	718
PB1598. Profiling the neurobiology underlying brain structure in living human subjects.....	719
PB1599. PRS-PheWAS of psychiatric/ behavioral traits to disentangle clinical heterogeneity in Substance Use Disorders.....	720
PB1600*. Quantification of race, ethnicity, and genetic ancestry disparities in anti-hypertensive drug efficacy in the All of Us Research Program	721
PB1601. Quantifying differential multiple sclerosis risk via polygenic risk scores in African American and Hispanic cohorts.....	722
PB1602. Quantifying mitochondrial dysfunction at biobank scale using insights from rare disease ...	723
PB1604. Rare copy number variants in <i>CACNA1H</i> implicated in essential tremor.	725
PB1605. Rare copy number variation in the GR@ACE/DEGESCO dementia dataset of spanish population.	726
PB1606. Rare <i>Plasmodium falciparum</i> coronin gene mutations following ACT treatment of malaria in South Western Nigeria	728
PB1607. Rare protein-truncating DNA variants in APOB or PCSK9, low-density lipoprotein cholesterol, and risk of coronary artery disease.....	729
PB1608*. Rare protein-truncating variants in <i>ZNF518A</i> are associated with shorter female reproductive lifespan.....	730
PB1609*. Rare variant genetic architecture of mitochondrial DNA copy number from 415,422 exomes.	731
PB1610. Rare variants in ADAMTS13 lead to COVID-19 autosomal dominant disorder, conditioned by SARS CoV-2 infection, sex, and age.....	732
PB1611. Rare variation in ADHD and related diagnoses in the Mass General Brigham Biobank.....	733

ASHG 2022 Annual Meeting Poster Abstracts

PB1612. Rare-Inherited variations in Sensory genes increased burden of Autism Spectrum Disorders: A Whole Exome Sequencing study of Indian families	734
PB1613. Relationship between the gut microbiome and depression in individuals with post traumatic stress disorder.....	735
PB1614. Results from largest GWAS in Gastroparesis point to macrophage polarization etiology	736
PB1615. <i>RGS3</i> and <i>IL1RAPL1</i> missense variants implicate defective neurotransmission in early-onset inherited schizophrenias.....	737
PB1616. Risk factors involved in Congenital Diaphragmatic Hernia, a case-control study in Bogotá and Cali, Colombia.	738
PB1617*. Risk factors that affect performance of polygenic risk scores across diverse cohorts	739
PB1618. RNA editing regulates interferon induction and host immune response in SARS-CoV-2 infection	740
PB1619. RNASeq in nasal epithelium from African ancestry subjects in the CAAPA consortium reveal <i>IL4</i> and <i>TGFB1</i> as upstream regulators of differentially expressed networks for asthma	741
PB1620. Role of amino acids in COVID-19 virulence and pathogenicity : an observational study	743
PB1621. SARS-CoV-2 sequencing: A comparison of high-throughput methods.	744
PB1622. Screening of variant rs11190870 nearby <i>LBX1</i> gene for association with Adolescent Idiopathic Scoliosis in the population of North India	745
PB1623*. Secretoglobin family 1D member 2 (SCGB1D2) protein inhibits growth of <i>Borrelia burgdorferi</i> and affects susceptibility to Lyme disease.....	746
PB1624. Self-reported and device-based physical activity and risk of Alzheimer's disease and related dementias: a Mendelian randomization study.....	747
PB1625. Sequencing-based genome-wide association study of triglycerides in East Africans.....	748
PB1626. Serum osteopontin levels in Mexican patients with systemic lupus erythematosus with lupus nephritis and molecular interaction review.....	749
PB1627. Serum proteomic signatures predicting unintentional weight loss in patients with chronic obstructive pulmonary disease	750
PB1628. Sex dependent transcriptional changes in response to stress in patients with myalgic encephalomyelitis/chronic fatigue syndrome.....	751
PB1629*. Sex-specific analysis of rare variant associations with quantitative traits in the UK Biobank.	752
PB1630. Sex-specific and multiomic integration to enhance accuracy of peripheral blood biomarkers of major depressive disorder	753
PB1631. Sex-Specific associations of gene expression in brain with Alzheimer's disease pathology and cognitive performance.	754
PB1632. Sex-specific genetic loci linked to early and late onset type 2 diabetes.....	755
PB1633. Sex-specific genetic predictors of brain amyloidosis in Alzheimer's disease.	756
PB1634*. Sex-specific genetic predictors of memory performance in older adults.....	758
PB1636. Sex-specific risk scores for coronary artery disease using machine learning models.....	760

ASHG 2022 Annual Meeting Poster Abstracts

PB1637. Sex-stratified meta-analysis of age-related cognitive decline across neurocognitive domains	761

PB1732. A Highly Polymorphic VNTR in the <i>DRD4-DEAF1</i> Intergenic Region.....	859
PB1733. A homozygous variant in a novel gene " <i>AP2A2</i> " causes an early-onset hereditary spastic paraplegia in a Malian family.....	860
PB1734. A multi-branch family with mutation in <i>SLC26A4</i> gene from a village in the southeastern region of Iran.....	861
PB1735. A new case of YARS1 associated multisystemic disorder with compound heterozygous in a patient with Klinefelter syndrome.....	862
PB1736. A novel de novo nonsense variant in <i>TBX2</i> cause osteochondrodysplasia.....	863
PB1737. A novel homozygous missense mutation in <i>ARSK</i> causes a new subtype of MPS.....	864
PB1738. A novel homozygous variant in <i>HECW2</i> gene is associated with intellectual disability and epilepsy in a Malian family.....	865
PB1739. A Novel Homozygous Variant in Homologous Recombination Repair Gene <i>ZSWIM7</i> Causes Azoospermia in Males and Primary Ovarian Insufficiency in Females.....	866
PB1740. A novel homozygous variant in <i>IBA57</i> causing multiple mitochondrial dysfunction syndrome type 3.....	867
PB1741. A novel <i>LZTR1</i> variant in a Brazilian familial case with Noonan syndrome: comparative modeling and structural analysis.....	868
PB1742. A novel <i>PUM1</i> heterozygous missense variant causing severe developmental delay and epilepsy from infancy with dysmorphic features.....	869
PB1743. A novel splice-site variant causes <i>MYH2</i> -associated myopathy in a large family.....	870
PB1744. A novel XL gene for autism with psychiatric illness in adults.....	871
PB1745*. A <i>Plod2</i> mutant mouse model of Bruck syndrome.....	872
PB1746. A prospective, longitudinal observational natural history study of patients with NGLY1 Deficiency.....	873
PB1747. A recessive variant in <i>TFAM</i> causes mtDNA depletion associated with primary ovarian insufficiency, seizures, intellectual disability and hearing loss.....	874
PB1748*. A recurrent missense variant in <i>ITPR3</i> causes demyelinating Charcot-Marie-Tooth neuropathy.....	875
PB1749. A single-center genetic analysis of oculopharyngeal myopathy.....	876
PB1750. A substantial proportion of high myopia is caused by mutations in <i>CACNA1F</i> (XL CSNB).....	877

ASHG 2022 Annual Meeting Poster Abstracts

PB1751. A Zebrafish Model of Congenital Muscular Dystrophy Caused by POMT1 Loss of Function	878
PB1752. Allele-specific inactivation of epidermolysis bullosa simplex mutations using CRISPR-Cas9 and spraying of the corrected cell suspension onto the wounds	879
PB1753. Alteration of mitochondrial proteostasis in Costello syndrome	880
PB1754. An initiative for the diagnosis and study of rare and undiagnosed diseases in Mexico	881
PB1755. Angelman syndrome with mosaic paternal uniparental disomy caused by mitotic nondisjunction	882
PB1756. <i>ARG1</i> variants in Arginase 1 Deficiency: genetic characterization of participants in the pegzilarginase clinical trials	883
PB1757. <i>ARHGAP32</i> , encoding the Rho GTPase Activating Protein 32, is a novel candidate gene involving in autosomal dominant neurodevelopmental disorder spectrum	884
PB1758. ATP2C1 as a candidate for Interstitial Cystitis/Bladder Pain Syndrome	885
PB1759. Atypical 260 kb deletion on distal 22q11.22 involving <i>TOP3B</i> shows the significance of this gene in autism spectrum disorder	886
PB1760. Atypical molecular findings in patients with capillary malformations	887
PB1761. Bi-allelic ACBD6 variants lead to a neurodevelopmental syndrome with progressive complex movement disorders	888
PB1762*. Biallelic <i>DMD</i> variants in a mildly-affected female without a Duchenne or Becker phenotype	889
PB1763. Biallelic founder mutation in <i>PDE2A</i> causes paroxysmal dyskinesia with Intellectual disability in Pakistani families	890
PB1764*. Bi-allelic <i>LETM1</i> variants perturb mitochondrial ion homeostasis leading to a clinical spectrum with predominant nervous system involvement	891
PB1765. Biallelic Loss of Function Mutations in <i>PYGM</i> Cause Hereditary Macular Dystrophy	892
PB1766. Bi-allelic loss of function variant in the <i>NRCAM</i> gene is associated with hereditary polyneuropathy phenotype	893
PB1767. Biallelic loss-of-function variants in mitochondrial phospholipase <i>PNPLA8</i> decrease in the number of basal radial glial cells and lead to microcephaly with simplified gyral pattern	894
PB1768. Bi-allelic loss-of-function variants in <i>PPFIBP1</i> cause a severe neurodevelopmental disorder with microcephaly, epilepsy and periventricular calcifications	895
PB1769. Biallelic nonsynonymous variants in <i>LTV1</i> are associated with LIPHAK syndrome, a novel poikiloderma-like disorder	897
PB1770. Biallelic pathogenic variants in the endosomal transport regulator <i>SNAPIN</i> cause a rare prenatal neuroanatomical syndrome	898
PB1771*. Biallelic <i>RAD51C</i> loss-of-function variants drive perizygotic SNV/indel hypermutator phenotype in a subject with Fanconi anemia complementation group O.	899
PB1772. Biallelic variants in <i>CSPG4</i> cause a novel neurodevelopmental disorder with intellectual disability, global developmental delay, and facial anomalies	900

ASHG 2022 Annual Meeting Poster Abstracts

PB1773. Biallelic variants in <i>FICD</i> leading to inactivation of BiP cause motor neuron disease.	901
PB1774. Bibliometric analysis of Alport Syndrome - the impact of next generation sequencing on diagnosis.	902
PB1775. Biallelic <i>ATOH1</i> Variant in Siblings With Pontocerebellar Hypoplasia, Developmental Delay, and Hearing Loss.....	903
PB1776. Biotin-thiamine responsive basal ganglia disease: A retrospective review of the clinical, radiological and molecular findings of cases in Kuwait with novel variants.....	904
PB1777. Brachyolmia with amylogenesis imperfecta: Identification of a Novel <i>LTBP3</i> gene Mutation in several Druze Arab patients from the north of Israel.....	905
PB1780. Characterization of associated non-classical phenotypes in patients with deletion in <i>WAGR</i> region identified by chromosomal microarray: new insights and literature review.....	906
PB1781. Characterization of <i>CFTR</i> Variants Across Ancestries.....	907
PB1782. Characterization of transthyretin <i>TTR</i> missense variants for associations with hereditary transthyretin-mediated (hATTR) amyloidosis and hallmark symptoms in 470,000 UK Biobank whole exome sequences.....	908
PB1783. Characterizing human disease-causing mutations: A zebrafish-based approach.....	909
PB1784. <i>Chd8</i> mutation in mouse impacts cerebellar function across anatomical, genomic, electrophysiological and behavioral axes	910
PB1785. <i>CHP2</i> is a genetic modifier of risk of chronic <i>Pseudomonas aeruginosa</i> airway infection in cystic fibrosis.	911
PB1787. Clinical and molecular characteristics of idiopathic midaortic syndrome in pediatric patients - preliminary results.	912
PB1788. Clinical diversity and molecular mechanism of <i>VPS35L</i> -associated Ritscher-Schinzel syndrome.....	913
PB1789. Clinical usefulness of a custom Next Generation Sequencing gene panel in providing molecular diagnosis to patients with a broad spectrum of Neurodevelopmental Disorders	914
PB1790. Combined brain abnormalities in patients with beta-tubulin mutations.....	915
PB1791. Comparing phenotypes across five developmental and epileptic encephalopathies (DEEs) through evaluation of 2490 patient data years.	916
PB1792. Compound heterozygosity for variants in <i>DCAF1</i> in fraternal twins with neurodevelopmental disorder	917
PB1793. Compound heterozygous <i>IFT81</i> variants causing brachydactyly with cone-shaped epiphyses and generalized metaphyseal dysplasia	918
PB1794. Compound heterozygous variants in <i>UFMI</i> gene in a case of hypomyelinating leukodystrophy	919
PB1795. Confirmation of association of <i>TGFBI</i> p.Ser591Phe mutation with variant lattice corneal dystrophy.....	920
PB1796. Congenital Anomalies Cluster: Linking clinicians and model system experts.	921
PB1797. Co-occurring anomalies in cases with achondroplasia	922

ASHG 2022 Annual Meeting Poster Abstracts

PB1798*. C-X3-C motif chemokine receptor 1 (<i>CX3CRI</i>) gene variants associated with lesion burden in Cerebral Cavernous Malformation	923
PB1799. De novo (deep-)intronic splicing mutations in patients with neurodevelopmental disorders	925
PB1800. <i>De novo</i> missense variants in <i>RPS5</i> cause a newly characterized ribosomopathy.....	926
PB1801. <i>De novo</i> missense variants in <i>SEPHSI</i> Cause a Novel Neurodevelopmental Disorder with Developmental Delay, Hypotonia, Muscle Weakness, Speech Delay, and Growth delay	927
PB1802. De novo non-synonymous <i>CTR9</i> variants are associated with motor delay and macrocephaly	928
PB1803. <i>De novo</i> truncating <i>ADNP</i> variants as a recurrent cause of neurodevelopmental disorders ..	929
PB1804. Deciphering a Diagnostic Odyssey of Atypical Free Sialic Acid Storage Disorder Associated with Tissue Specific Mosaic Variant in <i>SLC17A5</i>	930
PB1805. Deciphering the phenotypic variability of the most common deafness-causative <i>GJB2</i> p.V37I variant in Asia	931
PB1806. Deep resequencing of the 1q22 locus in non-lobar intracerebral hemorrhage.....	932
PB1807. Defining the clinical heterogeneity of <i>GARS1</i> -related Charcot-Marie-Tooth disease	933
PB1808*. Defining the nuclear genetic architecture of a maternally-inherited mitochondrial disorder.	934
PB1809. Delayed developmental milestones in <i>MBD5</i> -associated neurodevelopmental disorder (MAND) associated with 2q23.1 deletions highlight need for early diagnosis	936
PB1810. Deleterious <i>SNAPC4</i> Variants are Associated with a Neurodevelopmental Disorder.	937
PB1811. Deletions of 14q32.2 result in severe neurodevelopmental outcomes and multiple congenital anomalies: three affected males and review of the literature.	938
PB1812*. Delineation of gain-of-function <i>MYCN</i> -induced novel megalencephaly syndrome and possible out-of-brain complications implicated by a mouse model.....	939
PB1813. Developmental Delay at the Single Cell Level in Prader-Willi Syndrome.....	940
PB1814. Diagnosis, treatment, and follow-up care for patients with Barth syndrome is presented through the results from 1:1 interviews of pediatric cardiologists.....	941
PB1815. Diagnostic rate and clinical utility of whole genome sequencing in adults with intellectual disability.....	942
PB1816. Diagnostic utility of comprehensive genomic and transcriptomic profiling of anorectal malformations.	943
PB1817. Dilated cardiomyopathy in a 3-month-old female: The answer in genetics.....	944
PB1818. <i>Drosophila</i> model of <i>de novo</i> <i>MRTF-B</i> variants highlights the critical role of actin regulation.	945
PB1819. Effect of <i>FOXO3</i> and Air Pollution on Cognitive Function: A Longitudinal Cohort Study of Older Adults in China	946
PB1820*. Effective Genetic Diagnosis for Unilateral and Asymmetric Pediatric Hearing Loss via Exome Sequencing.....	947
PB1821. Ellis-Van Creveld Syndrome: Clinical and Molecular Analysis of 50 Individuals	948

ASHG 2022 Annual Meeting Poster Abstracts

PB1822. Enrichment of <i>RAI1</i> genetic aberrations associated with sleep disturbances in Smith-Magenis syndrome and autism spectrum disorder.....	949
PB1823. Enzymatic testing for MPSI in Kuwait: A Pilot Study toward newborn screening.	950
PB1824. ERF-Related craniosynostosis: further delineation of the new craniosynostosis syndrome..	951
PB1826. Exome Sequencing in Understanding the Etiologies of Ataxia in Children	952
PB1827. Exome sequencing leads to the identification of a rare case of an autosomal dominant non-syndromic hearing disorder in a German family.....	953
PB1828. Exome sequencing uncovers novel variants in two Malian families with Epileptic encephalopathies	954
PB1829. Expanding the Phenotypic spectrum of <i>SMARCA5</i> -related neurodevelopmental disorder....	955
PB1830. Expanding the phenotypic spectrum of <i>TAB2</i> related disorders.	956
PB1831. Expert perspectives on sequencing newborns for treatable genetic conditions	957
PB1832*. Exploration of Ubiquitin-Proteasome System involvement in neurodevelopmental diseases using cellular models.	958
PB1833. Exploring cancer cachexia on the spatial plane	959
PB1834. Exploring the distinct phenotypes of nine Romanian patients harboring a homozygous Arg355* variant in <i>BBS12</i>	960
PB1835. Family with case of HMG-CoA lyase deficiency with novel pathogenic variant in <i>HMGCL</i>	961
PB1836. First patient reported with a <i>TPP1</i> missense mutation pathogenic variant predicted insilico causing <i>CLN2</i>	962
PB1837. First report of severe hemolysis associated with <i>SCARB1</i>	963
PB1838. Fracture prevalence in children diagnosed with Ehlers-Danlos Syndrome and Generalized Joint Hypermobility	964
PB1839. Fragile X Syndrome in a female patient: A case of strong family history and developmental delay.....	965
PB1840. Frameshift <i>PPP1R12A</i> pathogenic variant in a mexican patient with differences of sex development (DSD), middle line defects and hemangiomas.....	966
PB1841. Frequency of Y chromosome microdeletion and its correlation with spermatogenesis defect in north Indian infertile males.	967
PB1842. Functional analysis of <i>EZH1-A678G</i> in <i>Drosophila melanogaster</i>	968
PB1843. Functional characterization of recurrent truncating variant in <i>UBAP1</i> associated with hereditary spastic paraplegia.	969
PB1844. Gaps in the phenotype descriptions of ultra-rare genetic conditions: Systematic review and recommendations	970
PB1845. <i>GATA3</i> -related pedigrees showing characteristic audiologic profile and inheritance pattern.	971
PB1846. Genealogy as a predictor of disease progression in patients with myotonic dystrophy type 1: A demonstration of the power of intersectorial research.	972

ASHG 2022 Annual Meeting Poster Abstracts

PB1848. Genetic analysis reveals that GNE Myopathy remains an underdiagnosed neuromuscular disorder	973
PB1849. Genetic and clinical landscape of childhood cerebellar hypoplasia and atrophy.	974
PB1850. Genetic and phenotypic heterogeneity of childhood-onset hearing loss and implications for the success of cochlear implants.	975
PB1851. Genetic insights from consanguineous cardiomyopathy families.	976
PB1852. Genetic Mapping Identifies A Founder Mutation of <i>GHRHR</i> Gene in Pakistani Family with Isolated Growth Hormone Deficiency Type 4.	977
PB1853. Genetic modifiers in Niemann-Pick type C1 disease.	978
PB1854*. Genetic modifiers of nutritional status in CF are both unique to CF and shared with the general population.	979
PB1855. Genetic underpinnings of moderate to severe hearing loss in singleton individuals born to consanguineous couples in Pakistan	980
PB1856. Genetics of intellectual disability in pakistani consanguineous families.	981
PB1857. Genome sequencing identifies coding and non-coding variants in hereditary deafness missed by exome sequencing	982
PB1858. Genomic and transcriptomic characterization of a novel <i>RYR1</i> variant in the French-Canadian population	983
PB1859. Genomic ascertainment and reverse phenotyping diabetogenic variants in a phenotypically unselected cohort.	984
PB1860. Genomic region identified on chromosome 22 contributing to lymphedema in Phelan-McDermid syndrome	985
PB1861. GGC repeat expansion within <i>NOTCH2NLC</i> causes behavioral deficits and neurodegeneration in a mouse model of Neuronal Intranuclear Inclusion.	986
PB1862. GWAS of cleft palate trios reveals novel associations and subtype-specific effects.	987
PB1863*. GWAS of Down Syndrome Associated Atrioventricular Septal Defect identifies three novel loci.	988
PB1864*. Haploinsufficiency and loss-of-function of <i>LEF-1</i> cause a novel Mendelian disorder by dysregulating WNT signaling	989
PB1865. Haplotype in interleukin 6 is associated with a reduction of blood transfusion events in sickle cell anemia patients.	990
PB1866. Hemizygous CNV in chromosome region Xq23 is associated with a complex psychiatric and bone mineral density disorder.	991
PB1867*. Here, There and Everywhere: Characterizing Variability in Approaches to Ascertaining Individuals with Rare Mendelian Disorders from EHRs	992
PB1868. Heterogeneity of Inherited Cone Dysfunction Disorders with Normal Fundus Appearances	993
PB1869. High Molecular Diagnostic Yields and New Phenotypic Expansions Involving Anorectal Malformations	994

ASHG 2022 Annual Meeting Poster Abstracts

PB1870. High prevalence of frontotemporal dementia in females of five Hispanic families with R159H VCP multisystem proteinopathy.	995
PB1871*. Highly recurrent histone H4 mutations cause a neurodevelopmental disorder.....	996
PB1872. Homozygous <i>EMCI</i> variant in four families from the same Kuwaiti tribe with cerebellar atrophy, visual impairment, and psychomotor retardation.....	997
PB1873*. How many diseases can one gene cause: Why mechanism matters for gene curation, variant classification, and clinical management.....	998
PB1874*. Human brains with Tay Sachs disease exhibit altered transcriptomes during fetal development.....	999
PB1875. Human mutations in <i>Slitrk3</i> implicated in GABAergic synapse development in mice	1000
PB1876. Hypophosphatemia gene panel sponsored program: a comparison of findings from 2019 through 2022 describing <i>PHEX</i> variant landscape and molecular diagnosis of XLH.	1001
PB1877. Identification and Functional Evaluation of Autosomal Recessive Non-Syndromic Hearing Impairment Genes in Rwanda.....	1002
PB1878. Identification of a novel compound heterozygous mutation in <i>RyR1</i> gene in an Indian family affected with congenital myopathy	1003
PB1879. Identification of a novel pathogenic variant in <i>HIST1H1E</i> encoding the H1 histone linker in a patient with a complex phenotype including progeroid feature, intellectual disability and lipodystrophy. Contribution of additional variants to the complexi.	1004
PB1880*. Identification of a Novel Therapeutic Target Underlying Atypical Manifestation of Gaucher Disease	1005
PB1881. Identification of a pathogenic gene mutation in <i>Med12</i>	1006
PB1882. Identification of <i>INHB</i> -related neurodevelopmental disorder.....	1007
PB1883. Identification of molecular causes of recessively inherited ataxic and neuropathic disorders in consanguineous Pakistani families.....	1008
PB1884. Identifying modifier genes in a PIGA-CDG pedigree with reduced penetrance.....	1009
PB1885. Identifying phenotypic expansions for congenital diaphragmatic hernia plus (CDH+) using DECIPHER data.	1010
PB1886. <i>In Silico</i> genomic interrogation reveals 16 autosomal dominant neurodevelopmental candidate genes at 1p13.3.....	1011
PB1887. Incontinentia pigmenti female with the <i>IKBKKG/NEMO</i> del4-10 deletion: A mosaic form. .	1012
PB1888. Integrating Genomic and Phenotypic Analyses of Autonomic Nervous System Dysfunction in a Rare Neurological Disease Cohort.....	1013
PB1889. Intraflagellar transport protein RABL5/IFT22 is required for normal visual function and retinal photoreceptor survival	1014
PB1890. Investigating SLC6A1 targeted therapeutics in <i>Drosophila</i>	1015
PB1891. Investigating the role of seryl-tRNA synthetase in mitochondrial biology and human recessive disease	1016

ASHG 2022 Annual Meeting Poster Abstracts

PB1892*. Investigating tissue specific defects in mitochondrial bioenergetics and quality control: new implications for cellular pathogenesis and therapeutic targeting in Barth syndrome	1017
PB1893. Investigating variants of uncertain significance in orofacial cleft trios.	1018
PB1894. Isolated acanthosis nigricans in a Mexican girl with a nonsense variant in <i>FGFR3</i> gene... ..	1019
PB1895. <i>ITGB8</i> is a candidate disease gene for autosomal dominant and recessive trait forms of muscular dystrophy and neurological disease.....	1020
PB1896. Joint analysis of de novo mutations in multiple traits and gene-expression data improves statistical power for the prioritization of genes associated with disease.....	1021
PB1897. <i>KIF1A</i> novel variant p.(Ser887Profs*64) exhibits clinical heterogeneity in a Pakistani family individuals with HSANIC	1022
PB1898. Large-scale genomic analyses of 150 consanguineous kindreds from the Middle East and North Africa identify novel neurodevelopmental disease mechanisms	1023
PB1899. Large-scale zebrafish-based functional analysis of genes associated with neurodevelopmental disorders.....	1024
PB1900. Leveraging orthogonal sequencing and optical mapping technologies for the precision diagnosis of neurodevelopmental disorders in a Middle Eastern family based cohort.	1025
PB1901*. LIM Homeobox 1 gene variants contribute to Mayer-Rokitansky-Küster-Hauser syndrome	1026
PB1902. Lisch epithelial corneal dystrophy is caused by heterozygous loss-of-function variants in <i>MCOLN1</i>	1027
PB1903. Lissencephaly spectrum disorders: Clinical, radiological molecular results of 70 Egyptian families.....	1028
PB1904. Local versus systemic control of bone and skeletal muscle mass by targeting components of the transforming growth factor- β signaling pathway using pharmacological and transcriptional approaches.....	1029
PB1905*. Long Read Sequencing and Expression Studies of <i>AHDC1</i> Deletions in Xia-Gibbs Syndrome Reveal a Novel Genetic Regulatory Mechanism.....	1030
PB1906. Long term prognosis in two adult patients with malonyl CoA decarboxylase deficiency ...	1031
PB1907. Long-term clinical course of Heyn-Sproul-Jackson syndrome.....	1032
PB1908*. Loss of adipocyte phospholipase gene <i>PLAAT3</i> causes lipodystrophy with neurological features due to inactivated arachidonic acid-mediated PPAR γ ;;; signaling	1033
PB1909*. Loss of C-terminal Mediator Complex subunit-11 impairs fetal brain development and cause severely progressive neurodegeneration	1034
PB1910*. Loss of FOCAD, operating in the SKI mRNA surveillance pathway, causes a pediatric syndrome with liver cirrhosis.....	1035
PB1911. <i>LYRM7</i> mutations causing mitochondrial complex 3 deficiency nuclear type 8 (MC3DN8)in a Five-year-old boy without cavitating leukoencephalopathy	1036
PB1912. <i>MED13L</i> knockout in cerebral organoids leads to a shifted developmental program through abnormal cis-regulatory element activation.....	1037

ASHG 2022 Annual Meeting Poster Abstracts

PB1913. Metatranscriptomics detects emerging multidrug resistant <i>Candida auris</i> in a family with a mild TP63 associated ectodermal dysplasia.....	1038
PB1914. Metatranscriptomics reveals association of α -, β -, and γ -HPVs with typical epidermodysplasiaverruciformis in a large cohort of patients with CIB1, TMC6, or TMC8 mutations	1039
PB1915. Modeling dystroglycanopathy in zebrafish through CRISPR-Cas9-mediated knockout of <i>pomgnt2</i>	1040
PB1916. Molecular and behavioral characterization of a novel mouse model of Snyder-Robinson Syndrome: A path towards therapeutic development	1041
PB1917. Molecular and clinical review of 95 Polish pediatric patients with the clinical suspicion of Alport syndrome.	1042
PB1918. Molecular Genetic Defects of Hereditary Angioedema in Saudi Arabia.	1043
PB1919*. Molecular insights into the pathogenesis of Chediak-Higashi syndrome and the biology of Lysosomal Trafficking Regulator.	1044
PB1920. Monoallelic variation in the DEXH-box helicase DHX9, a product of the <i>DHX9</i> gene paralog, perturbs neurodevelopment & causes peripheral nerve axon degeneration.....	1045
PB1921. Monogenic Familial Hypercholesterolemia in the eMERGE Network: Penetrance and Associated Coronary Heart Disease Risk	1046
PB1922. Multi-omic approach identifies a novel non-coding deletion at Xq28 in a patient with X-linked primary immunodeficiency	1047
PB1923. Mutational analysis of a Romanian Bardet-Biedl syndrome cohort revealed an overabundance of causal <i>BBS12</i> variants.....	1048
PB1924. Mutation-specific pathophysiological mechanisms of <i>AFF3</i>	1050
PB1925. Myelomeningocele: targeted search for novel variants in Mexican families.....	1051
PB1926. New <i>trans</i> -modifier genes in the most common monogenic eye disorder, ABCA4/Stargardt disease.	1052
PB1927. Novel clinical entity: Autosomal recessive missense GPC6-related skeletal dysplasia (ARM-GSD)	1053
PB1928. Novel homozygous nonsense mutation of <i>MLIP</i> and compensatory alternative splicing in a late-onset distal myopathy.	1054
PB1929. Novel homozygous variant in <i>TFAP2B</i> in a colombian family with Char syndrome and distinctive neurobehavioral features.	1055
PB1931. Novel locus identification for primary congenital glaucoma in a Pakistani family	1056
PB1932. Novel variants expand understanding of <i>PPP1R13L</i> - related cardio-cutaneous syndrome	1057
PB1933. Novel variants in the <i>PKD1</i> and <i>PKD2</i> genes in German patients with autosomal dominant polycystic kidney disease.....	1058
PB1934. One family, two disorders, three affected: a diagnostic odyssey highlighting the importance of WES as first-tier testing in patients with a specific phenotype but a consanguineous background....	1059

ASHG 2022 Annual Meeting Poster Abstracts

PB1935*. Osteogenically differentiated human fibroblasts - an alternative model to study bone diseases	1060
PB1936. Patients with biallelic GGC repeat expansions in <i>NOTCH2NLC</i> exhibiting a typical neuronal intranuclear inclusion disease phenotype.....	1061
PB1937. Patients with primary familial brain calcification due to variants in <i>SLC20A2</i> are not commonly diagnosed with Parkinson's disease.....	1062
PB1938. PHACE syndrome: New strategies to identify the disease mechanism for this unsolved recognizable condition	1063
PB1939. Phenotypic Characterization of 127 Individuals with <i>MECP2</i> Duplication Syndrome.	1064
PB1940. Phenotypic variation of outcomes for tail-domain <i>KIF5A</i> related variants.....	1065
PB1941. PhenylEc: Novel genotypes and nutritional management in phenylketonuria patients from Ecuador.	1066
PB1942. Polygenic risk scores and protein language models predict phenotype severity in individuals with rare clinical pathogenic variants	1067
PB1943. <i>PPP2R5D</i> -related Neurodevelopmental Disorder can be inherited from a mildly affected parent.	1068
PB1944*. Precision diagnostics for GLUT1 disorder using deep mutational scanning	1069
PB1945. Pre-clinical studies in induced Pluripotent Stem Cell (iPSC) lines with <i>SORD</i> mutations linked to a recessive neuropathy	1070
PB1946. Predictive modeling to define the locus heterogeneity of tRNA synthetase-related peripheral neuropathy.....	1071
PB1947*. Probing variants associated with neurodevelopmental disorders by studying social behaviors in <i>C. elegans</i>	1072
PB1948. Proposal of intervention of the IL-10 rs1800872 (-592 C>A) as a modulator in the cardiovascular variant of Fabry disease	1073
PB1949. Pulmonary function and structure in young adults with types III, IV and VI osteogenesis imperfecta.	1074
PB1950. Rapid Turnover Skeletal Disease from In-frame Tandem Duplication of Exons 4-9 in <i>TNFRSF11A</i> Encoding RANK	1075
PB1951. Rare <i>MECP2</i> variant associated with the development of Rett syndrome: a case report. ...	1076
PB1952. Rare variants in syndromic ciliopathy genes as novel causes of isolated renal disease in adults	1077
PB1953. Rate of Deleterious Copy Number Variants Similar in Early Onset Psychosis and Autism Spectrum Disorders: Implications for Clinical Practice.....	1078
PB1954*. RBM12 Variants Lead to a Novel Neurodevelopmental Syndrome With Atypical Genotype-Phenotype Correlations	1079
PB1955. Reanalysis of whole exome sequencing data of 50 Iranian families with hereditary hearing loss	1080

ASHG 2022 Annual Meeting Poster Abstracts

PB1956. Recessive variants in <i>SLC9A1</i> cause a syndrome of cerebellar ataxia, amelogenesis imperfecta and variable sensorineural hearing loss.	1081
PB1957*. Recessive variants in the C-terminal domain of <i>UFSP2</i> are associated with severe spondyloepimetaphyseal dysplasia.	1082
PB1958. Reconsidering <i>SIX5</i> as a monogenic cause for Congenital Anomalies of the Kidney and Urinary Tract (CAKUT) and Branchio-oto-renal syndrome (BOR).....	1083
PB1959. Report of a novel <i>LAMB3</i> variant and an overview of <i>LAMB3</i> variants associated with junctional epidermolysis bullosa.....	1084
PB1960. Report of <i>PLP1</i> Gene Mutation in Pelizaeus-Merzbacher Disease	1085
PB1961. Rewiring our understanding of the enteric nervous system: Identification of diverse developmental lineages of enteric neurons and cell-state specific roles in maintenance across aging.	1086
PB1962*. <i>RFC1</i> expansions in Italian population: Molecular analysis, structure/size determination and clinical features of patients with CANVAS/spectrum phenotypes.	1087
PB1963. RNF220, RING finger E3 ubiquitin ligase, is required for the generation of p2-derived V2 interneurons and its loss-of-function causes an interneuronopathy with a broad spectrum of neurodevelopmental phenotypes.....	1088
PB1964*. Rothmund Thomson syndrome with congenital cataracts and severe growth restriction is associated with a not previously described gene in an autosomal recessive inheritance pattern in seven families.....	1089
PB1965. Screening for Genetic Modifiers of <i>MED12/kto</i> Using Naturally Occurring Variation in <i>Drosophila melanogaster</i>	1090
PB1966. Seizures in a patient with Autosomal recessive Intellectual disability type 5.....	1091
PB1967*. Sequencing analysis of nonsyndromic cleft lip / palate in Brazilian patients reveals CTNNA1, ESRP1 and PRICKLE1 as novel candidate genes.	1092
PB1968. Severe ABCA4-retinal dystrophy caused by homozygosity for a novel double mutated allele.	1093
PB1969. Shared and divergent transcriptional dysregulation is present across brain regions and cell types in adult <i>Chd8</i> haploinsufficient mice.....	1094
PB1970. Siblings with hypophosphatemic rickets and homozygous <i>CYP27B1</i> variants	1095
PB1971. Six patients with genetic disorders with atypical symptoms: how to perceive them	1096
PB1972. Slc9a6 mutation causes Purkinje cell loss and ataxia in the <i>shaker</i> rat.....	1097
PB1973. Splicing noise is variable across human introns, tissues and age and modelling its characteristics can improve our understanding of age-related diseases of the human brain.....	1098
PB1974*. <i>SRSF1</i> haploinsufficiency is responsible for a syndromic developmental disorder with intellectual disability and variable marfanoid habitus	1099
PB1975. Subtle genomic duplication on Chromosome 6: a hypothesis for a causative mechanism..	1101
PB1976. Sunken symptoms of <i>SRCAP</i> mutation: A case report of atypical phenotype of Floating Harbor Syndrome.....	1102

ASHG 2022 Annual Meeting Poster Abstracts

PB1977. Systematic bioinformatic analysis promotes a missense variant in <i>XK</i> as potential cause of X-linked intellectual disability.	1103
PB1978*. Systematic identification of disease-causing near-coding variants in 29,759 individuals with rare disease.	1104
PB1979. Taking the <i>CPLANE INTU</i> the light: further defining the orofaciodigital syndrome phenotype association with biallelic <i>INTU</i> alterations.	1105
PB1980. Targeted deep sequencing analyses of long QT syndrome in a Japanese population.	1106
PB1981. <i>TCEALI</i> loss-of-function results in an X-linked dominant neurological syndrome and drives the neurological disease trait in Xq22.2 deletion.	1107
PB1982. Temtamy Preaxial Brachydactyly Syndrome: penetrance in heterozygotes for a <i>CHSY1</i> missense variant.	1109
PB1983. TGF β signaling is important for spermatogenesis.	1110
PB1984. The benefits and yields of whole exome sequencing data reanalysis in Iranian undiagnosed patients with intellectual disability.	1111
PB1985. The ClinGen Kidney Disease Clinical Domain Working Group: Defining solutions to the challenge of nephropathy ontology and nomenclature.	1112
PB1986. The genetic and phenotypic landscape of <i>STUB1/TBP</i> -associated disorders: Two genes and three patterns of inheritance sharing a continuous neurodegenerative phenotypic spectrum.	1113
PB1987. The genetic background in a group of 155 Polish pediatric patients with unexplained epilepsy.	1114
PB1988. The genetic landscape of <i>ATP7B</i> provides insights into Wilson Disease variant penetrance and prevalence.	1115
PB1989. The genetic landscape of neurodevelopmental disorders in a large cohort of multiplex consanguineous families from Turkey.	1116
PB1990*. The impact of NGS on rare and complex epilepsies: identification of novel causative variants for an efficient diagnostic pathway and personalized treatments.	1117
PB1991. The mechanism and current concepts and future research direction of rare hereditary disease White Sponge Nevus.	1118
PB1992. The Spectrum of PLEC Sequence Variants and Related Plectinopathies Including Novel Association with Epidermolysis Bullosa Pruriginosa.	1119
PB1993. Three cases of (likely) pathogenic <i>FGF10</i> variants: Examples of phenotypic variability in Lacrimoauriculodentodigital syndrome.	1120
PB1994. Three new founder Bukharian Jewish mutations in <i>COL4A4</i> are causative of autosomal dominant and recessive Alport syndrome.	1121
PB1995. TMEM161B mediates radial glial scaffolding in neocortical development.	1122
PB1996*. Toward precision medicine in Neurodevelopmental disability: identifying phenotypic differences in individuals with global developmental delay.	1123
PB1997. Transcriptional response of <i>Fundulus heteroclitus</i> embryos exposed to carbaryl.	1124
PB1998. Translated mutant <i>DSPP</i> mRNA expression level impacts the severity of dentin defects. .	1125

ASHG 2022 Annual Meeting Poster Abstracts

PB1999. Truncating variants in <i>RFC1</i> cause cerebellar ataxia, neuropathy vestibular areflexia syndrome (CANVAS).....	1126
PB2000. Tumor burden among members of the DiscovEHR cohort harboring deleterious constitutive variants in <i>NFI</i>	1127
PB2001. Two novel compound heterozygous variants identified in a new case of classic Donohue syndrome and literature review.....	1128
PB2002. Understanding the role of <i>TTC5</i> in the developing mouse brain: A novel null <i>TTC5</i> mouse model.	1129
PB2003. Using artificial intelligence driven NGS re-analyses followed by full genome profiling (HiFi-GBS) for unsolved pediatric white matter disorders	1130
PB2004. Using genetic relatedness within biobanks to understand genetic architecture of Retinitis Pigmentosa.....	1131
PB2005. Using remote methods to assess communication in Phelan-McDermid Syndrome.....	1132
PB2006. Variable expressivity in a four-generation ACDMPV family with a noncoding hypermorphic SNV in <i>trans</i> to the frameshifting <i>FOXF1</i> variant.....	1133
PB2007. Variants of <i>LRP2</i> , encoding a multifunctional cell surface endocytic receptor, are associated with hearing loss and retinal dystrophy	1134
PB2008. Vici syndrome in Israel: Clinical and molecular insights	1135
PB2009. Whole exome sequencing identifies novel variants in familial myoclonic epilepsy in Mali.	1137
PB2010. Whole exome sequencing in intellectual disability patients identifies de novo mutations in <i>KCNB1</i> , <i>PPP1R3F</i> , <i>SHANK2</i> , and <i>SYNGAP1</i> genes	1138
PB2011*. Whole exome sequencing reveals known and candidate genes in non-syndromic hearing impairment in Mali	1139
PB2012. Whole exome sequencing will miss Congenital Myotonic Dystrophy in the child on an asymptomatic mother.....	1140
PB2013. Whole genome sequencing identifies biallelic <i>SCLT1</i> splice-region variants in a child with a suspected ciliopathy: Delineating the <i>SCLT1</i> related ciliopathy spectrum.	1141
PB2014. Whole-Exome Sequencing of a French Canadian Cohort Reveals New Candidate Founder Mutations	1142
PB2015. Whole-exome sequencing of Pakistani consanguineous families identified variants in novel and known genes of severe intellectual disability.....	1143
PB2016. Whole-genome sequencing for comprehensive genetic modifier identification in CMT1A.....	1144
PB2017. A conditional knock-in preclinical mouse model for the <i>TRPV4</i> skeletal disorders.....	1145
PB2018. A cross-species approach using an <i>in vivo</i> evaluation platform in mice demonstrates that sequence variation in the human <i>RABEP2</i> gene modulates ischemic stroke outcomes.....	1146
PB2019. A drug repurposing screen to identify therapies for the rare disease DPAGT1-CDG	1147

ASHG 2022 Annual Meeting Poster Abstracts

PB2020. A Phase 1, Open-Label, Dose-Escalation Study to Evaluate the Safety and Efficacy of HMI-103, a One-Time Phenylalanine Hydroxylase Gene-Editing Vector in Adult Participants with Classical PKU Due to PAH Deficiency	1148
PB2021. A Structural Screen Approach and Molecular Simulation Identifies Potential Ligands Against the K700E Hot Spot Variant and Functional Pockets of SF3B1 to modulate splicing in Myelodysplastic Syndrome.....	1149
PB2022. AAV delivery of <i>ELPI</i> exon-specific U1 snRNA rescues retinal degeneration in a mouse model of familial dysautonomia.	1150
PB2023. Adjunct treatment with glycogen synthase (GYS1) antisense oligonucleotides and Enzyme replacement therapy (ERT) reduced glycogen in the Pompe disease mouse model.....	1151
PB2024. An allele- discriminative approach for efficient and specific CRISPR/Cas9 based gene therapy of Late Onset of Alzheimer's disease.....	1152
PB2025. An allele specific strategy for targeting mutant senataxin in patients with amyotrophic lateral sclerosis type 4.....	1153
PB2026*. An alternate translational start site allows 5' nonsense variants to escape NMD so that readthrough compound ELX-02 and modulators can restore CFTR function.	1154
PB2027*. An <i>in vivo</i> screen identifies small molecule modulators of retinitis pigmentosa and the ER stress response.....	1155
PB2028. Antisense oligonucleotide-based exon skipping therapeutic strategy for Cohen syndrome.	1156
PB2029. Characterization of novel mouse model with 35 bp deletion in <i>Champ1</i> gene and exploration of AAV gene therapy to correct syndromes arising from mutations in the <i>CHAMP1</i>	1157
PB2030. Comparison of AAVmyo and MyoAAV as promising vectors to deliver gene therapy in the VCP ^{R155H} KI mouse model.....	1158
PB2031. Deep phenotyping APOC3 Knockouts in a population with high consanguinity	1159
PB2032. Development of an AAV gene therapy for GNE myopathy: AAV9-CK8e-SV40- <i>hGNE1</i> -V5 shows robust GNE expression in mouse muscle tissue.	1160
PB2033. Dkk1 inhibition normalizes limb phenotypes in a mouse model of <i>Fzd2</i> associated omodysplasia Robinow syndromes.....	1161
PB2034. Down-regulation of <i>SCN8A</i> as treatment for developmental and epileptic encephalopathy	1162
PB2035. Drug repositioning network in rare and intractable diseases based on drug target gene analyses.....	1163
PB2036. Dynamin-2 interacts with SPEG and its reduction rescues the skeletal myopathy of SPEG-deficient mouse model	1164
PB2037. ECLIPSE, an automated CRISPR platform for the large-scale generation of cell models for the iPSC Neurodegenerative Disease Initiative (iNDI)	1165
PB2038. Effect of respiratory resistance exercise done remotely on respiratory function in individuals with familial myopathy.....	1166
PB2039. Efficacy and safety of elamipretide in subjects with primary mitochondrial disease resulting from pathogenic nuclear DNA mutations (nPMD) is investigated through this phase 3 study design.	1167

ASHG 2022 Annual Meeting Poster Abstracts

PB2040. Evaluation of Ataluren efficacy in fibroblasts from Neurofibromatosis Type 1 patients with nonsense mutation.....	1168
PB2041. Generation of eight human induced pluripotent stem cell lines from immortalized lymphoblastoid cells	1169
PB2042. Genetic subgroup learnings is presented from the MMPOWER-3 trial: elamipretide improves six-minute walk test in individuals with mtDNA replisome disorders.	1170
PB2043. Genome-wide CRISPR/Cas9 Screening Reveals ATR as a Therapeutic Target That Overcomes Osteosarcoma Chemoresistance.....	1171
PB2044. Genotyping analysis in patients with retinitis pigmentosa due to mutations in the <i>RHO</i> , <i>PDE6A</i> , or <i>PDE6B</i> gene: the PHENOROD2 study.....	1172
PB2045. Harmonization of phenotype ontologies and identification of novel gene/drug-disease associations with Natural Language Processing	1173
PB2046. Harnessing the power of natural variations of the human genome to support the discovery of new therapeutics: A systematic review	1174
PB2047. Implementing a Genetics-First Strategy in Clinical Development for Rare Brain Diseases	1175
PB2048. Interrogation of the role of androgens and their antagonists in the pathogenesis and treatment of Vascular Ehlers-Danlos Syndrome.....	1176
PB2049. Learnings from a randomized clinical trial with ARID1B patients	1177
PB2050. Leveraging Machine Learning to Improve Guide RNA Design for Efficient and Selective ADAR-Mediated RNA Editing.....	1178
PB2051. Localization of KK13 peptide and their potential against ALS.	1179
PB2052*. Long-term efficacy and safety of elamipretide in patients with Barth syndrome is presented through the 192-week open-label extension results of TAZPOWER.	1180
PB2053. New class of anaplerotic compounds ameliorates substantial loss of lysine succinylation in propionyl-CoA carboxylase deficient cells.....	1181
PB2054*. Novel ASO based treatment shows promise in treating CMT2S, preclinical data	1182
PB2055. Novel siRNA-based therapeutic approach for Megacystis Microcolon Intestinal Hypoperistalsis Syndrome (MMIHS).	1183
PB2056*. Personalized RNA interference approach as a nanotherapy for Crouzon syndrome: design of allele-specific siRNAs targeting FGFR2 mutant allele delivered by recombinant human nanoferritin.	1184
PB2057. Pre-clinical antisense oligonucleotide treatment of CMT2E in a human induced pluripotent stem cell (iPSC)-derived motor neuron model.....	1185
PB2058*. RNA editing of founder nonsense mutations causing inherited retinal diseases using site-directed endogenous adenosine deaminase acting on RNA.....	1186
PB2059. Sustained efficacy and safety up to 3.5 years in adults with glycogen storage disease type Ia (GSDIa): results from a phase 1/2 clinical trial of DTX401, an AAV8-mediated, liver-directed gene therapy.	1187
PB2060*. Testing gene therapy for achromatopsia-like visual deficits in nonhuman primates affected by naturally occurring missense mutations in <i>PDE6C</i>	1188

ASHG 2022 Annual Meeting Poster Abstracts

PB2061. The Jackson Laboratory Center for Precision Genetics: Preclinical research for rare diseases	1189
PB2062. Two years of venglustat combined with imiglucerase shows continued positive effects on neurological features and brain connectivity in adults with Gaucher disease type 3.....	1190
PB2063. Venglustat, a novel, investigational, brain-penetrant glucosylceramide synthase inhibitor, for Gaucher disease type 3: phase 3 LEAP2MONO trial design	1191
PB2064. A novel human mitochondrial donating cell type promotes maturation of GV oocytes.....	1192
PB2065. Assessing the accuracy of variant detection and coverage bias in mitochondrial DNA (mtDNA) after whole genome amplification of single fibroblast cells with known mtDNA heteroplasmic mutations to effectively optimize preimplantation genetic testing of mtDNA related disorders.....	1193
PB2066. Assessing the magnitude of clinical utility of preconception expanded carrier screening for prevention of neurodevelopmental disorders	1194
PB2067. Assisted reproductive technology and DNA methylation at imprinted genes	1195
PB2068. Capacity Building: Exploring the Use of Newborn Screening Data to Understand Neurodevelopmental Outcomes	1196
PB2069. Cell free fetal (cff) DNA assessment using Y- chromosome specific sequences and amplicon NGS of targeted SNPs for possible implementation in non-invasive prenatal testing of common chromosomal aneuploidies.....	1197
PB2070. Cell-informed atlas of gene, isoform, and splicing regulation in the developing human brain identifies candidate causal variants for neuropsychiatric GWAS.....	1198
PB2071. Characterization of the prenatal presentation of novel truncating variants in <i>ANKRD11</i>	1199
PB2073*. Comprehensive preimplantation genetic testing for monogenetic disorders (PGT-M) and aneuploidy (PGT-A) using whole genome sequencing and haplotyping.....	1200
PB2074. Contribution of BBS9 isoforms to the etiopathogenesis of non-syndromic craniosynostosis	1201
PB2075. <i>De novo</i> mutations disturb early brain development more frequently than common variants in schizophrenia	1202
PB2076. Developmental programming of vitamin b12 deficiency model in zebrafish.....	1203
PB2077. Developmental trajectory analysis of differentiating mouse sensory interneurons to further improve stem-cell differentiation protocols.....	1204
PB2078. Discordances among NIPT, QF-PCR and cytogenetic results in prenatal cases.....	1205
PB2079. DNA damage and antioxidant capacity as prenatal markers of placental epigenetic aging clock.....	1206
PB2080. Down Syndrome therapeutics: The integrated stress response and restoration of protein synthesis.....	1207
PB2081. Explore SOX9 haploinsufficiency in neural stem cells.	1208
PB2082. Exploring roles of distal enhancers in <i>SOX9</i> haploinsufficiency in sex determination	1209
PB2083. Fetal genetic autopsy: A five-year retrospective audit monocentric audit.....	1210

ASHG 2022 Annual Meeting Poster Abstracts

PB2084. Gaucher disease: systematic review.....	1211
PB2085. Genetic Characterization of VACTERL Association-Like Congenital Malformations.....	1212
PB2086*. Genetic deconvolution of fetal and maternal cell-free DNA in maternal plasma enables next generation non-invasive prenatal screening.....	1213
PB2087. Genetic determinants of gestational length in Indian women: A two-stage genome-wide association study.....	1214
PB2088*. Genome-wide analysis of preeclampsia identifies novel loci and loci previously associated with blood pressure traits.....	1215
PB2089. Heteroplasmy dynamics and segregation in pre-implantation embryos: Rare insights from complete mitochondrial genome sequencing of clinical trophectoderm biopsy.....	1216
PB2090. High-risk <i>APOL1</i> genotypes and infant growth restriction associations in Black women affected by preeclampsia.....	1217
PB2091. Host genomics and human milk exposure are associated with sex-specific changes in the gut microbiota of infants with asthma in the CHILD Cohort Study.....	1218
PB2092. Human engineered heart tissues uncover <i>MYH7</i> alleles associated with a frail sarcomere and ventricular noncompaction.....	1219
PB2093. Identifying genes associated with preeclampsia using whole exome sequencing data from participants in the Penn Medicine BioBank.....	1220
PB2094. Improving rare conditions diagnostic rates by standardizing practice and offering preclinical testing.....	1221
PB2095. Investigating uptake and impact of genetic and genomic evaluation following a perinatal demise.....	1222
PB2096. Knowledge and attitude of pregnant women in the Kingdom of Saudi Arabia toward Noninvasive prenatal testing: A single center study.....	1223
PB2097. Large-scale genome-wide association study meta-analysis of Hyperemesis Gravidarum confirms the nausea and vomiting hormone gene <i>GDF15</i> is the greatest genetic risk factor and identifies additional risk loci.....	1224
PB2098. Lethal genes and Mendelian disorders.....	1225
PB2099. Leveraging duplex DNA sequencing to investigate germline mutation rates in the context of sperm selection and paternal age.....	1226
PB2100*. Metabolomic analysis reveals altered omega-6 fatty acid processing as a marker of <i>FMR1</i> premutation carriers with FXPOI compared to premutation carriers without ovarian insufficiency.....	1227
PB2101. Molecular dysregulation in <i>Sox2</i> -expressing pituitary stem cells lacking <i>Prop1</i>	1228
PB2102. Molecular Epidemiological Status of Group B Streptococcus in Ile Ife South Western Nigeria.....	1229

PB2457*. Peripheral immune roles in bipolar disorder: genomic, epigenomic, and phenotypic integration	1581
PB2458. Rare inherited Copy Number Variants as genetic modifiers of Developmental Disorders..	1582
PB2459. Reduced-Representation Methylation Sequencing (RRMS): Oxford Nanopore’s alternative to RRBS enables accurate and easy to use methylation calling in CpG islands, shores, shelves, and promotor regions using a MinION flowcell.....	1583
PB2460. RFX transcription factors regulate genes involved with primary cilium in glioma.....	1584
PB2461*. Role of TET1-mediated epigenetic modulation in Alzheimer’s disease.....	1585
PB2462. Scoring individual cells in snATACseq dataset based on GWAS fine-mapping identifies disease-relevant cell-types in neurodegenerative diseases.....	1586
PB2463*. Serum miR-451a is up-regulated in sarcopenic patients compared to healthy controls.....	1587
PB2464. Simultaneous sequencing of genetics and epigenetics provides opportunities for new biological insights.	1588
PB2465*. Single-cell sequencing links reduced glucose metabolism to cocaine addiction-like behavior in rats.....	1589
PB2466. Single-molecule architecture and heterogeneity of human telomeric DNA and chromatin	1590
PB2467. SnapHiC-G: identifying long-range enhancer-promoter interactions from single cell Hi-C data via a global background model	1591

ASHG 2022 Annual Meeting Poster Abstracts

PB2468. SpliceVI: a visualization tool for predicting protein consequences based on SpliceAI data.	1592
PB2469. Stability of genetic regulation of gene expression over time.	1593
PB2470*. Subsetting systemic lupus erythematosus patients based on clustering of DNA methylation at the time of disease flare	1594
PB2471. TDP-43 depletion results in aberrant gene expression and TE activation via dysregulation of R-loop homeostasis.....	1595
PB2472. The association of cigarette smoking with DNA methylation and gene expression in human tissues.....	1596
PB2473. The interplay of epigenetic, genetic, and traditional risk factors on blood pressure: Findings from the Health and Retirement Study.	1597
PB2474. The role of genetic and epigenetic mechanisms in the definition of the circular RNA landscape in multiple sclerosis.....	1598
PB2475. Tobacco smoke-derived metabolites in plasma are associated with cardiometabolic traits, are genetically regulated, and may modulate adipose tissue DNA-methylation in African Americans...	1599
PB2476. Transcriptome and chromatin accessibility dynamics across 25 brain regions identify novel susceptibility gene sets for neuropsychiatric disorders	1600
PB2477. Transfer learning of a methylation based COVID19 severity model for DNA viral infection by eczema herpeticum.....	1601
PB2478. Transposable elements are associated with the variable response to influenza infection	1602
PB2479. Trinity of chromatin architects - The coordination of CTCF, RNAPOL2 and Cohesin in shaping the genomic landscape.....	1603
PB2480. Uncovering Novel Functions of Histone Demethylase KDM5 Through a Genome-wide Approach.....	1604
PB2481. Using allele-specific expression to assess intra- and inter- individual heterogeneity in X-chromosome inactivation within human tissues	1605
PB2482*. Using iPSC-derived microglia and oligodendrocytes to study ancestry-specific gene expression in the context of Alzheimer’s Disease (AD).....	1606
PB2483. Using machine learning to predict 3D genome organization across thousands of diverse individuals reveals conservation and population differentiation.....	1607
PB2484. Validation and Methylome analysis of the CRISPR-edited DUX4 locus in immortalized myoblast cell lines modeling FSHD using long-read sequencing.	1608
PB2485. Variablecis-regulatory landscapes associate with gene function and expression patterns...	1609
PB2486. Variation in DNA methylation is associated with cognitive function in post-surgery breast cancer patients prior to adjuvant therapy.	1610
PB2487. <i>Variation in miRNAs may contribute to orient future therapeutic strategies in hidradenitis suppurativa; An epigenome-widescreening approach.....</i>	1611
PB2488. Vitamin c contributes to epigenetic regulation of genes related to diabetic retinopathy in retinal endothelial cells.	1612

ASHG 2022 Annual Meeting Poster Abstracts

PB2489. Whole genome bisulfite sequencing identifies methylation markers in cord blood linked to maternal hyperglycaemia and childhood metabolic abnormalities	1613
PB2490. Whole-methylomics reveals differentially methylated genes in blood associated with Late-onset Alzheimer's disease	1614
PB2491*. Widespread age-associated changes in the chromatin architecture of skeletal muscle cell type populations	1615
PB2492. A Catalogue of Transcriptomes and Associated Genetic Effects on 2,000 Qataris Uncovering the Functional Impact of Middle Eastern Genetic Variation and Identifying Novel Pathways Underlying Human Traits and Diseases	1616
PB2493. A gain-of-function recurrent missense variant leads to a GABAergic/glutamatergic imbalance in a forebrain organoid model of PACS1 syndrome	1617
PB2494. A genome-first approach characterizing the frequency and phenotype of potentially pathogenic germline <i>DGCR8</i> variants in two large, unselected cohorts	1618
PB2495*. A Homozygous IER3IP1 Mutation Causes Secretory Protein Trafficking Defects in Neural Progenitor Cells	1619
PB2496. A humanized yeast model to identify disease-associated, dominant-negative effects on protein function	1620
PB2497. A lupus-associated variant in <i>IRF7</i> amplifies IFN- α production.	1621
PB2498. A Novel De novo Likely Pathogenic Variant of <i>WFS-1</i> gene in a Pakistani Child	1622
PB2499. A rare genetic variant in the cleavage site of <i>prepro-orexin</i> is associated with idiopathic hypersomnia	1623
PB2500. A risk variant for Barrett's esophagus and esophageal adenocarcinoma at chr8p23.1 affects enhancer activity and implicates multiple gene targets	1624
PB2501. A single-nucleus transcriptome-wide association study implicates novel genes in depression pathogenesis	1625
PB2502. A splicing variant found in the human myostatin gene encodes an isoform that inhibits myostatin	1626
PB2503. A structural variant of the C-terminal prion-like domain of TDP-43 causes vacuolar muscle degeneration	1627
PB2504*. A uniquely prevalent deleterious variant within <i>POMC</i> gene identified in Estonian Biobank cohort	1628
PB2505. <i>A2m11</i> -Knockout Mouse as a Potential Model of Chronic Otitis Media	1629
PB2506*. Aberrant splicing prediction across human tissues.	1630

PB2616. Human genetic variation reveals regulators of <i>Yersinia pestis</i> cellular Infection.....	1739
PB2617. Human pancreatic islet microRNAs implicated in diabetes and related traits by large-scale genetic analysis.....	1740
PB2618. Hypotonia due to homozygous mutation of <i>NALCN</i>	1741
PB2619. Identification of bidirectional regulatory regions for <i>FADS1</i> and <i>FADS2</i>	1742
PB2620. Identification of polyadenylation signals relevant to Mendelian disease variant interpretation.	1743
PB2622. Identification of susceptibility loci for frailty through a genome-wide scans and genetic association study of aging-related variants in Korean population	1744

ASHG 2022 Annual Meeting Poster Abstracts

PB2623. Identifying context-specific genetically regulated expression changes in monocytes associated with resilience to Alzheimer’s Disease	1745
PB2624*. Identifying functional variants related to heart development in African populations.	1746
PB2625. Impact of rare heterozygous mutations of <i>PCSK1</i> on obesity: implication for treatment with MC4R agonists.....	1747
PB2626. Improving generalizability of gene expression prediction models from African-ancestry populations.....	1748
PB2627. Inhibiting aurora kinase A in the HMC3 immortalized human microglia cell line increases phagocytosis of amyloid beta <i>in-vitro</i>	1749
PB2628. Integrated analysis of retinal eQTLs, meQTLs and eQTM identifies target genes and epigenetic mechanisms contributing to age-related macular degeneration.....	1750
PB2629. Integrative 3D structural analysis of <i>de novo</i> missense variants and their associated protein structures inferred by AlphaFold2 identifies the importance of β -strand/sheet features for congenital heart disease	1751
PB2630*. Investigating the impact of non-coding structural variants flanking epilepsy-associated gene, <i>FOXG1</i> on chromatin architecture and gene regulation.....	1752
PB2631. Investigating the molecular and cellular effects of pathogenic variants of <i>GNAI1</i> in developmental and epileptic encephalopathy	1753
PB2632. Investigating the potential roles of Importin-7 and Importin- β in LINE-1 retrotransposition.	1754
PB2633. KDM5A, a chromatin remodeler and newly identified autism gene, has a cell type-specific function in the hippocampus.....	1755
PB2634. KMT5B is required for early motor development.	1756
PB2635. Large-scale integrative analysis of 1.5 million single cells across diverse human tissues and immune cell types reveals dynamic regulatory effects on <i>HLA</i> gene expression.	1757
PB2636. Leveraging Mosaic Epileptogenic Human Brain Tissue to Study Cell-type Specific Transcriptional Changes Associated with a Pathogenic <i>PIK3CA</i> Variant.....	1758
PB2637. Limited overlap of eQTLs and GWAS hits due to systematic differences in discovery	1759
PB2638. Long-chain fatty acid oxidation disorder gene variants identified through a gene panel sponsored program: a diverse gene variant landscape.	1760
PB2639. Mapping the effects of genomic deletions and duplications on cognitive ability across cortex	1761
PB2640*. Massively parallel reporter assays with multi-layer annotations identified cell-type-specific functional variants and genes associated with melanoma.....	1762
PB2641. Massively parallel saturation genome editing of an essential mitochondrial targeting sequence.	1763
PB2642. Maternally Inherited novel <i>SUMO2</i> variant associated with a complex phenotype	1764
PB2643. Mechanisms of adaptation in high-altitude pregnancy: association of genotype with oxygen delivery and placental metabolism.....	1765

ASHG 2022 Annual Meeting Poster Abstracts

PB2644. Mendelian randomization reveals the causal interaction of <i>MICA</i> transcription levels with the risk of Graves' disease	1766
PB2645. Metabolomics to clarify the mechanism of <i>ALDH2</i> polymorphism-induced alcoholic liver injury.....	1767
PB2646. Mimicking NDD phenotypes and functional characterization of <i>PPP1R9A</i> ^{+/-} mutation using iPSCs- derived neurons and single-cell transcriptomics	1768
PB2647. Misexpression of inactive genes is associated with nearby rare structural variants.....	1769
PB2648. Mitochondrial Complex III (CIII) deficiency case study: Analysis of a likely pathogenic variant in <i>UQCRC2</i> gene as the etiology of intellectual disabilities and obesity.	1770
PB2649*. Mitotic recombination is a common mechanism of cellular mosaicism in Fanconi anemia.	1771
PB2650. Modeling single-cell activation states enhances power to identify ex vivo stimulation response eQTLs.	1772
PB2651. Modeling the effects of <i>KCNQ1</i> SNPs on type 2 diabetes risk in iPSC-derived pancreatic islets identifies an early role of methylation that alters islet composition and beta-cell mass.....	1773
PB2652. Mosaicism of a <i>de novo TP53</i> mutation in a patient with breast cancer: value of two germ layers study	1774
PB2653. Multiomics identifies dysregulation of Wnt-signaling through epigenetic gene regulation across tissues in Bohring-Opitz Syndrome	1775
PB2654. Mutant <i>Wac</i> mice exhibit phenotypes relevant to DeSanto-Shinawi Syndrome and provide initial insights into molecular and developmental mechanisms.....	1776
PB2655*. Mutational scanning to determine pathogenicity of Variants of Uncertain Significance in genes in the Sonic Hedgehog Pathway	1777
PB2656. NASP contributes to autism via epigenetic dysregulation of neural and immune signaling pathways	1778
PB2657*. Natural variants in <i>SEL1L</i> modify lethality, ERAD, and proteasome function in a model of NGLY1 deficiency.....	1779
PB2658. Novel actionable targets discovered by proteomic genome-wide association of 1715 unstudied proteins.....	1780
PB2660. Novel non-coding variant in <i>NMNAT1</i> reduces the transcription of <i>NMNAT1</i> , which leads to Leber Congenital amaurosis.....	1781
PB2661. Novel plasma and brain proteins that are implicated in multiple sclerosis risk	1782
PB2662. Novel splice variant in <i>PRUNE1</i> leads to aberrant neurodevelopment and neurodegeneration.	1783
PB2663. Nuclear abnormalities in novel <i>LMNA</i> variant segregating with <i>LMNA</i> -associated cardiocutaneous progeria syndrome.....	1784
PB2664*. Organ-specific prioritization of non-coding regulatory variants with stacking generalization.	1785
PB2665. Parallel functional screening of human duplicated genes in neurodevelopment at single-cell resolution using zebrafish	1786

PB2666. Pathogenic mechanisms associated with a recurrent *CUX2* missense variant in epilepsy... 1787

PB2667*. Pathogenic variants in *PLEKHO2* predispose to heritable thoracic aortic disease 1788

PB2668*. Patient-derived iPSC-CMs from TANGO2-deficient disorder revealed multi-channel defects, functional association between ERK1/2 and TANGO2, and folate as a potential therapeutic agent to mitigate arrhythmias in patients 1789

PB2669*. Phenotypic and functional genomic impact of complex structural variation at the 17q21.31 locus. 1790

PB2670. PIEZO2 as a molecular candidate of respiratory phenotype induced by Congenital Central Hypoventilation Syndrome mutations in *PHOX2B*. 1791

PB2671. Pooled RNA-IP approach to investigate variant effects on RBP binding and splicing..... 1792

PB2672. Population genetic study for 16 autosomal STR loci < and > for > in unrelated 15,546 Korean individuals 1793

PB2673. Population-specific non-coding and coding putative causal variants shape quantitative traits 1794

PB2674. Population-specific RNA-seq data empowers the functional follow-up of disease-associations from FinnGen..... 1795

PB2675. Possible complex Di-Genetic inheritance in Primary Congenital Glaucoma 1796

PB2676. Predicted nasal epithelial transcriptome-wide association study in African-ancestry populations..... 1797

PB2677. Predicting functional and fitness effect of missense variants..... 1798

PB2678*. Profiling Local Ancestry Effects on Gene Regulation in An Admixed Population..... 1799

PB2679*. Quantifying negative selection in human 3'UTRs uncovers deleterious non-coding genetic variation. 1800

PB2680. Rare protein-coding variants in the insulin receptor gene (*INSR*) identified in women with polycystic ovary syndrome (PCOS)..... 1801

PB2681. Regulation of stress granules by VCP in health and genetic degenerative diseases 1802

PB2682. Regulatory rare variant trait associations in 127,724 UK Biobank genomes..... 1803

PB2683. Role of SNPs of Leptin gene in Etiology of Venous Thromboembolism among Females contraceptive users in Pakistan Population..... 1804

PB2684. Scalable mQTL analysis of biochemical pathways with the UK Biobank using REVEAL:Biobank 1805

PB2685. Seamless integrative pipeline for QTL datasets enhance the discovery of putative causal variants for Alzheimer's Disease. 1806

PB2686. SEPT-GD: a decision tree to prioritise potential RNA splice variants in cardiomyopathy genes for functional splicing assays in diagnostics..... 1807

PB2687. Sex differences in gene expression affect host response to influenza A infection..... 1808

PB2688. Short chain fatty acid abnormalities:Genotype-Phenotype correlation in thirteen Puerto Rican patients. 1809

ASHG 2022 Annual Meeting Poster Abstracts

PB2689*. Single-cell caQTL reveals cell-state-dependent regulation in immune cells in rheumatoid arthritis.	1810
PB2690. Single-nucleus transcriptome analysis of 424 aging brains identifies cell type and subtype specific <i>cis</i> -eQTL and their relation to neurodegenerative disease susceptibility.	1811

PB2940. Combination of low-coverage whole genome and deep-coverage exome sequencing is the cost-effective way to drive large-scale genetics studies forward.....	2060
PB2941. Combined multiple structural variant algorithms achieved the highest recall rate in GIAB large deletion callsets.....	2061
PB2942. Community detection analysis in multilayer COVID-19 patient similarity networks.....	2062
PB2943. Comparison of exome performance in an inherited cancer context.....	2063
PB2944. Comparison of genotyping arrays and low-pass sequencing for predictive genomics research.	2064

ASHG 2022 Annual Meeting Poster Abstracts

PB2945. Competing sampling biases balance concordance of single-cell and nucleus RNA-seq	2065
PB2946. Comprehensive characterization of structural variants in human brain genomes using single flow cell nanopore sequencing protocol	2066
PB2947. Comprehensive detection of trait-associated structural variations using short read sequencing data	2067
PB2948. Comprehensive discovery of CRISPR-targeted sequences in the human gut metagenome	2068
PB2949. Comprehensive Structural Variant Detection: From Population to Mosaic level.....	2069
PB2950. CRISPR Streamline: Creating a Pipeline That Evaluates Phenotype Information From Off-Target Sequence Identification	2070
PB2951. Cryptic splice variants contribute to the genetic etiology of congenital heart disease.....	2071
PB2952. Custom morphology markers allow better tissue stratification to study tumor heterogeneity using NanoString® GeoMx® Cancer Transcriptome Atlas	2072
PB2953. D-CoMEx: Differential co-expressed module extraction to identify phenotype-specific miRNA biomarkers related to diseases.	2073
PB2954. <i>De novo</i> variant detection with HiFi reads.....	2074
PB2956. Deep immune repertoire analysis of SARS-CoV-2 antibodies from a vaccinated human patient via mass-spectrometry and synthetic long reads.	2075
PB2957. Deep learning approaches for predicting virus integration sites in the host genomes	2076
PB2958. Deep plasma protein profiling of Alzheimer’s subjects with a novel unbiased and scalable proteogenomics approach	2077
PB2959. DeepCell, A novel cell type specific marker detection machine learning tool for single cell transcriptome.....	2078
PB2960. DeepConsensus v0.3: Gap-aware sequence transformers for sequence correction.	2079
PB2961. <i>DeepLoop</i> robustly maps chromatin interactions from sparse allele-resolved or single-cell Hi-C data at kilobase resolution	2080
PB2962. DeepMod2: A deep learning framework for DNA and RNA modification detection using Oxford Nanopore sequencing.	2081
PB2963. Delivering Comprehensive, Single-molecule Proteomics Using Protein Identification by Short-epitope Mapping (PrISM).....	2082
PB2964. Depth normalization for single-cell genomics count data.....	2083
PB2965. Detecting and assembling non-reference LINE-1 insertions using clustered long reads.	2084
PB2966. Detection of 5-hydroxymethylcytosine using a modified EM-seq protocol.	2085
PB2967. Detection of somatic variation in human neurons using long-read sequencing approaches	2086
PB2968. Developing local compute capacity - a Ugandan experience Integrated Biorepository of H3Africa Uganda, Makerere University College of Health sciences.	2087
PB2969. Development of computational methods for analyzing single-cell spatial transcriptomic data with applications to murine spermatogenesis.	2088

ASHG 2022 Annual Meeting Poster Abstracts

PB2970. Diagnosis of neurodevelopmental disorders by RNA-Seq : From urine derived stem cells to induced neural stem cells, a promising alternative tissue.	2089
PB2971. Diagnostic metabolomic profiling of hypomyelinating leukodystrophy caused by DEGS1 deficiency.....	2090
PB2972*. Direct haplotype-resolved 5-base HiFi genome sequencing allows for linking rare disease variants to non-coding function	2091
PB2973. Magnified Convolutional Enrichment Representation Model	2092
PB2974. Efficiency of mutagenesis promoted by CRISPR-Cas9 in <i>THRAB</i> gene in zebrafish.	2093
PB2975. Efficient DNA sample contamination metric estimation using a novel variant representation and algorithm.	2094
PB2976. Empowering Discovery in Childhood Cancer: Genomic Harmonization at the Kids First Data Resource Center	2095
PB2977. Enabling flexible low throughput sample preparation for multiple sequencing platforms using the Miro Canvas	2096
PB2979. Ensure sample identity in sequencing workflows with the Twist Sample ID Kit.....	2097
PB2980. Establishing a baseline transcriptomic profile of human eccrine sweat glands via single-cell RNA-sequencing with validation by 3D imaging.....	2098
PB2981. Establishing best practice for structural variant discovery with long read sequencing in the Gabriella Miller Kids First Pediatric Research Program using Sentieon’s haplotype-resolved variant evaluation tool.....	2099
PB2982. Estimating and testing cell-type-specific gene co-expression from single-cell data: A robust and efficient method that mitigates technical confounding.	2100
PB2983. Evaluating deep learning for predicting epigenomic profiles	2101
PB2984. Evaluation of cell type annotation for peripheral blood mononuclear cells using single-cell RNA versus a deconvolution approach with bulk RNA sequencing.	2102
PB2985. Evaluation of single nuclei RNA sequencing in brain tissue using Pre-templated Instant Partitions (PIPseq)	2103
PB2986. Evercode™ Whole Transcriptome Single-Cell RNA-Seq with Focal Barcoding Enables Single-Cell Transcriptomes Coupled with Gene or Vector-Enriched Readouts.....	2104
PB2987. Exome sequencing reanalysis complemented with combined multi-omics approach reached to 60% diagnostic yield in previously undiagnosed rare disease cohort.....	2105
PB2988. Exome technology innovations advancing personalized medicine.....	2106
PB2989. Extensive differential cell type-specific gene expression and regulation by sex in human skeletal muscle.	2107
PB2990. Extracellular protein monitoring in the ResolveOME genomic and transcriptomic dual workflow to uncover cancer pathology mechanisms in single cells	2108
PB2991. faiGP: an evolutionary approach to discover governing equations in high-dimensional genomic data	2109
PB2992. Fast and gentle microfluidic cell sorting upstream of single cell transcriptomics	2110

ASHG 2022 Annual Meeting Poster Abstracts

PB2993. FastRNA: an efficient exact solution for PCA of single-cell RNA sequencing data based on a batch-accounting count model	2111
PB2994. FedExosome: mitochondrial DNA & microRNA profiling of neuronal-derived packages in Alzheimer's disease	2112
PB2995*. Fixing falsely duplicated and collapsed regions of the GRCh38 reference genome.....	2113
PB2996. Functional characterisation of the amyotrophic lateral sclerosis risk locus <i>GPX3/TNIP1</i> ..	2114
PB2997. Gene regulatory network inference using single-cell multiome ATAC-seq and RNA-seq data.	2116
PB2998. Generating long-range sequencing information without long-read sequencing.....	2117
PB2999. Generative Adversarial Networks Create High-Quality Synthetic Prostate Cancer Magnetic Resonance Images.....	2118
PB3001*. Genetics guided approach to infer unobserved covariates in functional genomics data....	2119
PB3002. <i>Genetics of Cardiovascular diseases: Mathematical Modeling & Development of a Predicting Simulator Prediction of the heart attack, the treatment to prescribe and the risk of secondary complications</i>	2120
PB3003. Genome-wide prediction of chromatin profiles from gene expression	2121
PB3004*. <i>Genome-wide prediction of pathogenic gain- and loss-of-function variants from ensemble learning of diverse feature set</i>	2122
PB3005. Genomic atlas of the plasma metabolome prioritizes metabolites implicated in human diseases: an analysis of the Canadian Longitudinal Study on Aging (CLSA).....	2123
PB3006. Genotyping known disease-associated short tandem repeats in 7,000 Project MinE genomes reveals their relation to ALS and assists in disease-association analysis of unknown short tandem repeats.	2124
PB3007*. GestaltMatcher supports classification of ultra-rare disorders and delineation of novel syndromes by facial phenotype descriptors	2125
PB3008*. GTAGMe-seq reveals the genome-wide long-range coordinated cis-regulatory elements at the single-molecule level	2126
PB3009. HD-Seq: A novel method for high accuracy sequencing.....	2127
PB3010. High accuracy Sequencing By Binding (SBB) improves human germline variant calling .	2128
PB3011. High throughput single-cell epigenomic profiling through split-pool combinatorial barcoding.	2129
PB3012. High throughput workflow for human whole genome sequencing using PacBio HiFi.	2130
PB3013. High-throughput CRISPR Inhibition Screen to Improve Interpretation of Noncoding Variants in Developmental Epileptic Encephalopathies	2131
PB3014. High-throughput metabolomics enabling discovery of tens of thousands of small molecule biomarkers that link genetics and disease	2132
PB3015. High-throughput RNA isoform sequencing using programmable cDNA concatenation.....	2133
PB3016. High-throughput RNA sequencing directly from cell lysates enables reproducible phenotypic profiling for CRISPR treatment phenotyping and cell response screening applications	2134

ASHG 2022 Annual Meeting Poster Abstracts

PB3017. High-Throughput Sample Processing workflow for rapid Vaginal microbiota profiling of women's health samples.	2135
PB3018*. High-throughput targeted enrichment for long read third-generation sequencing: A flexible, scalable, and cost-efficient method achieving similar throughput as for short read NGS.	2136
PB3019. Horizon - an ultrarapid platform for NICU/PICU whole genome clinical pathogenicity prediction	2137
PB3020*. Human cytomegalovirus infection extensively re-organizes the human genome at human disease risk loci	2138
PB3021*. Human microglia transcriptional changes associated with progression and development of Alzheimer's Disease.	2139
PB3022. Identification of FZD3 and SEMA3A as potentially secreted proteins involved in proliferative sickle cell retinopathy.	2140
PB3023. Identification of novel long non-coding RNA with distinct expression patterns in different multiple myeloma subtypes.	2141
PB3024. Identifying high-confidence de novo mutations in somatic and germline cells through duplex sequencing of diverse tissue types.	2142
PB3025*. Illuminating Dark Proteins using Reactome Pathways	2143
PB3026. Improved data quality for renal cell carcinoma samples with HIVE scRNAseq integrated storage.	2144
PB3027. Improved detection of functionally relevant aberrant splicing using the intronic Jaccard index	2145
PB3028. Improved sequence mapping using a complete reference genome and lift-over	2146
PB3029*. Improving gene detection sensitivity from clinically relevant low input and FFPE RNA samples utilizing a rapid whole transcriptome library prep workflow.....	2147
PB3030. Improving sensitivity of combinatorial barcoding-based single cell sequencing.	2148
PB3031. Imputing functionally impactful <i>CYP2A6</i> structural variants from SNP array data.	2149
PB3032. Imputing the whole metagenomic shotgun sequencing data using the 16s amplicon sequencing data.....	2150
PB3033. Increased mitochondrial expression is associated with increased <i>APOEε4</i> expression and affected by ancestry and sex.	2151
PB3034. Increasing throughput and decreasing cost for single-cell profiling using combinatorial indexing	2152
PB3035. In-depth analysis and comparison of different whole genome methylation sequencing library preparations with low DNA input.....	2153
PB3036. Individualized cellular ancestry: efficient reconstruction of cell lineage trees	2154
PB3037. Induced pluripotent stem cells (iPSCs) for functional genetic screen applications.	2155
PB3038. Infection with SARS-CoV-2 leads to variant-specific changes in gene expression in airway cell lines and primary cell cultures.	2156

ASHG 2022 Annual Meeting Poster Abstracts

PB3039. Inference of menopausal status from female reproductive tissue gene expression signatures	2157
PB3040. Insights from HLA transcriptome analysis of a cohort from the Qatar Genome Program ..	2158
PB3041. Insights into Molecular Pathways Associated with Juvenile Myositis through Single-Cell Transcriptome Profiling	2159
PB3042. Integrated genetic analysis of transcriptome sequencing data in congenital diaphragmatic hernia.	2160
PB3043. Integrated Proteotranscriptomics Analysis of Breast Cancer using Variational Autoencoders to Prioritize Pathogenic Genes	2161
PB3045. Integrating Knowledge in Breast Cancer Subtyping Deep Learning Classifiers	2162
PB3046. Integrating multiple human toxicogenomics datasets for drug repositioning	2163
PB3047. Integration of single nucleus and bulk adipose RNA-seq reveals distinct adipocyte subtypes for obesity and insulin resistance.	2164
PB3048*. Integrative computational analysis of long-read transcriptomes identifies alternatively spliced poison exons in iPSC-derived brain organoids	2165
PB3049. Integrative single-nucleus multi-omics across 287 skeletal muscle biopsies reveals context-specific e/caQTL and extensive caQTL-GWAS colocalization	2166
PB3050. Integrative single-nucleus multi-omics analysis identified candidate regulatory elements and variants and their target genes in Alzheimer's disease brains	2167
PB3052. Investigating somatic mutation rates and signatures across the length of the colon with duplex sequencing.....	2168
PB3053. ioSearch: A tool for searching disease-associated interacting omics.....	2169
PB3054. Is single nucleus ATAC-seq accessibility a qualitative or quantitative trait?	2170
PB3055. IsoMiGA: Combining long and short read RNA-seq in human microglia reveals novel isoforms and splicing events and insight into Alzheimer's disease	2171
PB3056. Large-scale single-cell RNA-sequencing in Japanese identified biological and host genetic involvement of innate immune cells in COVID-19 severity.....	2172
PB3057. Learning nonlinear causal relations in complex biological systems using a deep-learning approach and knockoff statistics	2173
PB3058. Leveraging a multi-'omics Parkinson's Disease dataset to understand the role of mitochondrial transcriptional control in the aetiology of Parkinson's Disease.	2174
PB3059. Linking GWAS risk variants to disease genes by epigenomic mapping and prediction of functional enhancer-promoter interactions.	2175
PB3060. Long read transcriptomes identify features not found with very deep short read sequencing	2176
PB3061. Long-amplicon variant-robust genome capture of SARS-CoV-2 using molecular inversion probes.....	2177
PB3062. Long-read capture with Twist target enrichment system	2178

ASHG 2022 Annual Meeting Poster Abstracts

PB3063. Long-read isoform sequencing reveals aberrant splicing of *PSEN2*, but not *PSEN1*, in individuals with sporadic Alzheimer’s disease. 2179

PB3064*. Long-read RNASeq in human brains aligned to T2T CHM13 complete human genome reveals new gene bodies and new transcripts, exons, & exon junctions in known genes. 2180

PB3065. LongReadSum: A fast and flexible quality control tool for long-read sequencing data. 2181

PB3066*. Low cost, noninvasive RNA-sequencing to enable massive scaling of transcriptome studies. 2182

PB3067. Low-pass whole genome sequencing as a cost-effective and improved alternative to genotyping arrays..... 2183

PB3068. Machine learning approach embedding an alternative splicing as a strategy for a multi omics integration 2184

PB3069. Major cell-types in imbalanced multiomic single-nuclei datasets impact statistical modeling of links between regulatory sequences & genes..... 2185

PB3070*. Making population-scale toxicogenomic analysis performant and cost-effective using REVEAL Biobank. 2186

PB3071. Massively parallel reporter perturbation assays uncover temporal regulatory architecture during neural differentiation 2187

PB3072. Max Read™: a novel high-throughput sequencing format for patterned flow cells 2188

PB3073. Metabolomic analysis of vitreous humor from the eyes with different uveal melanoma prognostic subtypes defined by tumor gene expression profiling..... 2189

PB3074. Metagenomic analyses coupled with metabolic and deep immune profiling reveal coordinate effects on host-microbe interactions in chronic kidney disease 2190

PB3075. Methods for screening candidate causal regulatory variants in primary immune cells by CRISPR ribonucleoprotein. 2191

PB3076. MHConstruct creates personalized full-length MHC locus haplotype sequences by finding optimal paths through a population variation graph. 2192

PB3077. MiRNA regulates potential genetic pathways involved in diabetic retinopathy: Implication for an early disease risk prediction 2193

PB3078. Mitigating challenges of large-scale single cell data management, querying, and analysis with REVEAL SingleCell..... 2194

PB3079. Mitochondrial Genomic ratio (mitscore) is an efficient biomarker to predict the implantation efficacy of human embryos..... 2195

PB3080. More bang for your buck! Universal Sequence Detection: A novel full spectrum variant genotyper for NGS data 2196

PB3081. Multi-Omics Integration for Osteoporosis Prediction through Mixture-of-Experts Framework 2197

PB3082. Multi-omics integration via similarity network fusion to detect subtypes of aging..... 2198

PB3083*. Multiset correlation and factor analysis enables exploration of multi-omic data 2199

ASHG 2022 Annual Meeting Poster Abstracts

PB3084. Neuroimmune insights through single-cell transcriptomics of paired brain and blood from living human subjects	2200
PB3085. New generative deep models to discover novel disease-gene associations in large-scale genomic cohorts	2201
PB3086. New genotyping and sequencing methods for high throughput molecular blood group typing	2202
PB3087. Novel Principal Component Analysis reveals rich gene expression contexts from snRNA-seq within and across cell-types.	2203
PB3088*. Novel sequencing platform using an open fluidics architecture and mostly natural chemistry for cost-efficient whole genome sequencing.....	2204
PB3089. NTSM: Fast sample swapping detection and ancestry estimation on unprocessed heterogeneous raw sequencing data	2205
PB3090. ODER: Optimising the Definition of Expressed Regions, a publicly available R package to improve annotation of RNAseq data and investigate novel transcription using short-read RNA-sequencing data.....	2206
PB3091. On statistical modeling of single-cell RNA-seq data accounting for technological and biological dropouts.....	2207
PB3092. Optimizing microbiome extraction methods for human intestinal resections.....	2208
PB3093. OrphaID: a new platform for rare intellectual disabilities in Orphanet in partnership with ERN-ITHACA	2209
PB3094. Outcomes from the Care4Rare Canada unsolved research pipeline for 950 patients with non-diagnostic exome sequencing data.....	2210
PB3095. Overcoming FFPE hurdles to enable high quality hybrid capture libraries and somatic mutation detection in matched tumor-normal patient samples.	2211
PB3096. PacBio HiFi sequencing provides highly accurate CpG methylation calls without bisulfite treatment.	2212
PB3097*. Paired whole genome and whole transcriptome sequencing of a large cohort of undiagnosed pediatric trios with neurological phenotypes	2213
PB3098. Papillary renal cell carcinoma (pRCC) functional heterogeneity unraveled by single nucleus sequencing (Sn-Seq) technologies	2214
PB3099. Peripheral leukocyte transcriptome dynamics following ischemic stroke of large vessel and cardioembolic etiologies	2215
PB3100. Perturb-seq analysis reveals key mediators of TNF α -induced transcriptional response.....	2216
PB3101. Peruvian Hospital<Urban Antibiotic Resistance found in Local Wastewater	2217
PB3102. PhaseDancer: Targeted assembly of the complex syntenic regions in non-human primates of the HSA2 fusion site.	2218
PB3103. Phenome-wide gene prioritisation leveraging Knowledge Graphs, Graph Convolutional Networks and UK Biobank PheWAS.	2219
PB3104. PIPseq, a novel and highly scalable technology based upon Pre-templated Instant Partitions (PIPs), is powering single-cell RNA sequencing into the million cell era.....	2220

ASHG 2022 Annual Meeting Poster Abstracts

PB3105. Population diversity and selection of recent gene duplications detected using a complete human genome sequence	2221
PB3106. Population Scale Genetic Interpretation Software for Reporting Pathogenic and Likely Pathogenic Variants Impacting the ACMG59 Genes.	2222
PB3107. Predicting the transcriptional activity and mechanism of action of small molecules using deep learning	2223
PB3108. Prokaryotic and viral genomes recovered from 787 Japanese gut metagenomes revealed microbial features associated with diets, populations, and diseases	2224
PB3109. Proteoform inference using proteogenomic approach in non-small cell lung cancer and healthy control plasma proteomes reveals disease-associated protein isoforms	2225
PB3110. Proteogenomic approaches improve genetic discovery across diverse human diseases.	2226
PB3112*. Pseudogenes limit the identification of common, functionally important transcripts generated by their parent genes	2227
PB3113. PubCaseFinder: Implementation of the new function designing Mondo-based virtual gene panels to increase diagnostic efficiency for rare genetic diseases.	2228
PB3114*. Pyro-Velocity: Probabilistic and scalable RNA velocity inference from single-cell data .	2229
PB3115. pyTCR: a comprehensive and scalable platform for TCR-Seq data analysis to facilitate reproducibility and rigor of immunogenomics research	2230
PB3116. Quantifying regional DNA methylation improves detection of biologically relevant associations in Alzheimer’s Disease	2231
PB3117*. Rapid whole genome and whole exome variant detection using a novel fluorescently labeled reversible terminated nucleotide sequencing system and GPU-based accelerated analysis	2232
PB3118. RedSpa: a method for Reference-based domain detection in multiple-sample Spatial transcriptomics studies	2233
PB3119. Regulome-wide association study identifies chromatin accessibility associated with pancreatic cancer risk	2234
PB3120. Revealing the sequence of neutralizing antibodies produced during infection using VyCAP B cell screening equipment coupled to an optimized single cell RNA sequencing protocol.	2235
PB3121. Rigorous benchmarking of HLA callers for RNA sequencing data	2236
PB3122. rMATS-turbo: An efficient and flexible computational tool for alternative splicing analysis of large-scale RNA-seq data.....	2237
PB3123. RNA monsters generated by human mitochondrial RNA polymerase	2238
PB3124*. Robust mapping of cell states from multiomics data using implicit feature selection.	2239
PB3125. SARS-CoV-2 genomic surveillance in Rwanda: Introductions and local transmission of the B.1.617.2/Delta variant of concern.	2240
PB3126. scNanoGPS enables high throughput single cell nanopore sequencing of same cell mega-omics in human tumors	2241
PB3127. Searching for Somatic Variation in Rapid-onset Obesity with Hypothalamic dysfunction, Hypoventilation and Autonomic Dysregulation (ROHHAD).....	2242

ASHG 2022 Annual Meeting Poster Abstracts

PB3128. SeeNV: a pipeline ready tool for the integration and visualization of CNVs and their callers	2243
PB3129. Sentieon DNAscope LongRead: a highly accurate, fast, and efficient pipeline for germline variant calling from PacBio HiFi reads.....	2244
PB3130. Sentieon DNAscope: high accuracy small variant calling using machine learning	2245
PB3131. Sequence-to-expression models of compact promoters for cell-type-specific promoter design	2246
PB3132. Sequencing By Binding (SBB) demonstrates superior performance in low-pass whole-human-sequencing applications	2247
PB3133. Sequencing By Binding (SBB) enables a lower limit of detection for Tuberculosis resistance genes <i>gyrA</i> and <i>katG</i>	2248
PB3134. <i>SigAlign</i> (Similarity-guided Align): A new, high-performance generalized pairwise alignment algorithm using simplified and intuitive regularization criteria.....	2249
PB3135. Simplified RNA-Seq Library Prep: Improved RNA sequencing results for FFPE and blood samples.....	2250
PB3136. Simulating pathogenic and likely pathogenic variants for bioinformatics pipeline testing .	2251
PB3137*. Simultaneous dimensionality reduction and cell-type annotation of single-cell RNA-seq data using marker enriched uniform manifold approximation and projection.	2252
PB3138*. Single cell dissection of Alzheimer's disease and related dementias.	2254
PB3139. Single cell RNA-seq analysis of Bone Marrow-derived Osteoblasts.....	2255
PB3140. Single neuron whole genome sequencing for somatic CNVs using three different genome amplification methods.....	2256
PB3141*. Single-cell allele-specific expression analysis reveals dynamic and cell-type-specific regulatory effects	2257
PB3142. Single-cell dissection of ALS and frontotemporal dementia in the human motor and prefrontal cortices.	2258
PB3143*. Single-cell genome-wide association reveals a nonsynonymous variant in <i>ERAPI1</i> confers increased susceptibility to influenza virus.	2259
PB3144. Single-cell multi-omics reveals gene regulation dynamics during mouse secondary palate development.....	2260
PB3145. Single-cell RNA sequencing (scRNA-seq) of fresh, neuronal tissue using Pre-templated Instant Partitions (PIPseq) and comparison to alternative scRNAseq methods.....	2261
PB3146. Single-molecule, modified base sequencing to identify frequency and cause of rAAV vector breakpoints.....	2262
PB3147. Single-nucleus profiling of the cerebellar cortex in essential tremor reveals Bergmann gliosis and oligodendrocyte myelin abnormalities as hallmarks of disease	2263
PB3148. Single-stranded library preparation for cfDNA identifies unique fragment length signature in myelodysplastic syndrome with multi-lineage dysplasia and ring sideroblasts.....	2264
PB3149*. SnapFISH: a computational pipeline to identify chromatin loops from DNA FISH data..	2265

ASHG 2022 Annual Meeting Poster Abstracts

PB3150*. Somatic genomic alterations in single neurons from brains with chronic traumatic encephalopathy (CTE)	2266
PB3151. sparQ mRNA-Seq: Consistent and high-quality mRNA library preparation from both abundant and limiting samples.....	2267
PB3152. STOC: A Simple Tool Of Compression	2268
PB3153. STRT-N: A newly optimised single-cell RNA sequencing method.	2269
PB3154. Structural and copy number variant detection, filtering, annotation, and classification by optical genome mapping in constitutional disorders.....	2270
PB3155. Structuring information via an immune-focused ontology enables the construction of a high-quality knowledge graph for the study of autoimmune diseases	2271
PB3156. SVPred: An integrated framework for Structural Variant Discovery	2272
PB3157. Systematic evaluation of transcriptome sequencing applied to real-world rare disease cohorts: Insights and limitations	2273
PB3158*. Tagmented, Indexed, and Pooled followed by ChIP Sequencing (TIP-ChIP) to generate high-throughput multi-target ChIP-Seq Results.....	2274
PB3159. Targeted sequencing of a 1 Mb carrier screening panel using molecular inversion probes.	2275
PB3160. Targeted sequencing of native telomeres reveals patterns of telomere length and subtelomere methylation at single chromosome resolution in human cells	2276
PB3161. Targeted transcriptome sequencing enables exponential scaling of combinatorial barcoding.	2277
PB3162. Tempo: an unsupervised Bayesian algorithm for circadian phase inference in single-cell transcriptomics.....	2278
PB3163. Temporal motif discovery in biological interaction networks	2279
PB3164. The impact of ageing on the transcriptome profile of human germline and somatic cells... ..	2280
PB3165. The impact of insert length on variant calling quality in whole genome sequencing.	2281
PB3166. Tissue specific transcript and protein isoforms in the human neural retina	2282
PB3167. Transcriptome analyses of congenital heart disease tissue from participants with Trisomy 21.	2283
PB3168. Transcriptome sequencing of RNA isolated from small volumes of blood stabilized in Tempus solution: a technical assessment of different extraction methods and DNase treatment.....	2284
PB3169. Transcriptome signature of sodium intake in and links to cardiovascular traits	2285
PB3170. Transcriptomic analysis of circulating endothelial colony-forming cells in patients with sickle cell anemia and ischemic stroke.....	2286
PB3171. Transcriptomic analysis reveals long-term effect of SARS-CoV-2 infection on host genetic regulation	2287
PB3172. Ultrasensitive Duplex Sequencing for Diverse Applications on the Singular Genomics G4 Platform.....	2288
PB3173. Ultra-sensitive TCR/BCR clonotyping and immunophenotyping.	2289

ASHG 2022 Annual Meeting Poster Abstracts

PB3174. Undergraduate research assistant	2290
PB3175. Untargeted metabolomics profiling in patients with and without epilepsy.....	2291
PB3176. Using an NGS readout for high-throughput proteome-wide analysis in large population health studies.	2292
PB3177. Using combinatorial barcoding to simultaneously profile the transcriptome and immune repertoire of 1 million T cells.	2293
PB3178. Using single cell CRISPR/dCas9-based regulatory element screening to dissect complex genetic loci.....	2294
PB3179. Using single nuclei multiomics and spatial transcriptomics to identify drivers of early pulmonary fibrosis	2295
PB3180. Utilization of Agena massARRAY to improve quality assessment of saliva samples for clinical genome sequencing	2296
PB3181. Utilization of multi-omic, multiplexed cell atlases and benchmark analysis demonstrates purity of product in the manufacture of induced pluripotent stem cell derived natural killer cells	2297
PB3182. Utilizing paraformaldehyde fixation to expand opportunities for single-cell RNA-sequencing.	2298
PB3183. Utilizing REVEAL SingleCell for single cell spatial transcriptomics data storage, analysis, and visualization	2299
PB3184. Visualize RNA biomarkers to spatially interrogate complex tissues using the RNAscope™ HiPlex v2 in situ hybridization assay.....	2300
PB3185. WES, with its limitations, continues to provide an attractive mode for genomic data collection	2301
PB3186. Whole genome sequencing of low input tagmentation-based libraries results in high quality somatic variant calling comparable to ligation-based PCR-free libraries.....	2302
PB3187. Why long-read sequencing is poised to become key to clinical genetics: an episodic ataxia study.....	2303
PB3188. A comprehensive analysis of the reusability of public omics data across 2.8 million research publications.....	2304
PB3189. A comprehensive database of Long-chain fatty acid oxidation disorder gene variants.....	2305
PB3190. A comprehensive Japanese genetic variation database TogoVar.....	2306
PB3191. A globally representative panel of human genomes: Resource and tutorials to support analyses of diverse populations	2307
PB3192*. A novel reference architecture for multi-party federation: enabling joint analysis of large-scale clinical-genomic data across distributed Trusted Research Environments.....	2308
PB3193. A Private, universal registry for patient engagement in biomedical research - Xia-Gibbs Syndrome as a model.....	2309
PB3194. A reference panel composed of Alzheimer's Disease enriched single-nucleotide and structure variants for structure variants discovery on SNP array data.....	2310

ASHG 2022 Annual Meeting Poster Abstracts

PB3195. A systematic assessment of the completeness of TCR databases across <i>Mus musculus</i> strains.	2311
PB3196. ALS/FTD Compute: an open, centralized repository of genomic data for ALS/FTD research	2312
PB3197. An improved platform for sharing genomic information of underrepresented populations: BIPMed 2.0.....	2313
PB3198*. Assessing the completeness of immunogenetics databases across diverse populations	2314

PB3258. 8 Billion Polygenic Risk Score distributions: building unique reference populations based on genetic ancestry to increase the performance of PRS	2372
PB3259. A Cox proportional hazards whole genome sequencing study of ischemic stroke risk in a Brazilian sickle cell population.....	2373
PB3260. A fast Bayesian screen to identify pleiotropic loci and describe pleiotropic profiles.	2374
PB3261. A fast variational inference approach for powerful genome-wide association of quantitative traits.	2375
PB3262. A framework to improve the interpretation and prediction of variant effect sizes using non-linear functional models.....	2376
PB3263. A gene-based association test of interactions for maternal-fetal genotypes identifies genes associated with non-syndromic congenital heart defects.	2377
PB3264. A generalized framework to decorrelate family or population structure that can easily incorporate epistasis, GxE interaction or multiple-variant analysis in GWAS and NGS studies	2378
PB3265*. A genetic correlation disease-disease network (gcDDN) for the improved identification of novel phenotype relationships.....	2379

ASHG 2022 Annual Meeting Poster Abstracts

PB3266. A genome-wide search for parent-of-origin effects in 4,505 unrelated individuals identifies the <i>8q21.3</i> locus as a novel genetic regulator of Factor V plasma levels.	2380
PB3267. A locus near <i>ICOS</i> modifies risk for <i>Mycobacterium avium</i> complex airway infection in people with cystic fibrosis.	2381
PB3268. A machine-learning approach for disease prediction improves GWAS and polygenic scores	2382
PB3269. A multi-omics risk score approach to identify individual risk for incident type 2 diabetes	2383
PB3270*. A network based approach for fine-scale population structure inference in genetic datasets	2384
PB3271*. A novel approach identified eight gene x alcohol or gene x smoking interactions that contribute to serum lipids.....	2385
PB3272. A novel computational deconvolution method to estimate sample-level cell-type-specific gene expression profile.....	2386
PB3273. A Novel Gene-Based Test for Sequencing Studies Based on a Bayesian Variable Selection of Rare Variants	2387
PB3274. A novel haplotype based approach allows for conducting ancestry agnostic genome wide association studies.....	2388
PB3275. A novel method for annotation-agnostic differential transcript usage analysis	2389
PB3276. A novel method for multiple phenotype association studies based on genotype and phenotype network	2390
PB3277. A pipeline for predicting pathogenicity of monogenic cardiovascular disease genetic variants.	2391
PB3278. A polygenic framework nominating causal SNPs, their target genes, and cell-types of action	2392
PB3279. A polygenic score method including recessive model for improving odds ratio.	2393
PB3280. A precise, combinatorial approach for the estimation of <i>de novo</i> mutation rate from short-read WGS data.	2394
PB3281. A Rare Missense Variant of Large Effect is Associated with Cataract in Puerto Ricans	2395
PB3282. A robust whole-genome Mendelian randomization approach for improved estimation and inference of causal effects.....	2396
PB3283. A scalable framework for robust linear mixed model association testing.....	2397
PB3284. A scalable pipeline for robust relatedness inference with application to a study of 1,144,542 individuals.....	2398
PB3285. A scalable statistical framework for genome-wide interaction testing harnessing cross-trait correlations with an application to Alzheimer's Disease	2399
PB3286. A simple distance-based model predicts effector genes at GWAS loci	2400
PB3287. A statistical framework for integrative genetic association analysis.	2401
PB3288. A statistical framework for local genetic correlation across populations using GWAS summary data.	2402

ASHG 2022 Annual Meeting Poster Abstracts

PB3289. A transcriptomic signature of late-life depression.	2403
PB3290. A two-stage mixed effects model to analyze longitudinal zero-inflated microbiome count data	2404
PB3291*. A virtual transcriptome approach identifies drug repurposing candidates for Alzheimer’s disease.	2405
PB3292*. Accurate and cost-effective imputation of genotypes at whole genome level with Sparse Denoising Autoencoders.	2406
PB3293. Accurate and efficient estimation of local heritability using summary statistics and linkage disequilibrium	2407
PB3294. Accurate <i>in silico</i> confirmation of rare copy number variant calls from exome sequencing data using transfer learning.....	2408
PB3295. Accurate variant calling of the camouflaged LPA KIV-2 VNTR in whole exome sequencing data.....	2409
PB3296. Adjusting for genetic confounders leads to reliable detection of causal genes from transcriptome-wide association studies.....	2410
PB3297. Admixture mapping for phenome-wide discovery in a diverse health system biobank.....	2411
PB3298. Allele frequency differences of causal variants explain the bulk of low portability of cross- ancestry PRS	2412
PB3299. Allelic imbalance of chromatin accessibility in cancer identifies candidate causal risk variants and their mechanisms.....	2413
PB3300. Alpha-2A adrenergic receptor (<i>ADRA2A</i>) modulates susceptibility to Raynaud’s disease.	2414
PB3301. AlphaCluster: Coevolutionary driven residue-residue interaction models enable quantifiable clustering analysis of <i>de novo</i> variants to enhance predictions of pathogenicity.....	2415
PB3302. An accelerated, massively scalable variant calling and filtering workflow for the detection of de novo mutations in whole genome sequencing data.	2416
PB3303. An accurate and efficient causal gene network inference method that handles many confounding variables.	2417
PB3304. An allelic series rare variant association test for candidate gene discovery.....	2418
PB3305. An alternative approach to the estimation of biological age	2419
PB3306. An evaluation of ancestry specific polygenic risk scores (PRS) for uterine fibroids across populations.....	2420
PB3307. An Exomiser-based R pipeline for gene burden testing aids novel gene discovery in rare Mendelian diseases.	2421
PB3308. An experimentally-based functional gene embedding	2422
PB3309. Analysis of follow up data in large biobank cohorts: a review of methodology.....	2423
PB3310. Analysis of vitamin D receptor-binding variants in susceptibility to pediatric-onset multiple sclerosis.....	2424
PB3311. Ancestry-specific eQTL associations in HIS/NHW Alzheimer's disease cohorts	2426
PB3312. Ancestry-Specific Polygenic Risk Scores for Telomere Length in TOPMed.....	2427

ASHG 2022 Annual Meeting Poster Abstracts

PB3313. Application of the colorectal cancer polygenic risk score to the VA CSP #380 “Prospective Evaluation of Risk Factors for Large (≥ 1 cm) Colonic Adenomas in Asymptomatic Subjects” longitudinal colonoscopy screening cohort.....	2428
PB3314. Applying human phenomics to electronic health records provides a framework for understanding skin-aging related phenotypes	2429
PB3315. Assessing the safety of lipid-modifying medications among East Asian adolescents using genetics: Evidence from Hong Kong’s “Children of 1997” birth cohort.....	2430
PB3316. Assessing the value of non-coding variants in 500,000 whole-genome sequences in the discovery of gene-phenotype associations.....	2431
PB3317. Assessment of correlated multi-SNP Mendelian Randomization method using brain eQTLs to discover schizophrenia genes as a case study	2432
PB3318. Association Between Brain Structure and Alcohol Use Behaviors in Adults: A Mendelian Randomization and Multiomics Study.....	2433
PB3319*. Association of genetically predicted iron homeostasis biomarkers in type 2 diabetes and glycemic traits: A two-sample Mendelian Randomization study	2434
PB3320*. Association testing in admixed and multiethnic data sets nominate genetic modifiers of age at onset of Alzheimer’s disease.....	2435

PB1001. 3D genomics with Arima Hi-C sequencing enables detection of clinically relevant gene fusions in pediatric cancer samples.

Authors:

K. Sikkink¹, M. Farooqi², A. Ahmed³, D. Reid¹, A. Schmitt¹; ¹Arima Genomics, San Diego, CA, ²Children's Mercy Hosp. Kansas City, Kansas City, MO, ³Seattle Childrens Hosp., Seattle, WA

Abstract Body:

Gene fusions are known to have oncogenic effects in various cancers and serve as disease biomarkers. Obtaining gene-level resolution of these large structural variants is not possible with karyotyping and can be challenging using fluorescence in situ hybridization (FISH) or RNA sequencing due to low transcript abundance or low-quality RNA. Here, we used a novel method, Arima-HiC sequencing, on 7 archived pediatric cancer samples to determine the technique's effectiveness in detecting gene fusions. We first adapted the Arima Hi-C method for use with formalin-fixed paraffin-embedded (FFPE) tissue. We then selected five archived pediatric alveolar rhabdomyosarcoma (ARMS) tumors (FFPE archival period range: 8-12 years)—known to be fusion-positive via prior clinical testing. Briefly, FFPE tissue scrolls were dewaxed, and the tissue rehydrated, underwent chromatin fragmentation, end-labeling, and proximity ligation prior to DNA purification per the Arima-HiC FFPE protocol. Purified DNA was next prepared as a short-read sequencing library and sequenced on a HiSeq. The raw reads were aligned and deduplicated, and structural variants were called using the HiC-Breakfinder software. We additionally selected 2 non-FFPE pediatric leukemia cases with cryopreserved blasts (archival period range: 1-3 years), for Arima-HiC sequencing (as above). These cases had undergone standard of care cytogenetic (karyotyping, FISH) and molecular (targeted cancer NGS sequencing panel) testing clinically and a genetic driver / known gene fusion had not been identified. Using Arima-HiC sequencing in the first ARMS cohort, we identified either a PAX3-FOXO1 (n=3) or PAX7-FOXO1 (n=2) gene fusion in each of our 5 cases, consistent with the original diagnostic cytogenetic finding. HiC data was additionally able to provide previously unknown partner gene information (PAX3 or PAX7) in 4 of the 5 cases where the partner was previously not known. We then analyzed the cryopreserved blasts from the two leukemia cases without previously detectable genetic drivers or gene fusions, a precursor B-cell acute lymphoblastic leukemia (B-ALL) in a 3-year-old male, and acute myeloid leukemia (AML) in a 2-year-old female. In the first case, we detected an EP300-ZNF384 gene fusion, which is a known, but rare, gene fusion seen in B-ALL. In the second case, we detected a rare KMT2A-MLLT10 gene fusion. These findings are clinically important as both fusions are prognostically relevant. In summary, this study demonstrates how Arima-HiC sequencing provides molecular diagnostic value in archived pediatric solid and liquid tumor specimens via the identification of clinically relevant gene fusions.

Cancer Posters - Thursday

PB1002*. 4C guided cis- and trans-interaction networks associated with the *RCCD1* gene at the 15p26.1 breast and ovarian cancer risk locus

Authors:

S. Chen¹, F. Segato Dezem², S. Dhungana¹, K. Ayaluri¹, B. Davis¹, S. Kar³, S. Gayther², **J. Plummer²**; ¹Cedars-Sinai Med. Ctr., Los Angeles, CA, ²Cedars Sinai Med. Ctr., Los Angeles, CA, ³Univ. of Cambridge, Cambridge, United Kingdom

Abstract Body:

Breast and ovarian cancers share common etiologies and similar genetics, such as mutations in *BRCA1/2* which are responsible for most multi-case breast and ovarian cancer in families. Previous meta-analysis of breast and ovarian combined GWAS revealed several shared risk regions including a region on 15q26. The *P53* interacting gene *RCCD1* in this region is a candidate susceptibility gene for both cancers. A colocalization analysis of breast and ovarian cancer case-control genetic association studies in over 145,000 and 146,000 controls fine mapped the shared association in this region to 17 pleiotropic credible causal risk variants ($P_{\text{breast}} < 1.16 \times 10^{-14}$ and $P_{\text{ovary}} < 7.50 \times 10^{-7}$). These variants had a strong *eQTL* associated with the *increased* expression of *RCCD1* in normal breast and ovarian tissues ($P_{\text{breast}} < 1.7 \times 10^{-21}$ and $P_{\text{ovary}} < 8.3 \times 10^{-6}$). To confirm *RCCD1* as the target gene, we utilized circular chromosome conformation capture (4C) to identify the physical interactions between this susceptibility gene and risk SNP. 4C analysis of *RCCD1* in breast and ovarian cancer cells identified similar patterns of cis-interaction and significant binding site enrichment for the *BRCA2* interacting gene *EMSY* ($P_{\text{adjusted}} = 9.24 \times 10^{-6}$). The 4C analysis pinpointed a single 2kB *RCCD1* that identified 9 shared cis- and 3 shared trans-interacting regions in four breast and ovarian cancer cell lines. *RCCD1* trans-interacting regions mapped to previously identified genome wide significant ($P < 5 \times 10^{-8}$) breast cancer risk loci (1p34.2 and 3p14.1) and to the pleiotropic breast-ovarian cancer risk locus at chromosome 9q34.2. Stable overexpression of *RCCD1* in breast and ovarian cancer precursor cells identified 13 and 11 differentially expressed genes (DEGs) respectively associated with breast and ovarian cancer risk at genome-wide significance ($\text{PMAGMA} < 2.6 \times 10^{-6}$ after Bonferroni correction). Eighty-two DEGs shared between breast and ovarian cancer were strongly enriched in *TP53* ($P = 9.9 \times 10^{-4}$), *Hippo* ($P = 2.51 \times 10^{-3}$) and *TNF* signaling ($P = 4.7 \times 10^{-3}$) pathways. This study describes a functional framework to identify and understand the biology of cis- and trans- interaction networks associated with common variant risk alleles identified by GWAS.

Cancer Posters - Wednesday

PB1003. A B-ALL pediatric patient with IGH rearrangement

Authors:

A. Zhao¹, W. Su¹, C. Stewart¹, K. Eastwood², M. T. Guardiola², J. Nahoul¹, C. A. Tirado³; ¹Univ. of California, Los Angeles, Los Angeles, CA, ²Baylor Scott & White, Temple, TX, ³Baylor Scott & White Hlth., Temple, TX

Abstract Body:

B-cell acute lymphoblastic leukemia (B-ALL) can afflict both adult and pediatric patients B-cell acute lymphoblastic leukemia (B-ALL) can afflict both adult and pediatric patients, and this disease is characterized by a build-up of B lymphoblasts. Here we present a case of a 25-year-old male patient with a history of B-ALL. Ninety percent of the bone marrow revealed pancytopenia with sheets of B lymphoblasts consistent with the diagnostic of B-ALL for acute pre-B lymphoblastic leukemia. The immunophenotype also presented predominant immature precursor B lymphoid cells positive for CD19, CD10, CD34, CD58, CD38, CD9, and TdT. Chromosome analysis of the bone marrow showed a complex karyotype described as 45~47,XY,i(8)(q10),der(10)add(10)(p11.1)add(10)(q23),-20,+1~2mar[cp3]/46,XY[36]. While *IGH* rearrangements were cryptic cytogenetically, DNA FISH analysis showed evidence of the *IGH* (14q32.2) gene rearrangement in 96.5% of the nuclei examined. These results were described as nuc ish(IGHx2)(5'IGH sep 3'IGHx1)[187/200],(5'IGH,3'IGH)x1~4(5'IGH con 3'IGHx0~2)[6/200]. The remaining probes were normal: nuc ish(PBX1, D4Z1,PDGFRB,CDKN2A,D9Z3,ABL1,D10Z1,KMT2A,ETV6,TCF3, RUNX1,BCR)x2[200]. Metaphase FISH showed the *IGH* signal on the derivative chromosome 8. In light of these results the karyotype was characterized as 45~47,XY,i(8)(q10),der(10)add(10)(p11.1)add(10)(q23),-20,+1~2mar[cp3].ish i(8)(q10) IgH+. *IgH* abnormalities are rare in B-ALL and are associated with a poor prognosis. Further studies using the MYC/IGH DC,DF probe from Abbott showed a gain of *IGH* signal in 7.5% of the nuclei examined: nuc ish(MYCx2,IGHx3)[15/200]. This is most likely the same abnormality that was seen in the patient's previous FISH study where we used instead an IGH break apart probe. But there was a significant decrease in the number of abnormal nuclei representing residual disease. However, up to 2022, the patient presented no evidence of persistent or residual disease characterized by the immunophenotype of a small population of immature B lymphoid cells, no monotypic B lymphoid or aberrant T lymphoid populations, and no phenotypic evidence of significant myeloid immaturity.

PB1004. A Case of A Hyperdiploid Complex Karyotype in a Patient with a Myelodysplastic Syndrome

Authors:

H. Robinson¹, A. Lozada², N. Elhajjaoui¹, J. Sung², K. Eastwood³, M. Guardiola³, C. A. Tirado³; ¹Univ. of California Los Angeles, Los Angeles, CA, ²Univ. of California, Los Angeles, Los Angeles, CA, ³Baylor Scott & White Hlth., Dept. of Pathology, Temple TX, USA., Temple, TX

Abstract Body:

We present a case study of a 73-year old female with a history of pancytopenia. Chromosomal analysis of the bone marrow revealed an abnormal karyotype including gain of chromosome 1, 4, 6, 8, 9, 19, and 20 in addition to loss of chromosome 11, 13, 15, 16, 17, and 22. Also, additional material of unknown origin found on 3q, 5p, 9p, 11p, 13p, 14p, and 15p, and two copies of 19p, a deletion of 8q, and rings and markers were present. This was characterized as:

75~77,XXX,+1,der(1;6)(p10;p10),add(3)(q27),+4,add(5)(p15.1),+6,+8,del(8)(q24.1),+add(9)(p24),-11,add(11)(p13),-13,add(13)(p10),add(14)(p11.2),-15,add(15)(p11.2),-16,-17,+19,add(19)(p13.3)x2,+20,-22,+0~4r,+4~10mar[cp11]/46,XX[8]. The cytogenetic analysis correlates with the concurrent FISH study which was positive for additional signals of *EVII* (3q26.2), *TAS2R1* (5p15.31), *EGR1* (5q31.2), *RELN* (7q22), *TES* (7q31), *RUNX1T1* (8q21.3), *ABL1* (9q34), *KMT2A* (11q23), *PML* (15q24.1), *CBFB* (16q22), *RARA* (17q21), *PTPRT* (20q12), *MYBL2* (20q13.12), *RUNX1* (21q22.12) and *BCR* (22q11.2). These results were described as nuc ish(EVI1x3~4)[74/100],(TAS2R1x3~6,EGR1x3~5)[91/100],(RELNx3~7,TESx3~4)[88/100],(RUNX1T1x2~4,RUNX1x3~4)[90/100],(ABL1x2~4,BCRx2~4)[84/100],(KMT2Ax3~6)[72/100],(PMLx2~4,RARAx2~5)[83/100],(CBFBx3~4)[66/100],(PTPRTx3~6,MYBL2x3~6)[84/100]. The present findings are suggestive of a diagnosis of myelodysplastic syndrome, unspecified (MDS-U). The presence of pancytopenia within the context of complex chromosomal structural and numerical abnormalities are usually associated with a poor prognosis in MDS.

Cancer Inst, Rockville, MD, ¹¹Inst. of Cancer Res., London, United Kingdom, ¹²Natl. Cancer Inst., Rockville, MD, ¹³Vanderbilt Univ. Med. Ctr., Nashville, TN, ¹⁴Stanford Univ., Burlingame, CA, ¹⁵Yale Sch. of Med., New Haven, CT, ¹⁶The Inst. of Cancer Res., Sutton, United Kingdom, ¹⁷The Inst. of Cancer Res., London, United Kingdom, ¹⁸Univ of Southern California, Los Angeles, CA

Abstract Body:

Previous genome-wide association studies (GWAS) identified 269 susceptibility loci for prostate cancer (PCa). To further our understanding of the genetic architecture of PCa, we combined the previous largest-available multi-ancestry PCa GWAS with 10 additional independent studies (UK Biobank, FinnGen Study, BioMe, BioVu, eMerge, PLCO, MVP, MDAnderson, CA UG, and NCI-MD) resulting in a total of 156,319 PCa cases and 788,443 controls from men of European (122,188/604,640), African (19,391/61,608), Asian (10,839/95,790), and Hispanic (3,931/26,405) ancestry. In total, 42,428,922 variants were examined for association with PCa risk using logistic regression adjusting for age, sub-study, and principal components. Per-allele ORs and SEs from individual studies were combined by a fixed-effects inverse-variance weighted meta-analysis. To identify and refine independent index risk loci for PCa, we implemented a forward-selection approach using multi-population Joint Analysis of Marginal summary statistics (mJAM) to identify index SNPs and any additional independent signals within each region via conditional analysis. In total, we identified 451 susceptibility loci for prostate cancer, 187 of which were novel. We constructed a genetic risk score (GRS) by summing risk allelic dosages weighted by the conditional per-allele log-ORs based on all 451 variants, and compared the performance to the GRSs based on past marker sets (n=100, 181, 269). The percentage of cases has increased for each population within higher GRS categories (e.g. from 40.5% in GRS₁₀₀ to 51.2% in GRS₄₅₁) and decreased within lower GRS categories (e.g. from 7.5% in GRS₁₀₀ to 4.4% in GRS₄₅₁). Correspondingly, the OR per GRS SD has also increased over time and for the current GRS₄₅₁ the estimated OR per SD ranged from 2.12 (95% CI: 2.08-2.17) for men of African ancestry to 2.47 (95% CI:2.44-2.50) for men of European ancestry. Moreover, in African ancestry, per SD of GRS₄₅₁ was significantly associated with higher risk of aggressive disease than of non-aggressive disease (OR 2.20 vs. 2.05, p_{het}=2.4x10⁻³), while no significant difference in disease aggressiveness was observed for other groups. Our finding of novel risk variants improves the ability of GRS in risk estimation and stratification across ancestral groups.

Cancer Posters - Thursday

PB1006. A genome-wide association study to identify predictive markers for the risk of nivolumab-induced immune-related adverse events

Authors:

H. Zembutsu¹, C. Udagawa², S. Tsuchida³; ¹Natl. Cancer Ctr., Res. Inst., Tokyo, Japan, ²Natl. cancer center, Tokyo, Japan, ³Tsuchida Hosp., Sapporo, Japan

Abstract Body:

In this study, we sought to identify the potential genetic variants that could predict the risk of nivolumab-induced immune-related adverse events (irAEs) in patients with cancer. We enrolled 622 Japanese patients who had been treated with nivolumab, and carried out a genome-wide association study (GWAS) on 315 cases (with irAEs) and 86 control subjects (without irAEs). The associations for 507 single nucleotide polymorphisms (SNPs) showing $P < 0.001$ were further investigated using an independent cohort of 205 cases and 16 control subjects as a replication study. In the combined analysis of the GWAS and replication studies, possible associations were found for a total of 90 SNPs. Although we did not identify any SNPs to be significantly associated with nivolumab-induced irAEs, the SNP most strongly associated with nivolumab-induced irAEs was rs469490 on chromosome 21q21.3 ($P_{\text{combined}} = 2.97 \times 10^{-7}$, odds ratio (OR) = 5.15). In a subgroup analysis for the identification of genetic markers for nivolumab-induced hypothyroidism, rs8023690 on chromosome 15q26.2 was possibly associated with nivolumab-induced hypothyroidism ($P = 2.58 \times 10^{-7}$, OR = 4.09). We consider this study to be an important hypothesis-generating study to guide future studies in larger and/or other ethnic cohorts. These findings may also help to contribute to the prediction of irAE risk for better prognosis and quality of life among patients with cancer.

PB1007. A genome-wide gene expression signature of Breast cancer in the Moroccan women

Authors:

S. Ayoubi¹, P. Ostano², M. Mello-Grand², I. Gregnanin², M. Elkarroumi³, S. Nadifi¹, G. Chiorino²; ¹Genetics molecular pathology Lab., Med. Sch., Univ. Hassan II of Casablanca, Casablanca, Morocco, ²Genomics Lab., Fondazione Edo ed Elvo Tempia, Biella, Italy, ³Mohammed VI Ctr. foCancer Treatment, Univ. Hosp. Ctr. Ibn Rochd, Casablanca, Morocco

Abstract Body:

Background Breast cancer (BC) is the commonest form of cancer in North African countries. Thus, the early diagnosis is crucial for deciding the course of treatment and saving lives. Long non-coding RNAs (lncRNAs) are non-coding RNA class, emerged as key regulators of several biological processes. It has been reported that aberrant expression of lncRNAs was involved in BC. No studies have specifically focused on lncRNAs in BC in developing countries like Morocco. The prime aim of the present study was to establish a unique “lncRNAs-mRNAs” expression signature specific of BC in the Moroccan women. **Material and Methods** We analyzed lncRNAs-mRNAs expression profiles in breast tumors and normal breast tissues by Agilent whole genome microarrays. Then, we screened out the differentially expressed (DE) genes. We performed functional analysis of DE-lncRNAs-mRNAs using public databases. RT-QPCR was employed to validate the previous results. **Results and discussion** 190 dysregulated lncRNAs and 2500 aberrantly expressed mRNAs were identified. 90 lncRNAs and 1500 mRNAs were down-regulated in breast tumors compared to normal tissues. While 100 lncRNAs and 1000 mRNAs were up-regulated genes. THNSL1-2 lncRNA was strongly up-regulated in all molecular subtypes of BC; while “MIR497HG lncRNA” was commonly under-expressed. Most of the genes were related to cancer-associated behaviors, such as the p53 signaling pathway and cell cycle. The RT-QPCR results confirmed the microarray’s data. **Conclusion** Our study is the first to analyze lncRNAs-mRNAs expression profiles of BC in Moroccan women; it provides useful information for exploring novel biomarkers in order to improve BC diagnosis and therapy in Morocco.

PB1008. A novel immunohistochemical marker helps in the diagnosis of Lynch syndrome: detection of deficient DNA mismatch repair pathway proteins crypts within non-tumor colonic mucosa.

Authors:

F. Coulet¹, S. Breton², N. Basset¹, M. Svrcek²; ¹APHP.Sorbonne Univ.-Genetics Dept., Paris, France, ²APHP.Sorbonne Univ.-Anatomo-pathology Dept., Paris, France

Abstract Body:

Lynch syndrome (LS) is the most common form of hereditary colorectal cancer (CRC), and is characterized by a germline monoallelic pathogenic variant in one of the genes of DNA mismatch repair pathway (MMR system). Tumor tissues of these patients show a microsatellite instability (MSI) phenotype and/or loss of MMR protein expression (dMMR). Few studies suggest the existence of morphologically normal colonic crypts losing the expression of one of the MMR proteins in patients with SL. These crypts, called "MMR-deficient colonic crypts", would be pathognomonic of LS. However, few data in the literature explain their precise frequency and the optimal way to detect them. The objectives of this work were (i) to specify the characteristics of dMMR crypts in patients with LS and to propose an optimal detection protocol; (ii) to investigate whether dMMR crypts detection could be a useful tool in case of patients with Lynch-like syndrome (LLS); or (ii) to add argument allowing classification of uncertain significance genetic variants (VUS). All patients were selected retrospectively, according to available tissues, among dMMR/MSI CRC patients from Sorbonne University hospitals. The study included 15 patients with SL (5 MLH1; 7 MSH2; 3 MSH6); 7 patients with LLS and 7 patients with VUS in MMR genes. For each patient, 10 IHC slides were stained with the antibody against the tumor-lost MMR protein on 1 or 2 blocks of normal colonic mucosa adjacent to and distant from the CRC. For each block, the number of dMMR crypts was counted and a crypt ratio (number of dMMR crypts/total number of crypts analyzed) was determined; dMMR crypts were identified in 80% of patients with SL, and were identified in 1 patient with LLS, becoming a strong candidate for further molecular exploration. Finally, dMMR crypts were identified in 4 patients with VUS, argument in favor of the pathogenicity of those variants. Our study confirmed the presence of dMMR crypts in 80% of patients with LS and established an immunohistochemical protocol for their optimal detection. Furthermore, our data suggest that this tool is relevant in front of interpretation difficulties such as LLS or VUS. The presence of dMMR crypts could help in the diagnosis of authentic SL even if it would only have a positive value.

PB1009. A polygenic risk score for prostate cancer risk prediction.

Authors:

M. Shi¹, K. Schaffer¹, J. P. Shelley², M. Bagheri¹, J. Tosoian¹, J. Mosley³; ¹VUMC, NASHVILLE, TN, ²Vanderbilt Univ. Sch. of Med., Nashville, TN, ³Vanderbilt Univ. Med. Ctr., Nashville, TN

Abstract Body:

Background: Prostate cancer is the second leading cause of cancer death among males. Screening protocols for prostate cancer frequently result in men undergoing a prostate biopsy that finds either no cancer or clinically insignificant (Grade Group [GG]=1) cancer. A polygenic risk score (PRS), which measures an individual's burden of common genetic risk variants, could improve risk stratification for high grade cancer. We compared the performance of a prostate cancer PRS against the Prostate Biopsy Collaborative Group (PBCG) clinical risk calculator to risk-stratify individuals with high-grade (GG>1) cancers. **Methods:** A retrospective cohort of 655 Black and White race men who underwent a first prostate biopsy were identified in Vanderbilt University Medical Center's BioVU resource. The prostate cancer PRS was based on a previously validated predictor comprising 269 SNPs identified in a trans-ancestry GWAS. To determine whether the PRS improved risk prediction for high grade (GG>1) cancer, as compared to the PBCG risk calculator, multivariable logistic regression model was used to test the association between PRS and the outcome of either any cancer or a GG>1 cancer with and without adjusted for the PBCG predictor. Prediction for the presence of a GG>1 cancer on prostate biopsy was evaluated based on discrimination (c-statistic), calibration and reclassification (Integrated Discrimination Improvement [IDI]). **Results:** Of 655 participants, 80 (8.2%) were of African ancestries, the median age was 63 (interquartile range [IQR], 57 - 69) years and the median PSA value was 5.3 (IQR, 4.3 - 6.8) ng/ml. The PRS is associated with a finding of any prostate cancer (age-adjusted odds-ratio, 2.0 [95% CI, 1.6 - 2.4]) and high-risk cancer (age-adjusted odds-ratio, 1.5[95% CI, 1.3 - 1.9]). The PRS, when added to the PBCG predictor, improved discrimination for identifying any cancer (c-statistic, 0.71 vs 0.67, difference= 0.042 [95% CI: 0.014, 0.073]), but not for GG>1 cancer (0.74 vs 0.74, difference = 0.002 [-0.011 - 0.012]). The IDI for any cancer was significant for any cancer (0.048 [0.015 - 0.078]) but was not significant for GG>1 cancer (0.009 [-0.008 - 0.022]). **Conclusions:** A prostate cancer PRS improved the prediction of any prostate cancer on biopsy, but did not improve discrimination, calibration, or reclassification for aggressive cancer, as compared to the PBCG risk predictor. This prostate cancer PRS may not help guide the decision-making to undergo a prostate biopsy.

Abstract Body:

Germline mutations in the tumor suppressor gene BRCA1-Associated Protein-1 (*BAP1*) gene are responsible for the *BAP1*-tumor predisposition syndrome (*BAP1*-TPDS), characterized by susceptibility to several tumor types, including mesothelioma, melanoma, renal cell carcinoma, and basal cell carcinoma. We report our ten-year experience in the molecular diagnosis of *BAP1*-TPDS. We sequenced by Sanger sequencing or targeted next-generation sequencing (tNGS) (using a custom panel designed to target: *BAP1*, *CDKN2A*, *CDK4*, *POT1* and *MITF*) the germline DNA samples from 101 individuals with suspected *BAP1*-TPDS. Moreover, a panel of 246 unrelated and unselected patients with mesothelioma were sequenced by tNGS using a custom panel of 107 cancer predisposing genes (including *BAP1*). We validated pathogenic variants (PVs) by assessing *BAP1* somatic loss in matching tumor specimens using immunohistochemistry (IHC), microsatellite analysis, and fluorescence *in situ* hybridization (FISH). We also performed multiplex ligation-dependent probe amplification (MLPA) on DNA extracted from fresh tumor samples. When feasible, cascade genetic testing was also performed. Moreover, *BAP1*-TPDS tumors were studied by tNGS (161 genes). Overall, we identified seven patients (7/101, 6.9%) carrying six different germline *BAP1* pathogenic variants (PVs), including one novel variant, among individuals with suspected *BAP1*-TPDS. Cascade testing identified other seven *BAP1* PV carriers. No somatic alteration besides *BAP1* was identified in the five tumors tested suggesting that *BAP1* is a strong driver of carcinogenesis. We also observed that certain tumors arisen in PV carriers do not show loss of the wild-type allele, suggesting a sporadic origin of the tumor or a functional role of heterozygous *BAP1* in carcinogenesis. Interestingly, we did not identify any germline PV in *BAP1* in the unrelated and unselected patient group (0/246, 0%), but we found that about 9% (23/246) of them carried germline PVs in other tumor suppressor genes, most of them involved in the DNA repair pathways. Altogether, our findings have important clinical implications in shaping personalized treatments.

PB1011. Accelerated Tumor Only Variant Analysis Utilizing a GPU Framework.

Authors:

P. Vats¹, A. Sethia², H. Clifford³, M. Samadi⁴; ¹NVIDIA, Santa clara, CA, ²Nvidia, Santa Clara, CA, ³NVIDIA, Santa Clara, CA, ⁴NVIDIA, San Jose, CA

Abstract Body:

In the last decade, Next Generation Sequencing (NGS) cancer genetics studies have grown exponentially. Due to the rapid decline in sequencing costs and the advancement in sequencing technologies, large scale consortium-based cancer genomics studies have been made possible. Increased accessibility of these large-scale genomic studies has provided access to massive amounts of NGS data, which has created a major challenge for existing bioinformatics software to process and analyze in a timely manner. With recent advancements in oncology genomics workflows, clinically relevant information can now be obtained by sequencing oncology gene panels however it is often limited by tumor only sequencing. In this study, we employ a GPU (Graphics Processing Unit) accelerated framework to perform tumor-only variant analysis on a whole genome dataset from three publicly available studies. Tumor-only variant analysis workflows are not limited to whole genomes, but more frequently used in exome and large cancer gene panels studies. The accelerated framework provides significant speedup over the two most widely used bioinformatics software and presents an opportunity to perform consensus variant calling on tumor-only samples from NGS. In this benchmarking study, we applied two state of art CPU (Central Processing Unit) based variant callers Mutect2 and LoFreq, along with their GPU-accelerated counterparts on three different publicly available datasets. All three WGS datasets (dataset1: Tumor41x WGS dataset2: Tumor 46x WGS, and dataset3: Tumor 37x WGS) were processed through the original CPU and corresponding accelerated variant callers to evaluate runtime and performance accuracy. The accelerated framework provided an average 10x speedup for LoFreq and around 53x speedup for Mutect2 without compromising the results. For LoFreq, we were able to reproduce identical Single Nucleotide Variant (SNV) calls on all the three datasets (COLO829: 7830816, SEQC2: 14602852 and LINST: 8636026 SNV variants) in comparison to baseline variant callers (100% sensitivity and 100% precision, respectively). For Mutect2 we achieved 99.9% sensitivity and 99.9% precision on all three datasets. The results in this study highlight the strength of a GPU accelerated framework and displayed how large-scale tumor only variant calling can be performed in a timely manner, while maintaining accuracy.

Cancer Posters - Wednesday

PB1012. AmpliconClassifier detects the mechanisms of focal genome amplifications in cancer

Authors:

J. Luebeck, V. Bafna; UC San Diego, La Jolla, CA

Abstract Body:

Focal somatic copy-number amplifications (fSCNA) are an important class of targeted genomic amplifications found frequently in cancer genomes. fSCNA arise frequently from genome instability and provide a basis for the overexpression of oncogenes through rapid expansion of copy number. Importantly, fSCNAs may appear in chromosomal or extrachromosomal (ecDNA) forms, depending on the mechanisms by which they occur - and also dictating how they respond to selective pressures. Recent studies highlighted the prognostic importance of distinguishing ecDNA amplification from other events due to its association with worsened patient survival and more rapid tumor evolution (Kim et al., *Nat. Gen.*, 2020). Importantly, due to the megabase scale of fSCNA events, and their complex, heterogeneous structures (Deshpande et al., *Nat. Comms.*, 2019), unambiguous genome assembly to identify the mechanism of amplification remains challenging without ultra-long reads. However, it is still possible to identify the signatures of such events from individual structural variants (SVs) and SV chains. Consequently, even in datasets composed only of NGS data, the frequencies of events such as ecDNA and breakage-fusion-bridges (BFBs) may be determined.

We present AmpliconClassifier (AC), which examines signatures of genomic structural rearrangements to detect fSCNA events from whole-genome NGS data. AC utilizes copy number-aware genome breakpoint graphs generated by the structural variant analysis tool AmpliconArchitect. AC detects signatures of ecDNA and BFB by examining possible substructures identified in the breakpoint graph, identifying SV chains which match to known biological mechanisms of amplification. Given a collection of copy number-weighted paths, AC computes the fraction of amplification which ends up decomposed into cyclic paths to assist in the discovery of ecDNA. It further distinguishes BFB by searching for the presence of palindromic BFB subsequences and foldback SVs. AC also quantifies the structural similarity of fSCNA to detect clonal amplifications and quantify structural evolution.

We applied AC to a cytogenetically validated selection of 81 genes across 43 cancer cell lines, achieving 87% sensitivity in detecting ecDNA. Subsequently, we applied AC to 329 cancer cell lines from the Cancer Cell Line Encyclopedia, revealing ecDNA in 165 cell lines (50%), BFB in 62 cell lines (19%), and multiple independent ecDNA species in 85 cell lines (26%). The classification identifies important functional differences between samples carrying ecDNA, BFB, and other modes of oncogene amplification, pointing to the value of AC as a tool for profiling complex SVs.

PB1013. Amplification of *RUNX1* in a patient with AML

Authors:

R. Hurtado¹, S. Tello-Vera², J. Juarez-Ynoñan³, R. O. Llontop¹, K. Eastwood⁴, M. Guardiola⁴, A. Lozada⁵, C. Tirado⁶; ¹Univ. Natl. Pedro Ruiz Gallo, Chiclayo, Peru, Peru, ²Hosp. Natl. Alanzor Aguinaga Asenjo, Chiclayo, Peru, Peru, ³Hosp. Natl. Alanzor Aguinaga Asenjo, Chiclayo, Peru, ⁴Baylor Scott & White, Temple, TX, ⁵Univ. of California, Los Angeles, Los Angeles, CA, ⁶Baylor Scott & White Hlth., Temple, TX

Abstract Body:

Acute myeloid leukemia (AML) is a heterogeneous disease, characterized by clonal expansion of undifferentiated myeloid precursors, leading to alterations in hematopoiesis and bone marrow failure. Characteristic chromosomal abnormalities in AML are translocations t(8;21), inv(16), t(15;17), t(9;22) as well as mutations of genes that regulate proliferation and survival (*FLT 3*, *PTPN 11*, *ETV 6 / PDGFB*), or genes responsible for differentiation and apoptosis (*RUNX-1 / RUNX 1 T 1*, *PML / RARA*, *KMT2A*, *CEBPA* and *CBFB*). Amplification of *RUNX1* is a rare event in AML. Herein we described a 60-year-old patient that was admitted to the hospital due to a clinical picture of symptoms of acute anemia, thrombocytopenia, leukocytosis, and profuse nasal bleeding. He reported that he had been taking Celecoxid for muscle cramps and denied comorbidities. A complete abdominal ultrasound was performed, which showed hepatomegaly, splenomegaly, and gallstones. The blood cell count indicated the presence of 72% blasts, 17% lymphocytes, 5% segmented, 4% myelocytes, and 2% monocytes. In the bone marrow aspirate, increased cellularity, infiltration by medium to large cells, ample cytoplasm, basophilic, granular, lax chromatin nucleus with 1 to 2 nucleoli, compatible with blasts of myeloid lineage, these blasts represent 97% of cellularity, neutrophils, and precursors represent <3% of the assessed cellularity. The flow cytometry study showed a population of precursors, MPO^{neg} / +, CD34 +, CD19^{neg} / + d, CD117 +, CD38^{neg} / +, HLA-DR ++, CD13^{neg} / +, CD33^{neg}, CD15^{neg}, D56^{neg}, CD123 +, CD7^{neg}, CD11b^{neg}, CD64^{neg}, CD41^{neg}, which represented 68% of the pathological cellularity. These findings are compatible with AML. Chromosome analysis showed an abnormal karyotype characterized as **47,XY, add(9)(p22),+21,i(21)(q10)x2[13]/44,ídem,-5,-6,-8[10]**. FISH Studies using the TEL/AML1 probe showed five signals for *RUNX1* in all cells examined and described as **nuc ish(RUNXT1x2,RUNX1x1~5)[200]**. Amplification of *RUNX1* is a rare event in AML with only few cases reported in the literature (mainly therapy related AML) and it is usually associated with poor prognosis.

Cancer Posters - Wednesday

PB1014. An active learning framework improves tumor variant interpretation.

Authors:

J. Capra¹, A. Blee², B. Li², T. Pecan³, Z. Nagel³, W. Chazin²; ¹Univ. of California San Francisco, San Francisco, CA, ²Vanderbilt Univ., Nashville, TN, ³Harvard Univ., Cambridge, MA

Abstract Body:

Accurate tools for interpreting variants of unknown significance (VUS) are essential for cancer precision medicine to reach its full potential to guide clinical decision-making. Tumor genetic variants are often critical in determining tumor progression and response to therapy. Thus, nonrecurrent tumor VUS pose a significant challenge to the implementation of precision medicine. However, current protein variant predictors are not accurate or specific enough for clinical use. The performance of most variant prediction tools is limited by the difficulty of acquiring sufficient training data to make testable mechanistic predictions.

To overcome these limitations, we developed an iterative “active learning” approach to predict the impact of tumor VUS in cancer relevant proteins from available biochemical, evolutionary, and functional annotations. Active learning augments traditional machine learning with iterative guided functional validation to refine the learned model. During each round, VUS that are most challenging to classify for the current model are functionally evaluated and then reincorporated with the phenotype label for subsequent iterations of algorithm training.

We first demonstrate the potential of active learning to improve variant interpretation on comprehensive deep mutational scanning (DMS) datasets for four cancer-relevant proteins. Given the consistent improvement observed, we then explore the utility of the approach to guide interpretation of tumor VUS in the nucleotide excision repair (NER) protein Xeroderma Pigmentosum Complementation Group A (XPA), a potential biomarker for cancer therapy sensitivity. We leverage a quantitative high-throughput cell-based NER activity assay to iteratively validate XPA VUS selected by the active learning strategy. In all cases, active learning yielded a significant improvement in variant effect predictions over traditional learning.

These analyses demonstrate that active learning is well suited to guide experimental validation and significantly improve interpretation of VUS in cancer patient genomes, a critical need in cancer research and precision medicine. Our new prediction model provides a foundation for deeper investigation of the correlation between genetic variants in NER genes and cisplatin sensitivity. More broadly, the active learning approach we introduce has potential for tumor VUS in other biomarkers of interest.

Cancer Posters - Thursday

PB1015. An AML patient showing an abnormal hyperdiploid karyotype.

Authors:

B. Hamid¹, C. Tran¹, H. Mendelsohn¹, C. Tirado²; ¹Univ. of California, Los Angeles, Los Angeles, CA, ²Baylor Scott & White Hlth., Temple, TX

Abstract Body:

Acute myeloid leukemia (AML) is the most common acute leukemia in adults. It usually presents with an increase in myeloid blast cells and a decrease in mature cells and a reduction in mature red blood cells, granulocytes and platelets. Herein, we present a 71-year-old male with a history of non-Hodgkin lymphoma, fever, and pancytopenia. Cytogenetic studies indicated a deletion of 5q in 7 of the 20 metaphase cells examined as well as additions of chromosomes X, 2, 4, 8, 13, 19, 21 and 22 in 3 of the 3 metaphase cells with a 5q deletion, while the remaining thirteen cells show a normal karyotype(46,XY,del(5)(q13q33[4]/50~59,idem,+X,+2,+4,+8,+13,+19,+21,+22,+22[cp3]/46,XY[13]). Additionally, immunohistochemistry indicated small populations of CD34, CD117, CD3, PAX5, CD138 positive cells. Scattered small non-caseating granulomas are seen. Their significance remains unclear as they are typically associated with systemic infection, autoimmune disease, malignancy, and as a drug reaction, but staining indicated no acid fast organisms identified or fungal forms. Deletion 5q and hyperdiploidy are both common abnormalities for myeloid malignancies, such as MDS and AML, and the patient's complex karyotype involving both abnormalities is associated with genomic instability and a poor prognosis. However, the patient unexpectedly presented with a non-diagnostic immunophenotype with a mixture of T and B lymphocytes, T lymphocyte predominance, small polyclonal B lymphoid population, and no phenotype evidence of significant myeloid immaturity.

Cancer Posters - Wednesday

PB1016. An integrative genomic transcriptomic and proteomic investigation to characterize differences between isogenic radioresistant prostate cancer cell lines.

Authors:

R. Haas¹, S. Khan², G. Frame³, W. Zhao¹, B. Carlin¹, T. Yamaguchi¹, Y. Z. Bugh¹, J. Livingstone¹, C. Zhu¹, R. Hugh-White¹, S. Tao¹, A. Macklin², V. Ignatchenko², N. Kurganovs², D. Vesprini³, A. Loblaw³, M. R. Downes^{3,4}, T. Kislinger^{3,2}, P. C. Boutros^{1,3}, S. Liu^{3,4}; ¹Univ. of California, Los Angeles, CA, ²Univ. Hlth.Network, Toronto, ON, Canada, ³Univ. of Toronto, Toronto, ON, Canada, ⁴Sunnybrook Hlth.Sci. Ctr., Toronto, ON, Canada

Abstract Body:

Relapse of Prostate Cancer (PC) following radiotherapy is a major clinical concern. Hypo-Fractionated (HF) radiotherapy, with high radiation doses per treatment, has recently become clinically preferable over Conventionally Fractionated (CF) due to better outcomes and substantial logistical benefits. Radioresistant phenotypes can emerge following both CF and HF treatments, but it is unknown whether or not similar mechanisms underlie resistance to these different therapeutic regimens. Here we investigated the genomic, transcriptomic, and proteomic differences between isogenic HF and CF radioresistant PC cells, that were originated from radiosensitive DU145 parental cells. We discovered that CF radioresistant cells gained twice the number of somatic single-nucleotide variation (sSNV) than HF. Nevertheless, the gained mutations irrespective of the treatment schedule converged on mutational signatures associated with DNA repair. The RNA abundance profiles of driver-genes and cancer-hallmark genes in CF cells were distinct from HF and parental profiles, which were relatively similar. The differences in protein abundance display cell-fraction-dependent clusters, foremost of which are elevated levels of DNA repair and P53 regulatory proteins in CF cell nuclei. Collectively, we observed a far more aggressive phenotype in CF cells compared to HF across all tested molecular levels. Finally, our top potential therapeutic targets for radioresistance were associated with clinical features in a cohort of ~300 PC patients, corroborating their involvement in shaping aggressive phenotypes. Our study provides a platform for the development of therapies for radio-recurrent prostate cancer. Ongoing proteogenomic integration will help understand the relationships amongst radioresistance-associated changes at the DNA, RNA, and protein levels.

Cancer Posters - Thursday

PB1017. Analysis of second-hit events in Tuberous Sclerosis Complex normal tissues and lesions.

Authors:

K. Klonowska¹, J. M. Grevelink², K. Giannikou^{1,3}, E. Aronica⁴, B. A. Ogorek¹, Z. T. Herbert⁵, A. R. Thorner⁶, T. N. Darling⁷, J. Moss⁸, D. J. Kwiatkowski¹; ¹Cancer Genetics Lab., Div. of Pulmonary and Critical Care Med., Brigham and Women's Hosp., Harvard Med. Sch., Boston, MA, ²Boston Dermatology and Laser Ctr., Massachusetts Gen. Hosp., Boston, MA, ³Div. of Hematology and Oncology, Cancer and Blood Disease Inst., Children's Hosp. Los Angeles, Los Angeles, CA, ⁴Dept. of (Neuro)Pathology, Amsterdam UMC, Univ. of Amsterdam, Amsterdam, Netherlands, ⁵Molecular Biology Core Facilities, Dana-Farber Cancer Inst., Boston, MA, ⁶Ctr. for Cancer Genomics, Dana-Farber Cancer Inst., Boston, MA, ⁷Dept. of Dermatology, Uniformed Services Univ., Bethesda, MD, ⁸Pulmonary Branch, NHLBI, NIH, Bethesda, MD

Abstract Body:

Background: Tuberous sclerosis complex (TSC) is due to inactivating mutations in *TSC2* or *TSC1*, and is characterized by tumor development in multiple tissues, including facial angiofibroma (FAF), and cortical tubers. Several TSC tumors are known to develop through a two-hit mechanism. Here we explored frequency of point mutation second-hit events in TSC. **Methods:** We developed a Multiplex High-sensitivity PCR Assay (MHPA) (Klonowska et al., JCI 2022), enabling mutation detection at extremely low (<0.1%) variant allele frequencies (VAF) in *TSC1*, *TSC2*, and *TP53*. **Results:** *TSC2*-MHPA analysis of 81 samples, including 24 FAF biopsies from TSC patients with *TSC2* mosaicism, led to the discovery that UV-induced second-hit mutation causing *TSC2* inactivation was pervasive in TSC facial skin, with an average of 4.8 mutations per 2-mm biopsy at median VAF 0.08%, generating more than 150,000 incipient facial tumors (subclinical 'micro-FAFs') in the average TSC subject (Klonowska et al., JCI 2022). *TSC1*-MHPA analysis of 6 FAF biopsies from patients with *TSC1* mosaicism showed that UV mutations are much less common in *TSC1* (average 0.8 mutations) than in *TSC2* (average 4.8 mutations, $p=0.006$), consistent with the overall lower severity of FAF involvement in TSC patients with *TSC1* mutations than in those with *TSC2*. *TSC2*-MHPA analysis of TSC brain tubers identified 9 nonsynonymous SNV/indel somatic mutations in 6 of 13 (46%) tubers at median VAF 0.06%. No clear UV signature mutations were identified in any of the brain samples, in contrast to previously analyzed TSC normal skin and FAF. **Conclusions:** Our *TSC2*-MHPA analysis of TSC FAF revealed that TSC facial skin can be viewed as harboring a patchwork of clonal fibroblast proliferations (micro-FAFs) with indolent growth, a small proportion of which develop into clinically observable FAF. Such lesions are much less common in *TSC1* than in *TSC2* patients. *TSC2*-MHPA analysis of TSC tubers identified low frequency second-hit *TSC2* mutations in some lesions, that will be studied further and validated. **Funding:** The study was funded by the FY2020 Tuberous Sclerosis Alliance Postdoctoral Fellowship Award; the Engles Family Fund; and the NIH, National Heart, Lung, and Blood Institute (U01HL131022-04 and Intramural Research Program).

Cancer Posters - Wednesday

PB1018. Analysis of the spatial transcriptomic profiles in tumor and tumor microenvironment of colorectal cancer in Alaska Native patients.

Authors:

M. Thomas¹, H. Yin¹, D. Redwood², A. L. Koehne¹, L. Zhang³, J. J. Tiesinga⁴, T. A. Harrison¹, L. Hsu¹, C. I. Li¹, T. K. Thomas⁴, J. R. Huyghe¹, U. Peters¹; ¹Fred Hutchinson Cancer Ctr., Seattle, WA, ²Alaska Native Tribal Hlth.Co, Anchorage, AK, ³NanoString Technologies, Inc, Seattle, WA, ⁴Alaska Native Med. Ctr., Anchorage, AK

Abstract Body:

Tribal Health Organizations recognize the high incidence and mortality rates of colorectal cancer (CRC) among Alaska Native people and are undertaking initiatives to address it including improved screening and engaging in research. Studying the transcriptomic profiles in tumor and tumor microenvironment (TME) in Alaska Native CRC patients will provide new insights into the disease and identify predictors for survival. Therefore, we performed a comprehensive spatial tissue analysis using the Whole Transcriptome Atlas (WTA) panel on the NanoString GeoMx® Digital Spatial Profiler (DSP). WTA panel enables high-plex data profiling of 18,676 protein-coding RNA targets simultaneously combined with spatial information from any area of interest (AOI) from a single tissue section using next generation sequencing (NGS) readout. In this study, a tissue microarray (TMA) comprising a total of 48 cores from 13 CRC patients, was profiled for 96 AOI by separating tumor and TME tissue compartments based on segmentation on the pan-cytokeratin antibody morphology marker and targeted normal epithelia tissue. Each AOI was spatially profiled for up to 18,676 genes. Using the GeoMx NGS Pipeline software, Illumina FASTQ sequencing files were automatically processed to GeoMx readable digital counts (DCC) and input back into the Data Analysis Suite for analysis. The DCC were mapped back to each AOI, generating a map of transcript activity within each AOI. The R BioConductor package GeoMxWorkflows was used to perform the analysis. In this study, NanoString GeoMx WTA panel offered by Nanostring's TAP lab was utilized to perform spatially resolved expression profiling of CRC samples to understand the genes and pathways involved in CRC cancer. Sequencing quality was inspected for sufficient saturations (>50%) and data was normalized to third quartiles (Q3) to account for cellularity and area of interest (AOI) sizes. In the downstream analysis, 11,080 genes normalized by 3rd quartile, which were expressed above limit of quantification in at least 15% of AOIs. Differential expression analysis helped identify several genes that are significantly expressed between regions and enrichment analysis identified pathways associated with TME of CRC such as extracellular matrix, CTLA4 and cytokine-cytokine receptor interaction pathways. Spatial deconvolution showed abundant immune cell types in TME. This study will be used to help understand the underlying biological mechanisms of CRC tumorigenesis and better understand the role of immune response in the Alaska Native population.

Cancer Posters - Wednesday

PB1019. ArCCH: Improving the Performance of Clonal Hematopoiesis Variant Calling and Interpretation using a Consensus Based Approach

Authors:

I. Chan¹, A. Panchot¹, E. Schmidt¹, B. J. Wiley¹, J. Liu¹, L. Moukarzel², A. Schmidt¹, Y. Zhang³, B. Lajoie⁴, K. Blease⁴, J. Zhao⁴, S. Kruglyak⁴, C. E. Mason⁵, D. C. Link¹, K. H. Stopsack³, K. L. Bolton¹; ¹Washington Univ. in Saint Louis - Sch. of Med., Saint Louis, MO, ²Mem. Sloan Kettering Cancer Ctr., New York, NY, ³Harvard T.H. Chan Sch. of Publ. Hlth., Boston, MA, ⁴Element BioSci.s, San Diego, CA, ⁵Weill Cornell Med. Coll., New York, NY

Abstract Body:

The acquisition of somatic mutations in hematopoiesis stem and progenitor stem cells with resultant clonal expansion, clonal hematopoiesis (CH), is linked to a higher risk of hematologic malignancies and other adverse health outcomes. The prevalence of CH is dependent on sequencing technique. With ultra-high depth sequencing, CH can be detected in the most adults. CH variant calling is challenging due to difficulty in distinguishing low frequency CH mutations from sequencing artifacts. Here we evaluated the performance of three somatic variant callers (Mutect2, Lofreq, and Vardict) and an ensemble approach using deep targeted sequencing datasets generated from AML tumor dilutions and independent sequencing data with orthogonal validation. We sequenced a tumor dilution series from six AML patients and 27 technical controls using a targeted panel with unique molecular indexes including nine common CH genes (DNMT3A, TET2, ASXL1, TP53, PPM1D, JAK2, SF3B1, SRSF2) with a mean unique coverage of 18,268x. For higher VAF mutations (>5%), Mutect2, Lofreq, and Vardict showed reasonable sensitivity and positive predictive values (PPV) but poor performance at lower VAFs. We applied additional filters based on sequencing quality, depth, regional complexity, and an empiric estimate of sequencing error at the position of a given called variant using our technical controls. Taking the consensus of three callers and including our additional filters, we not only retained sensitivity and PPV for high VAF variants (1.00 sensitivity, 1.00 PPV) but improved the PPV with retained sensitivity for variants below 1% (0.91 sensitivity, 0.83 PPV). Applying our consensus approach to a cohort of 31 individuals sequenced using the same targeted panel with variants validated using an orthogonal approach, we saw excellent sensitivity (0.99 [>5%], 0.85 [1-5%], and 0.82 [0.1-1%]) and PPV (1.00 [>5%], 1.00 [1-5%], 0.95 [0.1-1%]). In addition, we will present results of a second independent sequencing dataset using the AVITIÔ System in order to benchmark the performance of our approach using a non-Illumina sequencing technology. In conclusion, we developed ArCCH, an advanced artifact filtering and consensus CH calling pipeline that includes custom annotation features to facilitate pathogenicity determination that is available as a workflow package. Our results show that a consensus approach with advanced error correction filters can substantially improve performance of CH variant calling beyond single variant callers.

Cancer Posters - Thursday

PB1020. Artemis disease-associated variants and their effect on VDJ recombination and genome instability.

Authors:

M. Gavilan, W. Lu, J. Sekiguchi; Univ. of Michigan, Ann Arbor, MI

Abstract Body:

Human patients with Severe combined immunodeficiency disease (SCID) have been previously identified to carry inactivating mutations in the *DCLRE1C* gene. *DCLRE1C* encodes the ARTEMIS DNA nuclease. ARTEMIS participates in V(D)J recombination, the lymphocyte-specific DNA rearrangement that assembles the variable region genes of both T and B cell receptors. The variable regions of T and B cell receptors recognize antigens from the environment and start the mechanism of defense. ARTEMIS also mediates the repair of DNA double strand breaks by non-homologous end-joining (NHEJ) in all cells and tissues. Many missense mutations and variants in *DCLRE1C* have been found to be associated with a wide range of immune system disorders, including late onset immunodeficiency, autoimmunity, autoinflammation, and in some patients, cancer predisposition. However, the impact of the majority of these mutations on ARTEMIS functions has not been defined. This study focuses on two mutations identified in patients that presented a variety of phenotypes. The first mutation, p.T71P, was identified in an immunodeficient patient with residual B and T cell production and no radiosensitivity. The second mutation, p.P171R, was identified in a patient with a progressive immune dysfunction, low levels of B and T cells, a mild radiosensitivity, DSB repair defects and carcinoma. The relationships between these specific *DCLRE1C* mutations on ARTEMIS activities and patient phenotypes are poorly understood. My research takes advantage of an inducible, chromosomally-integrated V(D)J recombination reporter construct in an *ARTEMIS* null pre-B cell line to define the impact of these disease associated mutations on V(D)J recombination, DNA repair and maintenance of genome stability.

Cancer Posters - Wednesday

PB1021. Assessing the relationship between coding variation and cancer risk in known cancer GWAS susceptibility regions

Authors:

A. Hammermeister Suger¹, T. Jia¹, A. Fohner¹, A. I. Phipps^{1,2}, T. A. Harrison¹, S. Lindstrom^{1,2}; ¹Univ. of Washington, Seattle, WA, ²Fred Hutchinson Cancer Ctr., Seattle, WA

Abstract Body:

Purpose: Expanding our understanding of the genetic architecture of cancer could provide insights into cancer biology to help mitigate the health effects of increasing global cancer incidence. Prior work primarily focused on the genetic basis of susceptibility to individual cancer types but elucidating the shared genetic etiology of multiple cancer types could provide novel insights into cancer etiology and development. **Methods:** Our analysis included 195,507 subjects from UK Biobank who had whole-exome sequencing data. We identified 41,670 cases diagnosed with at least one cancer (in situ or invasive cancer) using ICD9/10 codes representing more than 45 distinct tumor sites. We investigated pleiotropic cancer associations for coding variants in 7,421 autosomal genes located within 1 Mb of a previously identified cancer GWAS SNP. We included variants predicted to change protein function, including splice, frameshift, missense, and predicted loss-of-function variants in gene-based variant set analyses using a generalized linear mixed-effects model framework to robustly control for population stratification and cryptic relatedness. **Results:** In gene-based analyses, we identified a significant association between coding variation in *BRCA2* and cancer diagnosis ($p = 1.09 \times 10^{-6}$), and a suggestive association for *BRCA1* ($p = 6.08 \times 10^{-6}$). We also identified a significant single variant association ($p = 1.83 \times 10^{-18}$, OR = 1.12) with cancer diagnosis for the *MC1R* missense variant rs1805007, which has previously reported associations with skin cancer risk. **Conclusions:** Our results highlight the potential for investigating genetic contributions to cross-cancer risk using large, population-based samples with sequencing data. These results also support prior evidence that deleterious *BRCA1*, *BRCA2*, and *MC1R* mutations influence risk across a variety of cancer types.

Cancer Posters - Thursday

PB1022*. Assessment of genomic instability in aggressive forms of breast cancer in Mali

Authors:

C. Ongoiba, O. Samassekou, G. Landouré, M. Traoré, M. Keita; USSTTB, Bamako, Mali

Abstract Body:

Introduction: In Mali, breast cancer is the first and the deadliest cancer in women. More than 90% of breast cancer patients are diagnosed at stage III, and the median survival rate of patients barely reaches 2 years after diagnosis, underscoring the high malignancy and the dire prognosis of this cancer. Data have indicated that the level of malignancy is correlated to the degree of genomic instability whose assessment at diagnosis might pave the way for finding a predictive biomarker, lacking for some aggressive forms of breast cancer such as the triple-negative. Currently, challenges exist to accurately assess genomic instability from tissue sections which is the most widely used clinical material for diagnosis. In this study, we developed a new approach to accurately assess genomic instability in breast cancer at the cellular level. Then, we hypothesize that from this new approach, we can accurately categorize aggressive forms of breast cancer.

Methodology: We enrolled breast cancer patients at different stages, and used serial tissue sections to determine genomic instability by assessing the telomeric nuclear organization (3D telomeric fluorescence in situ hybridization, the 3D-microscopy, and the 3D-telomere analysis) and centromere copies (centromere copy number for six different centromeric loci). Thereafter, we superimposed the digital images of telomeres, centromeres, and the tissue section to generate integrated images and data which allow us to assess cellular heterogeneity and genomic instability. Finally, we used bioinformatics and statistical approaches to analyze the cellular and genomic data and correlate them to the clinical parameters of the patients.

Results: We found that the alteration of the telomeric nuclear organization and changes in centromeric copy number was associated with tumor stages. By combining the telomeric, centromeric, and classical pathological data, we were able to determine cellular heterogeneity as well as the degree of genomic instability from different tumoral regions. Most importantly, we detected high genomic instability in cells presenting low nuclear grade or in a high proportion of cells from samples of patients diagnosed at an early stage. Finally, we detected genomic instability from patient samples that were considered by classical pathology assessment as non-aggressive tumors.

Conclusion: we developed a new approach to accurately assess genomic instability in breast cancer, and this approach might help discover a predictive biomarker for aggressive forms. Most importantly, this new approach can be rapidly translated into clinics for the benefit of breast cancer patients.

Cancer Posters - Wednesday

PB1023. Association of the rs12587 variant in the *KRAS* gene in patients with breast cancer and control group of the Mexican population

Authors:

A. Garibaldi Rios^{1,2}, L. E. Figuera^{1,2}, A. Rivera Camaras^{1,2}, M. G. Márquez Rosales², M. T. Magaña Torres², G. M. Zúñiga González³, D. P. Pacheco Verduzco², B. C. Gómez Meda⁴, E. J. Maciel Cruz¹, H. Moreno Alcocer², M. P. Gallegos Arreola²; ¹Doctorado en Genética Humana, CUCS, UDG., Guadalajara, México., Mexico, ²División de Genética, CIBO, IMSS., Guadalajara, México., Mexico, ³División de Med. Molecular, CIBO, IMSS., Guadalajara, México., Mexico, ⁴Departamento de Biología Molecular y Genómica, Inst. de Genética Humana "Dr. Enrique Corona Rivera", CUCS, UDG., Guadalajara, México., Mexico

Abstract Body:

Background: Variant of the *KRAS* gene have been shown to be associated with cancer. However, their association with breast cancer (BC) has been inconsistent. **Objective:** This study aimed to determine the frequency with which the rs12587 variant of the *KRAS* gene is associated with BC in patients of the Mexican population. **Patients and methods:** The rs12587 A>C variant was determined by PCR real-time in 325 healthy Mexican subjects and 281 BC patients. **Results:** The rs12587 variant was associated with BC susceptibility when the BC patients and the control group were compared for the *AA* genotype (WT) it was observed in 72% of patients with BC vs 82% of controls, comparing them with each other, they showed significant differences [OR 0.51 (Confidence intervals CI95% 0.35-0.76), p=0.001], *AC* genotype (heterozygous) variant rs12587 was observed in 26% of the patients compared with 17% of controls [odds ratio OR 1.81, Confidence intervals CI95% 1.22 - 2.68, p=0.004) and the *CC* polymorphic genotype it was not significant. **Conclusions:** Our results conclude that variant rs12587 was associated with BC susceptibility in BC patients in the Mexican population.

Cancer Posters - Thursday

PB1024*. Associations of genetic ancestry to the somatic mutational landscape from tumor profiling data of 100,000 cancer patients

Authors:

F. De La Vega, B. Rhead, Y. Pouliot, J. Guinney; Tempus Labs, Inc., Chicago, IL

Abstract Body:

The incidence and mortality of cancer vary widely across race and ethnicity. Such variation is influenced by socioeconomic factors, environmental exposures, and genetic background. Individuals of non-European descent are underrepresented in cancer genomic studies, which limits a comprehensive understanding of disparities in the diagnosis, prognosis, and treatment of cancer among these populations. Furthermore, the social constructs of race and ethnicity are far from precise categories to understand the biological underpinnings of such differences. In this study, we use a large real-world data (RWD) patient cohort to examine associations of genetic ancestry with somatic alterations in cancer driver genes. We inferred genetic ancestry from approximately 100,000 de-identified records of patients with diverse histology who underwent tumor genomic profiling with the Tempus xT 648-gene next-generation sequencing (NGS) assay. We selected 654 ancestry informative markers that overlap the capture regions of the assay to infer global ancestry proportions at the continental level: Africa (AFR), America (AMR), Europe (EUR), East Asia (EAS), and South Asia (SAS). While most patients are of European descent (72%), our cohort includes 8 to 12-fold more patients with substantial (>50%) non-European ancestry than TCGA. Logistic regression was used to examine associations between continental ancestry proportions and presence of nonsynonymous somatic mutations and copy number alterations (CNA) in cancer genes, controlling for assay version, gender and age. P-values were adjusted for multiple testing by the Benjamini-Hochberg method to control the false discovery rate at 5%. We identify 7 significant associations with small somatic mutations and 15 with CNAs with non-European ancestries (all $p < 0.0001$). Among others, we found associations between small somatic mutations in *CTNNB1* with EAS ancestry (OR=1.44; odds per 20% increase in given ancestry proportion), *EGFR* with EAS (OR=1.49) and AMR (OR=1.78) ancestries in lung cancer, and *ASXL1* with AMR ancestry in brain cancer (OR=2.48). Furthermore, we identified several associations between ancestry and CNAs: *MTAP* with AMR (OR=1.45) and *EGFR* with SAS (OR=1.46) in lung cancer, among others. Finally, we observed a reduction in actionable mutations (OncoKB levels 1, 2, and R1) with AFR ancestry in *BRAF* (OR=0.73) and *EGFR* (0.77) in colorectal and lung cancers, correspondingly. Our results support the use of genetic ancestry inference on RWD to improve upon the use of race and ethnicity to better understand the impact of ancestry on mutational processes that influence cancer incidence, progression, and outcomes.

Cancer Posters - Wednesday

PB1025. B cell repertoire analysis in prostate cancer identifies gene expression pattern differences in FC gamma receptors.

Authors:

R. Reddy¹, D. Van Booven², A. Vedenko¹, H. Arora^{1,2,3}; ¹Desai Sethi Urology Inst., Miller Sch. of Med., Univ. of Miami, Miami, FL, ²John P Hussman Inst. for Human Genomics, Miller Sch. of Med., Univ. of Miami, Miami, FL, ³The Interdisciplinary Stem Cell Inst., Miller Sch. of Med., Univ. of Miami, Miami, FL

Abstract Body:

INTRODUCTION: The progression of prostate cancer (PCa), from a benign androgen (AR) dependent stage to AR independent castration and neuroendocrine stages, is often complemented by therapeutic resistance. Such resistance necessitates methods that can aid in comprehending the etiology of progression to better patient outcomes. Therapeutics such as immune checkpoint inhibition focus on restoring antibody diversity to destroy tumor cells that elude immune recognition, but treatment efficacy is limited to a subset of patients. This limitation arises mainly due to molecular heterogeneity and tumor adaptability. Therefore, this study assesses the immune modulatory patterns correlated with the stages of PCa progression. **METHODS:** First, the RNAseq raw counts (n=499) from the PRAD project of The Cancer Genome Atlas (TCGA) were acquired. Next, a general principal component analysis (PCA) was conducted, and then using Gleason scores (GS) as a measure of tumor severity, patients were stratified into subclasses. Subsequently, the software packages TRUST and MiXCR were utilized to evaluate immunoglobulin (Ig) profiles. Both total CDR3 sequences, taken from Ig heavy chains, and amino acid (AA) length were examined and compared with mutation rates and switching events. Lastly, all stratifications were compared to known tumor severity by GS. **RESULTS:** No patterns of Ig expression correlatable with PCa subclass were observed. However, Ig profiles significantly differed (p=0.002) between high grade PCa (GS9) and low grade PCa (GS6), with an average of 780 and 300 unique CDR3 sequences, respectively. A significant increase in somatic mutations was also noted (GS9: 0.75 vs. GS6: 0.33, p=2.2e-5). Furthermore, a significant correlation existed when looking at differential expression in 6 of the 7 genes in the FC gamma receptor gene family (mean p=0.00005). Finally, with regards to the Shannon entropy index, lower diversity correlated with lower tumor severity, suggesting a significant change in the immune milieu (p=0.03). **CONCLUSIONS:** Overall, the findings indicate that there are immunomodulatory patterns associated with stages of PCa, and their correlation with components such as mutations, GS, and subclasses of PCa can help further elucidate the underpinnings of PCa progression and develop personalized treatment.

PB1026. Breast cancer genetics in non-Ashkenazi breast cancer patients - carrier rates and variant classification in a genetically diverse population

Authors:

S. Lieberman¹, O. Murik², F. Zahdeh², R. Beeri¹, P. Renbaum¹, M. Barzily¹, T. Klopstock¹, A. Tomer¹, D. A. Zeevi², T. Mann², O. Olsha³, T. Hadar^{3,4}, M. Carmon³, H. Goldvaser^{5,4}, S. Paluch-Shimon^{5,4}, E. Friedman^{6,7}, A. Lahad^{8,9}, R. Bernstein-Molho^{10,7}, **E. Levy-Lahad**^{1,4}; ¹Shaare Zedek Med. Ctr., Med. Genetics Inst., Jerusalem, Israel, ²Shaare Zedek Med. Ctr., Translational Genomics Lab, Med. Genetics Inst., Jerusalem, Israel, ³Shaare Zedek Med. Ctr., Dept. of Surgery, Jerusalem, Israel, ⁴Hebrew Univ., the Faculty of Med., Jerusalem, Israel, ⁵Shaare Zedek Med. Ctr., Dept. of Med. Oncology, Jerusalem, Israel, ⁶Sheba Med. Ctr., The Meiray Ctr. High Risk Clinic, Tel Hashomer, Israel, ⁷Tel Aviv Univ., Sackler Sch. of Med., Tel Aviv, Israel, ⁸Hebrew Univ., Dept. of Family Med., Jerusalem, Israel, ⁹Clalit Hlth.Services, Jerusalem, Israel, ¹⁰Sheba Med. Ctr., Dept. of Med. Oncology, Tel Hashomer, Israel

Abstract Body:

Background: There is limited information on the landscape of inherited breast cancer (BC) in non-Ashkenazi Jews. This heterogeneous, little tested population can offer insights into novel variants in known BC-predisposition genes. Methods: In 2015-2021 consecutively diagnosed non-Ashkenazi BC patients underwent multigene panel testing (MGPT). MGPT was also offered to a control group of unaffected non-Ashkenazi participants. Results: Genetic testing was performed in 743 affected and 813 unaffected women. *BRCA1/BRCA2* pathogenic variants (PV) were identified in 26 (3.5%) affected vs. 5 (0.6%) unaffected women ($P < .0002$). Only 3 *BRCA1* PVs were recurrent. PVs in other genes were found in 33 (4.6%) affected vs. 8 (1%) unaffected women. This included PVs in *ATM*, *CHEK2*, *BRIP1*, *TP53*, *MRE11*, *FANCM*, *NBN*, *PALB2* and *PTEN*. Rare variant classification: 9490 rare variants ($< .01$ MAF) were observed in 28 genes: 695 (7.3%) exonic, 8789 (92.7%) non-coding. 541 (78%) exonic variants were previously in ClinVar. Using frequencies from this cohort enabled downgrading of 15 ClinVar variants of uncertain significance (VUS) to Benign, based on MAF > 0.01 among unaffected low family history (FH) women. MAF by sub-ethnicity downgraded another 28 VUSs. Among non-coding variants, 68 were significantly more common in affected with significant FH, suggesting possible pathogenicity. Conversely, 52 non-coding variants were classified as benign based on higher frequency in controls. Conclusion: Non-Ashkenazi women exhibit low rates of PVs in known breast cancer genes, even in affected women with substantial FH. Genetic analysis in diverse populations can contribute to variant classification, especially of non-coding variants whose interpretation by standard tools is limited.

Cancer Posters - Wednesday

PB1027*. Breast cancer polygenic risk score as a tool to risk stratify participants in the Healthy Nevada Project.

C. Hajek¹, G. Elhanan², K. Schiabor Barrett¹, E. Cirulli³, N. Washington¹, J. Lu¹, A. Bolze¹, J. Grzymalski²; ¹Helix, San Mateo, CA, ²DRI, Reno, NV, ³Helix, Lakeside, CA

Abstract Body:

Background: Providers use clinical risk assessments to identify a woman at high lifetime risk for breast cancer who could thus benefit from enhanced screening measures such as breast MRI or evaluation in high risk breast cancer clinics. However, the application and usage of these assessments is inconsistent and based on factors such as the provider familiarity, or the patient's insurance. In Nevada, a new law requires payors to cover counseling and BRCA1/2 testing for women who meet certain family health history criteria. In parallel, polygenic risk scores (PRS) are emerging as a clinically relevant genomic predictor of breast cancer risk. In population genomics programs, all of these tools could be used to provide a more consistent approach to identifying women at increased risk for breast cancer.

Objectives: Assess the impact of using (i) BRCA1/2 pathogenic variants, (ii) family history and/or (iii) a polygenic risk score to risk stratify patients in the overall population in a US health system.

Methods: The analysis was based on genetic information and Renown Health electronic health records for 21,427 women participants in the Healthy Nevada Project.

Results: All three tools independently identified women at higher risk of breast cancer. Women with a BRCA1/2 pathogenic variant (n=128) had a 7.1x increased risk of breast cancer compared to those without a BRCA1/2 pathogenic variant. Women who reported a positive family history (n=1,431) had a 5x increased risk of breast cancer compared to those without a known family history. And women with a polygenic risk in the top 10% (n=2,118) had a 2x increased risk compared to women with a polygenic risk in the lower 90%.

However, each tool alone missed women at high risk. For example, only 49 (38%) of the women with a BRCA1/2 pathogenic variant reported a family history. A combination of these tools may be the best way to risk stratify patients. We showed that polygenic risk and family history could be combined. Women with a positive family history, negative for BRCA1/2 and in the top 10% of the PRS (n=167) had a 1.5x increased chance of developing breast cancer compared to women with a positive family history, negative for BRCA1/2 and in the bottom 90% of the PRS (n=1,264). The combined positive family history and high PRS group risk for breast cancer was similar to women with a BRCA1/2 pathogenic variant (27% vs. 33.6%).

Overall these results show that genetic screening for BRCA1 and BRCA2 pathogenic variants, collecting family history information, and calculating a polygenic risk score based on common variants are complementary tools that can be used together to stratify patients who would benefit from enhanced screening.

PB1028. Can impairment of kidney function cause kidney cancer? A bidirectional Mendelian randomization study.

Authors:

Y. Yang¹, Y. Lin^{2,3}, T. Fu¹, G. Liao⁴, B. Liao⁵, J. Huang¹; ¹Med. Device Regulatory Res. and Evaluation Ctr., West China Hosp., Sichuan Univ., Chengdu, China, ²West China Hosp., Sichuan Univ., Chengdu, China, ³Program in Genetic Epidemiology and Statistical Genetics, Dept. of Epidemiology, Harvard T.H. Chan Sch. of Publ. Hlth., Boston, MA, ⁴State Key Lab. of Oral Diseases, Natl. Clinical Res. Ctr. for Oral Diseases, West China Hosp. of Stomatology, Sichuan Univ., Chengdu, China, ⁵Dept. of Urology, Inst. of Urology (Lab. of Reconstructive Urology), West China Hosp., Sichuan Univ., Chengdu, China

Abstract Body:

Impairment of kidney function was reported to have a bidirectional relationship with kidney cancer in many observational epidemiology studies. However, whether these two kinds of traits were causally linked was still unclear. In the present study, two-sample Mendelian randomization (MR) methods were adopted to investigate the bidirectional causal relation between kidney cancer and kidney function biomarkers (creatinine-based estimated glomerular filtration rate (eGFR_{crea}), cystatin C-based estimated glomerular filtration rate (eGFR_{cys}), blood urea nitrogen (BUN), serum urate, and urinary albumin-to-creatinine ratio (UACR)). We used genetic instruments for these 5 kidney function traits, from a range between 288,649 and 1,004,040 European ancestry individuals, and kidney cancers from 408,786 European ancestry individuals (N_{case}:1338). To help down weight the potential bias of weak instruments, pleiotropy, and extreme outliers, we applied two state-of-art MR methods, contamination mixture (ConMix) and Robust Adjusted Profile Score (RAPS) in our main analysis. Various sensitivity analyses including other MR methods were also conducted to support the main results. In the forward, MR the eGFR_{crea} was found to play a negative role in the risk of kidney cancer (OR=0.007, 95%CI: 2.6×10⁻⁴ to 0.569, P=0.041). After adjusting for body composition and diabetes, genetically determined urate and UACR may potentially have a causal relationship with kidney cancer (P<0.05). Conversely, genetically determined kidney cancer was found to be causally associated with a decreased level of eGFR_{cys} (OR=-9.56×10⁻⁴, 95%CI: -9.56×10⁻⁴ to -9.56×10⁻⁴, P=0.003). Meanwhile, kidney cancer could increase the level of BUN with marginal significance (P = 0.070). Our results highlighted the bidirectional causal effect of kidney dysfunction on kidney cancer. Clinically, eGFR_{crea} and UACR could both be important predictors for the risk of kidney cancer, especially when patients were comorbid with obesity or diabetes. The level of eGFR_{cys} should be carefully monitored once diagnosed with kidney cancer, to identify whether the kidney function was harmed, regardless of the nephrectomy performed.

PB1030. Cancer subclone detection based on DNA copy number in single cell and spatial omic sequencing data.

Authors:

C-Y. Wu¹, A. Sathe², J. Rong¹, P. Hess¹, B. Lau², S. Grimes², H. Ji², N. Zhang³; ¹Univ. of Pennsylvania, Philadelphia, PA, ²Stanford Univ., Palo Alto, CA, ³Univ Pennsylvania, Philadelphia, PA

Abstract Body:

Cancer results from somatic mutations such as copy number alterations (CNAs) that continue to accumulate during disease progression. These mutations can lead to functional heterogeneity within tumors and can influence the efficacy of cancer therapy. Therefore, studying the functional characteristics and spatial distribution of genetically distinct subclones is crucial to the understanding of tumor evolution and the design of cancer treatment. Here, we present Clonalscope, a method for subclone detection using copy number profiles that can be applied to spatial transcriptomics (ST) data and data from single-cell sequencing platforms such as scRNA-seq and scATAC-seq. Clonalscope implements a nested Chinese restaurant process, which mimics the tumor evolutionary process, to identify *de novo* subclones within one or multiple samples from the same patient. Clonalscope incorporates prior information from paired whole-genome or whole-exome sequencing (WGS/WES) data to achieve more reliable subclone detection and malignant cell labeling. On scRNA-seq and scATAC-seq data from four gastrointestinal tumor samples, Clonalscope successfully labeled malignant cells and identified genetically different subclones, which were validated in detail using matched scDNA-seq data. On ST data from a squamous cell carcinoma and two invasive ductal carcinoma samples, Clonalscope was able to label malignant spots, trace subclones between associated datasets, and identify spatially segregated subclones expressing genes associated with drug resistance and survival. Using Clonalscope, we detected subclones based on (allele-specific) copy number profiles in spatial and single cell tumor sequencing data, enabling the investigation of the interplay between genome, transcriptome, and spatial environment during tumor evolution.

PB1031. Cancer-driving mutations are enriched in genic regions intolerant to germline variation

Authors:

R. Dhindsa¹, D. Vitsios², D. Matelska², J. Mitchell³, Z. Zou², J. Armenia², F. Hu², Q. Wang⁴, B. Sidders², A. Harper², S. Petrovski⁵; ¹Baylor Coll. of Med., Houston, TX, ²AstraZeneca, Cambridge, United Kingdom, ³AstraZeneca, Melbourn, United Kingdom, ⁴AstraZeneca, Chapel Hill, NC, ⁵AstraZeneca, Fulbourn, United Kingdom

Abstract Body:

Large reference datasets of protein-coding variation in human populations have allowed us to determine which genes and genic sub-regions are intolerant to germline genetic variation. There is also a growing number of genes implicated in severe Mendelian diseases that overlap with genes implicated in cancer. Despite their success in prioritizing germline variants, population genetics-based approaches have yet to be applied in the context of distinguishing between somatic cancer driving mutations and neutral “passenger” mutations. Here, we hypothesized that cancer-driving mutations might be enriched in genic sub-regions that are depleted of germline variation relative to somatic variation. We introduce a new metric, OncMTR, which uses 125,748 exomes in the gnomAD database to identify these genic sub-regions. We demonstrate that OncMTR can significantly predict driver mutations implicated in hematologic malignancies. Divergent OncMTR regions were enriched for cancer-relevant protein domains, and overlaying OncMTR scores on protein structures identified functionally important protein residues. OncMTR outperformed every population- and evolutionary-based scores, including CADD, ncER, LINSIGHT and phyloP in predicting leukemia-causing missense variants. Finally, we performed a rare variant, gene-based collapsing analysis on an independent set of 394,694 exomes from the UK Biobank and find that OncMTR dramatically improves genetic signals for hematologic malignancies, with up to 1,000-fold increased effect sizes for certain associations. Our web app enables easy visualization of OncMTR scores for each protein-coding gene (<http://oncmtr.public.cgr.astrazeneca.com>).

PB1032. Case report: Olaparib use in metastatic lung adenocarcinoma with *BRCA2* pathogenic variant

Authors:

J. Soon, D. Tan Shao Weng, J. NGEOW, J. Chiang; Natl. Cancer Ctr. Singapore, Singapore, Singapore

Abstract Body:

Poly (ADP-ribose) polymerase (PARP) inhibitors are approved in malignancies associated with germline *BRCA1* or *BRCA2* pathogenic variants, such as breast, ovarian, prostate and pancreatic cancer. In cancers not associated with germline *BRCA1* or *BRCA2* pathogenic variants (PV), the therapeutic relevance of PARP inhibitors is less clear. We describe a 64 year old Chinese gentleman with a smoking history of forty pack years who presented with a skin lump over the epigastrium. Family history was significant as his sister had breast cancer in her forties and had surgery. Excision of the lump led to the diagnosis of a metastatic lung adenocarcinoma with an *EGFR* Exon 18 mutation, with c.2126A>C(p.Glu709Ala) and c.2156_2157delins CA(p.Gly719Ala). Afatinib was started with partial response. After four months, he progressed with symptomatic left femur and ulnar metastases. Afatinib was resumed after orthopaedic intervention and radiotherapy, continued till progression, with a disease control of eleven months. Liquid biopsy and repeat lung biopsy were negative for T790M mutation. The lung biopsy showed a PD-L1 TPS score of 70%. After two cycles of pembrolizumab, he progressed with symptomatic brain metastases, and whole brain radiotherapy was delivered. Next generation sequencing of the lung biopsy revealed a somatic *BRCA2* PV. Analysis of the tumor showed somatic *BRCA2* c.1411G>T(p.Glu471Ter) variant with variant frequency of 28.4%, *RBI* c.1807G>A(p.Ala603Thr) variant with variant frequency of 35.6%, and estimated tumour mutation burden of 14 Muts/Mb. The two *EFGR* mutations found on initial molecular testing were found. Three variants of unknown significance (VUS) in *ATR*, *CREBBP* and *SLX4* gene were found. Olaparib was started at 300mg twice a day. He achieved partial response four months later, and his progression free survival was extended by eight months. In view of a somatic *BRCA2* PV and positive family history of *BRCA2* associated cancer, germline testing was performed on his blood. This showed *EGFR* c.3353C>T(p.Ala1118Val) VUS. No germline *BRCA2* PV was found. Post olaparib, he received two cycles of pemetrexed carboplatin and then two cycles of docetaxel before demise. The G>T variant within *BRCA2* at genome coordinate Chr13:32332889 is predicted to result in an amino acid substitution of glutamic acid with a stop codon, causing a nonsense variant with loss of normal protein function. Loss of function variants in *BRCA2* are pathogenic which increases the risk of tumorigenesis and susceptibility to PARP inhibitors. This study shows that patients with metastatic lung adenocarcinoma with somatic *BRCA2* PV may respond to PARP inhibitors, expanding the indications of olaparib.

Cancer Posters - Wednesday

PB1033. Case-control likelihood ratio calculation for clinical classification of *BRCA1* and *BRCA2* variants of uncertain significance

Authors:

M. Zanti¹, D. O'Mahony¹, M. T. Parsons², H. Li³, J. Dennis⁴, B-J. Feng³, D. F. Easton⁴, F. J. Couch⁵, A. B. Spurdle², D. E. Goldgar³, K. Michailidou¹, Breast Cancer Association Consortium (BCAC), Evidence-based Network for the Interpretation of Germline Mutant Alleles (ENIGMA); ¹Biostatistics Unit, The Cyprus Inst. of Neurology and Genetics, Nicosia, Cyprus, ²Population Hlth.Res. Program, QIMR Berghofer Med. Res. Inst., Brisbane, Australia, ³Huntsman Cancer Inst., Univ. of Utah, Salt Lake City, UT, ⁴Ctr. for Cancer Genetic Epidemiology, Univ. of Cambridge, Cambridge, United Kingdom, ⁵Mayo Clinic, Rochester, MN

Abstract Body:

Following the recommendations and guidelines of the American College of Medical Genetics and Genomics (ACMG) and Association for Molecular Pathology (AMP), population data can be used to inform the interpretation of variants identified via clinical genetic testing. The specific criterion states that a Relative Risk (RR) or an Odds Ratio (OR) > 5.0 , with nominal significance, from case-control data can provide strong evidence in favor of pathogenicity (PS4). We detail a likelihood ratio-based method incorporating gene-specific age-related penetrance. We used this method to derive case-control likelihood ratios for rare variants in the *BRCA1* and *BRCA2* genes, using a large series of case-control studies (75,657 breast cancer cases and 52,987 healthy controls) genotyped as part of the Breast Cancer Association Consortium (BCAC) OncoArray project. We also performed power calculations using simulated case-control data. This likelihood ratio method provides more informative results compared to classical OR calculations. A larger number of variants reached evidence in favor of pathogenicity, and a substantial number of variants had evidence against pathogenicity - findings not explicitly captured in the ACMG/AMP guidelines. It is also more powerful, as shown by the analysis of simulated data. We provide user-friendly scripts for implementation of the method for rare variants in *BRCA1*, *BRCA2* and other high-risk genes with known penetrance.

PB1034. Cell-free DNA fragmentation patterns predict the response to immunotherapy in head and neck squamous cell carcinomas

Authors:

H. Zheng¹, H. Fu¹, L. Wang¹, S. Gulati², D. Hildeman¹, T. Wise-Draper², Y. Liu¹; ¹Cincinnati Children's Hosp. Med. Ctr., Cincinnati, OH, ²Univ. of Cincinnati, Cincinnati, OH

Abstract Body:

Background

Head and neck squamous cell carcinoma (HNSCC) is the sixth most common cancer worldwide, with a ~50% recurrence rate. Immunotherapy by nivolumab or pembrolizumab, which the FDA recently approved, could significantly improve the survival rate of metastatic or recurrent HNSCC patients. However, only ~18% of HNSCC patients benefit from immunotherapy. It is urgent to identify the clinical biomarkers for predicting HNSCC patients that can benefit from the immunotherapy treatment.

Methods

We developed a cell-free DNA (cfDNA) fragmentomics-based approach to predict the immunotherapy responses in head and neck cancer patients by using low-pass (~1X) plasma whole-genome sequencing (WGS). In a prospective cohort across six institutes, we collected 184 plasma samples up to three different time points from 92 HNSCC patients receiving pembrolizumab therapy. Based on the cfDNA fragmentation pattern, we built a machine learning model to predict the responses to the immunotherapy with the area under the curve (AUC) of 0.79 even before the treatment, which shows a higher performance than other reported state-of-art predictive biomarkers. Based on the response prediction by cfDNA fragmentomics, we performed a Kaplan-Meier survival analysis. Patients predicted to be responsive to the therapy showed significantly different disease-free survival (DFS) and overall survival (OS) curves that were predicted to be non-responsive (p-value < 0.0001, log rank test). However, PD-L1 expression measured by Immunohistochemistry (IHC) assay from the same patients showed lower performance on the prediction of responses to immunotherapy (AUC=0.7) and insignificant separation of DFS and OS curve between groups.

Conclusion

Our study illustrates the potential prognosis power of plasma cfDNA fragmentomics to monitor the HNSCC patients after the immunotherapy. Potentially, our findings can be used as a screening method to determine if a patient with HNSCC benefits from PD-1/PD-L1 immunotherapy prior to the treatment.

Cancer Posters - Wednesday

PB1035. Cell-intrinsic metabolism and cofactor balancing define the metabolomic impact of NAD⁺ supplementation in pancreatic cancer cell metabolism

Authors:

S. Milosavljevic^{1,2}, X. Li¹, **S. H. Elsea**¹; ¹Baylor Coll. of Med., Houston, TX, ²Harvard Med. Sch., Boston, MA

Abstract Body:

While NAD⁺ precursor supplementation has been purported to prevent cancer and extend life as an essential component of DNA repair and cell growth, multiple studies have shown contrasting data for this supplement use in cancer prevention and treatment. Cancer is often characterized by an oxidative redox shift, with decreased redox buffer protection and increased production of free radical reactive oxygen species. Furthermore, with aging comes a decline in the levels of cofactors and coenzymes that function in the metabolic pathways that moderate and buffer oxidative stress in healthy cells. Our data have shown that pancreatic cancer (PaCa) etiology may involve dysregulation of NADK and allied pathways in NAD⁺ metabolism to facilitate metabolic reprogramming by reducing reactive oxygen species and increasing the production of NADPH, supporting cancer cell growth and proliferation. However, these findings contradict the common practice of NAD⁺ supplementation in cancer prevention. We purport that cofactor balancing is critical for cellular homeostasis and that altered metabolic pathway function is dependent upon both diet-sourced cofactors and genetic variation. Our hypothesis is that dysregulation of NADK and its allied pathways causing either increased or reduced oxidative stress may manifest as cancer cell proliferation in a cell-intrinsic manner, potentially dependent on genetic variation involving NADK and other genes in these linked pathways. To investigate this theory, we used untargeted metabolomics to define the cellular and biochemical impact of NAD⁺ supplementation and depletion in both healthy and PaCa cells to assess the effects of either enhancing or impairing NAD⁺ biosynthesis and utilization. PaCa cell lines with different genetic backgrounds were treated with a panel of NAD⁺ precursors and inhibitors of NAD⁺ biosynthesis to specifically pinpoint key molecules and entry points with the greatest impact on cellular pathways and redox control in PaCa metabolism. Metabolomic data indicate multiple perturbations in purine and pyrimidine metabolism, endocannabinoid pathways, the folate and methionine cycle, redox control, and nicotinate and nicotinamide biosynthesis in PaCa cells, highlighting the broad cellular impact of targeting this essential cofactor. Further, identifying the cell-intrinsic metabolic pathways affected by altered NAD⁺ metabolism are essential as these pathways underlie an individual's risk for disease versus maintaining healthy aging in the context of PaCa. These data will elucidate optimal cofactor utilization for redox metabolic control/balance and will reveal key targets for PaCa treatment.

Cancer Posters - Thursday

PB1036. Characterization of molecular differences between normal weight and overweight/obese cancer patients

Authors:

F. Huang¹, P. Xu², Z. Yue¹, M. Gao¹, Z. Chong²; ¹Univ. of Alabama at Birmingham, Birmingham, AL, ²UAB, Birmingham, AL

Abstract Body:

Overweight and obesity refer to abnormal or excessive body fat accumulation and associated comorbidities that pose a high burden on human health. Epidemiological studies have demonstrated strong associations between overweight/obesity and multiple cancer types. However, the differences in molecular features between overweight/obese and normal-weight cancer have not been investigated systematically. To comprehensively characterize the molecular differences between normal-weight and overweight/obese cancers in a large cohort of cancer patients, we performed a comprehensive analysis using the data from The Cancer Genome Atlas (TCGA) and investigated overweight/obesity-biased characteristics including mutation patterns, gene expression, and immune features across multiple cancer types. To overcome the confounding effects, we applied a propensity score weighting algorithm to balance confounder factors including age, gender, race, and tumor stage that may introduce bias to the molecular features. Through rigorous, multidimensional analysis, we identified that the mutation patterns in overweight/obese tumors were distinct from normal-weight tumors and identified several obesity-biased mutated genes in several cancers. The overweight/obesity-biased mutational patterns reflected differences in endogenous oncogenic processes such as defective DNA mismatch repair signature. We also identified obesity-biased mutated genes CDH11, MDGA2, HUWE1, FAT4, and SYNE1 in esophageal carcinoma (ESCA); BCOR, ATM, CSMD1, PPP2R1A, MTOR in uterine corpus endometrial carcinoma (UCEC). The differential expression genes (DEGs) between overweight/obese and normal-weight cancers were enriched in several immune and hormone relative pathways. In addition, compared to normal-weight tumors, overweight tumors did not show higher immune cells fractions, while obese tumors had significantly higher non-activated T cells, mast cells, macrophages, and lymphocytes in multiple cancers. All these differences may indicate the underlining molecular mechanisms of overweight/obesity in cancers. Overall, our study provides a systematic molecular-level understanding of the molecular basis for body weight disparities in multiple cancer types and sheds light on future development of precision therapy for overweight/obese associated cancers.

Cancer Posters - Wednesday

PB1037. Characterization of nucleosome positions and chromatin interactions of regulatory elements comparing Hi-C, Micro-C, and promoter capture Micro-C.

Authors:

S. Rhie, B. Lee, Z. Wu; Univ. of Southern California, Los Angeles, CA

Abstract Body:

Three-dimensional chromatin organization is important for gene regulation. To study chromatin interactions of regulatory regions, we performed Hi-C, Micro-C, and promoter capture Micro-C in human prostate cancer cells. We found that Micro-C identified more high-resolution chromatin loops including ones around structural variants than Hi-C. By evaluating the effect of deep-sequencing, we revealed that more than 2 billion reads of Micro-C are needed to capture chromatin interactions at 1kb resolution. We also showed that promoter capture Micro-C identifies chromatin loops near promoters with a lower amount of sequencing reads. By integrating Micro-C with NOMe-seq and ChIP-seq, we found that promoters that are involved in chromatin loops have a more accessible region with lower levels of DNA methylation and more highly phased nucleosomes compared to promoters that are not involved in loops. This work provides a framework for understanding the chromatin loops among regulatory elements and nucleosome-depleted regions in human cancer cells.

Cancer Posters - Thursday

PB1038. Characterization of the *2q22* renal cancer susceptibility locus

Authors:

A. Souza¹, L. Costa¹, L. Jessop¹, T. Myers², K. Brown³, S. Chanock⁴, L. Colli⁵; ¹USP, Ribeirão Preto, Brazil, ²NIH, Bethesda, MD, ³Natl. Cancer Inst., Rockville, MD, ⁴Natl. Cancer Inst, Rockville, MD, ⁵Univ. of Sao Paulo, Ribeirão Preto, Brazil

Abstract Body:

Genome-wide association studies (GWAS) have identified approximately 13 different genomic regions associated with the risk of developing RCC, however, most of these regions have not yet been functionally characterized. Among these, we seek to characterize the region 2q22 marked by rs12105918 ($p = 1.80 \times 10^{-8}$; odds ratio 1.29) which presents the SNP rs72858496. This SNP has a chromosomal loop that allows physical interaction with the promoter region of the *ZEB2* gene and is located in an intron region. To determine whether rs72858496 acts as an enhancer element in the context of renal cancer and to understand the function of its target gene (*ZEB2*), we adopted two recent techniques that modulate gene expression, CRISPRa (CRISPR activation) for gene activation, and CRISPRi (CRISPR interference) for gene expression interference. For CRISPRi, we targeted a catalytically inactive cas9 (dCas9) fused to a KRAB-ZIM3 repressive domain and for CRISPRa, we use a dCas9 fused to an activation domain (VP64). Both techniques were performed by targeting the SNP region in UO-31 and Caki-1 cell lines, as well as the transcription start site (TSS) of the *ZEB2* gene in cell lines (UO-31, 786-O, ACHN, HK2). Our initial results point to rs72858496 as a potential functional SNP in the 2q22 region, decreasing *ZEB2* gene expression when the SNP region is blocked by the dCas9-KRAB-ZIM3 domain targeted by 3 out of 4 different gRNAs targeting rs72858496 in the UO-31 cell line. In conjunction with data obtained by electrophoretic mobility shift assay (EMSA), we note that this SNP has a role associated with the gene modulation of *ZEB2*. The generation of stable cell lines for the dCas9-VP64 and dCas9-ZIM3 domains proved to be sufficient to increase and reduce, respectively, the expression of this gene. Additional functional studies are now underway to understand the *ZEB2* molecular mechanisms linked to the 2q22 region that may contribute to a better understanding of RCC.

Cancer Posters - Wednesday

PB1039*. Chromatin accessibility of primary human cancers ties regional mutational processes and signatures with tissues of origin

Authors:

J. Reimand, O. Ocsenas; Ontario Inst Cancer Res., Toronto, ON, Canada

Abstract Body:

Cancer genomes are shaped by complex and spatially variable mutational processes whose functional and genetic determinants remain poorly understood. At the megabase scale, somatic mutation burden correlates with DNA replication timing and chromatin accessibility. However, these observations are based on the epigenomes of common cell lines while the contribution of cancer epigenomes remains uncharacterised. Here we model megabase-scale mutation frequencies in thousands of whole cancer genomes using a compendium of hundreds of genome-wide epigenetic and replication-timing profiles that represent primary human cancers, normal tissues, and cell lines. Using a machine learning framework, we show that the chromatin profiles of primary cancers, rather than the profiles of normal cells, are the major determinants of regional mutation burden in most cancer types. Chromatin profiles of matching disease and cell types are the strongest predictors of these mutational processes based on feature analysis of our models, indicating tissues of origin, cancer heterogeneity, and exposures to mutagenic agents. Mutational signatures also associate with chromatin accessibility: signatures of carcinogen exposure and unknown origin are best predicted by chromatin profiles while the associations with endogenous signatures appear weaker. Further, our models point out specific genomic regions where the highly enriched mutations remain unexplained by the diverse epigenetic profiles. These regions include known driver mutations, suggest novel intergenic regions with putative non-coding drivers, and indicate an over-representation of developmental and lineage-specific genes and pathways. This analysis of mutational processes suggests that most chromatin-associated somatic passenger mutations in cancer genomes follow the epigenetic landscapes of cancer cells, indicating that cancer epigenomes capture better the inter-tumor heterogeneity of mutational processes and suggest that many somatic mutations in cancer genomes occur after normal cells have transformed to cancer.

Cancer Posters - Thursday

PB1040. Chromosomal alteration profiling of lymph node metastases in non-small cell lung cancer

Authors:

J. Valdebenito^{1,2}, J. Wong², Y. Jakubek³, D. Chang², T. McDowell², G. A. Eapen^{4,1}, H. Kadara⁵, P. Scheet^{2,1}; ¹The Univ. of Texas MD Anderson Cancer Ctr. UTHlth. Graduate Sch. of BioMed. Sci., Houston, TX, ²Dept. of Epidemiology, The Univ. of Texas MD Anderson Cancer Ctr., Houston, TX, ³Coll. of Med., Dept. of Internal Med. at the Univ. of Kentucky, Lexington, KY, ⁴Dept. of Pulmonary Med., Div. of Internal Med., The Univ. of Texas MD Anderson Cancer Ctr., Houston, TX, ⁵Dept. of Translational Molecular Pathology, Div. of Pathology/Lab Med., The Univ. of Texas MD Anderson Cancer Ctr., Houston, TX

Abstract Body:

Goal: We sought to assess mosaic chromosomal alterations (mCAs) as a marker in lymph node involvement of a prospective cohort of lung cancer patients. **Background:** Lung cancer is the leading cause of cancer death worldwide, often presenting with metastatic disease. Lymph nodes are thought to be a gateway to distant metastasis and offer an opportunity to study the genomics of this transitional state. Mosaic chromosomal alterations (mCAs) are megabase-scale structural variants, such as deletions or duplications, known to drive the clonal expansion of mutated clones. Their presence (aneuploidy) is considered a hallmark of cancer and thus a potential biomarker for diagnosis or prognosis. **Methods:** We processed paired primary tumors and lymph node samples using a biospecimen collection from non-small cell lung cancer (NSCLC) patients undergoing endobronchial ultrasound transbronchial needle aspiration (EBUS/TBNA). EBUS and matched germline blood samples were analyzed using SNP array intensity data. To detect mCAs, we applied hapLOH, a sensitive haplotype-based method to detect copy number events. **Results:** We discovered 322 autosomal mCAs in 80 participants, most concentrated between ages 60-80 and in late TNM stages. Testing specific genomic regions where other mCAs were observed in the same patient demonstrated an increase of 58% mCAs in pathologically negative lymph nodes. In addition, smoking was significantly associated with the metastatic status ($p=0.054$) and recurrence of the disease ($p=0.012$). **Conclusions:** Preliminary analyses suggest chromosomal alterations may precede phenotypic and histological changes at the tissue level and are consistent with tobacco use as a leading risk factor. Not surprisingly, participants with a higher number of mCAs are older and at advanced stages of the disease. Studying the recurrence will require the maturation of this clinical cohort, but the discovery of mCA calls in both lymph node-negative and positive samples might suggest regions of interest for potential recurrence of the disease. In summary, our study helps demonstrate the utility of mCAs as a potential marker for NSCLC diagnosis and prognosis.

Cancer Posters - Wednesday

PB1041. Chromosome Arm Copy Number Profiling using a Clinical, Targeted NGS Panel

Authors:

J. Gascoyne, A. Olvera-Morales, J. Fowler, H. Alvarez, A. San Lucas, P. Scheet; MD Anderson Cancer Ctr., Houston, TX

Abstract Body:

This study assesses the performance of calling chromosomal arm-level copy number variation (caCNV) using “MDA MAPP”, a clinical NGS panel for cancer patients implemented at MD Anderson Cancer Center targeting 610 genes and 2MB of the genome at 1000x average read-depth. MDA MAPP profiles solid tumor FFPE samples with paired PBMC normals, providing characterization of mutations, gene-level somatic CNVs, and structural variations in addition to calling microsatellite-instability and estimating tumor mutation burden. However, this panel does not currently provide caCNV biomarkers which have clinical actionability in solid tumors. In this study, 20 pairs of solid tumor FFPE tissues and PBMC normals are profiled using both MDA MAPP and whole-exome sequencing, the latter of which is used to infer a caCNV “gold standard”. It has been widely shown that caCNV calling is accurate using WGS and exome sequencing, but the feasibility of calling caCNV on smaller targeted panels has not been demonstrated. In our approach, caCNV calling is implemented as a heuristic algorithm that incorporates both sequencing read-depth and haplotype-informed allelic imbalance, leveraging off-target reads. We use CNVkit to call segmental CNVs and perform post-processing to estimate an initial chromosome copy number. To attempt to further discriminate noise from true amplifications and deletions, we then assess evidence of chromosome-level allelic imbalance using hapLOHseq, an existing haplotype-based method to detect allelic imbalance, for caCNV near average CN thresholds at borderline levels (2.45 - 2.5 for amplifications and 1.5 - 1.55 for deletions). At amplification and deletion copy numbers of 2.5 and 1.5 respectively, a sensitivity of 0.917, a specificity of 0.977, a PPV of 0.846, and a NPV of 0.989 were observed. Although our results are promising, we have identified areas in which our approach can be improved: due to optimization of the platform for specific oncogenes, individual chromosome arms do not exhibit equal performance and thus performance characteristics may improve if we apply chromosome-specific thresholding; moreover, another limitation of this analysis is that copy-neutral LOH is not considered in the chromosomal event assessments and therefore inflate our calculated false positive rate. Overall, our analysis demonstrates the feasibility of using targeted panels for caCNV profiling. For future clinical testing using MDA MAPP and other targeted NGS panels, we plan to evaluate chromosome calling on specific arms of importance (such as 1p19q co-deletion in gliomas), and potentially augment the panel with strategic targets on the arms of interest.

PB1042. Circulating miRNA signature for diagnostic prediction in breast cancer.

Authors:

S. Yerukala Sathipati¹, M-J. Tsai^{2,3}, S. Shukla¹, S-Y. Ho^{4,5,6}; ¹Marshfield Clinic Res. Inst., Marshfield, WI, ²Hinda and Arthur Marcus Inst. for Aging Res. at Hebrew Senior Life, Boston, MA, USA, Boston, MA, ³Dept. of Med., Beth Israel Deaconess Med. Ctr. and Harvard Med. Sch., Boston, MA, USA, Boston, MA, ⁴Inst. of Bioinformatics and systems biology, Natl. Yang Ming Chiao Tung Univ., Hsinchu, Taiwan, ⁵Dept. of Biological Sci. and Technology, Natl. Yang Ming Chiao Tung Univ., Hsinchu, Taiwan, ⁶Ctr. for Intelligent Drug Systems and Smart Bio-devices (IDS2B), Natl. Yang Ming Chiao Tung Univ., Hsinchu, Taiwan

Abstract Body:

Breast cancer (BC) is one of the most commonly diagnosed cancers worldwide. A better understanding of the molecular markers that can detect breast tumors at early stages may lead to improved survival and development of new therapeutic strategies. As key regulatory molecules in several biological processes, microRNAs (miRNAs) are potential biomarkers for cancer. The aim of this study was to develop a machine learning based evolutionary learning method called BSig to identify a BC specific circulating miRNA signature for diagnostic prediction in patients with BC. BSig established a compact set of miRNAs as potential markers from 1,280 patients with BC and 2,686 healthy samples retrieved from gene expression omnibus database (GSE73002) for the diagnostic prediction. BSig achieved a prediction performance: training accuracy, sensitivity, specificity, and area under the receiver operating characteristic curve of 100%, 1.00, 1.00, and 1.0, respectively; and an independent test accuracy, sensitivity, specificity, and area under the receiver operating characteristic curve of 99.90%, 1.00, 0.99, and 0.99, respectively. BSig identified 13 miRNAs, hsa-miR-658, hsa-miR-3648, hsa-miR-3656, hsa-miR-4476, hsa-miR-642a-5p, hsa-miR-5100, hsa-miR-5698, hsa-miR-6088, hsa-miR-6768-5p, hsa-miR-6800-5p, hsa-miR-6803-5p, hsa-miR-6807-5p, and hsa-miR-6836-3p, contributed significantly towards diagnostic prediction in BC. Bioinformatics analysis of the miRNA signature revealed their involvement in several biological and signaling pathways, including ErbB signaling pathway (hsa04012) that control proliferation, angiogenesis, metastasis and survival of breast cancer. The miRNA signature involved in some of significant Kyoto Encyclopedia of Genes and Genomes pathways, including prion diseases (hsa05020), renal cell carcinoma (hsa05211), glioma (hsa05214), and thyroid hormone signaling pathway (hsa04919). The miRNA signature significantly involved in top five gene ontologies annotations are organelle (GO:0043226), ion binding (GO:0043167), cellular nitrogen compound metabolic process (GO:0034641), biosynthesis process (GO:0009058) and nucleic acid binding transcription factor activity (GO:0001071). Furthermore, this circulating miRNA signature is associated with several major cancer/diseases and some miRNAs of the signature showed significant expression difference between BC and healthy groups. BSig may serve as the basis for cancer screening and therapeutic selection in BC.

PB1043*. *Cis*- and *trans*-eQTL TWAS of breast and ovarian cancer identify more than 100 risk genes in the BCAC and OCAC consortia.

Authors:

T. Head¹, A. Todor¹, J. Yang¹, J. Plummer², S. Gayther², S. Kar³, J. Schildkraut¹, M. P. Epstein¹; ¹Emory Univ., Atlanta, GA, ²Cedars Sinai Med. Ctr., Los Angeles, CA, ³Univ. of Bristol, Bristol, United Kingdom

Abstract Body:

Genome-wide association studies (GWAS) have identified numerous common risk variants for breast and ovarian cancer, with most GWAS-derived risk variants lying in non-coding regions of the genome. This has spurred considerable interest in transcriptome-wide association studies (TWAS) that aim to investigate how genetically regulated transcriptional activity plays a role in both the shared and distinct etiologies of these two complex diseases. However, the TWAS methods utilized to date have only considered the regulatory effects of variants located close to the target gene (*cis*-SNPs). With growing evidence for non-trivial distal regulatory effects of common variants (*trans*-SNPs) on gene expression, we performed TWAS of breast and ovarian cancer using a recently proposed Bayesian genome-wide method (BGW-TWAS) that incorporates both *cis*- and *trans*-expression quantitative trait loci (eQTL). We used whole genome sequencing and RNA sequencing data in breast and ovarian tissue from the Genotype-Tissue Expression Project V8 to train genome-wide gene expression imputation models with BGW-TWAS. We then used these imputation models to perform a TWAS on large-scale GWAS summary statistic data from the Breast Cancer and Ovarian Cancer Association Consortia (BCAC and OCAC) to identify genes whose genetically predicted expression levels are associated with risk of breast cancer overall, five breast cancer subtypes (luminal A-like, luminal-B like, luminal B/HER2-negative-like, HER2-enriched-like, triple-negative), non-mucinous epithelial ovarian cancer, and five ovarian cancer histotypes (high grade serous, low grade serous, mucinous, endometrioid, clear cell). We identified 104 unique significant genes after Bonferroni correction across breast cancer phenotypes and 9 across ovarian cancer phenotypes. These loci include both established GWAS risk genes such as *ANKLE1* at the 19p13 breast/ovarian cancer risk locus and several novel loci such as *ACAP3* (overall breast cancer risk) whose associations are predominantly driven by *trans*-eQTL effects. These *trans*-driven genes were not identified by a competing TWAS approach that considered *cis*-eQTL only. Results provide further insight into the complex genetic architecture underlying risk of breast and ovarian cancer subtypes in individuals of European ancestry. Efforts to validate expression prediction models of top genes using external data from the Cancer Genome Atlas are ongoing.

PB1044. Classification of Central Nervous System Tumors with DNA methylation - The Brazilian Experience

Authors:

B. Wolff¹, J. Castro², Y. Gasparini¹, V. Almeida¹, G. Carvalho¹, L. Vieira¹, A. Nascimento¹, F. Costa¹, L. Kulikowski³; ¹Faculdade de Med. da Univ.e de São Paulo, São Paulo, Brazil, ²AC Camargo Câncer Ctr., São Paulo, Brazil, ³Univ.e de Sao Paulo, São Paulo, Brazil

Abstract Body:

The vast range of Central Nervous System (CNS) tumor entities makes the standardization of the histopathological classification of CNS tumors a challenge, leading to misleading decision in clinical practice, as well as the interpretation and validity of the results of clinical trials. The World Health Organization (WHO) establishes the criteria for classifying CNS tumors and recommends an integrated diagnosis, using clinical, morphological and molecular aspects, and the methylation profile is already recommended for the diagnosis of some tumor entities. **Objective:** We report a proof of concept of the usability and implantation of the diagnosis of CNS tumors through DNA methylation in the Brazilian diagnostic routine. **Methodology:** We analyzed seven samples of CNS tumors from paraffin material provided by the archive of the Department of Pathological Anatomy of the AC Camargo Cancer Center. We performed methylation assay using the Infinium HumanMethylation450 BeadChip (Illumina, Inc., San Diego, CA). The data obtained was submitted to the MolecularNeuropathology.org platform for classification based on methylation and Copy Number Variation (CNV) graph. The analysis was performed as proposed by Capper et al. (2018) evaluating a combination of tumor entities and classes. **Results:** The platform showed some relevant findings: (a) C1 sample as *High grade hemispheric glioma, H3 K27M-mutant*, and the classifier indicated a match with the class *Diffuse midline glioma, histone 3 K27-mutant* with a calibrated score of 0.99 and the MGMT gene promoter status as unmethylated; (b) C3 sample was classified as *anaplastic pleomorphic xanthoastrocytoma* with a calibrated score of 0.91 and promoter status of the gene as unmethylated, in agreement with the previous diagnosis; (c) C4 and C6 samples initially classified as *Astroblastoma, MNI-altered* and *Diffuse hemispheric glioma, H3 G34-mutant* were corroborated by the classifier with a calibrated score of 0.95 and 0.99 respectively. Sample C4 does not have the methylated MGMT gene promoter, while sample C6 does. Samples C2, C5 and C7 showed no match. **Conclusion:** Our experience applying methylation array and using the Heidelberg classification platform presented effective results to improve the analysis of CNS tumor entities and facilitate the diagnosis and treatment for patients.

PB1045. Clinical and genetic features of patients with multiple endocrine neoplasia type 1 in Korea

Authors:

B. Kim, J-S. Lee, M. KIM, M-W. Seong; Seoul Natl. Univ. Hosp., Seoul, Korea, Republic of

Abstract Body:

Introduction Multiple endocrine neoplasia type 1 (MEN1) is a hereditary syndrome characterized by the predisposition to endocrine tumors. It shows an autosomal dominant inheritance pattern and is caused by inactivating variants of the *MEN1* gene. Here, we analyzed the clinical and genetic features of MEN1 patients in Korea. **Methods** We enrolled patients who were diagnosed as MEN1 in Seoul National University Hospital between 2012 and 2022. We retrospectively reviewed the clinical and genetic characteristics of the patients from medical records. We adopted the recent proposition of TENGAN for the interpretation of MEN1 variants. **Results** Totally, 39 patients were diagnosed as MEN1 and primary hyperparathyroidism (69%) is the most common presentation. Twenty-six *MEN1* variants were identified and distributed along the *MEN1* gene. Twelve frameshift, 7 nonsense, 3 missense, 2 splice sites, 1 large deletion, and 1 intronic variants were detected. **Conclusion** This study broadens the understanding of clinical and genetic characteristics of MEN1 patients.

Cancer Posters - Thursday

PB1046. Clinical utility of genomic sequencing for hereditary cancer syndromes: A retrospective chart review

Authors:

R. Kodida¹, S. Shickh², C. Mighton², M. Clausen¹, J. Sam¹, D. Hirjikaka¹, E. Reble¹, E. Adi-Wauran², S. Krishnapillai², K. Schrader³, N. Baxter⁴, A. Laupacis², J. Lerner-Ellis⁵, R. Kim⁶, Y. Bombard²; ¹Li Ka Shing Knowledge Inst. of St. Michael's Hosp., Unity Hlth.Toronto, Toronto, ON, Canada, ²Univ. of Toronto & Li Ka Shing Knowledge Inst. of St. Michael's Hosp., Unity Hlth.Toronto, Toronto, ON, Canada, ³Univ. of British Columbia, Vancouver, BC, Canada, ⁴Univ. of Melbourne & Univ. of Toronto, Melbourne, Australia, ⁵Mount Sinai Hosp. & Univ. of Toronto, Toronto, ON, Canada, ⁶Univ. Hlth.Network, Mount Sinai Hosp., The Hosp. for Sick Children, Ontario Inst. for Cancer Res., Univ. of Toronto, Toronto, ON, Canada

Abstract Body:

Background Identification of patients with hereditary cancer syndromes (HCS) is important to detect families who can benefit from preventive surgeries and surveillance that reduce morbidity and mortality. However, most patients with query HCS who undergo standard panel tests receive uninformative results and are unable to access risk-reducing strategies. Genomic sequencing (GS) may reduce the diagnostic gap in this population. However, most studies evaluating GS utility have used small cohorts and phenotype-driven panels, and only reported yield of pathogenic/likely pathogenic (P/LP) variants. **Aim** Describe the yield of all types of cancer results for patients who received GS for HCS from an RCT. **Methods** An observational, retrospective chart review was conducted for cancer patients with previous uninformative panel results, who received GS from an RCT. Charts were reviewed by 5 team members to extract demographics, clinical history, genomic results and recommendations made by study clinicians and ordering clinicians. Descriptive statistics were used to describe demographics and clinical history. Proportions were calculated to compare frequencies of patients with different types of cancer results and recommendations made for cancer results. **Results** 276 patients were eligible and included. Participants were mostly female (240), of European descent (158) with breast cancer history (240). Twenty-five patients (9.1%) received ≥ 1 P/LP variant in a cancer gene, 246 patients (89%) had ≥ 1 VUS in a cancer gene and 27 (10%) were negative. Most P/LP variants (20/26) were in low/moderate risk genes and half (13/26) were considered secondary cancer findings. LP/P variants led to 94 recommendations in 21/25 patients. The most common recommendations were for genetic counseling (21), communication to relatives (21), and cascade testing (21), followed by clinical evaluation (9) and validation (7). Patients with preliminary evidence results (genes with limited literature and no management guidelines) did not receive recommendations for clinical evaluation from study clinicians; 2 did receive clinical evaluations at the request of the ordering clinician. 663 cancer VUS were identified: 253 were primary and the rest secondary. The mean number of VUS was 2.7/patient and was higher in patients of Non-European ancestry versus European (3.5 vs. 2.5, $p < 0.05$). **Conclusion** Although we identified modest clinical utility of GS for HCS, the variability in management highlights a need for guidelines to standardize management of patients with low/moderate risk results. To optimize use of GS, future research is needed to evaluate the clinical utility of GS as a first-tier test.

PB1047*. Clinicogenomic Neural Networks with Real World Evidence: Predicting Outcomes and Targeting Interventions at a Comprehensive Cancer Center.

Authors:

M. Flagg¹, C. Ramsey¹, K. Fisch², J. Califano¹; ¹Univ. of California San Diego, La Jolla, CA, ²UC San Diego, La Jolla, CA

Abstract Body:

Recent advancements in extraction of real-world data (RWD) from electronic health records (EHR) offer unprecedented precision in analysis of oncologic clinical events. Through bulk RWD extraction from a clinical data warehouse such as UCSD's Clinical Data Warehouse for Research (CDWR), the full operational records of oncologic care at a comprehensive cancer center can serve as inputs to machine learning (ML) models. However, genomic data is not routinely contained in the EHR; as such, we draw on the genomic data in the Registry for Molecular Oncology Research (ARMOR), all of which originates from genetic testing ordered in the course of ongoing care. Combining CDWR and ARMOR enables the creation of an integrated clinicogenomic dataset derived entirely from RWD to drive prediction of mortality, hospitalization, and other key outcomes. To this end, we developed a pipeline to extract RWD for a large population of patients receiving care at a comprehensive cancer center (n = 28,016), integrate the data with genomic results from ARMOR when available (n = 5,100), and train multiple off-the-shelf ML models such as random forest and conventional neural network architectures. The input features include a broad range of clinical data such as demographics, encounters, medications, tumor staging, referrals, and more. The feature set derivation highlights clinically meaningful values such as abnormal test results. We capture fluctuations in the density of data reporting frequency, representing temporal distinctions in patterns of care. ARMOR data on polymorphisms, mutational burden, copy number alterations, and fusion genes are incorporated, enabling association of genomic features with these clinical phenotypes. We iterate this pipeline across multiple cancer types, presenting the challenge of biases such as cancer type and differences in feature availability. To account for this issue, we employ a Few-Shot transfer learning approach derived from Ma et al.'s Transfer of Cellular Response Prediction (TCRP) to transfer predictions between cancer types. By combining clinicogenomic data with a novel ML approach, we produce robust predictions of adverse oncologic outcomes. On trials with a test population of 268 patients with 9739 clinicogenomic features, we effectively predicted inpatient admissions with an AUC of 0.82 with random forest and accuracy of 0.836 with a dense neural network. These can be immediately operationalized to guide population health interventions across our health system, along with presenting a scalable framework for extension of this approach to other health systems with a CDW.

Cancer Posters - Thursday

PB1048. CML with a typical BCR-ABL1 fusion in a 15-year-old male patient presenting with marked leukocytosis, thrombocytosis, left-shifted granulocyte maturation in the peripheral blood

Authors:

M. Solanki^{1,2}, A. Cheng^{1,2}, T. Basso^{1,2}, N. Madhu^{1,2}, K. Eastwood³, M. Guardiola³, C. A. Tirado^{3,2}; ¹Univ. of California, Los Angeles, Los Angeles, CA, ²The Intl. Circle of Genetics Studies, Los Angeles, CA, ³Baylor Scott and White Hlth., Dept. of Pathology, Temple, TX

Abstract Body:

Chronic Myelogenous Leukemia (CML) is a slow-progressing bone marrow cancer that is typically characterized by acquired BCR-ABL gene mutations (caused by the presence of the Philadelphia chromosome) in immature myeloid cells. CML affects approximately 1 in 526 people, and makes up about 15% of all leukemia cases. The primary risk factors of CML are radiation exposure, old age, and gender, specifically in correlation to males. Here, we present a case of a 15-year-old male patient diagnosed with CML who was further assayed using conventional cytogenetic analysis, DNA fluorescence in situ hybridization (DNA FISH) analysis, and flow cytometric analysis to determine correlation with other diagnostic testing alongside being BCR/ABL1-positive. Conventional cytogenetic analysis on bone marrow aspirates using G-banding techniques following short-term cell culture without mitogens revealed the presence of an abnormal clone exhibiting a t(9;22)(q34;q11.2), which is a chromosome 9 and 22 translocation consistent with a Philadelphia chromosome positive form of CML. DNA FISH analysis was conducted on bone marrow samples using the LSI BCR/ABL Dual Color/Dual Fusion probe, and the findings indicated an abnormal chromosomal translocation between 9q34 (ABL1) and 22q11.2 (BCR) with a result description of nuc ish(ABL1,BCR)x3(ABL1 con BCRx2)[182/200]. Peripheral blood smear analysis found indications of normochromic, normocytic anemia, leukocytosis with left-shifted granulocytes, increased basophils, and prominent eosinophils along with marked thrombocytosis, which is consistent with patient's recent diagnosis of CML. Flow Cytometry revealed a non-diagnostic immunophenotype with: 1) Small population of T and B lymphocytes with T lymphoid predominance, 2) Predominant maturing granulocyte population, and 3) No phenotypic evidence of significant myeloid immaturity. Due to the chronic phase presentation of CML in this patient, it can be concluded that the patient has a favorable prognosis and could have promising remission results from standard CML therapies. Clinical correlation was indicated.

Cancer Posters - Wednesday

PB1049*. Co-delineating genomic and transcriptomic modes of resistance to MEK inhibition in individual triple negative breast cancer cells.

Authors:

D. Arvapalli¹, I. Gonzalez¹, T. V. Morozova¹, D. R. Goulet², G. L. Johnson², V. J. Weigman¹, J. A. A. West¹, G. L. Harton¹, J. Zawistowski¹; ¹BioSkryb Genomics, Inc., Durham, NC, ²Univ. of North Carolina Sch. of Med., Chapel Hill, NC

Abstract Body:

Triple negative breast cancer (TNBC) tumors are frequently driven by MAPK signaling and are initially susceptible to MEK inhibition, yet resistance invariably develops. This resistance occurs, in part, by transcriptional adaptation where signaling is bypassed to reactivate MAPK signaling through a different node, yet resistance can also develop or co-develop through genomic modification. We therefore exploited single-cell ResolveOME chemistry to simultaneously capture whole genome single nucleotide variation (SNV), copy number variation (CNV) and full-transcript RNAseq from the same individual cell to define multifaceted contributions to drug resistance and to probe single-cell heterogeneity of these contributions for lineage identification. We employed two TNBC models of resistance to the MEK inhibitor trametinib whereby transcriptional and epigenetic contributions to the resistance have been extensively characterized, yet in which comprehensive assessment of genomic contributions to resistance has not yet been performed. In an epithelial subpopulation of SUM-229PE cells, previous work demonstrated resistance to trametinib coincided with upregulated *KRAS* expression relative to treatment-naive parental cells and manifested as one of the most statistically significant differentially-expressed genes. The genomic arm of ResolveOME and BaseJumper analysis software unveiled a genomic lesion, a ~650 kilobase block of differential allelic identity between parental and trametinib-resistant cells encompassing the *KRAS* gene—indicating structural variation at the locus and a candidate genomic mechanism underlying *KRAS* transcript upregulation and consequential MEK inhibitor resistance. The transcriptomic arm of the ResolveOME workflow concurrently validated the upregulation of *KRAS* and previously known gene sets while defining single-cell heterogeneity within. We also subjected parental and trametinib-resistant SUM-159PT cells, a mesenchymal model of the claudin-low molecular subtype of TNBC, to ResolveOME profiling. We observed expression modulation of CEBP family of enhancer factors and SMARC family chromatin remodeling factors, and current efforts are focused on linking resistant cell-specific SNVs proximal to these and other upregulated factors in both models as candidate regulatory variants in the paradigm of epithelial mesenchymal transition (EMT). The unification of genomic and transcriptomic data here uncovered DNA variation underlying the observed transcriptional modulation and provides a framework for ultimately seeking targetable variation in longitudinal primary patient samples.

Cancer Posters - Thursday

PB1050. Combined FISH and cytogenetic testing increases the accuracy of classification and risk stratification of multiple myeloma samples.

Authors:

J. Smith^{1,2}, W. Bi^{1,2}, N. Owen^{1,2}; ¹Baylor Coll. of Med., Houston, TX, ²Baylor Genetics Lab., Houston, TX

Abstract Body:

Laboratories face cost cutting mandates as test costs rise and reimbursements fall. At the same time, discovery of new cytogenetic abnormalities in hematologic diseases with diagnostic/prognostic significance requires new FISH probe validations and more intense scrutiny of chromosome preparations, both of which come with additional expense for the laboratory. Multiple myeloma (MM) was once considered one disease entity. Now, analysis of plasma cells extracted from bone marrow enables classification of MM into distinct subtypes based on cytogenetic anomalies. Knowledge of these subtypes has led to refined risk stratification and continues to lead to better therapeutics. Significant increase in diagnostic yield on plasma cell FISH and difficulties in culturing plasma cells have prompted many laboratories to offer FISH only testing for MM. We present cases showing the value of cytogenetics in correctly classifying MM in concert with plasma cell FISH. FISH from patient 1 detected gain of 1q, trisomies 7, 9, 15 and 17, and an IGH rearrangement. Without chromosomes, it cannot be determined if this represents a rare case of two co-occurring primary abnormalities or hyperdiploidy with a secondary IGH rearrangement. Complex karyotypes from an IL-4 stimulated culture showed a co-occurrence of two primary abnormalities: hyperdiploidy and a t(6;14) IGH-CCND3 rearrangement. CCND3, unlike many other primary IGH rearrangements, does not confer poor prognosis. Patient 2 showed gains of 1q, loss of 1p, trisomies 7, 9 and 15, monosomy 13, and loss of p53, by deletion and monosomy. FISH data were suggestive of hyperdiploid MM with secondary high-risk abnormalities. Chromosome analysis revealed a highly complex pseudodiploid karyotype containing an 8;22 MYC-IGL translocation and a jumping 1q translocation. Abnormal cells were detected in both unstimulated and IL4 stimulated cultures indicating a highly proliferative clone. Both jumping 1q and MYC-IGL are high risk with possible treatment implications. The clone was also found to not be hyperdiploid as the FISH suggested. FISH from patient 3 indicated hyperdiploid disease with an IGH rearrangement and gain of 1q. Similar to the first case, FISH cannot distinguish between primary and secondary IGH translocations in the setting of hyperdiploidy. Cytogenetics confirmed hyperdiploidy and identified a secondary t(8;14) MYC-IGH translocation in this case; MYC rearrangements in hyperdiploid MM are associated with high risk disease. Chromosomes on MM patients allow for concurrent genome-wide assessment of abnormalities that provide additional essential information beyond that obtained by FISH alone.

Belfast, Belfast, United Kingdom, ³Leeds Inst. for Data Analytics, Sch. of Med., Univ. of Leeds, Leeds, United Kingdom, ⁴QIMR Berghofer Med. Res. Inst., Brisbane, Australia, ⁵Div. of Cancer Epidemiology and Genetics, Natl. Cancer Inst., Rockville, MD, ⁶Dana Farber Harvard Cancer Ctr., Boston, MA, ⁷Johns Hopkins Sch. of Med., Baltimore, MD, ⁸Univ. of Texas MD Anderson Cancer Ctr., Houston, TX, ⁹Dept. of Hlth.Sci. Res., Mayo Clinic Coll. of Med., Rochester, MN, ¹⁰Dept. of Epidemiology, Univ. of Washington, Seattle, WA

Abstract Body:

Genome wide association studies (GWAS) have identified ten distinct associations at 5p15.33 in as many cancer types, all with notable pleiotropy. This region harbors two plausible target genes: *TERT* and *CLPTM1L*. To comprehensively evaluate known candidate causal variants (CCV) at 5p15.33, assign target genes and characterize functional pleiotropy between cancer types, we are conducting CRISPRi/a screening in eight cell lines from four types (pancreatic cancer, melanoma, bladder cancer and lung cancer) whose proliferation has been shown to be dependent on both *TERT* and *CLPTM1L* expression. Massively parallel reporter assay (MPRA) of fine mapped variants in the same cell lines will accompany CRISPR screening. Furthermore, we have used PacBio long read sequencing to document two novel 5p15.33 CCVs which may explain one of the risk associations. 7244 sgRNAs were tiled across chr5:1,233,287-1,365,002 (hg19), with each of the 178 CCVs identified via Bayesian and LD-based fine mapping targeted by at least three sgRNAs within a ± 100 bp window. CRISPRi screening of the MIA PaCa-2 pancreatic cancer cell line revealed significant sgRNA depletion (FDR <0.01) within ± 100 bp of 71 fine mapped SNPs. 17 of these variants also exhibit significant (FDR <0.01) allele-specific cis-regulation in MPRA in the same cells, suggesting these as strong CCVs. Forthcoming CRISPR and MPRA data for seven additional cell lines aims to characterize the pleiotropy observed in the region.

PacBio sequencing has been used to identify two CCVs which could explain one of the ten 5p15.33 signals. Two highly polymorphic variable number tandem repeats intronic to *CLPTM1L* (denoted here VNTR1 & VNTR2) show segregation of longer VNTR copy number on the risk haplotype and are inherited in a Mendelian pattern in HapMap trios. Both VNTRs are enriched for biologically relevant transcription factor binding motifs and histone marks in relevant cell lines. Resequencing of 944 pancreatic cancer cases and 878 controls revealed that single repeat unit increases in VNTR length are a significant predictor of case/control status (VNTR1; $P = 1.20 \times 10^{-6}$, VNTR2; $P = 1.99 \times 10^{-7}$) in a logistic regression model (OR of longest diploid repeat length relative to the median: VNTR1: 2.46, VNTR2: 2.39). Imputation of VNTR copy number into GWAS and eQTL datasets to assess whether these variants are associated with disease risk of other cancers, as well as expression of *cis*-genes at this locus is ongoing.

These findings suggest that upon completion, our work will mark a significant progression in the

ASHG 2022 Annual Meeting Poster Abstracts

fundamental understanding of the mechanisms mediating cancer predisposition at the 5p15.33 pan-cancer risk locus.

Cancer Posters - Thursday

PB1052. Comprehensive CRISPR-based dissection of a complex common and familial melanoma risk locus on chromosome band 9p21.

Authors:

R. Hennessey¹, H. Sowards¹, M. Xu¹, R. Thakur¹, J. H. W. Wong², J. Barbour², R. Chari¹, Melanoma Meta-Analysis Consortium, A. Pritchard³, N. Hayward⁴, A. M. Goldstein¹, X. R. Yang¹, M. H. Law⁴, K. Brown¹; ¹Natl. Cancer Inst., Rockville, MD, ²The Univ. of Hong Kong, Pok Fu Lam, Hong Kong, ³Univ. of the Highlands and Islands, Inverness, United Kingdom, ⁴QIMR Berghofer Med. Res. Inst., Brisbane, Australia

Abstract Body:

The 9p21 locus has been established as a common melanoma risk locus through multiple GWAS (lead SNP rs871024, $P=3.32 \times 10^{-65}$, OR=1.18), where the region of association includes multiple independent signals not explained by protein-coding sequence variants. While this locus harbors a well-established, high-risk melanoma gene, *CDKN2A*, the association signal spans several genes which are also frequently deleted somatically in tumors, suggesting multiple genes may play a role in melanoma risk. We used both iterative conditional analysis and Bayesian fine-mapping to comprehensively identify candidate causal variants (CCVs) and identified six signals and 98 CCVs. Independent of GWAS analysis, exome sequencing of high-risk melanoma families identified three rare variants within ten base pairs of each other in the first intron of *CDKN2B* that abrogate CTCF binding. To determine the function of both the common and familial variants, we designed pooled CRISPRi/a gRNA libraries targeting all CCVs, familial variants, and genes at the locus, as well as a larger library with gRNAs tiled approximately every 75bp across the locus. We performed proliferation screening in immortalized melanocytes with and without ultraviolet radiation B (UVB) exposure. Inhibition of control genes with known effects on proliferation (*TP53*, *CCND1*) resulted in strong increases and decreases of proliferation, respectively. Consistent with a well-established role as a tumor suppressor in melanocytes, gRNAs inhibiting *CDKN2A*-p16^{INK4A} were significantly enriched, while *CDKN2B*-targeted gRNAs were moderately enriched. In contrast, gRNAs inhibiting *CDKN2A*-p14^{ARF} and *MTAP* were depleted. CRISPRi targeting of multiple CCVs located within intronic regions of p16 had similar effects to p16-targeted gRNAs, while CCVs within the first intron of p14 had effects in both directions, indicating potential roles for CCVs in the regulation of an established risk gene. In contrast, CCVs from a signal intronic to *MTAP* had opposite effects of p16 targeting, suggesting that inhibition of CCV enhancers from this signal may regulate *MTAP* and or potentially lead to upregulation of p16. Targeting of familial variants had a similar effect as targeting p16 and *CDKN2B* and will require further investigation to tease apart target genes. Finally, we identified multiple distant intergenic regulatory elements that have a strong effect on melanocyte proliferation and viability in both non- and UV-exposed cells, allowing for interpretation of additional non-coding variation found in melanoma cases and families. These results paired with region capture C, ATAC-seq, and HiChIP will help disentangle this complex locus.

Cancer Posters - Wednesday

PB1053. Comprehensive study of gene expression outliers and their regulation mechanisms in pan-cancer.

Authors:

J. Han, P. Boutros; UCLA, Los Angeles, CA

Abstract Body:

Cancer is a disease characterized by remarkable heterogeneity, with many molecular features significantly associated with tumour progression in specific subsets of patients. Gene expression varies drastically between tumours and within cells of a single tumour. This variability in gene expression can be caused by gene-regulatory mechanisms such as DNA copy number changes, extrachromosomal DNA, or aberrant methylation, amongst many others. These mechanisms sometimes generate extreme outliers: transcripts that show atypically high or low gene expression in a small percentage of cancers. These outliers increase the molecular and phenotypic diversity between individuals, contributing to tumour heterogeneity. Gene expression in cancer has been well studied with many reports of differential gene expression patterns between specific cancer types or subtypes. Importantly, many of these differences were strongly associated with tumorigenesis and tumour progression. For example, the *BCR-ABL* fusion was discovered in chronic myeloid leukemia with drugs targeting this fusion gene dramatically increasing the survival rate. The *EML-ALK* fusion gene is another example of a gene-expression outlier and drug target. It occurs in about 4% of non-small-cell lung carcinomas and has been routinely screened for. These examples demonstrate the critical role gene expression outliers play in cancer progression and highlight their potential as biomarkers for diagnostics and identifying novel drug targets. Despite their importance, there has not yet been a comprehensive pan-cancer study of gene expression outliers and their general properties. We lack the answers to fundamental questions such as how many outliers exist in a typical tumour, whether this differs across cancer types, what mechanisms generate the most outliers, whether specific clinical or somatic mutational features correlate with the number or type of outliers, and how many recurrent outliers exist. To answer these questions, we performed a comprehensive and systematic analysis of cancer gene-expression outliers using molecular data from multiple cancer genomics projects. We have created a new statistical outlier detection method and applied it to transcriptomics and proteomics data across 33 cancer types. We used this resource to describe the fundamental landscape of gene-expression outliers, including the most likely genetic and epigenetic mechanisms driving them. The resulting outliers will be further studied for their impact on cancer progression and validated hits will serve as clinically relevant biomarkers and targets for future functional and therapeutic investigations.

Biology, Genetics and Clinical Genetics, Faculty of Med., Comenius Univ. in Bratislava, Bratislava, Slovakia, ⁶Dept. of Molecular Biology, Faculty of Natural Sci., Comenius Univ. in Bratislava, Bratislava, Slovakia, ⁷Inst. of Clinical and Translational Res., BioMed. Res. Ctr., Slovak Academy of Sci., Bratislava, Slovakia

Abstract Body:

Recent advances in sequencing technologies have enabled affordable testing for various genetic diseases. Their application in the field of oncology has great potential for early detection and monitoring of tumor progression. A promising way is the thorough characterization of microsatellites, where the detection of their unstable forms can be used as a cancer biomarker.

We compared sequenced DNA fragments isolated from tumor and control tissues. We first mapped them to the reference human genome. Then, thousands of selected microsatellite loci across the genome were thoroughly characterized to detect typical anomalies of unstable forms. The changes were aggregated across the analyzed loci to obtain compact features for each sample. Finally, the features were analyzed with classification methods to distinguish between tumor and control tissue.

We show that microsatellite instability is readable in our tumor samples. The method has therefore the potential to automate the detection and characterization of ongoing oncology disease from the sequenced genomic data.

The presented work was supported by the Slovak Research and Development Agency (grant ID APVV-18-0319), and by the OP Integrated Infrastructure within projects with ITMS codes 313011W988, 313011F988, and 313011V578, 313011W428, all co-financed by the European Regional Development Fund.

PB1055. Concurrent Core-binding factor beta subunit (CBFB) gene rearrangement/inv(16)(p13.1q22) in p210 BCR-ABL1 positive chronic myelogenous leukemia

Authors:

J. Reid¹, K. Semenova¹, K. Dang¹, J. Tso¹, L. Yang¹, A. Fleishman¹, X. Zhao¹, F. Quintero-Rivera²; ¹Univ. of California Irvine Med. Ctr., Orange, CA, ²Univ. of California Irvine (UCI), Irvine, CA

Abstract Body:

The concurrent identification of core-binding factor beta subunit (CBFB) gene rearrangement associated with inv(16)(p13.1q22) in a patient with chronic myelogenous (CML) is an extremely rare phenomenon. Herein, we present a 60-year-old male who was transferred to the emergency department; he was confused and found to have left sided deficits. His CBC showed hyperleukocytosis with WBC of 600,000/MCL and hemoglobin of 7.3g/dL. His peripheral blood smear showed severe normocytic anemia, severe leukocytosis/neutrophilia with basophilia/eosinophilia and increased myeloid blasts (3%) and mild thrombocytopenia. Bone marrow biopsy identified a markedly hypercellular marrow with marked left-shifted myeloid hyperplasia, megakaryocytic hyperplasia with dysplasia and moderate fibrosis, blasts were not increased (1-2%), consistent with CML-chronic phase (CP). Flow cytometric/immunohistochemistry analysis showed 1.5 % myeloid blasts expressing CD34, CD117, HLA-DR, CD38, CD33, and MPO. Cytogenetics analysis identified a 9 and 22 translocation in 20 cells, with half of them also showing an inversion of chromosome 16, consistent with cytogenetics clonal evolution and accelerated phase -AP- (formerly considered blast phase (BP)). FISH detected a CBFB gene rearrangement in 8.5% of nuclei examined. PCR and NGS detected, BCR ABL p210 transcript, and BCR-ABL1 fusion transcript [VAF % 59.2] and CBFB-MYH11 fusion transcript [VAF % 53.4], respectively. Patient underwent angioplasty, and leukapheresis; hydroxyurea was given for the refractory hyperleukocytosis. He also received cytarabine, dasatinib with decadron. His principal diagnosis was acute basal ganglia hemorrhage, and secondary diagnoses: shock, likely hypovolemic, acute hypoxic respiratory failure, right middle cerebral artery stroke, CML-AP, tumor lysis syndrome, acute kidney injury. Patient passed away 6 days after admission. 25 cases of CML with inv(16) and eosinophilia have been reported in which patients are either in CP, BP or AP. The prognosis has been poor consistently displaying aggressive clinical progression of the disease and rapid decline, if treated only with chemotherapy [PMID: 16203287]. Only two patients treated with FLAG-Ida plus tyrosine kinase inhibitors and allo-SCT had a favorable response [PMID:2825353]. Detection of the inv(16) by karyotyping is technically challenging, in addition, FISH for CBFB is not usually run in the context of CML, thus raising the possibility that similar cases have been underdiagnosed. With the routine use of NGS for gene fusion detection, in addition to cytogenetics, more patients like this one should be diagnosed and treated accordingly.

Cancer Posters - Thursday

PB1056. Confirmation of pathogenic germline variants identified by tumour testing in British Columbia

Authors:

P. Cheng, K. Compton, I. Bosdet, T. Tucker, S. Young, S. Yip, K. Schrader, S. Sun; BC Cancer, Vancouver, BC, Canada

Abstract Body:

Background

Multi-gene panel tumour testing (TT) has been used in the evaluation of various solid and hematologic cancers in British Columbia (BC) since mid-2016, including advanced non-small cell lung cancer (NSCLC), colorectal cancer (CRC), melanoma (MEL), low-grade glioma (LGG), and gastro-intestinal stromal tumour (GIST), ovarian cancer (OVA) added in 2018, as well as acute myeloid leukemia (AML), myelodysplastic syndrome (MDS), and myeloproliferative neoplasms (MPN). In addition to somatic driver mutations, TT may reveal potential pathogenic germline variants (pPGVs) associated with inherited cancer predisposition syndromes. Herein, we analyzed rates of pPGV detection by TT and referral to the Hereditary Cancer Program (HCP) for confirmatory germline testing, and clinical implications for patients (pts) with positive results.

Methods

All pts with TT performed from January 1, 2018 to June 30, 2021 were identified. Next-generation tumour sequencing (Oncopanel) was used to screen the following genes: *AKT1*, *ALK*, *BRAF*, *BRCA1*, *BRCA2*, *CCND1*, *CCND3*, *CIC*, *EGFR*, *ERBB2*, *ERBB3*, *FUBP1*, *HRAS*, *IDH1*, *IDH2*, *KIT*, *KRAS*, *MAP2K1*, *MET*, *NRAS*, *PDGFRA*, *PIK3CA*, *PTEN*, *ROS1*, *SDHA*, *SDHB*, *SDHC*, *SDHD*. Additional hereditary genes were added in 2019: *APC*, *BMPR1A*, *CDHI*, *CDK4*, *CDKN2A*, *GNAI1*, *GNAQ*, *MLH1*, *MSH2*, *MSH6*, *MUTYH*, *NF1*, *PALB2*, *PMS2*, *POLD1*, *POLE*, *SMAD4*, *STK11*, *TP53*. Targeted genes in the Myeloid panel included: *ASXL1*, *BCOR*, *CALR*, *CBL*, *CEBPA*, *CSF3R*, *DNMT3A*, *ETV6*, *EZH2*, *FLT3*, *GATA2*, *HRAS*, *IDH1*, *IDH2*, *JAK2*, *KDM6A*, *KIT*, *KMT2A*, *KRAS*, *MPL*, *NPM1*, *NRAS*, *PHF6*, *PIGA*, *PRPF40B*, *PTEN*, *PTPN11*, *RAD21*, *RUNX1*, *SETD2*, *SF1*, *SF3A1*, *SF3B1*, *SH2B3*, *SMC1A*, *SMC3*, *SOCS3*, *SRSF2*, *STAG2*, *TET2*, *TP53*, *U2AF1*, *U2AF2*, *WT1*, *ZRSR2*.

Results

In total, 8391 TTs were performed, with pPGVs detected in 273 pts. Of 177 pts referred to the HCP, 130 had germline testing, and 57 PGVs were confirmed in 55 pts (2 pts had 2 PGVs), including 33 that would not have met referral criteria based on personal or family history. Confirmation of PGVs did not impact treatment decisions; however, all pts with PGVs received individualized genetic counselling, and 7 family members subsequently self-referred for testing, with PGVs identified in two.

Discussion

TT detected pPGVs in 3.3% of pts with advanced solid organ and myeloid cancers, with 65% referred to the HCP and germline testing confirming at least one PGV in 42% of cases. Increased clinician and pt awareness with targeted follow up of cases with pPGV's detected by TT could increase referral rates and facilitate identification and screening of at risk pts and families.

Cancer Posters - Wednesday

PB1057. Congenital uterine abnormalities and the risk of gynecological cancers

Authors:

N. Abdelmoula, B. Abdelmoula, A. Karra; Med. Univ. of Sfax, Sfax, Tunisia

Abstract Body:

Background: Women with a history of miscarriage and infertility have higher prevalence of congenital uterine anomalies compared with the general population (diagnosed in 2-4% of women with a normal reproductive outcome). These malformations result from developmental disorder during the formation, fusion or resorption of the Müllerian ducts. Generally, development of the female reproductive tract is a complex and dynamic process that involves a complex regulation via multiple signaling pathways. This study assessed the management of the risk of gynecological cancers in female patients harboring congenital uterine abnormalities among patients who presented at our genetic counselling during the genetic exploration of miscarriages and/or infertility. Methods: This observational study retrospectively obtained data on all patients who were admitted to our genetic counselling during the genetic exploration of miscarriages and/or infertility between January 2002 and November 2016. Out of these patients, we selected female patients for whom congenital uterine anomalies were recorded and genetic counselling was delivered. Results: This study recruited ten patients with congenital uterine abnormalities (3% of the population of infertile patients of our genetic counselling). Out of these patients, a bicornuate unicollis uterus was recorded in 50% of patients, a septate uterus with complete vaginal septum in one case (10%) and a segmental Müllerian agenesis with Mayer-Rokitansky-Küster-Hauser syndrome phenotype in four patients (40%). One of them had in association to unicornuate uterus and vaginal diaphragm at the superior third, a unilateral renal agenesis. Complete agenesis of the uterus was recorded in two patients. At the productive level, miscarriages and recurrent pregnancy losses with and without live birth were recorded in two patients, ectopic pregnancies were recorded in one patient and primary amenorrhea was recorded in two patients. The others presented a primary infertility and were candidate to ART techniques. Cytogenetic analysis of the ten patients showed a 46,XX formula. All of them received a genetic counselling and were informed about a minor risk of gynecologic cancers which requires regular monitoring. Conclusion: In fact, there is an evidence that clear cell adenocarcinomas of the ovary, endometrium, cervix, and vagina are associated with Müllerian duct abnormalities with/without renal malformations. These rare histologically gynecologic cancers and tumors are characterized by upregulation of the mTOR and RAS signaling pathways and demonstrate more likely microsatellite instability than other gynecologic cancers.

Cancer Posters - Thursday

PB1058*. Copy number variation at *ATF7IP* is associated with increased risk for testicular germ cell tumors.

Authors:

M. Fan¹, J. Pluta¹, C. Ruan¹, B. Weathers¹, K. P. D'Andrea¹, R. Karlsson², F. Wiklund², P. A. Kanetsky³, K. L. Nathanson^{1,4}, Testicular Cancer Consortium; ¹Div. of Translational Med. and Human Genetics, Dept. of Med., Perelman Sch. of Med., Univ. of Pennsylvania, Philadelphia, PA, ²Dept. of Med. Epidemiology and Biostatistics, Karolinska Inst., Stockholm, Sweden, ³Dept. of Cancer Epidemiology, Moffitt Ctr. and Res. Inst., Tampa, FL, ⁴Abramson Cancer Ctr., Perelman Sch. of Med., Univ. of Pennsylvania, Philadelphia, PA

Abstract Body:

BACKGROUND Testicular germ cell tumor (TGCT) is one of the most heritable cancer types. Genome-wide association studies (GWAS) have identified 66 susceptibility loci associated with risk of TGCT, which in total account for 44% of disease heritability. The contribution of copy number variation (CNV) to TGCT susceptibility has not been previously evaluated. **METHODS** SNP-array genotyping was conducted using the Infinium HumanCore-24 chip with 6,920 customized and 306,040 pre-designed probes. We used PennCNV (v1.0.5) to generate raw CNV calls in 5,287 men with and 4,967 men without TGCT, matched by age and ancestry. We used HandyCNV (v1.1.7) to call and annotate CNV regions (CNVRs). Associations were modeled using logistic regression and performed using custom scripts in R v4.0.1. After Bonferroni correction, the threshold for significance was $p < 10^{-05}$. rt-PCR was used for *in vitro* validation. To examine the relationship between copy number and gene expression, we utilized copy number, RNA seq, and CpG methylation data from 116 TGCA TGCT cases. We performed a linear regression analysis to assess the association of expression and CNV. **RESULT** We identified 58,960 CNV calls in 8,945 men; 31,448 calls were found in men with TGCT and 27,512 in men without TGCT. After CNVR calling and case-control comparisons, four duplications, and one deletion met the significance threshold. The most significant ($p=1.17 \times 10^{-27}$) CNV was a segmental duplication overlapping the 5' end of *ATF7IP*, which was validated by rtPCR. The other identified CNVs were a duplication of ~69kbp ($p=1.40 \times 10^{-15}$) overlapping *CADPS2*, *TAS2R16*, and *SLC13A1*; a duplication of ~29kbp ($p=5.53 \times 10^{-12}$) overlapping *NIPSNAP3A*, *NIPSNAP3B*, and *ABCA1*; a deletion of ~2kbp ($p=2.42 \times 10^{-09}$) overlapping *ABC5*; and a duplication of ~150kbp ($p=6.09 \times 10^{-08}$) overlapping *CSN1S1*, *CSN2*, *STATH*, *HTN3*, *HTN1*, and *CSN1S2AP*. Three genes had a statistically significant association between CNV and expression: *ABCA1* ($p=0.009$), *NIPSNAP3A*, and *NIPSNAP3B*. *SLC13A1* and *ATF7IP* also showed increased expression with higher copy number, though the results were not statistically significant. **CONCLUSION** This study is the first to identify segmental duplications/deletions significantly associated with an increased risk for TGCT. Variation at *ATF7IP*, a modulator of transcription regulation and chromatin formation, has been associated with TGCT susceptibility before; the identified promoter CNV is independent of the known association. Many genetic regions showing overlap with significant CNVs contain genes involving solute transport (*ABC5*, *CADPS2*, *SLC13A1*), suggesting a novel biologic pathway important to TGCT susceptibility.

PB1059. Cost-utility of universal screening for common BRCA1 and BRCA2 variants among Ashkenazi Jewish women: a real-life analysis

Authors:

R. Michaelson-Cohen^{1,2}, A. Ben Shoham^{2,3}, S. Lieberman^{1,2}, M. Cohen^{2,3}, C. Cohen¹, E. Levy-Lahad^{1,2}, A. Lahad^{2,3}; ¹Shaare Zedek Med. Ctr., Jerusalem, Israel, ²Faculty of Med., Hebrew Univ., Jerusalem, Israel, ³Clalit Hlth.Services, Jerusalem, Israel

Abstract Body:

Objectives: Identifying carriers of pathogenic *BRCA1/BRCA2* variants can reduce cancer morbidity and mortality through surveillance and prevention. Universal testing for founder *BRCA1/BRCA2* variants, found in 2.5% of Ashkenazi Jews (AJ), fulfills WHO disease screening criteria. We analyzed the cost-effectiveness of *BRCA1/BRCA2* population screening (PS) in AJ, as an alternative to two existing strategies: cascade testing (CT) in carrier's relatives (>25% carrier probability) and international family history (IFH)-based guidelines (corresponding to >10% carrier probability). **Methods:** A decision analytic model was performed to estimate quality-adjusted life-years (QALY) gained, and incremental cost-effectiveness ratio (ICER) for PS vs. CT and IFH strategies. Analysis was conducted from a payer-perspective using lifetime horizon, based on actual costs. **Results:** Per 1000 women, the PS model vs. CT strategy predicted 21.6 years gained, a lifetime decrease of 3 breast cancer (BC) cases and 4 ovarian cancer (OC) cases, and the PS model vs. IFH strategy predicted 6.3 years gained, a lifetime decrease of 1 case of BC and 1 case of OC. PS was less costly compared with CT (-3097 US\$/QALY). Although PS was more costly than IFH-based testing (+18,968 US\$/QALY), it was still highly cost-effective, from a public health policy perspective. PS was more effective than other strategies in all sensitivity analyses). **Conclusions:** Our findings, based on actual expenditures from health care systems, indicate that from a public health policy perspective, there is an advantage in expanding the use of genetics for identification of women who are *BRCA1/BRCA2* carriers, and thus at high risk to develop cancer. The CT strategy, the standard protocol in Israel till recently, severely restricts the number of carriers identified, and precludes effective surveillance and prevention in many women who are not identified as carriers. Compared to both CT and IFH policies, the PS strategy is cost-effective, and has the greatest effectiveness in gain in lifespan and reductions in BC and OC incidence. Therefore, our study suggests that founder *BRCA* variant testing should be available to all AJ women, irrespective of family history. Implementation of PS for BRCA variants in these women would be the first example of using Precision Medicine for cancer screening. This can also serve as an informative paradigm as genomics is increasingly integrated into large-scale prevention for additional populations.

Cancer Posters - Thursday

PB1060. *CRLF2* Rearrangements in a Patient with B-ALL.

Authors:

Y. Lin^{1,2}, R. Tang^{1,2}, A. Bajpai^{1,2}, W. Yeh^{1,2}, S. Karamooz³, K. Eastwood³, M. T. Guardiola³, C. A. Tirado^{3,4,2}; ¹Univ. of California, Los Angeles, Los Angeles, CA, ²Intl. Circle of Genetics Studies, Los Angeles, CA, ³Baylor Scott & White Hlth., Temple, TX, ⁴Texas A&M Sch. of Med., Temple, TX

Abstract Body:

Leukemia is the most common pediatric malignancy, and B-cell acute lymphoblastic leukemia (B-ALL) is one of the prevalent pediatric leukemias, accounting for 26% of cancers diagnosed in children 0-14 years of age. We present a case of an 11-year-old girl with B-ALL. Conventional cytogenetics showed a karyotype described as

46,XX,del(5)(q31q35),add(6)(q23),del(7)(q32q36),add(11)(q23),ider(21)(q10)add(21)(q22),inc[20].

DNA FISH analysis was performed on a tissue sample from the bone marrow and showed variant rearrangements of *CRLF2*, as well as loss of *ETV6* signals and gain of *RUNX1* signals. The presence of *CRLF2* rearrangements is often associated with *CRLF2* overexpression and poor prognosis. Complex karyotypes also reflect genomic instability and poor prognosis. The patient was in complete remission nine months after diagnosis but passed away a month later from chemotherapy-induced hepatic failure, renal failure, and febrile neutropenia.

Cancer Posters - Wednesday

PB1061. Cross disorder genetic analysis identifies autoimmune disease loci inversely associated with diverse cancer types

Authors:

J. Chen¹, M. Epstein¹, J. Schildkraut², S. Kar³; ¹Emory Univ., Atlanta, GA, ²Emory Univ., Augusta, GA, ³Univ. of Cambridge, Cambridge, United Kingdom

Abstract Body:

The emergence of immune-checkpoint inhibitors has revolutionized the cancer treatment landscape. It is known that increased autoimmune adverse events correlate with better responses to cancer treatment, suggesting a joint mechanism underlying autoimmunity and cancer. We hypothesized that pleiotropic alleles which confer increased risk of autoimmune diseases, but decreased risk of cancer may offer vital insights into this joint mechanism. We searched for such alleles using some of the largest genome wide association study (GWAS) datasets from European-ancestry populations for four common cancer (breast, ovarian, prostate, and endometrial cancers) and their subtypes and four adult autoimmune/autoinflammatory disorders (Rheumatoid arthritis, systemic lupus erythematosus, ulcerative colitis and Crohn's Disease). We performed a meta-analysis for each cancer-autoimmune disease pair using the inverse-variance approach implemented in METAL and clumped the resulting METAL statistics. In order to obtain METAL statistics for variants that specifically have opposite effects on the two outcomes, we multiplied beta coefficients from autoimmune diseases GWAS summary statistics by '-1' before conducting the meta-analysis. Additionally, we performed a Transcriptome-wide association study using sparse-canonical correlation (sCCA-TWAS), which integrates multiple tissues for increased power, to identify genes associated with both cancer and autoimmune disease. We identified 41, 18, 47 and 26 autoimmune disease loci that are inversely associated with Breast, Ovarian, Prostate, and Endometrial Cancers, respectively, where the lead variant was associated with at least one cancer and autoimmune disease at $P < 10^{-3}$ individually and the combined association in METAL had $P < 5 \times 10^{-8}$. For example, allele A of rs2384061, located in *ADCY3*, was negatively associated with breast cancer ($P = 1.02 \times 10^{-11}$) and positively associated with Crohn's disease ($P = 2.85 \times 10^{-6}$), where METAL $P = 6.45 \times 10^{-16}$. Our sCCA-TWAS results showed that gene expression of *ADCY3* was associated with Breast cancer ($P = 4.08 \times 10^{-10}$) and Crohn's disease ($P = 3.10 \times 10^{-7}$). In the analysis of ER-negative breast cancer and autoimmune diseases, multiple genes that have inflammation roles such as *IRF6*, *IFITM2* and *CCL11* were identified. We confirmed autoimmune effects at many known cancer risk loci and identified several cross-disorder loci that were not detected in previous cancer GWAS. These loci may be valuable genomic targets linking autoimmune disorders with cancer development, offering insights into the interplay between immunity, inflammation and cancer risk, prevention, and treatment.

PB1062. Deciphering a prognostic DNA methylation signature in tubo-ovarian high-grade serous cancer.

Authors:

B. Jorgensen¹, C. Wang¹, J. Cunningham², S. Armasu¹, N. Traficante^{3,4}, The Australian Ovarian Cancer Study Group, D. Garsed^{3,4}, S. Fereday^{3,4}, D. Ariyaratne³, S. Winham¹, D. Bowtell^{3,4,5}, E. Goode¹; ¹Mayo Clinic, Rochester, MN, ²Mayo Clinic & Fndn, Rochester, MN, ³Peter MacCallum Cancer Ctr., Melbourne, Australia, ⁴Sir Peter MacCallum Dept. of Oncology, The Univ. of Melbourne, Parkville, Australia, ⁵Ctr. for Cancer Res., The Westmead Inst. for Med. Res. and Dept. of Gynaecological Oncology, Westmead Hosp., The Univ. of Sydney, Sydney, Australia

Abstract Body:

Background: We have identified a quantitative tumor DNA methylation signature in tubo-ovarian high-grade serous carcinomas (HGSC) that indicates poor prognosis. The signature associates with shorter time to recurrence, independent of clinical factors (N=325 discovery set, HR 2.87, $p=2.2 \times 10^{-13}$; N=715 validation set, HR 1.65, $p=0.015$) and inversely correlates with expression of immune genes on chromosome 6p21.3. Factors underlying this signature remain unknown. **Methods:** We sought to evaluate additional tumor characteristics related to this signature and/or its role in disease outcome in The Cancer Genome Atlas, Mayo Clinic, and Australian Ovarian Cancer Study participants. We examined the following tumor-based data: tumor RNA-based transcriptomic molecular subtype (N=746), expression of the ATP-binding cassette transporter *TAP1* (N=605), and levels of CD8⁺ TILs (N=222). Multivariate testing adjusting for age, stage, study site, and debulking status utilized linear and Cox regression. **Results:** Higher methylation signature scores were found in tumors with no CD8⁺ TILs or with a low/moderate CD8⁺ TIL level, compared to those with high CD8⁺ TIL levels ($p=5.7 \times 10^{-12}$ and 1.1×10^{-4} , respectively). *TAP1* mRNA levels (6p21.3) negatively correlated with methylation signature (p-values < 0.05). Methylation signature associated with molecular subtype: immunoreactive (C2.IMM) subtype tumors had the lowest signatures and proliferative (C5.PRO) subtype, the highest. Considering age, stage, debulking status, study site, *BRCAl/2* germline mutation status, *TAP1* RNA expression, and molecular subtype, only age at diagnosis, *TAP1* RNA expression and, molecular subtype associated with the signature (p-values 0.017, 4.69×10^{-19} ; 1.24×10^{-9} , respectively). Multivariate survival analyses suggest that stage, debulking status, and methylation signature associated with time to recurrence/death at $p < 0.05$ with adjustment for age at diagnosis, study site, *TAP1* RNA expression, and molecular subtype (methylation signature HR 2.22, $p=4.46 \times 10^{-8}$). Similar results were seen when limiting to participants with CD8⁺ TIL and *BRCAl/2* data, wherein methylation signature remained significantly associated with time to recurrence/death ($p=0.009$), while CD8⁺ TIL levels, *TAP1* RNA expression, and molecular subtype did not. **Conclusion:** These results suggest differential methylation in the tumor-immune microenvironment. As multiple yet independent factors appear to be associated with methylation signature (*TAP1* expression, molecular subtype, CD8⁺ TIL levels), we do not expect methylation signature to be a simple surrogate for any of these tumor features.

Cancer Posters - Thursday

PB1063. Deep and error corrected sequencing via the low-cost Ultima Genomics platform enables ultra-sensitive circulating tumor DNA cancer monitoring

Authors:

A. Cheng¹, A. J. Widman², A. Arora², I. Rusinek³, W. F. Hooper², R. Murray², D. Halmos², T. Langanay², G. Inghirami¹, S. Germer⁴, M. Marton², R. Furatero², J. McClintock², L. Winterkorn², Z. Robine⁴, G. Boland¹, D-A. Landau¹; ¹Weill Cornell Med., New York City, NY, ²New York Genome Ctr., New York City, NY, ³Ultima Genomics, Newark, CA, ⁴New York Genome Ctr., New York, NY, ⁵Mem. Sloan Kettering Cancer Ctr., New York City, NY, ⁶Mass Gen. Cancer Ctr., Boston, MA, ⁷The Frank Crick Inst., London, United Kingdom

Abstract Body:

In many areas of oncology, we lack sensitive tumor-burden monitoring to guide critical decision making. While circulating tumor DNA (ctDNA) promises to enable disease monitoring, this approach is limited by the sparsity of ctDNA in the plasma. To overcome this challenge, error-corrected deep targeted sequencing has been proposed. Nonetheless, this framework is limited by the low number of genomic equivalents (GEs, typically $\sim 10^3$ /mL of plasma), imposing a ceiling on effective sequencing depth. We have previously shown that genome-wide mutational integration through plasma whole genome sequencing (WGS) can sever the dependency between available GEs and assay sensitivity (Zviran *et al*, Nature Medicine, 2020). In this approach, tumor-informed mutational profiles are applied to plasma WGS, allowing detection of tumor fractions as low as 10^{-5} . However, the higher cost of WGS limits practical depth of coverage (20-30X) and may limit broad adoption.

Lower sequencing costs may thus allow for enhanced ctDNA cancer monitoring via WGS. We therefore applied emerging lower-cost WGS (\$1/Gb, Almogy *et al*, biorxiv, 2022) to plasma from 7 patients with metastatic cancer at 80-100X coverage depth. Read depth profiling and error rates were comparable between matched Ultima and standard platform datasets. Integration of deep learning architectures for signal to noise enrichment (Widman *et al*, biorxiv, 2022) with deeper WGS coverage enabled ctDNA detection at the parts per million range.

We further reasoned that lower sequencing cost can be harnessed for duplex error-corrected WGS. Applying this to PDX samples showed order of magnitude decrease in errors, and error rates $\sim 6 \times 10^{-7}$ in samples from patients with metastatic melanoma. We further used this approach to tackle the more challenging context of cancer monitoring in early-stage melanoma without matched tumor sequencing. While in uncorrected WGS, *de novo* mutation calling yielded limited ability to detect melanoma specific mutations, duplex-corrected WGS allowed us to harness melanoma mutational signatures for disease monitoring without matched tumor profiling.

In summary, these data demonstrate the exciting potential of low cost WGS for ultra-sensitive ctDNA cancer monitoring. In the tumor-informed setting, deeper sequencing increased sensitivity for mutational profile detection. Moreover, the application of duplex error-correction at genome scale allowed for sensitive cancer monitoring without matched tumor profiles. We envision that the era of low-cost sequencing will thus empower ultra-sensitive cancer monitoring via WGS, with transformative impact on cancer care.

Cancer Posters - Wednesday

PB1064. Deep learning identifies gene expression and DNA methylation as highly predictive of lung cancer histologic subtype.

Authors:

M. Betti¹, E. R. Gamazon^{1,2}, M. C. Aldrich¹; ¹Vanderbilt Univ. Med. Ctr., Nashville, TN, ²Clare Hall, Univ. of Cambridge, Cambridge, United Kingdom

Abstract Body:

Genomics-based molecular assays such as RNA-seq and DNA methylation profiling have gained traction in the clinic. This increase in clinical use has been particularly true in the context of cancer diagnosis and treatment, where biomarker-based tumor characterization plays a key role in targeted treatments. While high dimensionality often limits the interpretability of large genomic datasets, deep learning-based approaches have shown enormous promise due of their ability to model non-linear relationships within high-dimensional data types. We aimed to evaluate the applicability of deep learning to histological subtype categorization in lung cancer using datasets from three commonly utilized genomic profiling techniques: RNA-seq, DNA methylation, and miRNA-seq.

From The Cancer Genome Atlas (TCGA), we identified 962 lung cancer cases (477 squamous cell carcinoma and 485 adenocarcinoma) for which RNA-seq, DNA methylation, and miRNA-seq were performed with biopsied tumor tissue. Using each of these three distinct data types, we defined and trained an ensemble of three multilayer perceptron architectures, with hyperparameters optimized independently using grid search, to distinguish between lung cancer histologic subtypes.

Before model training, 20 percent of each training set was randomly partitioned to use as an independent validation set. Classification performance of each model was evaluated using the area under the receiver operating characteristic curve (AUC) statistic. Of the three models, the one trained on CpG methylation showed the highest performance, with an impressive AUC of 0.98 in the validation set. The gene expression-based model was a close second, with an AUC of 0.94. Finally, we found miRNA expression to be the poorest predictor of lung cancer histological subtype, with an AUC of 0.61.

Our results suggest that both gene expression and DNA methylation may have strong potential utility as clinical predictors of lung cancer histologic subtype. Although the same was not observed using miRNA, the use of a more complex model architecture such as a convolutional (CNN) or graph neural network (GNN) might improve the diagnostic accuracy of this data type. The high performance of our trained multi-layer perceptron-based models suggests that gene expression and DNA methylation merit further exploration as potential diagnostic biomarkers of lung histology, capable of enhancing dominant imaging-based approaches.

PB1065. Deep learning morphology profiling identifies and enriches carcinoma cells from effusion samples in real-time for cytological and molecular analysis

Authors:

A. Mavropoulos¹, J. Cruz¹, J. Nieto¹, K. Saini¹, W. Austin¹, M. Phelan¹, J. Kim¹, J. Mei¹, W. Yu², C. Johnson¹, S. Boutet¹, T. Lee², N. Li¹, J. Rao², M. Salek¹, M. Masaeli³; ¹Deepcell Inc, Menlo Park, CA, ²Univ. of California, Los Angeles, Los Angeles, CA, ³Deepcell, Menlo Park, CA

Abstract Body:

Cell morphology is a fundamental cell feature essential for pathological identifications, but is currently analyzed with low throughput, subjective, and laborious methods. We developed a platform that generates high-dimensional morphology data using high resolution bright-field imaging that can classify and sort cells in real time when coupled with our Deep Neural Network architecture. Enriched cells are label-free, unperturbed, and viable, making them amenable to downstream molecular and functional analysis.

Effusion samples are a valuable source of tumor cells used for diagnostic, precision medicine, and biomarker discovery purposes but detection and molecular characterization of cancer cells in body fluids is generally limited by low tumor cell content and high background of non-malignant cells. To address these challenges, we used the Deepcell platform and trained an AI model using >3 million cell images from malignant effusion samples. In silico analysis was used to validate the model (AUC=0.96). AI model performance was tested on clinical samples, with carcinoma cells detected in 100% (n=25) of the carcinoma-positive cytology clinical samples and percent frequency highly concordant to flow cytometry data.

Cell images were used to generate high-dimensional profiles based on morphological features, and tSNE analysis revealed multiple distinct clusters characteristic of carcinoma cells that were also classified as carcinoma that were present in the malignant and absent in the benign ascites sample. Pap staining showed higher purities in sorted versus pre-sorted samples, verifying malignant cell enrichment capability of the platform. Additionally, sorted samples had increased amplitude of deletion and amplification peaks and increased TP53 mutation frequency compared to pre-sorted samples, as demonstrated by CNV analysis and targeted sequencing, respectively. scRNA-seq analysis showed enrichment of EpCAM(+) tumor cells and presence of EpCAM(-) tumor cells with high levels of Claudin-4 and CD24 in sorted cells.

Combined, these data show the Deepcell platform is consistent with current cytology and biomarker assay results, with added benefits of greater accuracy and enrichment of live malignant cells present in effusion samples. The gentle workflow yields label-free, viable cells with unaltered morphological features and transcriptomic profiles that could be used for further downstream analysis. Additionally, high-dimensional morphology analysis provides a new dimension that can be integrated into single cell multi-omics to elucidate tumor cell heterogeneity within effusion fluids to ultimately improve precision medicine.

PB1066. Detecting pleiotropic breast cancer susceptibility variants from genome-wide association studies.

Authors:

X. Li, M. Zhou, M. Henricks, V. Loch; St. Cloud State Univ., St. Cloud, MN

Abstract Body:

Breast cancer is the most common invasive cancer and the second leading cause of cancer deaths in women. There exists compelling evidence that some genetic variants are associated with the risk of multiple cancer sites and other cancer-related phenotypes. (i.e., pleiotropy). For example, cross-cancer Genome-Wide Association Studies (GWAS) for two to five cancers have been conducted to identify pleiotropic variants. Previous work has also estimated the genetic correlation between pairs of cancers using data from GWAS for multiple cancer sites. Currently, the association pathways from a variant to different cancer types and cancer-related phenotypes remain poorly characterized. In this study, we investigated different possible pathways between genetic variants and breast cancer. We began by detecting outliers in a single exposure-outcome mendelian randomization (MR) analysis, hypothesizing they are due to horizontal pleiotropy. In MR analysis, variants that exert horizontal pleiotropy are typically treated as a nuisance. Here, we exploited horizontal pleiotropy as an opportunity to understand the underlying shared biological pathways between ovarian cancer and breast cancer. We performed the MR analysis of ovarian cancer and breast cancer using GWAS summary statistics. We identified five horizontal pleiotropy SNPs, three of them were previously reported to be associated with both breast and ovarian cancer (rs10069690/ 5p15/TERT, rs8170/ 19p13/ BABAM1, rs635634/ 9q34/ABO). Index variants in two additional regions (rs1243180/10p12.31/MLLT10, rs183211/17q21.31/NSF) that were only previously associated with ovarian cancer also showed horizontal pleiotropic effects with breast cancer. We also examined the potential causal association between breast cancer and two risk factors, alcohol consumption and smoking. We found a significant association between genetic liability to alcohol consumption and breast cancer ($P=0.014$). Our findings can enhance the understanding of breast cancer and help to target the investigation of genes with greater clinical evidence.

PB1067. Detection of androgen receptor splice variants from clinical sequencing

Authors:

S. Hwangbo, S. Lee, S. Kim, H. Yun; Seoul Natl. Univ. Hosp., Seoul, Korea, Republic of

Abstract Body:

Androgen receptor (*AR*) splice variants (*AR*-Vs) have been widely studied on its important role in prostate cancer (PC) progression. In particular, *AR*-Vs lacking ligand binding domains, such as *AR* splice variant 7 (*AR*-v7) that links exon 3 and cryptic exon 3 or *AR* variant that losses exons 5 to 7 (*AR*^{v567es}), have been demonstrated as one of the resistant mechanisms to androgen deprivation therapy in PC. Despite its clinical importance, the current algorithms to detect fusions such as TopHat-Fusion have limitation to detect intra-chromosomal rearrangements including *AR*-Vs. In this respect, we propose a novel approach to identify *AR*-Vs from targeted RNA sequencing (RNA-seq) dataset. In short, our two-step approach first gathers soft-clipped or divided reads that are adjacent to the splicing sites of *AR*-Vs and then yields the number of splitting reads that support the existence of *AR*-Vs. Next, the algorithm selects the paired-end reads whose one side and the other side are mapped to the preceding and following exons, respectively. The final number of spanning reads are calculated following to the removal of low-quality reads. We validated the proposed approach using two large-scale, independent RNA-seq datasets of PC samples: 54 samples from Seoul National University Hospital (SNUH) and 558 samples from The Cancer Genome Atlas (TCGA) dataset. Overall, our approach successfully identified samples with putative *AR*-Vs, including *AR*-v7 and *AR*^{v567es}. In addition, our approach successfully detected *AR*-v7 with reliable number of supporting reads, from the RNA-seq dataset of *AR*-v7-expressing cell line. Finally, statistical analyses of 54 SNUH PC patients suggested potential detection threshold in clinical sequencing settings (at least 8 split reads). In the SNUH dataset, The *AR*-v7 positive group, which included 12 patients (22.2%) with 8 or more split reads, had higher *AR*-v7 expression levels than the negative group ($p=0.0147$). The similar pattern was also found in the analysis of TCGA dataset. Owing to its flexibility, we also confirmed that the developed approach can be used to detection of other *AR*-Vs, including *AR*-v3 and *AR*^{v567es}. We expect that the further in-depth analyses including larger samples and clinical outcomes can discover clinical applicability of *AR*-Vs.

PB1068. Detection of APC and MUTYH germline mutations in two south Indian families with hereditary colorectal cancer.

Authors:

S. Akula, S. Valmiki, K. K. Mandapati, D. R. Vegulada; Genes N Life Hlth.Care, Hyderabad, India

Abstract Body:

Globally, colorectal cancer (CRC) is recognized both as the second most deadly cancer and third most prevalent disease, with significant projected growth in incidence. Addressing this concern requires a thorough understanding of its medical origins. Most colorectal cancers are somatic, but 5-10% of CRC are associated with germline mutations, including within APC and MUTYH genes that cause familial adenomatous polyposis (FAP). This study was carried out with the aim to identify these specific germline mutations in two South Indian families with CRC incidence. The primary step was the collection of formalin-fixed paraffin-embedded tumor tissue sections from the index patient and screening for microsatellite instability by immunohistochemistry to rule out hereditary nonpolyposis CRC, which was negative. To detect germline mutations, adhering to Mayo Clinic and American College of Medical Genetics' guidelines for genetic testing, researchers collect blood samples from the index patient and eleven other family members. All coding regions and intron-exon junctions of APC and MUTYH genes were analyzed using Sanger sequencing. No mutations were detected in the MUTYH gene in the index patient. However, a missense mutation (c.5465A>T p.D1822V) was identified within the APC gene in the index patient. All eleven family members were screened for the targeted c.5465A>T mutation, with 4/11 family members having it. Sigmoidoscopy revealed the presence of the polyps in two of the family members having the mutation. The APC mutation has previously been reported to be the most common allele associated with increased risk of CRC triggered by dietary fat intake, indicating an aspect that affected family members must remain attentive to. Through this study's genetic counseling, these family members were given precise, early diagnoses and guided clinical management for future surveillance, which must be accomplished on a wider scale through further research.

Cancer Posters - Thursday

PB1069*. Detection of circulating tumor DNA in resectable pancreatic ductal adenocarcinoma

Authors:

J-S. Lee¹, S. Cho¹, M-W. Seong¹, J. Jin-Young¹, S. Park²; ¹Seoul Natl. Univ. Hosp., Seoul, Korea, Republic of, ²Seoul Natl. Univ Hosp, Seoul, Korea, Republic of

Abstract Body:

Background: Circulating tumor DNA (ctDNA) is a promising biomarker for early tumor detection and minimal residual disease (MRD) assessment in early-stage cancer, but quantifying minute amounts of ctDNA in the early stage of disease is challenging. Here, we adapted an ultrasensitive next-generation sequencing (NGS) technology and performed parallel analysis of pre- and post-operative ctDNA and matched tumor tissues in a prospective cohort of patients with resectable pancreatic ductal adenocarcinoma (PDAC). **Methods:** In total, 70 consecutive patients undergoing curative resection for resectable PDAC were enrolled from August 2020 through October 2021. We performed integrated digital error suppression enhanced cancer personalized profiling by deep sequencing (CAPP-Seq) NGS of triple-matched samples [pre/post-operative plasma cell-free DNA (cfDNA), tumor tissue, and germline DNA] targeting 77 genes. **Results:** Preoperative ctDNA was detected in 37.7% of the evaluable patients, with a median variant allele frequency of 0.09%. Twelve additional oncogenic mutations were detected exclusively in pre-operative ctDNA but not in tissue. The risk of early recurrence tended to be higher in patients with detectable post-operative ctDNA than in patients with negative conversion of ctDNA after surgery. cfDNA variants from 24.5% of patients had features compatible with clonal hematopoiesis. **Conclusion:** An optimized NGS approach might add value beyond tissue analysis through the highly sensitive detection of minute amounts of ctDNA in resectable PDAC. Pre/post-operative ctDNA changes could be a potential tool for MRD assessment. Moreover, parallel analyses of matched tissues and leukocytes might be required to accurately detect clinically relevant ctDNA in the clinical laboratory.

PB1070. Detection of *EGFR* exon skipping variants using clinical sequencing and its application

Authors:

S. Kim, S. Hwangbo, S. Lee, H. Yun; Seoul Natl. Univ. Hosp., Seoul, Korea, Republic of

Abstract Body:

The epidermal growth factor receptor (EGFR) gene is amplified in multiple tumors including brain and lung cancers, and some of those amplifications accompany EGFR exon skipping variants of which resultant transcript lacks a specific range of exons. To date, many EGFR exon skipping variants have been reported, such as vII (skips exon 14 and 15), vIII (skips exon 2 to 7), and vIV (skips exon 25 to 27 or 25 and 26). Since many studies successfully showed their oncogenic roles, those exon skipping variants are considered as a promising anti-cancer drug target. Despite its potential, detecting the exon skipping variants from clinical data is still limited, and only a few studies demonstrated its identification using Next-Generation Sequencing (NGS) technology. In this study, we developed a straightforward approach to identify EGFR exon skipping variants using targeted sequencing which is frequently used for clinical purposes. The developed algorithm enables identification of three EGFR exon skipping variants (vII, vIII, and vIV) from either DNA or RNA targeted sequencing dataset. We applied the variant detecting algorithm to a large-scale clinical sequencing dataset of 2,897 DNA-RNA matched cancer samples and successfully identified 44 putative EGFR exon skipping variants (5 EGFRvII, 30 EGFRvIII, and 9 EGFRvIV) from 35 (1.21%) samples. Most (38/44, 86.4%) of the EGFR variants were identified from glioblastoma multiforme (GBM) and several variants (3/44, 6.8%) came from lung cancer. All the EGFR exon skipping variants except 1 specific case was accompanied by EGFR amplification. In conclusion, our developed approach effectively detected the EGFR exon skipping variants from targeted sequencing data for clinical use. To accurately identify the exon skipping variants, both DNA and RNA sequencing would be necessary.

Cancer Posters - Thursday

PB1071. Detection of somatic copy number alterations using paired DNA and RNA sequencing

Authors:

M. Lastrapes^{1,2}, Z. Ozcan^{1,2}, Y. Jakubek³, J. Wong², P. Scheet^{1,2}; ¹UTHIth.MD Anderson Graduate Sch. of BioMed. Sci., Houston, TX, ²Dept. of Epidemiology, MD Anderson Cancer Ctr., Houston, TX, ³Dept. of Internal Med., Univ. of Kentucky, Lexington, KY

Abstract Body:

Somatic copy number alterations (SCNAs) have long been known to contribute to tumorigenesis and even show prognostic importance in many different types of cancer, though robust detection of SCNAs requires significant coverage across the genome. Detection of SCNAs is classically done using DNA microarray or whole-genome sequencing of DNA, but recent work has shown promising results in detecting SCNAs from whole exome sequencing (WES) data. With the increase in multi-omic cancer datasets, we hypothesize that the combination of paired DNA sequencing and RNA sequencing (RNAseq) data can further improve detection of SCNAs from NGS data by increasing overall genomic coverage. Here, we evaluate SCNA detection using a haplotype-based approach, applied to both WES data alone and in combination with RNAseq from 95 participants of The Cancer Genome Atlas glioblastoma (TCGA-GBM) project. Genotyped single-nucleotide polymorphisms (SNPs) from each data type were aggregated within unique samples, then input into our computational pipeline for detecting SCNAs from SNP data (hapLOH). The resulting detected SCNAs were benchmarked against the Affymetrix SNP array data, and performance of our analysis of combined data was compared to our analysis of WES alone. We report that SCNA detection using combined data resulted in a 10% absolute increase in sensitivity with only a 2% decrease in specificity at the gene-level relative to WES data alone, showing potential for the use of aggregation of DNA and RNA sequencing to better detect SCNAs in cancer tissue. To further account for this decrease in specificity, we plan to extend this work by exploring additional methods of combining genotype information from data sources and controlling for possible confounders such as RNA coverage bias due to highly expressed genes or genotype disagreements between data types. Our initial analysis of SCNA detection from combined DNA and RNA sequencing shows promising improvements compared to using either DNA or RNA alone, highlighting the clinical benefit of fully leveraging multi-omic datasets in genomic characterization of tumors.

Cancer Posters - Wednesday

PB1072. Determining the mechanisms of radioresistance in breast cancer

Authors:

B. McBean¹, A. Michmerhuizen¹, K. Wilder-Romans¹, B. Chandler², L. Lerner¹, M. Liu¹, A. Boyle¹, C. Speers¹; ¹Univ. of Michigan, Ann Arbor, MI, ²Dana-Farber Cancer Inst., Boston, MA

Abstract Body:

Background: Breast cancer (BC) is the most diagnosed cancer globally and is the deadliest for women. Clinical management of BC includes radiation therapy (RT), with upwards of 85% of women receiving RT as part of their treatment regimen after breast conserving surgery. Although effective, over 10% of women will develop a local recurrence despite RT, a rate that is much higher in women with triple-negative or inflammatory BC. Unfortunately, the molecular mechanisms that underly RT response and intrinsic radioresistance or radiosensitivity are poorly understood. We hypothesized that transcriptomic and proteomic changes that occur early and late after ionizing radiation in intrinsically radiosensitive and resistant BC models would offer mechanistic insight into mediators of this differential response. To test this, we conducted time-course RNA-seq and reverse-phase protein array (RPPA) experiments to characterize transcriptomic and proteomic changes following RT across a panel of BC cell lines of varying levels of intrinsic radiation. **Methods:** Clonogenic survival assays were used to measure the surviving fraction (SF) after 2 Gy of RT across 21 BC cell lines where SF was used as a continuous. On 12 of these cell lines, we also treated cells with 4 Gy RT and RNA was collected 3, 12, and 24 hours after treatment for sequencing and differential gene expression analysis with DeSeq2. Protein was collected 1, 12, and 24 hours after radiation for RPPA analysis with SuperCurve. **Results:** Clonogenic survival identifies a range of radiation sensitivity in human BC cell lines (SF 77%-17%) with no significant correlation ($r < 0.3$) to the intrinsic BC subtype. Using the most radiosensitive (ACC-422 and HCC-1937) and radioresistant (MDA-MB-453 and BT-549) cells, we performed pathway enrichment analysis for genes differentially expressed after RT. Among the most highly enriched pathways from the transcriptomic data, we found processes including DNA damage repair, apoptosis, and cell cycle maintenance. From the proteomic data, we found that proteins including p53, Bcl-2 family proteins, and cell cycle proteins exhibit expression changes after 1 hour. **Conclusions:** Ionizing radiation induces transcriptomic and proteomic expression changes that differ between intrinsically sensitive and resistant BC models. These pathways offer potential insight into the mechanisms underlying intrinsic radioresistance and suggest biologic vulnerabilities that may be targeted to more effectively treat women at a high risk of local BC recurrence. Genome wide CRISPR/Cas9 screens are currently underway in these breast cancer models to confirm these vulnerability targets.

Cancer Posters - Thursday

PB1073. Developing a high-quality, sample-to-result Hereditary Breast and Ovarian Cancer Panel Assay Pipeline for using a novel sequencing platform.

Authors:

A. Bhattacharjee¹, G. Liu¹, E. Frise¹, S. Kruglyak², B. Lajoie², K. Blease², J. Zhao², M. Reese¹, S. Levy²; ¹Fabric Genomics, Oakland, CA, ²Element BioSci.s, San Diego, CA

Abstract Body:

Background: Recent testing recommendations for *BRCA1/2* emphasize the changing landscape for hereditary breast and ovarian (HBOC) from medical history-based to genomic screening approach, and the public health benefit due to clear actionability and ascertainment of the latter approach. Currently, 20 genes are recommended for screening for HBOC based on payor reimbursement and evidence-based guidelines. However, prevention remains inadequate; plagued by a) high test cost, and b) challenges in NGS data quality in genes that are difficult to resolve by standard targeted sequence capture. Most sequencing platforms offer cost effective sequencing with substantial multiplexing. Therefore, high-throughput sequencers do not often fit well with smaller scale clinical testing platforms that require fast turn-around times and the ability to process a few samples at a time. **Approach:** We developed a cost-effective comprehensive testing approach using a novel sequencing platform that enables flexibility in scale while matching the cost of the highest throughput platforms. The Element Aviti benchtop sequencer provides a testing solution with flexible scale that enables small batch sizes with low error rate and novel performance for mutation detection of both point mutations and indels. Nine genes (*BRCA1*, *BRCA2*, *EPCAM*, *MLH1*, *MSH2*, *MSH6*, *PMS2*, *PTEN*, *STK11*) often include challenging CNV events that are relevant to report in the screening test. We explore software and library preparation methods to enhance the detection of complex variants in these genes. Screening accuracy performance was assessed on all workflows on a blinded series of samples using custom CNV calling tools across the 9 genes. **Results:** In a pilot study of 51 patient samples we have compared current clinical short read sequencing with a new sequencing platform by Element Biosciences. The error profiles look similar and overall concordance for a total of 272 clinical relevant variants from ClinVar show concordance in 270 cases with 2 sites being inconclusive due to a neighboring homopolymer run for both platforms. All 10 pathogenic variants including CNV variants could be detected on both platforms. We will further present a summary and comparison of the utilized workflows for target capture and sequencing with a focus on CNV workflow to detect CNV events in challenging regions. **Conclusion:** A novel NGS algorithm was optimized for detecting SNVs, indels and CNVs including difficult CNV events that met the cost and quality aspects. Its routine use would therefore enable early surveillance. The approach can be extended to other application of screening of public health importance.

Cancer Posters - Wednesday

PB1074. Development and Clinical Validation of a Bioinformatics Pipeline for Cancer Transcriptome Sequencing

Authors:

K. Cao¹, L. Fumin², F. Xu¹, Z. Fan¹, M. Li¹; ¹Children's Hosp. of Philadelphia, Philadelphia, PA, ²Univ. of Los Angeles, Los Angeles, CA

Abstract Body:

Tumor transcriptome profiling has emerged as the method of choice to identify cancer-related genomic alterations, especially for fusion genes and targetable altered pathways. However, the clinical application of transcriptome sequencing (TS) is lagging due to a lack of clinically validated bioinformatics pipeline. We designed, validated, and implemented a clinical bioinformatics pipeline (ConcordR) for the cancer TS test to support the needs of precision cancer care.

The ConcordR aligns paired fastq files of tumor samples to the human reference genome; the alignments are then analyzed for gene fusion using multiple tools to maximize the detection rate. After stepwise-structured multiple-layer filtrations using internal databases, the fusion results from different callers are merged and annotated. In parallel, the TPM of each gene is calculated and normalized based on selected housekeeping genes. The gene expression data of the tumor are then compared to that of pan-cancer and different tumor cohorts to identify differentially expressed (DE) genes for potentially targetable biomarkers, gene expression signature and pathway analyses to inform personalized patient care.

The accuracy and precision of fusion detection using ConcordR were evaluated using 66 tumor samples previously studied. ConcordR correctly identified all fusions in positive cases and no fusion in negative cases in a double-blind manner, resulting in 100% sensitivity and specificity. The reproducibility and repeatability of gene expression profiling were assessed by sequencing five tissue types each in triplicates in different batches. Statistical analyses showed that the identification of DE genes is highly reproducible on all tissue types except FFPE samples, which demonstrated significant variations. Clinical validation showed that ConcordR successfully identified cases with gene overexpression such as *MYCN* overexpression in pediatric neuroblastomas, *CCNE1* and *MYC* overexpression in pediatric osteosarcomas. Clinical application of ConcordR has facilitated the diagnosis of many undiagnosed cancers, such as the identification of a novel fusion *ATXNIL-NUTM2A* in a patient with congenital disseminated tumor of unknown origin leading to the diagnosis of *CIC*-rearranged sarcoma. ConcordR has also detected biomarkers for targeted therapy, such as targeting *EGFR* overexpression in high grade gliomas.

In summary, we have developed a clinical bioinformatics pipeline for pediatric cancer transcriptome sequencing. The validation results demonstrate robust analytic accuracy and precision in gene fusion identification and gene expression profiling in most tissue types.

Cancer Posters - Thursday

PB1075*. Development and Clinical Validation of a Liquid Biopsy Assay for Neurofibromatosis 1.

Authors:

F. Xu¹, C. Kotch¹, M. Koptyra¹, M. Lueder¹, W. Fu¹, K. Cao¹, A. Long¹, Z. Fan¹, S. Brown¹, T. De Raedt¹, J. Foster¹, M. Fisher¹, M. Li^{1,2}; ¹Children's Hosp. of Philadelphia, Philadelphia, PA, ²Univ of Penn, Philadelphia, PA

Abstract Body:

Introduction: Neurofibromatosis type 1 (NF1) is an autosomal dominant tumor predisposition syndrome affecting 1 in 2500 individuals. Common NF1-associated tumors include low and high-grade gliomas, and peripheral nerve sheath tumors. NF1 patients often have a high number of low-grade tumors of which only some will undergo malignant transformation. Detecting this progression early is challenging but extremely important, as the associated mortality is very high. Moreover, NF1 patients often have multiple tumors and standard imaging is unable to distinguish benign from malignant tumors. We developed a liquid biopsy (LB) NGS assay to detect tumor-associated mutations in cell-free DNA (cfDNA) with the goal of early detection of transforming or transformed tumors and defining the molecular makeup of the tumors. **Methods:** The assay interrogates 20 genes commonly mutated in NF1-related malignancies. A total of 45 plasma samples were collected from NF1 or other patients with tumors harboring mutations covered by the assay. Two positive and 9 negative cfDNA controls were used to evaluate the accuracy and precision of the assay. cfDNA was extracted using QIAamp Circulating Nucleic Acid Kit. The yield and integrity of cfDNA were determined by Qubit and qPCR, respectively. The regions of interest were enriched using the anchored multiplex PCR method and sequenced using NovaSeq 6000 or MiSeq. The sequence data were processed using Archer Analytics v6.0. **Results:** All known variants including 19 samples with known NF1 germline mutations and 32 mutations in the positive controls were correctly identified at comparable variant allele fractions (VAF), demonstrating 100% sensitivity. No false-positive variants were identified in the negative controls, indicating 100% specificity. The reproducibility and repeatability of the assay were 100% based on the inter-run and intro-run of two positive controls. The assay reliably detected variants at 0.5% VAF and can detect variants with VAF <0.1% using a modified bioinformatics pipeline. 13 mutations found in the tumor samples were identified in 8 plasma samples with a VAF range from 0.07% to 3.60%. Early data suggest that the presence of tumor-associated mutations in cfDNA appeared to be associated with tumor size; however, more cases are needed to confirm this finding. **Summary:** We developed and validated an NF1 LB panel that can effectively detect mutations in cfDNA with a 100% sensitivity and specificity using validation samples. Hence, this assay could potentially be used as a non-invasive method to monitor patients with NF1 serially to identify early-stage malignancies and potentially tumors under malignant transformation.

Cancer Posters - Wednesday

PB1076. Development of a breast cancer risk prediction model with carrier status, a polygenic risk score, and epidemiologic risk score.

Authors:

S. Kalia¹, N. Boddicker², S. Yadav², C. Hu², F. Couch², **P. Kraft¹**, the CARRIERS Consortium; ¹Harvard T.H. Chan Sch. of Publ. Hlth., Boston, MA, ²Mayo Clinic, Rochester, MN

Abstract Body:

Breast cancer has been associated with monogenic, polygenic, and epidemiologic (clinical, reproductive and lifestyle) risk factors, but direct empirical data on their joint effects is limited. We extended a risk model incorporating pathogenic variants (PV) in six breast cancer predisposition genes and a 105-SNP polygenic risk score (PRS) to include an epidemiologic risk score (ERS). This study was performed in a population-based sample of more than 22,700 cases and a similar number of age-matched controls from the Cancer Risk Estimates Related to Susceptibility (CARRIERS) Consortium. We assessed effect measure modification among the modeled factors, age, and family history of breast cancer: interaction terms were chosen via penalized logistic regression with cross validation. Our final model includes a synergistic interaction between the ERS and PRS, and antagonistic interactions among age, PRS and *BRCA1/2* status. Adding the ERS increases risk discrimination from an AUC of 0.67 (95% CI: 0.66-0.67) for a model with PV and PRS, to an AUC of 0.68 (0.68-0.69) with addition of the ERS. A 40-year-old female at the median PRS with the highest ERS has an odds of breast cancer two times that of an age-matched female at the median PRS but with the lowest ERS, while the same odds ratio among 70-year-old females is 4.5.

Our results illustrate that the ERS, alone and in combination with the PRS, can contribute to clinically meaningful risk stratification across high-risk thresholds for recommending risk-reducing medications and breast MRI screening, especially for carriers of a PV in a moderate penetrance gene such as *ATM* or *CHEK2*. Although all *ATM* or *CHEK2* carriers are classified above the 20% lifetime risk threshold for breast MRI based on their monogenic risk alone, 28.5% of *ATM* carriers and 17.0% of *CHEK2* carriers with a family history of breast cancer and 60.1% of *ATM* carriers and 46.6% of *CHEK2* carriers without a family history are reclassified below the threshold when the ERS and PRS are incorporated into the risk prediction. *CHEK2* carriers at the 10th percentile of the joint distribution of ERS and PRS, without a family history of breast cancer, have a predicted lifetime risk of 12.5%, near the average of 13% for a female in the US. Appropriately integrating monogenic, polygenic, and epidemiologic risk factors to improve breast cancer risk prediction models may inform personalized screening protocols and prevention efforts.

Cancer Posters - Thursday

PB1077. DHGAN, Digital Histology Generative Adversarial Networks Used in Creating Synthetic Genitourinary Tissue Slides

Authors:

H. Arora¹, D. Van Booven², A. Noman³, F. Ismael³, I. Xu¹, V. Sandoval⁴, J. A. Gomez⁵, S. Punnen¹; ¹Univ. of Miami, Miami, FL, ²Univ Miami Miller Sch Med, Miami, FL, ³Dow Univ. of Hlth.Sci., Karachi, Pakistan, ⁴Western Univ., Dept. of Surgery Div. of Urology, London, ON, Canada, ⁵Western Univ., Dept. of Pathology and Lab. Med., London, ON, Canada

Abstract Body:

Introduction: Recent integration of open-source data to machine learning models, especially in the medical field, in the domain of image analysis has opened new doors to studying disease progression and/or regression. However, limitations of the medical data for machine learning approaches is the insufficient quantity and quality (technical variation including bubbles in the slide, discoloration, and tissue folding) of data to a particular medical condition. In this context, synthetic data augmentation by using generative adversarial networks (GAN) could potentially generate high-quality data that preserve clinical variability. **Methods:** Tissue images were downloaded from 11 different genitourinary tissues from the Genotype-Tissue Expression Database (GTEx) Histology Repository. Images were subjected to quality control using HistoQC, and then segmented to patch sizes which ranged from 64, 128, and 256 with PyHIST. A conditional GAN was coded to create new synthetic images based of these training segments. The synthetic segments were then given to board certified pathologists for inspection and quality control. A separate classification machine learning step was used at the final stage that included the RNA sequencing data obtained from GTEx to assign accuracy to classify synthetic images to their proper tissue group. **Results:** Upon inspection 80% of the synthetic tissue images were assigned as “passed QC” by our pathologists. Further, the classification algorithm was able to assign on average 73.2% of the synthetic images to their correct origin. Patch size accuracy was determined to be lower than larger patches (45.5% vs 73.2%). Final accuracy numbers were found to be higher in the RNA sequencing classification network at an average of 91.0%. **Conclusions:** Using the GAN to create synthetic images is approaching a level of accuracy similar to any other successful classification method. With some work on the image analysis, the synthetic images will reach a quality which can assimilate clinical variability of original histology.

PB1078. Diagnostic gene fusion detection in cancer by adaptation of short-read CHOP Fusion Panel to Oxford Nanopore long-read sequencing.

Authors:

K. Rybacki^{1,2}, L. Fang², F. Xu², Y. Hu², M. Ahsan², M. Li^{2,3}, K. Wang²; ¹Univ. of Pennsylvania, Philadelphia, PA, ²Children's Hosp. of Philadelphia, Philadelphia, PA, ³Univ. of Pennsylvania Med. Sch., Philadelphia, PA

Abstract Body:

Gene fusion is the process where two distinct genes fuse, typically as the result of structural variants such as chromosomal translocation, interstitial deletion, or chromosomal inversion, or rarely, trans-splicing events. Gene fusions can be used as biomarkers in cancer diagnosis and possible therapeutic targets. However, current short-read next-generation sequencing techniques have limitations in detecting the full spectrum of gene fusions and in resolving repetitive or low-complexity regions. In addition, indexing and pooling multiple samples can take a few days, which is not ideal for time-sensitive scenarios where gene fusions provide decision support for cancer diagnosis, treatment and prognosis. The Division for Genomic Diagnostics (DGD) at the Children's Hospital of Philadelphia (CHOP) previously developed a custom-designed RNA sequencing panel, CHOP Fusion panel, using anchored multiplex PCR technology. The panel interrogates 117 cancer genes known to be involved in gene fusions with diagnostic significance, and it works on bone marrow, blood, fresh/frozen tissue, and formalin-fixed, paraffin-embedded (FFPE) samples. We evaluated the possibility to adapt the CHOP Fusion Panel through long-read sequencing on the Flongle flowcell for fast-turnaround and low-cost sequencing with potential point-of-care applications. We performed pilot sequencing on five positive samples with paired Illumina data and determined gene fusion events by LongGF and other computational tools. Due to the high number of sequencing reads needed to confidently identify gene fusions, PCR validation was carried out for the identified gene fusions from LongGF. We also "Illuminized" the Nanopore long-read data into 150bp paired-end Illumina reads and evaluated short-read based computational pipelines. Our preliminary results suggest that sequencing can be stopped within 8 hours and data analysis can be completed within 1 hour, therefore offering significant advantages over conventional Illumina sequencing. In summary, this study demonstrated technical feasibility to adapt CHOP Fusion Panel and use an automated workflow for rapid detection of known and potential novel gene fusions on the Flongle flowcells via long-read sequencing.

PB1079. Dietary factors and endometrial cancer risk: A Mendelian randomization study.

Authors:

T. O'Mara, D. Glubb, X. Wang; QIMR Berghofer Med. Res. Inst., Brisbane, Australia

Abstract Body:

Given the strong association between obesity and endometrial cancer risk, dietary factors may play an important role in the development of this cancer. However, observational studies of micro- and macronutrients and their role in endometrial cancer risk have been inconsistent. Clarifying these relationships are important to develop nutritional recommendations for cancer prevention.

Using Mendelian randomization (MR), we investigated the effects of circulating levels of 14 micronutrients (α -carotene, β -carotene, calcium, copper, folate, iron, magnesium, phosphorus, retinol, vitamin B6, vitamin B12, vitamin C, vitamin E and zinc) as well as corrected relative macronutrient intake (protein, carbohydrate, sugar and fat) on endometrial cancer risk.

Two-sample MR for endometrial cancer and its subtypes (endometrioid and non-endometrioid histologies) was performed using genome-wide association study summary statistics from the Endometrial Cancer Association Consortium (up to 12,270 cases and 46,126 controls). Inverse-variance weighted MR analyses were performed, with sensitivity analyses (including MR-Egger and MR-PRESSO analyses) to verify MR assumptions. For macronutrient analyses, multivariable MR was performed to account for genetic correlation between phenotypes.

A relationship was observed between increased genetically predicted circulating vitamin C and endometrial cancer risk (OR per SD increase 1.41 95%CI 1.16-1.72 $P=0.0007$), consistent with a previous MR study. Investigation of macronutrients found increased sugar intake associated with risk of endometrial cancer (0.43 95%CI 0.24-0.79 $P=0.006$), and its subtypes (endometrioid 0.38 95%CI 0.19-0.77 $P=0.007$; non-endometrial cancer 0.09 95%CI 0.02-0.37 $P=0.0008$). Carbohydrate intake associated with reduced risk of endometrioid endometrial cancer risk (0.34 95%CI 0.15-0.74 $P=0.006$). Increased fat intake associated with increased risk of non-endometrioid endometrial cancer risk (10.7 95%CI 1.8-63 $P=0.008$). These results were consistent across sensitivity analyses. There were no significant results observed in multivariable MR analyses including all macronutrients.

In summary, these findings suggest that certain dietary factors influence endometrial cancer risk but further investigation is required.

PB1080*. Differentially expressed serum RNAs as potential early markers for primary sclerosing cholangitis-associated cholangiocarcinoma.

Authors:

G. Hemmrich-Stanisak¹, S. Juzenas¹, T. Folseraas², K. Boberg³, C. Schramm⁴, T. Karlsen², A. Franke¹; ¹Univ. of Kiel, Kiel, Germany, ²Res. Inst. for Internal Med., Div. of Surgery, Inflammatory Diseases and Transplantation, Oslo Univ. Hosp. Rikshosp.et and Univ. of Oslo, Oslo, Norway, ³Res. Inst. of Internal Med., Oslo Univ. Hosp. Rikshosp.et, Oslo, Norway, ⁴Univ. Med. Ctr. Hamburg-Eppendorf, Hamburg, Germany

Abstract Body:

Cholangiocarcinoma (CCA) is a common malignancy in patients with primary sclerosing cholangitis (PSC) and carries a high rate of mortality. Although the pathogenesis of CCA in PSC is largely unknown, inflammation-driven carcinogenesis concomitant with various genetic and epigenetic abnormalities are underlying factors. When PSC-associated CCA is diagnosed, most tumors are unresectable, and no effective medications are available. Given the poor therapeutic outcome, the surveillance and management of PSC patients who are at an increased risk of developing CCA are of importance. In this study we aim to identify differentially expressed candidate microRNAs and/or other small RNAs, that could be used as early markers to stratify PSC patients, which will develop PSC-associated CCA. To do so we performed differential expression analysis in a German cohort (n=65) between patients with PSC-associated CCA (n=11), PSC patients who developed CCA during a 3.5y follow-up period (n=21) and PSC patients that did not develop a malignancy (n=33). To identify potential prognostic RNA-markers we furthermore conducted survival and progression analyses on this data set. To validate our findings we plan to use a similar matched Norwegian cohort comprising 21 PSC-associated CCA patients, 19 patients that developed CCA (7y follow-up) and 25 PSC-only patients. Our exploratory results derived from the German data set already indicate several differentially expressed microRNAs that a) represent potential markers for the development and/or presence of PSC-associated CCA and b) are also among the top significant prognostic candidates in the survival analysis, thus might even serve as early cancer markers. All of the identified serum microRNAs await now validation in the above described independent Norwegian cohort.

PB1081. Discovery of novel predisposing coding and noncoding variants in familial Hodgkin lymphoma

Authors:

J. Myers¹, J. Flerlage¹, J. Maciaszek¹, N. Oak¹, S. Rashkin¹, Y. Hui¹, Y-D. Wang¹, W. Chen¹, G. Wu¹, T-C. Chang¹, K. Hamilton², S. Tithi¹, L. Goldin³, M. McMaster⁴, M. Rotunno⁵, N. Caporaso⁶, A. Vogt⁶, D. Flamish⁷, K. Wyatt⁷, J. Liu⁷, M. Tucker⁶, C. Mullighan¹, K. nichols¹, M. Metzger¹, J. Yang¹, E. Rampersaud¹; ¹St. Jude Children's Res. Hosp., Memphis, TN, ²Dana-Farber Cancer Inst., Boston, MA, ³DCEG/NCI, Bethesda, MD, ⁴DCEG/NCI/NIH/DHHS, Bethesda, MD, ⁵Natl. Cancer Inst., Bethesda, MD, ⁶NCI, Bethesda, MD, ⁷NIH, Bethesda, MD

Abstract Body:

Familial aggregation of Hodgkin lymphoma (HL) has been demonstrated in large population studies, pointing to a genetic predisposition to this hematological malignancy. To understand the genetic variants associated with the development of HL we performed whole-genome sequencing on 234 individuals with and without HL from 36 pedigrees that had 2 or more first-degree relatives with HL. Our pedigree selection criteria also required one affected individual to be less than 21 years of age and overall, the median age at diagnosis was 21.98 years of age (3 - 55 years). Rigorous family-based segregation analysis was performed for the identification of coding and noncoding variants using linkage and filtering approaches. Our rule-based variant prioritization identified 44 HL risk variants in 28 pedigrees, of which 33 are coding, and 11 are noncoding. Overall, there were 4 highly prioritized recurrent variants: a coding variant in KDR (rs56302315), a 5'UTR variant in KLHDC8B (rs387906223), a noncoding variant in an intron of PAX5 (rs147081110), and another noncoding variant in an intron of GATA3 (rs3824666). The GATA3 variant overlaps a DNase I hypersensitivity locus as well as TCF3 and TCF12 binding motifs and in silico prediction indicates a loss of binding potential for the variant compared to the reference allele. A newly identified splice variant in KDR (c.3849-2A>C) was observed for one pedigree and high confidence stopgain variants affecting IRF7 (p.W238*) and EEF2KMT (p.K116*) were also observed. KDR, KLHDC8B, PAX5, and GATA3 are well known HL candidate genes whereas IRF7 is known to play a role in innate immune response which could have implications with regard to viral infection for that pedigree, and EEF2KMT is a methyltransferase that could affect the epigenetic landscape in the pedigree it was observed in. Gene-level recurrence of different truncating variants was seen for POLR1E in three independent pedigrees as well. POLR1E was not on our candidate gene list; however, the finding is intriguing since interchromosomal arrangements involving POLR1E have been described in other types of B-cell lymphomas. While germline variants in KDR and KLHDC8B have previously been reported, PAX5, GATA3, IRF7, EEF2KMT, and POLR1E represent novel observations. Although there may be environmental factors influencing lymphomagenesis, we observed segregation of candidate germline variants likely to predispose Hodgkin lymphoma in the majority of pedigrees studied.

Cancer Posters - Thursday

PB1082. Discovery of transcriptomic predictors of colorectal cancer mortality by race and ethnicity

Authors:

H. Yin^{1,2}, J. R. Huyghe², D. Redwood³, T. A. Harrison¹, A. D. Dawson², S. S. Thomas², B. W. Seaton², A. K. Koehne², H. Green⁴, K. Nasir⁵, J. J. Tiesinga⁶, C. Whitlow⁴, L. Hsu², J. C. Figueiredo⁵, L. Li⁴, T. K. Thomas³, L. Christopher^{2,1}, U. Peters^{2,1}; ¹Univ. of Washington, Seattle, WA, ²Fred Hutchinson Cancer Ctr., Seattle, WA, ³Alaska Native Tribal Hlth.Consortium, Anchorage, AK, ⁴Ochsner Clinic Fndn., New Orleans, LA, ⁵Cedars-Sinai Med. Ctr., Los Angeles, CA, ⁶Alaska Native Med. Ctr., Anchorage, AK

Abstract Body:

Tribal Health Organizations recognize the high rates of colorectal cancer (CRC) among Alaska Native people and are undertaking initiatives to address it including improved screening and engaging in research. Tumor profiling study in patients from diverse racial and ethnic groups will lead to novel molecular insights about CRC. So, we designed a nested case-control study with including of 840 African American, Alaska Native, Hispanic, and non-Hispanic White CRC patients. We included 70 cases and 140 controls within each group. Cases were patients who died of CRC and controls were CRC patients who survived at least as long as the case and were matched on stage, tumor site, age, sex, race and ethnicity, and year of diagnosis. We are generating RNA-seq data using RNA extracted from formalin-fixed paraffin-embedded (FFPE) tumor tissues. Using the tumor transcriptomic data, our study aims to characterize tumor gene expression and immune microenvironment features, and evaluate their relationships with CRC mortality and risk factors (e.g. family history). Our initial RNA-seq run included 87 patients who were equally distributed across four racial and ethnic groups. Quality control and alignment metrics demonstrated good quality with a mean alignment rate of 96.4%, 80.4% mean specificity for exons, 17,368 mean number of genes detected, and a mean sequencing depth of 14.5 million uniquely mapping paired-end reads. One sample failed due to low exonic rate (17.7%) and 13 samples failed due to low sequencing depth (<5.5). Consensus molecular subtypes (CMS) were called among 74 patients. We observed 11 patients (14.8%) in CMS1, 30 patients (40.5%) in CMS2, 9 patients (12.2%) in CMS3, 7 patients (9.5%) in CMS4, and 17 patients (23.0%) in mixed types. We calculated a T cell-inflamed gene expression profile (GEP) score, a biomarker predicting response to checkpoint inhibitors and CRC-specific mortality. We observed differences in median GEP scores between populations and tumors from African American and Alaska Native patients having the highest GEP scores. Those preliminary results were limited by the small sample size and small proportion of lethal CRC outcomes (16.1%). We expect to have over 300 samples completed by summer 2022 and further analyses will be conducted then. With the inclusion of patients from more diverse populations, our study will help advance understanding of differences and similarities in the molecular and cellular landscape of CRC across racial and ethnic groups. This may also enhance the identification of novel clinically useful predictors of lethal CRC and potential novel therapeutic targets that could meaningfully reduce long-standing CRC disparities.

PB1083. Dissecting admixture effects on a 313-variant polygenic risk score model for breast cancer in a census-based cohort of Brazilians.

Authors:

T. Almeida¹, R. Barreiro², A. Farias¹, G. Souza¹, G. Tunes¹, E. Duim¹, C. Gomes³, M. Frederico², M. Farias¹, E. Amaro Jr.¹, B. Domingues Bitarello⁴, H. Brentani², M. Naslavsky⁵; ¹Hosp. Israelita Albert Einstein, São Paulo, Brazil, ²Hosp. Israelita Albert Einstein, Univ.e de São Paulo, São Paulo, Brazil, ³Univ.e de São Paulo, São Paulo, Brazil, ⁴Bryn Mawr Coll., Bryn Mawr, PA, ⁵Hosp. Israelita Albert Einstein, Univ. of Sao Paulo, Sao Paulo, Brazil

Abstract Body:

Complex disorders like breast cancer are described by a heritable polygenic component, environmental factors, and their interactions. Polygenic risk scores (PRS) partially represent the heritability captured by GWASs, but PRS transferability across populations is hampered by a complex interaction of population-specific factors, ultimately leading to differences in variant effects: demographic history, linkage disequilibrium (LD), variant frequency (AF-diff), presence of rare variants, epistasis, and GxE. This study aims to assess the transferability of a 313-SNP PRS (PRS₃₁₃) for breast cancer derived from a European ancestry (Eur) cohort in a census-based tri-hybrid - Eur, African (Afr), Native American - admixed sample of whole-genomes from Brazil (SABE1171, n=1171, abraom.ib.usp.br). We computed PRS₃₁₃ in 750 women (21 cases + 729 controls) in SABE1171 and used the UK Biobank (UKBB) as a gold-standard comparison. We find that the overall PRS distribution for SABE1171 was increased compared to the UKBB. Still, our area under the receiver operator curve (AUC) of 0.62 was equivalent to the UKBB-Eur AUC (0.63). To understand the influence of our small number of cases on the observed AUC, we contrasted the SABE1171—UKBB difference between mean and median PRS₃₁₃ values for cases and controls to 5,000 bootstraps of equally sized cases and control sets from the UKBB. SABE1171 mean PRS₃₁₃ difference adheres to the bootstrap, but the median PRS₃₁₃ difference is inflated, suggesting a few Brazilian cases might disproportionately impact the AUC result. To understand the effects of LD and AF-diff, we compared ancestry-stratified - Eur, Afr, East Asian (Eas) - LD patterns of 400kb windows around each PRS₃₁₃ SNP inferred from the 1000 Genomes Project (1KGP) to the LD pattern observed in SABE1171. For each LD window surrounding a PRS₃₁₃ variant, we calculated principal components (PCs) of LD values and the AF-diff between SABE1171 and each of the 1KGP ancestry groups. Based on the LD PCs and AF-diff, we conclude that SABE1171 cohort is more similar to Eur-1KGP than to either Afr- or Eas-1KGP, in agreement with the equivalent AUC results we obtained. Our preliminary findings indicate that using an LD and AF-diff informed PRS₃₁₃ for the SABE1171 cohort might be beneficial but will probably not suffice to achieve optimal prediction values. Alternatively, using effect sizes derived from admixed cohorts might yield better results. In brief, our study highlights the limitations of currently available PRSs when used outside of their respective discovery cohorts and showcases how deeply genotyped admixed populations can help understand PRS properties in admixed populations.

Cancer Posters - Thursday

PB1084. Does non-coding variation in known breast cancer susceptibility genes contribute to breast cancer risk?

Authors:

M. Akamandisa, B. Wubbenhorst, K. D'Andrea, H. Symecko, R. Gillette, P. Shah, A. Bradbury, K. Maxwell, S. Domchek, K. Nathanson; Univ. of Pennsylvania, Philadelphia, PA

Abstract Body:

Breast cancer (BC) is the most common malignancy and leading cause of cancer mortality in women. Average lifetime BC risk for a woman in the United States is 13%. However, pathogenic variants in BC susceptibility genes such as *BRCA1/2* and *PALB2*, or high polygenic risk scores substantially increase BC risk. Women with a family history of >2 1st or 2nd degree relatives with BC and/or ovarian cancer < age 60, BC < age 40, or BC and second primary tumor are considered high-risk and have greatly increased likelihood of having a pathogenic variant in a BC susceptibility gene. Yet, 70% of women with high-risk BC test negative for coding variants. In these women, possible causal variation could be non-coding in deep intronic or regulatory regions (promoters and enhancers), or cryptic structural variants (SV). To determine whether non-coding variation contributes to BC in 515 high-risk women testing negative for pathogenic coding variants in BC genes, we performed deep intronic splicing analysis using SpliceAI. We identified 7 potentially causal splicing variants in 13 (2.5%) samples in *BRCA1*, *ATM*, *RAD51C*, and *BRIP1*, three within 10bps of the exon border and the rest deeper in the introns, up to 1970bps. One *BRCA1* (c.4986+6T>G) and one *ATM* (c.8418+5_8418+8delGTGA) variant are known pathogenic but had not been previously reported. *In vitro* analysis to assess the impact of the identified variants on splicing and SV evaluation are underway. We performed whole genome sequencing of 24 high risk women (25% EOBC, 79.2% family history under 60, 25% multiple primaries) with no known mutations. We did not identify any splicing variants using SpliceAI or SVs likely to affect protein structure using Manta. To evaluate regulatory variation, we identified rare (<0.1% population frequency), heterozygous promoter and enhancer variants, and bioinformatically selected candidates for functional validation using GREEN-DB. Eighteen candidate non-coding variants in *BRCA1*, *PALB2*, *BARD1*, *ATM*, *CHEK2*, *RAD51C*, and *STK11* were identified in 10 (41%) samples. The variants have predicted scores of less than -1 for promoter/enhancer activity by DeepSea, lie within the 90th percentile of predicted deleteriousness by deep learning noncoding functional predictors JARVIS and/or ncER, and disrupt transcription factor binding sites. The candidate regulatory variants will be functionally validated *in vitro*. Understanding the level of contribution of non-coding variation in known BC susceptibility genes is critically important going forward, as results impact sequencing offered to patients, and if positive, their medical management.

Cancer Posters - Wednesday

PB1085. Dosing-specific modes of resistance to quizartinib in individual acute myeloid leukemia cells exposed by ResolveOME combined genomics and transcriptomics chemistry

Authors:

S. Velivela¹, i. González¹, V. Weigman¹, G. Harton², J. West³, J. Zawistowski⁴; ¹BioSkryb Genomics, Chapel Hill, NC, ²BioSkryb Genomics, Durham, NC, ³BioSkryb, Inc., Durham, NC, ⁴BioSkryb Genomics, Inc., Durham, NC

Abstract Body:

Dose and dose scheduling influence mechanisms of resistance to targeted therapeutics in clinical trials at both genomic and transcriptomic levels. To ascertain interplay between these levels, we created a model of quizartinib resistance in an acute myeloid leukemia (AML) cell line harboring an internal tandem duplication (ITD) mutation in *FLT3* with continual near-IC₅₀ (2 nM) dosing, and a second dose-escalation model where an initial 200 pM dose was increased by 100 pM at weekly intervals until the growth rate of the cells was near that of the treatment-naïve parental cells. We hypothesized that in utilizing single cell analysis between models we would see distinct, single-nucleotide and copy number changes, in conjunction with transcriptional adaptation and therefore employed ResolveOME to concomitantly assess DNA and RNA modulation. Copy number variation (CNV) analysis with BaseJumper showed that treatment-naïve parental single cells harbored Chr.5, 6 & 13 trisomies and pentasomy of Chr.8, consistent with karyotypic analysis. In the continual dosing model, resistance was correlated with gain of Chr. 19q and loss of Chr.5 trisomy to 2n level, whereby these modulations were heterogenous in single cells. By contrast, the dose-escalation model revealed Chr. 1q gain and Chr. 2p loss and ploidy reduction of Chr. 8 to 2n level in a fraction of the individual cells. At the single nucleotide variation (SNV) level, we identified a secondary mutation N841K in the drug target *FLT3*, present in all resistant cells of the continual dosing model and previously found in AML patients. We identified *FLT3* N841K only in a subset of dose-escalation single cells, and, intriguingly, the single cells that harbor this missense mutation lack the CNV specific to that model. This suggests differential mechanisms of resistance among single cells of a given treatment model, whereby N841K may be sufficient to drive resistance in isolation, but in other cells copy number alterations acquired during dosage increases were a primary mode of resistance. In addition to these divergent CNV paradigms we have defined AXL pathway bypass of FLT3 signaling inhibition via *GAS6* upregulation in resistant cells of the continual-dosing model and contrast the magnitude of this adaptation between single dose-escalation single cells. These data highlight distinct and heterogeneous modes of single-cell drug resistance depending on the nature and duration of the dosing and spotlight the necessity of joint genomic and transcriptomic information to comprehensively elucidate drug resistance mechanisms.

Cancer Posters - Thursday

PB1086. Dynamic play between human N a-acetyltransferase D and H4-mutant histones: Molecular dynamic study

Authors:

K. Srivastava, S. Rathod; CSIR-Central Drug Res. Inst., Lucknow, India

Abstract Body:

N-terminal acetyltransferases (NATs) are overexpressed in various cancers. Specifically in lung cancer, human N- α -acetyltransferase D (hNatD) is upregulated and prevents the histone H4 N-terminal serine phosphorylation, leading to the Epithelial-to-mesenchymal transition (EMT) of cancer cells. hNatD facilitates histone H4 N- α -terminal serine acetylation and halts the CK2 α -mediated serine phosphorylation. In the present study, we report the effects of four N-terminal mutant (S1C, R3C, G4D and G4S) histone H4 peptides on their bindings with hNatD by employing a molecular dynamics simulation. We also used graph theory-based analyses to understand residue correlation and communication in hNatD under the influence of WT and MT H4 peptides. Results show that S1C, R3C and G4S mutant peptides have significant stability at the catalytic site of hNatD. However, S1C, G4D and G4S peptides disrupt hNatD structure. Additionally, intramolecular hydrogen bond analysis reveals greater stability of hNatD in complex with R3C peptide. Further, intermolecular hydrogen bond analysis of acetyl-CoA with hNatD and its RMSD analysis in five complexes indicate that cofactor has greater stability in WT and R3C complexes. Our findings support previously reported experimental study on impacts of H4 mutations on its hNatD-mediated acetylation catalytic efficiency. The Betweenness centrality (BC) analysis further gives insight into the hNatD residue communication dynamics that can be exploited to target hNatD using existed or novel drug candidates therapeutically.

PB1087. EagleC: A deep-learning framework for detecting a full range of structural variations from bulk and single-cell contact maps.

Authors:

X. Wang, **Y. Luan**, F. Yue; Northwestern Univ., Chicago, IL

Abstract Body:

Hi-C technique has been shown to be a promising method to detect structural variations (SVs) in human genomes. However, algorithms that can use Hi-C data for a full-range SV detection have been severely lacking. Current methods can only identify inter-chromosomal translocations and long-range intra-chromosomal SVs (>1Mb) at less-than-optimal resolution. Therefore, we develop EagleC, a framework that combines deep-learning and ensemble-learning strategies to predict a full-range of SVs at high-resolution. Importantly, we show that EagleC can uniquely capture a set of fusion genes that are missed by WGS or nanopore. Furthermore, EagleC also effectively captures SVs in other chromatin interaction platforms, such as HiChIP, ChIA-PET, and capture Hi-C. We apply EagleC in over 100 cancer cell lines and primary tumors, and identify a valuable set of high-quality SVs. Finally, we demonstrate that EagleC can be applied to single-cell Hi-C and used to study the SV heterogeneity in primary tumors.

Cancer Posters - Thursday

PB1088. Efficacy of universal testing for hereditary cancer syndromes: A community based cancer center (CBCC) experience.

Authors:

A. Hamblett¹, E. Molle¹, C. Van Der Walt², K. Kunze², M. Golafshar², A. Malon¹, E. Edward³, R. Nussbaum³, J. Samadder², J. Drew¹; ¹Middlesex Hlth., Middletown, CT, ²Mayo Clinic, Scottsdale, AZ, ³Invitae, San Francisco, CA

Abstract Body:

Background: Identification of pathogenic germline variants (PGVs) can inform cancer treatment, identify family members at increased cancer risk, and alter cancer screening/risk reduction recommendations. Historically, genetic testing has been pursued for patients who meet published guidelines based on age at cancer diagnosis, tumor characteristics, or family history. Research has shown that guideline directed germline testing misses 50% of PGVs in cancer patients at academic medical centers, but 85% of cancer patients receive care in community settings. A knowledge gap exists as to the ability of guidelines to predict PGVs in cancer patients seen outside of academic medical centers. The study aimed to evaluate whether using existing guidelines is sufficient for identifying patients with PGVs in a CBCC.

Methods: We completed a prospective study of germline genetic testing among patients with solid tumor malignancies aged 18-75 at a CBCC between December 2019 - May 2022. The patients were unselected for cancer type, stage, family history, and race/ethnicity. PGVs were identified using an 84-gene panel and were stratified by penetrance. National Comprehensive Cancer Networks (NCCN) 2020/2021 guidelines were used to determine incremental PGV rate which describes those patients with PGVs who did not meet NCCN guidelines or had PGVs that were not consistent with their history.

Results: 269 patients were enrolled, majority were female (56.5%), white (90.0%) with a median age of 63.0 years. The cohort was composed primarily of breast (27.9%), prostate (24.2%), and lung (12.3%) cancer patients. A total of 46 PGVs were identified in 44 of 269 (16.4%) patients, with 41.3% of PGVs stratified as high or moderate penetrance. Of those with detected PGVs, 56.8% did not meet NCCN guidelines based on cancer diagnosis or family history. Of those with detected PGVs, those with variants of uncertain significance (VUS), and those with negative results, 43.2%, 51.8%, 52.3% respectively met NCCN guidelines. Although not statistically significant ($p > 0.05$), this shows an 8-9% lower rate of meeting NCCN guidelines for those with PGVs. The incremental PGV rate was 67.4%.

Conclusions: This study found that patients with PGVs were not more likely to meet guidelines than negative or VUS patients, indicating that NCCN guidelines were not more efficient in detecting PGVs. A large percentage of patients had PGVs which would have been missed based on NCCN guidelines or recommended cancer-specific testing panels, suggesting that guideline directed testing was not effective in identifying cancer patients with PGVs in a CBCC.

Cancer Posters - Wednesday

PB1089. EG VEGF in ovarian cancer and preeclampsia as an early diagnostic marker: toward a targeted therapy in the treatment of tumors, especially those resistant to chemotherapy.

Authors:

M. Benfateh, T. Abouessaouira; Univ. hassan ii, Casablanca, Morocco

Abstract Body:

EG VEGF is an angiogenic factor whose biological activity is mediated via two receptors coupled to the G protein, the prokineticin receptor (PROKR1) and (PROKR2). The expression of this factor in the placenta and the female reproductive system opens perspectives of its implication and that of its receptors in many processes other than placentation. This will allow establishing its value as a predictive marker in the occurrence of many pregnancy pathologies, such as preeclampsia, but also in female cancer pathologies, such as ovarian cancer. The aim of this work is to study was first to identify the epidemiological profile of the risk factors for the occurrence of these two pathologies and secondly, to characterize the role of EG VEGF and its receptors PROKR1 / PROKR2 in epithelial ovarian cancer. The thesis project was based on an epidemiological and a molecular study. The study is a retrospective descriptive one, that was undertaken over a period of 2 years, during which we collected the cases of preeclampsia and ovarian cancer, managed in the department of Gynecology-Obstetrics "C" Service and the oncology center of Ibn Rochd University Hospital of Casablanca. The molecular study is a prospective, control cases, spread over four years, during which serum assays and an immunohistochemical studies, were carried out on patients with ovarian cancer. Our results showed that the frequency of preeclampsia was about (7.1%). The epidemiological profile was represented by primiparous woman, with average age 30 years that have not been followed up on their pregnancy. The risk factors frequently found are obesity and chronic hypertension associated with vascular-renal history; abortion and perinatal death associated with history of obstetrics. For ovarian cancer, the prevalence is 2.7%, the average age of patients is 51.47 ± 13 years, and the significant risk factors observed are multiparity, menopause as a personal history and hypertension as a medical history. Cystic-looking tumors, on the right side, cystadeno-carcinoma constituted the most frequent histological type. 74.8% cases of metastasis were reported, including 44.3% of peritoneal carcinosis. The molecular showed a potential involvement of the EG-VEGF / PROKRs system in the development and progression of the epithelial ovarian cancer.

The determination of the role of this pro-angiogenic and pro-inflammatory factor could constitute an early diagnostic marker of these pathologies, along with the possibility to constitute a targeted therapy in the treatment of tumors, especially those resistant to chemotherapy.

PB1090. Eligibility, uptake and response to germline genetic testing in women with DCIS

Authors:

R. Ellsworth¹, L. Turner², L. Lovejoy³, C. Turner⁴, C. Shriver⁵; ¹Murtha Cancer Ctr., Bethesda, MD, ²Anne Arundel Med. Ctr., Annapolis, MD, ³Windber Res. Inst., Windber, PA, ⁴NIH, Bethesda, MD, ⁵Uniformed Services Univ. of the Hlth.Sci. and Walter Reed Natl. Military Med. Ctr., Bethesda, MD

Abstract Body:

Background Ductal carcinoma *in situ* (DCIS) is both a malignant, yet pre-invasive disease of the breast. While the majority of DCIS have a low risk of recurrence, a subset of women with germline pathogenic variants (PV) in cancer predisposition genes are at increased risk for breast cancer recurrence. Uptake of genetic testing and subsequent surgical intervention in women with DCIS has not been well-studied. The aim of this study was to evaluate test eligibility, uptake and impact on surgical decision making in women with DCIS. **Methods** All women diagnosed with unilateral DCIS 2001-2020 enrolled in the Clinical Breast Care Project were identified. Demographic, commercial genetic test results and surgical procedures were extracted from the database. Test-eligibility was assigned using National Comprehensive Cancer Network (NCCN) criteria. Panel genetic testing was performed in the research setting using DNA from 465 women. Statistical analyses were performed using Fisher's exact tests and Chi-square analyses with $p < 0.05$ defining significance. **Results** Forty-two percent of women were test-eligible at diagnosis with an additional 12.8% meeting eligibility criteria >1 year after diagnosis. Within the test-eligible group, 34.5% pursued clinical genetic testing and 17.3% pursued testing only after a second cancer event. Of the 39 women with PV, 20 (51.3%) were detected only in the research setting, with 11 (28.2%) of these women not eligible for genetic testing based on NCCN criteria. In women who did not undergo BM at diagnosis, recurrence was significantly higher ($p=0.001$) in women with PV (33.3%) compared to those without PV (11.8%).

Conclusion Pursuit of genetic testing and subsequent use of risk-reducing surgeries in women with PV was suboptimal in women with a primary diagnosis of DCIS. In conjunction, >50% of PV were detected only in the research setting. Because omission of genetic testing in women with DCIS may represent a lost opportunity for prevention, genetic testing at the time of diagnosis should be standard for all women with DCIS. **Disclaimer** The contents of this publication are the sole responsibility of the author(s) and do not necessarily reflect the views, opinions or policies of Uniformed Services University of the Health Sciences (USUHS), The Henry M. PB1091. Elongin C (*ELOC/TCEB1*) gene: a novel cause of von Hippel-Lindau disease

Authors:

A. Andreou¹, B. Yngvadottir¹, L. Bassaganyas¹, G. Clark¹, E. Martin¹, J. Whitworth², A. J. Cornish³, Genomics England Research Consortium, R. Houlston⁴, P. Rich⁵, C. Egan⁶, S. V. Hodgson⁷, A. Y. Warren⁸, K. Snape⁹, E. Maher²; ¹Univ. of Cambridge, Cambridge, United Kingdom, ²Univ Cambridge, Cambridge, United Kingdom, ³Div. of Genetics and Epidemiology, The Inst. of Cancer Res., London, United Kingdom, ⁴The Inst. of Cancer Res., Sutton, United Kingdom, ⁵Dept. of Neuroradiology, St George's Univ. Hosp. NHS Fndn. Trust, London, United Kingdom, ⁶Moorfields Eye Hosp. NHS Fndn. Trust, London, United Kingdom, ⁷St George's Hosp Med. Sch, London, United Kingdom, ⁸Dept. of Histopathology, Cambridge Univ. NHS Fndn. Trust, Cambridge, United Kingdom, ⁹St George's Hosp., London, United Kingdom

Abstract Body:

Background: Around 95% of patients with clinical features diagnostic of Von Hippel-Lindau disease (VHL) have a detectable inactivating germline variant in *VHL*. The VHL protein (pVHL) functions as part of the VCB-CR complex which plays a key role in oxygen sensing and degradation of hypoxia inducible factors. To date, only variants in *VHL* have been shown to cause VHL disease. **Materials and Methods:** We undertook trio analysis by Whole-exome sequencing (WES) in a proband with VHL disease but without a detectable *VHL* mutation. Molecular studies were also performed on paired DNA extracted from the proband's kidney tumour and blood and bioinformatics analysis of sporadic renal cell carcinoma data set was undertaken. **Results:** A *de novo* pathogenic variant in *ELOC* (NM_005648.4:c.236A>G [p.Tyr79Cys]) gene was identified in the proband. *ELOC* encodes elongin C, a key component [C] of the VCB-CR complex. The p.Tyr79Cys substitution is a mutational hotspot in sporadic VHL-competent renal cell carcinoma (RCC) and has previously been shown to mimic the effects of pVHL deficiency on hypoxic signalling. Analysis of a RCC from the proband showed similar findings to that in somatically *ELOC* mutated RCC (expression of hypoxia responsive proteins, no somatic *VHL* variants and chromosome 8 loss). **Conclusions:** These findings are consistent with pathogenic *ELOC* variants being a novel cause for VHL disease and suggest that genetic testing for *ELOC* variants should be performed in individuals with suspected VHL disease with no detectable *VHL* variant.

Cancer Posters - Thursday

PB1092*. Enhanced expression of mutant alleles of cancer driving genes in pan-adenocarcinoma

Authors:

C. Lo^{1,2}, N. Fujito¹, H. Nakaoka³, K. Hosomichi⁴, I. Inoue¹; ¹Human Genetics Lab., Natl. Inst. of Genetics, Mishima City, Shizuoka Prefecture, Japan, ²Dept. of genetics, Sch. of Life Sci., The Graduate Univ. for Advanced Studies (SOKENDAI), Kanagawa Prefecture, Japan, ³Dept. of Cancer Genome Res., Sasaki Inst., Tokyo, Japan, ⁴Dept. of Bioinformatics and Genomics, Kanazawa Univ., Kanazawa Prefecture, Japan

Abstract Body:

Among cancer driver genes, the effects of oncogenesis or the impacts of insufficiency in tumor suppression can be intensified by increasing the expression of mutant alleles through the observed **allelic imbalance in transcriptional efficiency (AITE)** effect. And, this is in contrast to those mutated passenger genes, whose normal alleles are instead increased in the expression for buffering the mutant proteins. We have analyzed large-scale pan-adenocarcinoma samples from The Cancer Genome Atlas (TCGA) program (n=3256). The genotypes and allele specific copy numbers inside each gene were firstly checked by SNP array and whole exome sequencing data (WESeq). Then, based on the paired RNA sequencing data (RNASeq), the AITE effects were screened for those heterozygous positions without existing allele specific somatic copy number alterations (SCNA). Among those somatic mutations, most nonsynonymous SNV mutations of well-known **cancer driver genes biased their expression toward the mutant allele** in statistically significant ways, where the average mutant allele frequency (MAF) in RNASeq was significantly **higher** than that in WESeq (Welch's t-test, $p = 1.63 \times 10^{-5}$ for *TP53*; $p = 1.36 \times 10^{-14}$ for *KRAS*; $p = 9.75 \times 10^{-4}$ for *CTNNB1*; $p = 3.80 \times 10^{-3}$ for *PTEN*). In contrast, the nonsynonymous SNV mutations of **passenger genes biased their expression toward the normal (reference) allele**, where the average MAF in RNASeq was significantly **lower** than that in WESeq (Welch' t-test, $p = 2.33 \times 10^{-20}$ for *COL3A1*; $p = 1.52 \times 10^{-5}$ for *CDH11*; $p = 5.82 \times 10^{-23}$ for *MYH11*; $p = 2.59 \times 10^{-5}$ for *PDGFRB*; $p = 4.41 \times 10^{-3}$ for *TNC*; $p = 1.01 \times 10^{-12}$ for *PTPRC*). Especially, those AITE genes with increased mutant allele expression could mostly be found with a few sites which equipped relatively high mutation frequency, belonged to positive selection signals. Overall, the tumors showed the significant higher AITE occurring rates in their genomes when being compared to the paired-solid-normal tissues (Welch's t-test, $p < 2.2 \times 10^{-16}$, n=152). By further comparing their whole genome sequencing data (WGSeq), more *de novo* transposable elements (TE) insertion sites were also detected inside tumors than that inside normal tissues with significance (Welch's t-test, $p=0.0456$, n=27). Within 1 Mbp around of AITE genes, tumor-specific *de novo* TE insertions were discovered to be associated with AITE occurrence.

PB1093. Estimating total tumor-specific microRNA content in human tissues using computational deconvolution

Authors:

M. Montierth^{1,2}, G. A. Calin², W. Wang²; ¹Baylor Coll. of Med., Houston, TX, ²Univ. of Texas MD Anderson Cancer Ctr., Houston, TX

Abstract Body:

Transcriptomic change is a hallmark of cancer, and thus quantification and characterization of these changes is a key feature of modern clinical oncology. Recently, it has been shown that a deconvolution-based estimate of total mRNA expression per tumor cell (TmS) varies across and within cancer types and is a predictor of patient survival outcomes. It stands to reason that variation in total tumor cell expression of other RNA species may further capture important biological changes. MicroRNAs (miRNAs) are one of the many RNA species presented within a cell and are important post-transcriptional regulators with well-documented diverse roles in cancer, from initiation to progression and metastasis. Methods for studying tumor cell specific miRNAs have lagged behind mRNAs. Single cell miRNA studies are essentially nonexistent, and many existing transcriptomic computational deconvolution methods are inadequate to study miRNAs. To address these needs, we adapted DeMixT, a semi-unsupervised transcriptomic deconvolution method, to miRNA, and we introduce a deconvolution-based estimate of total tumor cell miRNA content (TmiS). Using matched DNaseq/miRNAseq data for 4,167 patient samples across 14 cancer types from The Cancer Genome Atlas (TCGA), we quantified tumor-specific total miRNA expression, using tumor miRNA proportion, which is estimated from deconvolution of bulk miRNAseq data, and further adjusting for tumor purity and ploidy, which are estimable through genomic deconvolution. We found that TmiS varies across cancer types and differs between relevant clinical subtypes within cancer type. We observed that generally across cancers, high TmiS is associated with increased risk of disease progression and death, after adjusting for stage and age. We replicated the associations between TmiS and breast cancer subtypes that we observed in TCGA-BRCA in 1,293 patient samples from the Molecular Taxonomy of Breast Cancer Consortium (METABRIC). Taken together, we find evidence for TmiS as a potential pan-cancer biomarker and prognostic indicator

PB1094. Evaluating biomarker potential of germline genomic factors for predicting clinical outcomes in prostate cancer.

Authors:

N. Zeltser¹, K. E. Houlahan¹, S. M. Al-Hiyari¹, S. E. Eng¹, Y. Patel¹, T. N. Yamaguchi¹, S. Tao¹, R-R. Huang¹, R. E. Reiter¹, H. Ye¹, A. S. Kinnaird^{1,2}, P. C. Boutros¹; ¹Univ. of California, Los Angeles, CA, ²Univ. of Alberta, Edmonton, AB

Abstract Body:

Prostate cancer is the second-most diagnosed cancer and the second leading cause of cancer death in American men. Early detection is common, but is followed by the more challenging task of prognosing a highly variable clinical course. Current clinical risk-assessment strategies such as serum abundance of prostate specific antigen (PSA), tumor size and extent, and tumor grade based on biopsy are highly imprecise: over a third of patients are over-treated. An improved method of risk stratification may lie in hereditary factors. Prostate cancer is one of the most strongly inherited ($h^2 = 57\%$), with accumulating evidence associating rare variants, common variants, and genetic ancestry to clinical outcomes. We have performed germline sequencing on blood from thousands of patients diagnosed with localized prostate cancer and with extensive follow-up data. We quantify the interactions of rare and common variants, and demonstrate that germline features provide insights into patient outcomes and optimal management strategies.

PB1095. Evaluation of miR-21 and miR-938 expression in the progression of gastric cancer in the Magellanic Chilean cohort - MAGIC.

Authors:

D. Zapata-Contreras^{1,2}, A. Altamirano³, S. Karelavic³, C. Urrea³, F. Orellana³, C. Delgado³, M. Iriarte³, M. Puente³, L. Leiva³, L. Godoy³, O. Gallardo¹, P. Zúñiga^{1,2}, Y. Espinosa-Parrilla^{1,2,4}; ¹Med. and Evolutionary Genomics in Magallanes (GEMMa), Ctr. for Ed., Hlth.care and Investigation (CADI-UMAG), Punta Arenas, Chile, ²Sch. of Med. – Univ. of Magallanes, Punta Arenas, Chile, ³Regional Clinical Hosp. of Magallanes, Punta Arenas, Chile, ⁴InterUniv. Ctr. for Hlth.y Aging (CIES), Punta Arenas, Chile

Abstract Body:

Gastric Cancer is a leading cause of global cancer morbidity and mortality, being the third-leading cause of cancer death worldwide. Its clinical outcome is highly dependent on local progression and metastasis development, which is partially controlled by oncogenes and tumour suppressor genes that are further regulated by microRNAs, small endogenous regulatory RNAs involved in the control of multiple biological pathways. Aberrant microRNA expression in cancer has been found to correlate with the diagnosis and stage of many cancer types including gastric cancer and, due to its high stability, microRNAs have emerged as potential effective prognostic and diagnostic biomarkers. In view of the high mortality rates of gastric cancer in Latin America, it is necessary to find specific biomarkers to trace its diagnosis and progression for these specific populations that have not yet been studied and have a different genetic pool, as the Chilean population. For that purpose, we recruited a cohort (MAGIC) in the extreme south of Chile, Magallanes, of more than 500 individuals with suspected gastric disease through endoscopy from 2018 to date. A liquid biopsy, together with tissue from biopsies and gastrectomies (if the procedure was necessary for diagnosis/recovery) were obtained from patients at different stages of gastric cancer progression. As a first approach, a comparative expression analysis of two microRNAs involved in gastric cancer was performed for their validation in the MAGIC cohort. The microRNAs evaluated were miR-21, which has been reported to be upregulated in gastric cancer in other populations, and miR-938 for which we previously reported a genetic association with gastric cancer probably through deregulation of the *CXCL12* axis. The expression analysis by qRT-PCR in tumoral and adjacent normal tissues of patients at different stages of the disease showed an increase of 0,5 in the expression of miR-21 in advanced tumoral tissues compared with normal tissues and of 2 in the expression of miR-938 in early tumoral tissues compared with normal and advanced tumoral tissues (Tukey's Anova test, $p < 0.05$). The expression analysis of these two miRNAs and their target genes is now under further investigation in the MAGIC cohort. These results are consistent with the recognized value of miR-21 as a biomarker of gastric cancer in other populations and point towards a potential significance of miR-938 as a diagnostic biomarker of early gastric cancer.

Cancer Posters - Wednesday

PB1096. Evaluation of non-coding regulatory variants in susceptibility of Chordoma

Authors:

S. Yepes Torres¹, J. Bai², C. Li², S. Gui², W. Luo¹, J. Liu¹, H. Koka¹, B. Hicks¹, A. Goldstein¹, R. Yang¹; ¹Div. of Cancer Epidemiology and Genetics, Natl. Cancer Inst., NIH, Bethesda, MD, ²Beijing Tiantan Hosp., China, China

Abstract Body:

Chordoma is a rare bone cancer with etiologic factors largely unknown. Brachyury, which is encoded by *TBXT*, a transcription factor critical for notochord develop, is essential for chordoma pathogenesis. We previously identified *TBXT* as a major chordoma susceptibility gene. However, genetic causes in the majority of familial and sporadic chordoma patients remain largely unknown. The role of non-coding variants in chordoma susceptibility has not been explored. Computationally predicting non-coding regulatory variants is important because of the high volume of causal candidate variants in regulatory regions and the challenges of functional validation. The goal of this study is to identify potentially functional non-coding regulatory variants in a previously described 1.5-Mb *TBXT* super-enhancer associated region and the 5p15.33 *TERT* promoter region, which is a well-characterized regulatory region that contains genetic variants associated with multiple cancer types, in a Whole-Genome Sequencing (WGS) dataset of 80 Chinese patients with skull-base chordoma. Prediction scores based on different assumptions of causality and complementary statistical models from aggregated scores and ensemble prediction models from the comprehensive resource regBase, which integrates non-coding variant prediction scores from 23 tools (Zhang S, Nuc Acid Res, 2019), were applied for variant prioritization. We also used the GWAS catalog to incorporate significant disease-associated SNPs (P-value < 5E-8) at the *TERT* region from 10 GWAS fine-mapping studies that confer risk of multiple cancers to investigate those variants in the chordoma dataset. The analyses identified several score peaks, with approximately 19 score peaks colocalized with significant disease-associated variants identified from the *TERT* promoter region, e.g., rs13172201, rs10069690, and rs2853669. Among prioritized variants identified by regBase models, rs2853669 showed one of the most significant scores. This SNP was previously validated and shown to disrupt the *TERT* promoter and confer cancer risk by extensive functional experiments. Potential variants upstream of *TBXT*, such as g.166478324 (G>A), had the largest cancer driver potential prediction score and warrant further investigation. Analyzing the score spectrum of the ensemble prediction models applied across the studied regions has facilitated the identification of non-coding regulatory variants with functional, pathogenic, and driver potential that may contribute to chordoma susceptibility. Future investigations include expanding candidate gene regions and replicating top variants in independent datasets.

Doddato^{1,2}, R. Tita³, M. Bruttini^{1,2,3}, A. Fabbiani^{1,2,3}, C. Lo Rizzo³, A. Pinto³, A. Carrer^{1,2,3}, L. Loberti^{1,2,3}, P. Ilardi^{1,2,3}, M. Manara^{1,2,3}, F. Mari^{1,2,3}, F. Ariani^{1,2,3}, A. Renieri^{1,2,3}; ¹Med. Genetics, Univ. of Siena, Siena, Italy, ²Med Biotech Hub and Competence Ctr., Dept. of Med. Biotechnologies, Univ. of Siena, Siena, Italy, ³Genetica Medica, Azienda Ospedaliera Univ.ria Senese, Siena, Italy

Abstract Body:

The majority of cancer driver genes have moderate to low penetrance. However, the molecular bases of incomplete penetrance have still not been fully understood yet. We wanted to explore the model of transmission by performing Exome Analysis (EA) in 40 families in which the DNA of at least two affected members was available. In a relevant percentage of cases (30%) the pathogenic variant (P) identified in one cancer gene did not segregate with the disease in the family. We found another variant of unknown significance (VUS) in another cancer driver gene segregating with the disease. Relevant cases will be presented, including one familial melanoma with not segregating *P/RAD50* and segregating *VUS/PMS2*, one familial breast cancer with not segregating *P/ERCC2* and segregating *VUS/ERCC5*, one familial colon cancer with not segregating *P/MSH6* and segregating *VUS/MSH3*. We then explored additional cases (80) in which only one affected member was available. In a significant fraction of patients (10%) we identified P variants in 2 different cancer driver genes. Combinations among others were: *P/ATM/P/MSH3* in pancreatic cancer, *P/SMAD9/P/SEC23B* in breast cancer, *P/RAD50/P/PRKN* in melanoma, *P/SBDS/P/BRCA2* in prostate cancer, *P/RBI/P/ERCC3* in melanoma, *P/BRCA1/P/SLC26A3* in breast cancer, *PMS2-deletion/P/ERCC4* in colon cancer. Finally, we explored if the number of rare P-VUS (MAF<0,01) in cancer driver genes of cancer patients (30 patients) differs from that identified in non-cancer subjects (50 subjects). We identified a mean of 2,8 P-VUS in patients and a mean of 1,6 P-VUS in controls with a p-value between them of 0,0008 obtained with Mann-Whitney U Test. In summary, these data can give us the evidence that cancer may have a polygenic inheritance and that also familial cancer genetic susceptibility, could be the result of more than one variant in cancer driver genes.

Ctr., Leiden, Netherlands, ²⁹Dept. of Human Genetics, Leiden Univ. Med. Ctr., Leiden, Netherlands

Abstract Body:

Genetic susceptibility to breast cancer is known to be conferred by a combination of common variants identified through genome-wide association studies together with rarer coding variants with higher disease risks. The latter include protein-truncating variants (PTVs) and/or rare missense variants in *ATM*, *BARD1*, *BRCA1*, *BRCA2*, *CHEK2*, *RAD51C*, *RAD51D*, *PALB2* and *TP53*. However, these variants explain ~20% of the familial relative risk of breast cancer and the overall contribution of coding variation

to breast cancer is unclear. To evaluate the role of rare coding variants more comprehensively, we performed a meta-analysis across three large whole-exome sequencing datasets: 2 datasets from the Breast Cancer Association Consortium together with UK Biobank. These datasets comprised 16,498 cases and 182,142 controls primarily of European ancestry. Burden tests were performed for protein-truncating and rare missense variants in 16,562 and 18,681 genes respectively. To improve power, we incorporated data on family history of breast cancer. Associations between protein-truncating variants and breast cancer were identified for 7 genes at exome-wide significance ($P < 2.5 \times 10^{-6}$): the five known susceptibility genes *BRCA1*, *BRCA2*, *CHEK2*, *PALB2* and *ATM*, together with novel associations for *ATRIP* and *MAP3K1*. Predicted deleterious rare missense or protein-truncating variants were additionally associated at $P < 2.5 \times 10^{-6}$ for *SAMHD1*. All 3 novel genes have prior evidence of involvement in tumorigenesis or DNA repair. *MAP3K1* is a well-established breast-cancer GWAS locus; however, the observed PTV burden was independent of the GWAS associations. We used an empirical Bayes approach to estimate the overall exome-wide contribution of protein-truncating variants to the familial relative risk (FRR) of breast cancer: under the best fitting model, the contribution of rare PTVs beyond previously known genes explains ~2% of the FRR, with ~130 genes being associated. We demonstrate that large exome sequencing studies, combined with efficient burden analyses, can identify additional breast cancer susceptibility genes, and that further large-scale analyses are likely to identify further genes, but that most of the “missing” heritability is likely to be found in the non-coding genome.

Cancer Posters - Thursday

PB1099. Expanding the clinical and molecular spectrum of hereditary *TINF2* cancer predisposition syndrome reporting a family with Hodgkin Lymphoma

Authors:

E. Agolini¹, F. Locatelli¹, F. Berardinelli², A. Alesi¹, S. Russo¹, S. Genovese¹, A. Sgura², R. Amato², M. Matraxia¹, S. Petrocchi¹, D. Cocciadiferro¹, M. Lodi¹, K. Girardi¹, R. De Vito¹, A. Novelli¹, L. Vinti¹; ¹Ospedale Pediatrico Bambino Gesù, Rome, Italy, ²Università Roma Tre, Rome, Italy

Abstract Body:

TINF2 (TERF1 Interacting Nuclear Factor 2) gene encodes TIN2 protein, a critical subunit of the shelterin complex, which protects telomere ends from being recognized as damaged DNA sites and also serve to regulate telomere length maintaining chromosome stability. Pathogenic missense and truncating *TINF2* variants are causative for dyskeratosis congenita (DC), a rare bone marrow failure syndrome, inherited as autosomal dominant disorder, characterized by mucocutaneous abnormalities associated with very high risks of developing aplastic anemia, myelodysplastic syndrome, leukemia, and solid tumors. TIN2-DC variants localize to a 30 amino acid coding stretch in exon 6 called the 'DC cluster'. Recent reports show that specific *TINF2* truncating variants act as high penetrance cancer predisposition alleles outside DC context, with a relevant risk to develop different tumors including melanoma, thyroid and breast cancer. Based on these reports, *TINF2* acts as a haploinsufficient tumor suppressor resulting in excessive telomere elongation. Here, we describe a novel heterozygous loss-of-function germline variant c.248_249del (p.Leu83GlnfsTer53) in *TINF2* (NM_001099274.3) in a family with two young sisters affected by nodular sclerosing Hodgkin lymphoma without any of the DC symptoms. This variant was identified by family-based clinical exome sequencing and was inherited from the apparently healthy mother. Further studies on patient's lymphocytes to evaluate telomere length and additional cytogenomics analysis on the tumor DNA are currently in progress. In conclusion, this report expands the clinical and molecular spectrum of hereditary *TINF2* cancer predisposition syndrome, reporting for the first time an association between a novel deleterious variant of this gene and Hodgkin lymphoma risk.

Cancer Posters - Wednesday

PB1100. Exploring the non-invasive potential of miRNA 145 and miRNA 363 in Prostate Cancer

Authors:

A. Manoj, A. MAHDI, M. AHMAD, M. Kumar; King George's Med. Univ., Lucknow, India

Abstract Body:

Owing to the misdiagnosis and over-treatment of prostate cancer, due to its indolent growth and false-positive errors produced by diagnostic ways like PSA level, DRE, and biopsy. Consequently, there is an urgent need for reliable diagnostic and detection technologies to diagnose aggressive prostate cancer non-invasively by exploring the potential of circulating microRNAs. Efficient and reliable markers within the body fluids can help in personalized treatment decisions for monitoring disease and survival. MicroRNA (miRNA) are highly conserved small non-coding RNA that modulate genes involved in numerous biological processes and form part of complex networks that play a significant role in prostate cancer initiation and progression. In keeping this view, we have designed our study to investigate biomarker potential miRNA 145 and miRNA 363 in prostate cancer. We determined the comparative expression of miRNA 145 in benign prostatic hyperplasia (BPH) and prostate cancer blood samples by Real Time-PCR and performed the Receiver Operating Characteristics (ROC) curve analysis. Further, we explored target genes of miRNA using In-Silico tools like TargetScan, miRDB, and miRWalk3.0 and performed gene and pathway enrichment analysis using DAVID 6.8. Our observation suggests a significant tumor-suppressive role of miRNA 145 and the oncogenic role of miRNA 363 in prostate cancer compared to BPH. Computational analysis reveals that miRNA 145 and miRNA 363, both target genes like E2F3, NRAS, PTEN, FOXO1, etc., play a significant role in prostate cancer survival and progression. Finally, ROC curve analysis predicts that miRNA 145 (AUC 0.822***) and 363 (AUC 0.852***) have good biomarker potential for distinguishing BPH from prostate cancer. Collectively these results reveal that miRNA 145 and miRNA 363 expression may act as a non-invasive biomarker for effective diagnosis of Prostate Cancer. For future suggestions, the target genes evaluation may provide therapeutic targets for better treatment and management of prostate cancer.

PB1101. Family History-Based Risk of BRCA Mutations in the Malian Populations

Authors:

B. Baba; USTTB, Bamako, Mali

Abstract Body:

In 2021, the US Preventive Services Task Force recommended that women at a high risk of deleterious BRCA mutations, based on family history, be referred by primary care providers for genetic counseling and evaluation for testing. It is estimated that 2% of U.S. women have a family history necessitating referral for genetic counseling. The estimated combined frequency of BRCA mutations in the U.S. is approximately 0.25%. We assessed the proportion of women in Mali at high risk of carrying a BRCA mutation based on family history. We analyzed data from the 2021 Mali Health Interview Survey (CHIS), a population-based telephone survey that collects state and local data on a range of health topics. The 2021 survey included a detailed cancer family history module. We estimated the probability the respondent carried a BRCA mutation using BRCAPRO. We imputed the current age of family members and their age at cancer diagnosis. We estimated the current age as a function of the respondent's age. We estimated the age of cancer diagnosis of family members who had cancer before age 50 years as a random variable from a uniform distribution with a lower limit of the estimated current age and an upper limit of 50 years. The minimum ages for breast cancer and ovarian cancer onset were set at 25 and 35 years, respectively. The minimum estimated probability was 0.0000014% and the maximum was 94%. The 98.5 percentile for the population was 0.63%. Therefore, <1.5% of the population had an estimated probability of BRCA mutations > 1.0%; <0.5% had an estimated probability of BRCA mutations > 10.0%. The CHIS data had some other limitations. The respondent's history of ovarian cancer was not available. No information was available on BRCA mutation testing, so the predictive value of the risk estimate could not be determined. CHIS asks respondents about breast cancer twice -during the regular questionnaire and in the family history module, but only asks for age of diagnosis in the family history module. Therefore, we had to estimate the age at diagnosis for women who reported breast cancer only in the regular questionnaire. The methods we used to estimate the age of cancer diagnosis are biased towards underestimating the age of cancer diagnosis, since cancer incidence increases with age. Since younger age at diagnosis is associated with an increased risk of having a BRCA mutation, we may have overestimated the probability of carrying a BRCA mutation.

PB1102. Filling gaps in whole genome analysis in hematology: A chance for optical mapping and long-read NGS.

Authors:

J. Savara^{1,2}, J. Manakova¹, R. Nesnadna¹, A. Petrackova¹, J. Minarik³, T. Papajik³, P. Gajdos², E. Kriegova¹; ¹Dept. of Immunology, Faculty of Med. and Dentistry, Palacky Univ. and Univ. Hosp., Olomouc, Czech Republic, ²Dept. of Computer Sci., Faculty of Electrical Engineering and Computer Sci., VSB-Technical Univ. of Ostrava, Ostrava, Czech Republic, ³Dept. of Hemato-Oncology, Faculty of Med. and Dentistry, Palacky Univ. and Univ. Hosp. Olomouc, Olomouc, Czech Republic

Abstract Body:

Background: Genomic profiling is widely recognised as a key approach for patient management and the development of treatment strategies in hematology. Yet traditional methods have limitations and novel techniques such as whole genome mapping, long-read/single-cell sequencing and epigenomics may further impact our knowledge about the disease-associated aberrations.

Methods: To demonstrate the potential of novel whole genome approaches, we applied optical mapping (OM; Bionano Genomics; ~350x coverage) and long-read next-generation sequencing (lr-NGS) (TELL-Seq; ~100x coverage) to analyze myeloma cells (CD38+CD138+, >86%) enriched from paired samples of peripheral blood (PB; infiltration 27%) and bone marrow aspirate (BM; infiltration 62%) obtained from a patient with extramedullary multiple myeloma (MM; female, 39 years, IgG lambda, stage IIIA, ISS II). Comparison of OM and lr-NGS data was performed using om-annotsv-svc tool (<http://olgen.cz/en/resources>).

Results: OM in BM-derived MM cells detected five translocations (VAF 12-63%), two large deletions on chromosomes (chr)1 (30.6 Mbp) and chr6 (29.3 Mbp), and 1249 deletions (size 1.8 kbp-4.5 Mbp), most of them hardly detected by short-read NGS. Out of these structural variants (SVs) in BM, PB-derived MM cells carried t(1;8), two different t(4;7), large chr6 deletion, but not t(2;15), t(14;19) and large chr1 deletion. Comparison with lr-NGS confirmed 57% (4/7) translocations/large deletions detected in BM. Regarding other SVs, 45% deletions (561/1249), 3% inversions (5/167) and 8% duplications (6/74) detected by OM were confirmed using available lr-NGS variant callers. However, our preliminary results showed that many of missed SVs detected by OM are also present in lr-NGS data. Detected translocations encompassed numerous MM-associated genes (e.g. t(1;8) *TENT5C* and *POU5F1B* in close proximity to *MYC* and t(4;7) *NSD2* and *CREB3L2* genes) as well as genes associated with other cancers (e.g. t(14;19) *NACCI* and t(12;15) *SLC12A6* genes). All aberrations detected by diagnostic FISH/array-CGH (4p16 *NSD2/FGFR3*, 8q24 *MYC*, 13q14 *RBI*, trisomy chr3, chr15 and monosomy chr13, chr23) were confirmed by OM.

Conclusions: Our data revealed that OM may detect additional disease-associated genetic aberrations in hematologic cancers, not detected by NGS. Our pilot analysis suggests that these aberrations are missed in lr-NGS due to the limitations of currently available variant callers. Both OM and lr-NGS may help to improve our understanding of the genomic landscape, not only in hematology.

PB1103. Finding Therapeutic Targets in Cancer Cells Using Essential Genes

Authors:

T-V. Tran, K. Pull, K. Bussey; Midwestern Univ., Glendale, AZ

Abstract Body:

Essential genes are those with functions required for an organism to live and reproduce. Essential genes in one species may not be essential in other species. This suggests essentiality is dependent on context. The atavism theory of cancer proposes cancer represents a reversion to ancestral unicellular pathways and phenotypes. We hypothesize that mode of life, e.g., unicellular or multicellular, is a context for essentiality. Furthermore, if cancer is a reversion to unicellular behavior, genes that are essential in the unicellular context but non-essential in the multicellular context represent targets for therapeutic development.

To test our hypothesis, we focused on nine model species (*E. coli*, *S. cerevisiae*, *S. pombe*, *A. thaliana*, *D. melanogaster*, *C. elegans*, *D. rerio*, *M. musculus*, and *H. sapiens*) that are well-characterized both genetically and phenotypically. We mined Ensembl PanCompara Genomes to obtain a list of orthologous genes that included all the species of interest. This ensured that a lack of essentiality was not due to a lack of an orthologous gene. We used the Online Gene Essentiality (OGEE) Database v2 to define whether a gene was essential for a species. We then classified orthologous gene groups by how many species in which the gene was essential. Genes that were only found to be essential in *E. coli*, *S. cerevisiae*, and *S. pombe* were defined as essential in unicellular life (UCL). Orthologs that were essential in all examples of multicellular life, but not essential in UCL, were defined as essential in multicellular life (MCL).

We did not find any genes that were essential in all species. We discovered 43 genes that were essential in only yeast and mice. Functional enrichment analysis using DAVID revealed these genes are enriched in functions related to glucose transport and metabolism. We identified 12 genes that are essential in a UCL context and 11 genes that are essential in a MCL context. Using Ensembl VEP, we examined the differences in the types and functional outcome of observed variation between UCL and MCL essential genes in multicellular organisms. Chi-square analysis of mouse data demonstrated that the distribution of variant consequences was different between those genes classified as essential in UCL versus those classified as essential in MCL. UCL essential genes had three times as many observed variants as did MCL essential genes. UCL essential genes also had all classes of variants observed, while MCL essential genes had no instances of variations leading to alterations in stop codons or frameshifts and proportionally more synonymous variants.

The findings of the study demonstrate that mode of life can serve as a context for gene essentiality.

Cancer Posters - Wednesday

PB1104. Frequently mutated TOP2B binding sites reveal candidate structural and regulatory cancer drivers of hepatocellular carcinoma

Authors:

L. Uuskula-Reimand¹, C. Lee², D. Abd-Rabbo², S. Ahktar Alvi¹, M. Bhat³, M. Wilson⁴, J. Reimand²; ¹The Hosp. for Sick Children, Toronto, ON, Canada, ²Ontario Inst. for Cancer Res., Toronto, ON, Canada, ³Univ. Hlth.Network, Toronto, ON, Canada, ⁴SickKids Res. Inst./ Univ. of Toronto, Toronto, ON, Canada

Abstract Body:

Whole genome sequencing (WGS) of many cancer types has revealed an enrichment of somatic mutations at the binding sites of CTCF and the cohesin complex at boundaries of topologically associating domains (TADs). This is an unexplained phenomenon that is especially evident in hepatocellular carcinoma (HCC). We previously demonstrated that topoisomerase II beta (TOP2B), an enzyme that catalyses transient DNA double strand breaks (DSBs), interacts and extensively co-localizes with CTCF and cohesin in mouse liver, leading to the hypothesis that TOP2B activities may contribute to the mutational processes in HCC.

To understand the role of TOP2B in somatic mutagenesis in HCC, we characterized the genome-wide binding of TOP2B, CTCF and the cohesin complex subunit RAD21 in the genomes of primary human HCCs. Our analysis of somatic mutations in the WGS data of 300 HCC tumors demonstrated that the enrichment of somatic mutations is focal to the co-binding of TOP2B, CTCF and RAD21, including TAD boundary regions shared by a large number of human tissues. Interestingly, TOP2B-RAD21 binding sites associated with liver enhancers are also strongly enriched in mutations. Genome-wide cancer driver discovery revealed 49 frequently mutated candidate drivers in HCC, 36 of which occurred at binding sites of TOP2B. Furthermore, we observed significantly frequent non-coding driver mutations in additional cancer types that are exposed to exogenous carcinogens, such as esophagus, colorectal, lung and skin cancers. Since the majority of candidate non-coding driver mutations are located in TOP2B-associated structural and regulatory elements of the cancer genome, we propose that TOP2B-mediated DSBs represent a mutational mechanism at CTCF and cohesin binding sites that is active in liver and other cancer types.

Cancer Posters - Thursday

PB1105. Functional characterization of the 1p36.33 pancreatic cancer GWAS locus

Authors:

K. Connelly¹, E. Abdolalizadeh¹, J. Zhong¹, D. Eiser¹, J. Hoskins², A. O'Brien¹, A. Jermusyk³, I. Collins⁴, Pancreatic Cancer Cohort Consortium, Pancreatic Cancer Case-Control Consortium, R. Stolzenberg-Solomon¹, A. Klein⁵, J. Shi⁶, B. Wolpin⁷, J. Smith⁸, G. Petersen⁹, L. Amundadottir¹⁰; ¹Natl. Cancer Inst., Bethesda, MD, ²Natl. Cancer Inst., Rockville, MD, ³Natl. Cancer Inst., NIH, Bethesda, MD, ⁴NIH, Bethesda, MD, ⁵Johns Hopkins Med Sch, Baltimore, MD, ⁶Natl. Cancer Institute, Bethesda, MD, ⁷Dana Farber Cancer Inst., Boston, MA, ⁸Georgetown Univ., Washington, D.C., DC, ⁹Mayo Clinic, Rochester, MN, ¹⁰NIH, Rockville, MD

Abstract Body:

Pancreatic ductal adenocarcinoma (PDAC), the third leading cause of cancer-related deaths in the US, is often difficult to diagnose. Genome-wide association studies (GWAS) have identified twenty common susceptibility loci for PDAC. One locus identified, at chr1p36.33 (tagged by rs13303010, OR=1.26, $P=8.36 \times 10^{-14}$), maps to a gene-dense topologically associated domain (TAD) containing four genes: *NOC2L*, *KLHL17*, *PLEKHNI1*, and *SMAD11*. Bayesian and other fine-mapping strategies identified 13 candidate causal variants within this genetic signal to carry forward for functional studies. Of these 13 variants, four demonstrated allele-specific binding in electrophoresis mobility shift assays (EMSA). These four variants were then examined for allele-specific regulatory effects using luciferase assays. Three variants (rs13303327, rs13303010, rs13303160) demonstrated allele-specific regulatory effects with the alternate (protective) alleles having higher activity. To identify transcription factors that exhibit allele-specific binding and mediate allele-specific gene regulation, we performed SNP-proteomics and *in silico* transcription factor binding prediction on these variants. We identified several proteins exhibiting allele-specific binding. For rs13303327, we focused on ELF2, an ETS family transcription factor, identified in both the proteomics and *in silico* analysis. We further confirmed that ELF2 is involved in allele-specific binding of rs13303327 by EMSAs. For rs13303160, *in silico* analysis revealed AP1 transcription factors as likely allele-specific binding proteins. Ongoing *in vitro* experiments aim to validate the *in silico* prediction. The top candidate functional variants in 1p36.33 have significant expression quantitative trait loci (eQTL) associations with *NOC2L* (rs13303160, $P=8.2 \times 10^{-6}$, normalized effect size = -0.27) and *KLHL17* (rs13303160, $P=2.3 \times 10^{-10}$, normalized effect size = 0.37, GTEx v8, pancreas). Co-localization analyses suggest the GWAS, *KLHL17* and *NOC2L* eQTLs represent a single, common genetic signal (posterior probability= 0.99 and 0.75, respectively). *KLHL17* and *NOC2L* knockdown decrease cell proliferation in pancreatic cancer cell lines. Ongoing work aims to validate the allele-specific binding of the functional variants and better understand their downstream biological consequences influencing PDAC pathogenesis.

Cancer Posters - Wednesday

PB1106*. Functional screens implicate candidate breast cancer risk genes in T cell-mediated immune-surveillance

Authors:

J. Beesley¹, W. Shi¹, J. M. Burrows¹, A. Civitaresse¹, J. Rosenbluh², C. Smith¹, G. Chenevix-Trench¹; ¹QIMR Berghofer, Brisbane, Australia, ²Monash Univ., Melbourne, Australia

Abstract Body:

Most loci identified by genome-wide association studies (GWAS) contain many candidate causal variants (CCVs), with molecular pleiotropy implicating multiple target genes, not all of which may be causal. CRISPR (clustered regularly interspaced short palindromic repeats) screens using trait-relevant phenotypes can provide an efficient way of identifying causal genes. We previously performed such screens to identify breast cancer (BC) risk genes involved in proliferation, tumorigenicity and DNA damage repair. To extend to other cancer hallmarks, we hypothesized that some risk genes are involved in immune system processes to detect and destroy transformed cells. Our previous analysis of the 191 target genes we computationally predicted at BC risk loci found immune system processes amongst the most enriched pathways. In order to identify GWAS target genes expressed by a BC cell line (MCF7) which might render it more sensitive or resistant to T cell killing (the dominant effector of immune-surveillance), we established a MCF7 and HLA-matched HER2-restricted T cell co-culture cytotoxicity assay. Using this assay, we have performed two CRISPR knockout (ko) screens: one genome-wide screen, and a custom library containing guides targeting predicted BC risk genes. We detected positive control genes (e.g. *IFNGR1*, *IFNGR2*, *JAK1* and *JAK2*) in both screens, and observed strong overall correlation of gene-level statistics ($r=0.45$). The genome-wide screen identified 13 genes and the custom screen identified 85 genes ($FDR<0.1$), including *CASP8*, *GATA3*, and *ESR1* (knockout rendered the cells resistant to T cell killing) and *CFLAR*, *SRM* and *EWSR1* (sensitivity genes) common to both. In order to determine whether *CASP8* expression might be regulated by the single fine-mapped CCV, we cloned a putative enhancer that contains rs3769821. The protective allele (associated with increased expression in breast tissue in GTEx) was significantly more active in a luciferase assay than the risk allele. Our results therefore suggest that one way in which *CASP8* acts as a BC risk gene is by conferring resistance to T cell killing when expression levels are reduced. We are now carrying out CRISPR inhibition screens, validation, bioinformatic analyses and luciferase assays to identify the causal variants regulating these risk genes. In conclusion, CRISPR screens are an efficient method to follow up GWAS findings.

Cancer Posters - Thursday

PB1107. Functionalizing methylation-derived gene panels in the UK Biobank, TCGA, and HCA datasets

Authors:

U. Mudgal, M. Pietras, Z. Pitluk, S. Moore, S. Sarangi; Paradigm4, Waltham, MA

Abstract Body:

Epigenetic perturbations are inheritable gene expression alterations without modification of the DNA sequence, and accumulation of such alterations are implicated in different types of cancer pathogenesis. One of the major epigenetic mechanisms involving direct chemical modification to the DNA is called DNA methylation, which has been shown to regulate gene expression by recruiting proteins involved in gene repression or by inhibiting the binding of transcription factors to DNA. Studies that identify methylation-derived gene biomarker panels are crucial for better understanding the etiology of cancers and to discover possible therapeutic targets. However, much work needs to be done to validate and functionalize these gene signatures for prospective classification of risk. Conducting population-scale hypotheses-driven validation studies pose challenges such as efficient storage of multi-omics data (e.g., TCGA, UK Biobank, Human Cell Atlas), running complex queries and computations at scale and across datasets, and creation of cohorts based on different metadata fields. The REVEAL FLASH software stack, comprising of a suite of data-specific apps, elastic scaling infrastructure, and a POSIX compliant networked file system, is ideal for performing these kinds of studies. In this poster, we present a use-case with a methylation-derived eight gene panel (*TCTEX1D4*, *MALE*, *LIME1*, *KLHL38*, *HPDL*, *ESR1*, *UCP2*, and *COMMD7*) from a published study on breast cancer (*Frontiers in Genetics*, 2020). First, we ran GWAS analysis using the UK Biobank for associations between variants in the gene panel members from the 200K Whole Exome Sequence dataset and phecodes derived from ICD10 diagnoses of multiple cancer types and other phenotypes of interest. We used SAIGE & REGENIE for the GWAS analysis and a custom linkage disequilibrium (LD) plus burden test algorithm for testing pairs of variants. Next, we looked for evidence of synthetic interactions in the TCGA dataset by querying for co-occurrence in the gene panel of - loss-of-function (LOF) mutations (present in the UK Biobank dataset), LOF mutations and copy number variants, and LOF mutations and non-synonymous mutations. To assign cell type specificity, we queried the Human Cell Atlas and Tabula Sapiens datasets for expression of members of the gene panel. Finally, we perform a Kaplan-Meier survival analysis using TCGA and UK Biobank data for the top associations and interactions.

Cancer Posters - Wednesday

PB1108. Gene fusion detection and characterization in long-read cancer transcriptomes with FusionSeeker

Authors:

Y. Chen¹, Y. Wang², W. Chen¹, Y. Song¹, H. Chen¹, Z. Chong²; ¹Univ. of Alabama at Birmingham, Birmingham, AL, ²UAB, Birmingham, AL

Abstract Body:

Gene fusions are prevalent in a wide array of cancer types and often play critical roles in tumorigenesis and progression. Long-read RNA sequencing technologies, such as PacBio Iso-Seq and Nanopore direct RNA sequencing, can generate full-length transcript sequencing reads and therefore show great potential in gene fusion detection. However, only two long-read gene fusion detection tools are currently available, and their performance is limited in terms of sensitivity and precision. Here, we present FusionSeeker to comprehensively characterize gene fusions and reconstruct accurate fused transcripts using long-read cancer transcriptome data.

FusionSeeker consists of three major steps: raw signal detection, candidate event clustering and filtering, and transcript sequence reconstruction. It first scans the read alignments for split-read patterns and records gene fusion raw signals if two alignments from the same read reside in distinct genes. All raw signals are then clustered with a density-based clustering algorithm into candidate fusions. FusionSeeker discards candidates supported by few reads as noise and only reports confident gene fusions. For each event, FusionSeeker collects fusion-containing reads to generate an accurate consensus sequence with partial order alignment algorithm. The final output of FusionSeeker includes a list of confident gene fusion events and their transcript sequences.

We benchmarked the performance of FusionSeeker, JAFFAL, and LongGF on both *in silico* and real cancer transcriptome datasets. In three replicate simulated datasets, FusionSeeker outperformed the other two fusion callers, with accuracy over 93% for both Iso-Seq and Nanopore-like reads. FusionSeeker also successfully reconstructed full-length transcript sequences for more than 99.5% of simulated gene fusion events, with an average sequence identity over 99%. When applied on SKBR-3 cell line, FusionSeeker identified 15 previously validated gene fusion events, while JAFFAL and LongGF detected 13 and 10 events, respectively. When comparing gene fusion calls from the three tools, 19 events were reported only by FusionSeeker. 17 out of these 19 FusionSeeker-unique events were cross-validated in DNA sequencing data with a validation rate of 89.47%, which was higher than JAFFAL-unique (27.27%) and LongGF-unique events (60.00%). In MCF-7 cell line, we designed PCR primers and validated 7 novel gene fusion events that have not been previously reported. In both SKBR-3 and MCF-7 cell lines, FusionSeeker transcript sequences showed significantly higher base accuracy than raw reads, indicating that most sequencing errors have been corrected.

Cancer Posters - Thursday

PB1109. Gene-environment interaction of antioxidant genes and a healthy lifestyle index (HeLiX) on breast cancer risk reduction

Authors:

L. Gómez Flores Ramos¹, L. Sánchez-Zamorano², A. Ángeles-Llerenas², R. Rodríguez-Valentín², G. Torres-Mejía²; ¹CONACYT-Natl. Inst. of Publ. Hlth., Cuernavaca, Mexico, ²Natl. Inst. of Publ. Hlth., Cuernavaca, Mexico

Abstract Body:

Oxidative stress (OS) is a well-known risk factor for tumorigenesis. Lifestyle factors are associated with breast cancer (BC) through different pathways, including OS. Antioxidant enzymes are the endogenous defense against OS damage, and this response might change by the variation in these enzyme-coding genes. We aimed to analyze the synergistic effect of genetic variants in antioxidant family genes and a Healthy Lifestyle Index (HeLiX, composed by principal components of Western dietary pattern, alcohol consumption, smoking, and physical activity) on BC risk. We analyzed data from a population-based case-control study with 636 BC cases and 678 controls. We included 176 SNPs from *SOD*, *GPX*, and *CAT* family genes. Only SNPs in Hardy-Weinberg equilibrium in controls were included in the final models. Twelve *CAT* SNPs were associated with BC after adjustment for Native American Ancestry (*rs475043*, *rs494024*, *rs511895*, *rs533425*, *rs554576*, *rs560807*, *rs2073058*, *rs2179625*, *rs2300181*, *rs7104301*, *rs7933285*, *rs12270780*). Only *CAT rs554576* (g.28423A>T) remained significant after correction for multiple comparisons. In postmenopausal women, compared to the reference category (lowest HeLiX tertile T1 and *AA* genotype), women in the highest HeLiX tertile (T3) with *TT* or *AT* genotypes showed 0.15 times the odds of BC (OR= 0.15, 95% CI 0.07-0.32). Women in the medium HeLiX tertile (T2) with *TT* or *AT* genotypes also showed a protective effect (OR= 0.26 95% CI 0.13-0.54; OR= 0.24, 95% CI 0.12-0.45, respectively). For premenopausal women, we observed an odds reduction in women at the highest tertile of HeLiX (T3) with the *TT* (OR= 0.21, 95% CI 0.08-0.51) and *AT* genotypes (OR= 0.29, 95% CI 0.13-0.62). We observed an inverse association for the medium tertile of HeLiX (T2) for women with the *TT* genotype (OR= 0.39 95% CI 0.17-0.87). *CAT rs554576* is a polymorphism located at intron 9; it is a modifier variant and an expression of quantitative trait loci (eQTL) with a cis-regulatory effect on *CAT* and the upstream gene *ABTB2*. *CAT* has higher expression in adipose and breast tissues and is responsive to lifestyle exposures. Our study shows a significant synergistic gene-environment interaction, contributing to understanding BC etiology and prevention pathways.

Ctr., Gynecologic Cancer Ctr. of Excellence, Uniformed Services Univ. of the Hlth.Sci., Bethesda, MD, ⁶Women's Hlth.Integrated Res. Ctr., Women's Service Line, Inova Hlth.System, Annandale, VA, ⁷Women's Hlth.Integrated Res. Ctr., Inova Hlth.System, Falls Church, VA, ⁸Gynecology Cancer Ctr. of Excellence, Dept. of Gynecologic Surgery and Obstetrics, Uniformed Services Univ. of Hlth.Sci., Walter Reed Natl. Med. Ctr., Bethesda, MD, ⁹The Henry M Jackson Fndn. for the Advancement of Military Med., Inc., Bethesda, MD

Abstract Body:

Endometrial cancer incidence has risen over the last 20 years. Self-described black individuals in the United States show higher incidence and worse outcomes for endometrial cancer than white individuals. Socioeconomic factors and comorbidities that disproportionately affect black individuals play a major role in creating these disparities but do not explain them entirely. Molecular, histopathologic, and genetic elements also contribute to disparities in patient outcome and treatment response. Here we examine how genetic ancestry correlates with somatic mutation rates in endometrial cancer. Germline genetic ancestry and somatic mutation status were examined using normal adjacent tissue and tumor-derived whole exome sequencing data from 297 patients (including 171 self-described black individuals). This data was obtained from Karmanos Cancer Institute and Henry Ford Hospital, and supplied by collaborators at Wayne State University. Local ancestry analysis was performed using RFMix ver. 2. Correlations between African local ancestry and the number of somatic mutations were examined in each local ancestry block along the genome using a negative binomial regression model. A single region in chromosome 8p11.21 reached genome-wide significance. This region contains the gene *SFRP1*, a tumor suppressor; wherein mutations are associated with worse prognostic outcomes in endometrial cancer. This finding necessitates further exploration into the relationship between germline African ancestry and mutations in *SFRP1*. An intra-individual comparison of somatic mutation rates under ancestral diplotypes (a combination of ancestral backgrounds, eg. [European(Eur)-Eur] or [African(Afr)-Eur]) in self-described black individuals showed that somatic mutation rates were significantly higher in Afr-Eur ancestral regions than in Eur-Eur regions. This trend does not persist when comparing Afr-Afr regions to Eur-Eur regions, suggesting that heterozygosity may influence somatic mutation rates in these individuals. An interaction between heterozygosity and somatic mutation burden has yet to be investigated in endometrial cancer. To explore this hypothesis, an F-statistic (inbreeding coefficient) and somatic mutation abundance were computed for target windows of 1Mb for each of the 171 self-described black individuals in this cohort. A meta-analysis of this distribution, using Fisher's combined probability test, showed that heterozygosity correlated with a higher rate of somatic mutations in these individuals. These findings help to shed light on the relationship between germline genetic ancestry and somatic mutations in endometrial cancer.

Cancer Posters - Thursday

PB1111*. Genetic ancestry differences in tumor mutation between early and average onset colorectal cancer

Authors:

B. Rhead¹, D. Hein², Y. Pouliot¹, J. Guinney¹, F. M. De La Vega¹, N. Sanford²; ¹Tempus, Chicago, IL, ²UT Southwestern Med. Ctr., Dallas, TX

Abstract Body:

The incidence and mortality of early onset (EO) colorectal cancer (CRC), defined as CRC diagnosed prior to age 50, are rising when compared to the declining rates of average onset (AO) CRC. Epidemiologic trends for CRC differ by race/ethnicity, which could be connected to underlying differences in tumor mutation and gene expression. Previous research has used self-reported race/ethnicity categories, which are often missing or uninformative for understanding biological underpinnings of such differences, particularly in highly admixed groups such as Black and Hispanic. Hence, we compared tumor mutation profiles of EO and AO CRC - within a de-identified dataset of 1,643 and 3,175 patients, respectively - in the context of genetic ancestry groups. Ancestry informative markers were utilized to estimate ancestry proportion likelihoods for the five continental groups defined in the 1000 Genomes Project: Africa, Americas, East Asia, Europe, and South Asia. Recognizing the complexity of ancestry and race relationships, we imputed several race/ethnicity categories using admixture thresholds based on literature and comparisons with available metadata. Similar numbers of Black and Asian patients were observed in both EO and AO groups (13% and 5-6%), however, more Hispanic/Latino patients were found in the EO subgroup (16%) compared to AO (10%). We assessed the association of genetic ancestry proportions (per 20% increase in each ancestry proportion) with the presence of protein altering somatic mutations or copy number changes in 22 CRC driver genes. Across all ages of onset, African ancestry was associated with higher odds of somatic mutations in *APC* (OR=1.11) and *KRAS* (OR=1.14) and lower odds of *BRAF* mutations (OR=0.84). East Asian ancestry was associated with higher odds of mutations in *TP53* (OR=1.15). Furthermore, we found a novel association between Native American ancestry with higher odds of somatic mutations in the *MLH1* gene (OR=1.61), unexplained by misclassified germline variants in this gene (*i.e.* Lynch syndrome), as we limited our analysis to cases with matched tumor/normal sequencing. When testing for interactions between the effects of onset age (EO vs. AO) and genetic ancestry on gene mutations, we observed a significant interaction ($p=0.031$) between African ancestry and onset age on *APC*: African ancestry was associated with mutations in this gene in AO (OR=1.16) but not EO (OR=0.98). When compared to race/ethnicity classes, genetic ancestry provides a more quantitative and precise profile of shared genetic background that can underlie biological race differences in cancer etiology and outcomes in EO and AO CRC.

Cancer Posters - Wednesday

PB1112. Genetic Modifiers of *KRAS*-Mutant Colorectal Cancer

Abstract Body:

Somatic mutations in *KRAS* are a common driver of colorectal cancer (CRC) tumorigenesis in 30-40% of patients, yet *KRAS*-mutant tumors remain difficult to treat. Germline variants may influence what somatic mutations occur or provide a selective advantage such that a mutated cell is more likely to progress to a cancer. This “GxM” effect, or genetic variants impacting somatic mutation status, is observed in other cancers and supported by our preliminary studies in CRC. African Americans with CRC are more likely to have tumors with *KRAS* mutations than non-Hispanic Whites, even after considering differences in socioeconomic status and other risk factors. Relatedly, tumors of the proximal colon are more frequent in African Americans and are more likely to have *KRAS* mutations than those of the distal colon. Transcriptional differences between the proximal and distal colon may influence GxM variant interactions in tumorigenesis. We hypothesized that germline variants will alter molecular pathways that support *KRAS* tumorigenesis and differ by proximal-distal colon location. To test this hypothesis, we performed an association study using existing genome-wide germline genotypes and mutation data from 6,386 non-Hispanic White colorectal cancer patients from the Cancer Genome Atlas and the GECCO consortium. We compared germline single nucleotide variants (SNVs) in patients with *KRAS*-mutant tumors to patients with *KRAS*-wild type tumors. No variants met strict thresholds for genome-wide significance. We identified 3 SNVs that associated with *KRAS* mutation status with p -values $<1 \times 10^{-6}$ and 50 with p -values $<1 \times 10^{-5}$. Of 53 SNVs with p -values $<1 \times 10^{-5}$ or $<1 \times 10^{-6}$, 35 had a minor allele frequency $>10\%$ in individuals of African or European ancestry. In a stratified analysis, we identified 29 common SNVs specifically associated with *KRAS* mutations in the proximal colon, 2 in the distal colon, and 10 in the rectum (p -value $<1 \times 10^{-4}$). By patient sex, 32 SNVs specifically had an effect in males and 34 in females (p -value $<1 \times 10^{-4}$). From excluding SNVs in linkage disequilibrium and reviewing relevant genomic features, we identified 90 loci which will be validated in our future studies using a more diverse dataset of ~8,000 patients from multiple sources. In summary, we identified SNVs with suggestive evidence for association with *KRAS* somatic mutations in CRC which may inform the cellular context that supports development of colorectal tumors from cells with *KRAS* mutations.

Cancer Posters - Thursday

PB1113. Genetically Predicted Telomere Length and Risk of Multiple Primary Cancers in the Prostate, Lung, Colorectal and Ovarian Cancer Screening Trial.

Authors:

S. He¹, W-Y. Huang¹, M. J. Machiela¹, N. Freedman¹, S. I. Berndt²; ¹Natl. Cancer Inst., Bethesda, MD, ²Natl. Cancer Inst., Rockville, MD

Abstract Body:

Objectives: Telomeres are important in cell division and senescence and critical for chromosomal stability. Leukocyte telomere length is highly heritable and genome-wide association studies have identified over 190 variants associated with telomere length, but little is known about its link with the risk of developing multiple primary cancers. **Methods:** To determine if genetically predicted telomere length (TL) is associated with multiple primary cancers, we conducted a case-control study including 6,399 multiple primary cancer cases and 75,012 controls (92.5% European, 4.1% African, 3.4% Asian) from the Prostate, Lung, Colorectal and Ovarian Cancer Screening Trial. Multiple primary cases were individuals with two or more confirmed primary cancers at different sites. Using up to 160 previously identified variants, we estimated polygenic risk scores (PRS) for telomere length. Logistic regression was used to estimate odds ratios (ORs) for the association of PRS with multiple primary cancers, adjusting for age, sex, genotype platform and ancestry. The PRS was analyzed both as a continuous measure and as quintiles. We also evaluated the association between the PRS of telomere length and the risk of subgroups of multiple primaries, including subgroups composed of multiple primaries with at least one malignancy being adenocarcinoma (N=3,454), squamous cell cancer (N=470), lymphoma (N=895), or sarcoma (N=956). **Results:** Genetically predicted telomere length was associated with an increased risk developing multiple primary cancers (OR=1.78 for one unit increase in TL PRS, 95% confidence interval (CI): 1.53-2.08, P=4.7e-13). The increased risk was strongest for multiple primary cases with at least one cancer being a lymphoid malignancy (OR=2.26, 95%CI: 1.60-3.19, P=8.2e-6). Significant associations were also observed between genetically predicted telomere length and higher risk of multiple primaries with at least one cancer being adenocarcinoma (OR=1.83, 95%CI: 1.54-2.17, P=7.3e-12) or sarcoma (OR=2.19, 95%CI: 1.56-3.07, P=1.1e-5). No significant association was observed for multiple primaries with at least squamous cell cancer (OR=1.17, 95%CI: 0.77-1.76, P=0.47). **Conclusions:** Our study demonstrates that higher genetically predicted telomere length is associated with an increased risk of developing multiple primary cancers, particularly where at least one cancer is a lymphoid malignancy. Further studies are needed to understand the biological mechanisms between telomere length and the risk of multiple primary cancers.

Cancer Posters - Wednesday

PB1114. Genome and transcriptome landscape of familial pancreatic cancer and implications for altered glucose metabolism in moderate-penetrance cancer susceptibility.

Authors:

Abstract Body:

Pancreatic cancer is one of the leading causes of cancer-related deaths worldwide. Although genetic factors contribute to a significant proportion of pancreatic cancer risk, the causal genes are largely unknown. Around 15-20% of non-syndromic familial pancreatic cancer (FPC), defined as a family with at least two affected first-degree relatives, is caused by pathogenic germline variants in *ATM*, *BRCA2*, and *PALB2*. Genes involved in cancer or tissue biology, including mediators of metabolic, immune and microenvironmental response, may also play a role in pancreatic cancer susceptibility. To investigate the molecular pathogenesis of FPC, we performed tumour-normal genome sequencing and tumour RNA sequencing in two affected siblings from a genetically undiagnosed kindred with a multigenerational history of pancreatic cancer. The FPC tumours were characteristic of the stable genomic and classical mRNA subtypes, showing common somatic alterations in RAS, p16-mediated and TGF-beta signalling pathways. Notably, aberrant expression of the genes encoding PDX1, insulin, and other regulators of glucose-mediated hormone secretion in the familial tumours suggested a putative role for altered glucose metabolism in tumourigenesis. These findings could not be explained by an enrichment of pancreatic endocrine cells estimated by transcriptome-based cell type deconvolution. A germline loss-of-function variant was identified in *PIK3C2G*, a gene encoding a liver-specific class II phosphoinositide 3 kinase that has been associated with metabolic phenotypes in humans and mice. History of dyslipidemia and type II diabetes mellitus indicated the presence of other possible related phenotypes in these siblings. Our findings suggest a putative role for altered insulin signalling in pancreatic cancer susceptibility associated with a candidate moderate-penetrance gene. Further studies will be required to evaluate the role of *PIK3C2G* in aberrant glucose metabolism, insulin resistance, and pancreatic cancer.

Cancer Posters - Thursday

PB1115*. Genome-wide Analysis of Rare Haplotypes Associated with Breast Cancer Risk: Discovery, Replication, and Generalizability Evaluation

Authors:

F. Wang¹, W. Moon¹, W. Letsou¹, Y. Sapkota¹, Z. Wang¹, C. Lm², J. Baedke¹, L. Robison¹, Y. Yasui¹; ¹St. Jude Children's Res. Hosp., Memphis, TN, ²Univ. of Alberta, Edmonton, AB, Canada

Abstract Body:

Studies have shown that breast cancer (BCa) risk is influenced by common low-risk variants in numerous loci and rare pathogenic variants in high-risk genes (e.g., *BRCA1/2*). However, the full genetic architecture of BCa risk remains elusive. An inference from the Nordic female twin data provides evidence that rare high-risk variants may be the major determinants of BCa risk. Testing rare-variant associations with disease risk requires large-scale whole-genome sequencing (WGS) data, which are currently being collected. Here, we use haplotypes, sets of variants on a single chromosome, rather than single rare variants, to identify rare loci that explain inherited BCa risk. With 646,446 computationally phased, genotyped variants from 181,034 “white British” women provided by the UK Biobank (UKBB), we conducted a genome-wide haplotype analysis using sliding windows of 5-500 consecutive variants. In the discovery stage, haplotype associations with BCa risk were evaluated retrospectively in the pre-study-enrollment portion of the UKBB data, which included 5,487 BCa cases. BCa hazard ratios (HRs) for additive haplotypic effects were estimated using Cox regression with age as the time axis, adjusting for the top ten genotype principal components. The replication analysis included women free of BCa at enrollment, of whom 3,524 later developed BCa. This two-stage analysis detected 193 rare haplotypes (frequency less than 1%) clustered into 13 distinct loci; each locus spanned a region of 0.1-1.4 Mb and was associated with an appreciable BCa risk increase (discovery: HRs=2.84-6.10, P-value<5x10⁻⁸; replication: HRs=2.08-5.61, P-value<0.01). In contrast, variants that formed these rare haplotypes individually exhibited no or small risk effects. In a separate validation analysis using phased, imputed genotypes from 30,064 female cases and 25,282 controls of European ancestry in the DRIVE OncoArray case-control study, six of the 13 rare loci showed a significant risk increase (logistic-regression-based odds ratio estimates, controlling for the same covariates and imputation uncertainty: 1.48-7.67, P-value<0.05). Functional annotation revealed extensive regulatory DNA elements in BCa-related cells underlying the validated haplotypes, suggesting the influence of intrachromosomal interactions on BCa risk. This study demonstrates both the advantages of using rare haplotypes to find novel risk loci and the possibility of explaining additional BCa heritability. Because our analysis was limited to variants on the UKBB's genotyping array, it implies the discovery of many more risk haplotypes once large germline WGS datasets become available.

Cancer Posters - Wednesday

PB1116. Genome-wide association study identifies 4 novel risk loci including a missense variant in *LGR5* for small intestinal neuroendocrine tumors

Authors:

A. Kumar^{1,2}, M. Aavikko¹, J. Karjalainen^{1,3}, J. Mehtonen¹, K. Palin¹, N. Valimak¹, A. Karhu¹, S. Benjamin⁴, H. Runz⁴, H. Joensuu⁵, T. P. Mäkelä¹, S. Ollila¹, I. E. Kostiaainen¹, C. S. Jantti⁵, FinnGen, A. Palotie¹, L. A. Aaltonen¹, M. J. Daly¹; ¹Univ. of Helsinki, Helsinki, Finland, ²Finnish Cancer Inst., Helsinki, Finland, ³Broad Inst., Boston, MA, ⁴Biogen Inc., Cambridge, MA, ⁵Univ. of Helsinki and Helsinki Univ. Hosp., Helsinki, Finland

Abstract Body:

Small intestine neuroendocrine tumor (SI-NET) is a rare disease with variable clinical symptoms potentially leading to delayed diagnosis and treatment. Understanding of the genetic risk factors underlying SI-NETs might help in the early detection and identification of the individuals at risk. To our knowledge, we report here the largest genome-wide association study (GWAS) of SI-NET with 472 cases and 679,833 controls. We used samples from 307 cases and 287,137 controls in the FinnGen study database to discover SI-NET-associated genetic variants. Next, we performed a meta-analysis with the summary statistics from the United Kingdom Biobank cohort (92 SI-NET cases and 392,696 controls; Fisher test $p = 4.93 \times 10^{-18}$). We found novel associations of SI-NETs with 4 loci near *LGR5*, *FERMT2*, *SEMA6A*, and *CDKAL1* at a genome-wide significance level of (p less than 5×10^{-8}) and replicated the earlier suggested loci near *LTA4H-ELK3* and *KIF16B*. Interestingly, the top variant at the *LGR5* locus (rs200138614, $p = 1.80 \times 10^{-19}$) is a missense variant (p.Cys712Phe) highly enriched in the Finnish population (approximately 25-fold). We further validated the association of *LGR5* p.Cys712Phe with SI-NET in an independent collection of 73 SI-NET patients from Finland and in the United Kingdom Biobank cohort. Functional analyses suggest that *LGR5* p.Cys712Phe is likely a loss of function mutation. Our results demonstrate 4 new associated GWAS loci to SI-NET, among them a novel missense mutation (rs200138614) at *LGR5*.

Cancer Posters - Thursday

(WPI-IFReC), Osaka Univ., Suita, Japan, ²⁰RIKEN Ctr. for Integrative Med. Sci., Yokohama, Japan

Abstract Body:

Intracranial germ cell tumors (IGCTs) are a heterogeneous group of rare brain tumors mainly diagnosed in children and adolescents, with a substantially higher incidence in East Asian countries than in Western countries (e.g., an incidence of 2.7/million/year in Japan but 0.6/million/year in the United States). Due to the low disease incidence, only a limited amount of basic research has been conducted on this rare disease. Here, through nationwide efforts in patient recruitment, we perform an initial genome-wide association study (GWAS) of 133 IGCTs cases and 762 controls, both of Japanese ancestry. The case sample size is the largest ever reported on IGCTs genetics, enabling us to identify a genome-wide significant locus at 6p21 ($P = 2.4 \times 10^{-9}$, odds ratio = 2.46 [95% CI 1.83-3.31]), which is replicated in an independent dataset of 99 cases and 1026 controls ($P = 1.7 \times 10^{-7}$, odds ratio = 2.22 [95% CI 1.63-3.03]). The lead variant rs3831846 (risk allele frequency = 0.43) is a common 4-bp deletion polymorphism residing in a candidate *cis*-regulatory element E38E2460759, a promoter-proximal enhancer-like element by ENCODE, adjacent to the promoter of *BAK1*. Expression quantitative trait locus (eQTL) analysis using the GTEx dataset reveals that the risk allele of rs3831846 has a down-regulating effect on *BAK1* expression in a wide range of tissues ($P < 0.05$ in the 42/49 tissues, minimum $P = 5.9 \times 10^{-14}$). We further perform *in-vitro* reporter assays to test the allelic difference of rs3831846 in regulatory effect, validating that the risk allele attenuates the enhancer activity of the E38E2460759 sequence, consistent with the eQTL analysis. Finally, given the histological resemblance between IGCTs and testicular GCTs (TGCTs), a subtype of the more common gonadal GCTs, we refer to the previous European TGCTs GWAS and examine the statistics in our IGCTs GWAS for 57 TGCTs risk loci. The effect sizes show a positive overall correlation between Japanese IGCTs and European TGCTs ($P = 1.3 \times 10^{-4}$, Spearman's $\rho = 0.48$). Of the 57 loci, 11 exhibit significant association with IGCTs ($P < 0.05$ with a consistent direction of effect): *CLPTMIL*, *PITX1*, *SPRY4*, *TNXB*, two loci of *BAK1*, *KATNAI*, *DEPTOR*, *GAB2-NARS2*, *HNF1B*, and *TKTL2*. These loci were implicated in a broad range of biological pathways, including KIT/KITLG signaling, apoptosis regulation, and telomerase activity. Our study indicates the shared genetic background of GCTs beyond ethnicity and primary sites, not limited to a specific biological pathway.

Cancer Posters - Wednesday

PB1118. Genome-wide profiling of DNA N6methylation from a breast cancer and a matched normal cell lines

Authors:

C. Xiao, V. Schneider; NIH, Bethesda, MD

Abstract Body:

DNA N6-methyladenine (m6A) modification has been found widely presented in the human genome, and genome-wide DNA methylation profiling in cancer may reveal epigenetic signatures with significant clinical outcomes. Whole genome sequencing data from PacBio single-molecule real-time (SMRT) system provides signals for identifying the presence of m6A in human genomic DNA. We identified 343,199 m6A modification sites with an average density of 122 per Mb in the HCC1395 breast cancer cell line, whereas 722,303 m6A modification sites with average density of 257 per Mb were observed in a matched normal HCC1395BL cell line, meaning that the total number and the average density of m6A methylation sites in the cancer cell line were reduced more than 50% than that in normal cell line. Only small fraction of the methylation sites was found to be shared between the two cell lines, indicating that significant de-methylation (loss) and new methylation (gain) events occurred in HCC1395 cancer cells. A broad distribution of m6A methylation sites across autosomal chromosomes was observed, but the density of m6A methylation sites on chromosome X was extremely low for both HCC1395 and HCC1395BL cell lines. In contrast, the m6A densities on chromosome 7 and chromosome 22, particularly on their q-arms, from HCC1395 were substantially higher (hypermethylation) than other autosomal chromosomes, suggesting that copy number variations may be associated with these chromosomal regions. Most of the m6A methylation sites were located in intergenic and intronic regions, whereas only about 2~3% of the m6A methylation sites were situated in exonic regions, and 12% on ncRNAs. We investigated enriched motifs from the flanking sequences of the m6A sites and found that the m6A modifications occurred the most at the sites with GAG motif in both HCC1395BL (57.3%) and HCC1395 (58.26%). The next most frequent motifs (7 ~ 9% each) for m6A sites is GAA/AAG/GAC for HCC1395BL, and GAC/AAG/GAA for HCC1395. Understanding the genome-wide distinction of DNA methylation between cancer and matched normal cell lines makes it possible to ask more targeted questions and further investigate the role of methylation in cancer.

Cancer Posters - Thursday

PB1119*. Genomic landscape of malignant peripheral nerve sheath tumor (MPNST) reveals novel pathways of tumor evolution that correlate with tumor behavior.

Genetics, Huntsman Cancer Inst., Univ. of Utah, Salt Lake City, UT, ²³GeneHome, Dept. of Individualized Cancer Management, H. Lee Moffitt Cancer Ctr. and Res. Inst., Tampa, FL

Abstract Body:

Malignant peripheral nerve sheath tumors (MPNSTs), a type of soft tissue sarcoma, are the most common cause of early mortality among people with neurofibromatosis type 1 (NF1). Currently available treatments offer less than a 50% 5-year survival. With the goal of identifying either tumor vulnerabilities or biomarkers for early tumor detection, we formed an international consortium to facilitate a comprehensive genomic analysis of 90 MPNSTs (61 NF1-related; 29 sporadic). All samples were assessed by whole genome sequencing (WGS), RNAseq, and methylation array profiling. Multi-regional exome sequencing was performed on a subset. Comparison of our methylation profiles to pathology and clinical data confirmed prior reports that H3K27 trimethylation (Me3) status correlates with prognosis. Our approach yielded new genomic information, including: (1.) that complex chromosomal rearrangements involving *CDKN2A*, and subsequently the PRC2 complex, are early events in a majority of the tumors, but do not involve recurrent breakpoints; (2.) recurrent gains or losses of particular chromosome arms are indicative of H3K27me3 status, but are actually more predictive of prognosis than H3K27me3 status, pathology characterization, or clinical history; (3.) the combination of WGS, multi-regional exome sequencing, and ploidy analysis facilitated identification of a previously unrecognized complex pattern of divergent tumor evolution along two main pathways that correlate with H3K27me3

status. MPNSTs with loss of H3K27Me3 showed amplification of chromosome 8 and extensive LOH, whereas those with H3K27Me3 retention instead evolve through extensive chromosome instability and chromothripsis, and display more heterogeneous karyotypes; (4.) Transcriptomic data revealed that tumors with loss of H3K27me3 show downregulation of markers of immune infiltration and activation of the adaptive immune system compared to tumors with retention of H3K27me3, suggesting that tumors retaining H3K27Me3 may be more responsive to immunotherapy; (5.) The genomic profiles of different subsets of MPNSTs can be detected through analysis of cell-free DNA (cfDNA). Overall, our results provide the foundation for an MPNST clinical care model that incorporates the genomic architecture of the tumor to refine the diagnosis, prognosis, and treatment approach.

Cancer Posters - Wednesday

PB1120. Germline functional non-coding variants associated with ovarian cancer predisposition

Authors:

S. Ezquina¹, E. Dicks¹, R. Corona², K. Lawrenson², S. Gayther³, M. Jones⁴, M. Freedman⁵, R. Drapkin⁶, P. Pharoah⁷; ¹Univ. of Cambridge, Cambridge, United Kingdom, ²Cedars-Sinai Med. Ctr., Los Angeles, CA, ³Cedars Sinai Med. Ctr., Los Angeles, CA, ⁴Cedars Sinai Med Ctr, Los Angeles, CA, ⁵Broad Inst., Boston, MA, ⁶Univ. of Pennsylvania, Philadelphia, PA, ⁷Univ Cambridge, Cambridge, United Kingdom

Abstract Body:

Epithelial ovarian (EOC) cancer has a substantial hereditary component - rare coding variants in multiple genes that confer moderate to high penetrance have been identified and GWAS have identified many low-penetrance common risk alleles. However, the known risk alleles explain <50% of the inheritable component of risk. Some of the missing heritability is likely to be due to rare variation in the non-coding genome. The aim of this study was to assess whether rare variation in active PAX8 transcription factor binding sites is associated with risk of EOC. PAX8 is highly expressed in high grade serous ovarian cancer (HGSOC) and fallopian tube surface epithelial cells (FTSEC), the putative precursor cells of HGSOC. If rare variation in these regions is disease-associated, the number of variants in these regions would be expected to differ between cases and controls. We used H3K27ac ChIP-seq data from two FTSEC and five primary HGSOCs to identify active chromatin, and PAX8 ChIP-seq from three FTSEC and five ovarian cancer cell lines (JHSO4, Kuramochi, OVSAHO, IGROV, Heya8) to identify PAX8 binding sites. We defined 1,687 active regions covering 309Kbases of genomic DNA as those with overlap between H3K27ac marks in at least three of seven tumour or normal fallopian tube cell lines and PAX8 marks in at least three of eight tumour or normal fallopian tube cell lines. Variants were called in germline genomes of 581 ovarian cancer patients and 2750 non-cancer controls sequenced by Genomics England for the UK 100k Genomes Project. Variants with a frequency higher than 0.01 in the gnomAD dataset and in our dataset were excluded. A Kruskal Wallis test was used as a simple burden test to compare the number of variants carried by cases and controls. The median number of variants in active PAX8 binding sites carried was 5 (IQR 3 - 6) in both controls and cases ($P = 0.47$) suggesting that rare variation in these regions are not associated with a moderate risk of EOC. The power to detect a weak association is very limited. It is also possible that the functional genomic data used to define active PAX8 binding sites is insufficiently sensitive or specific - some or many of the regions identified may not be functionally important. Furthermore, some of the variants identified might not be functionally active, that is they may not disrupt the PAX8 binding site. Further work is required to identify better functional regions and to determine which variants in such regions are functionally disruptive. This study has shown an approach to detecting disease-associated rare genetic variation in the non-coding genome. Rare variation in other transcription factors may be important in the aetiology of EOC and other cancers.

PB1121. Germline genetics of venous thromboembolism (VTE): Non-cancer polygenic risk scores improve risk stratification in cancer patients

Authors:

S. Groha¹, A. H. Nassar², E. El-Am³, A. Bejjani², V. Naranbhai⁴, A. Gusev⁵; ¹Dana Farber Cancer Inst., Boston, MA, ²Brigham and Women's Hosp., Boston, MA, ³Indiana Univ. Sch. of Med., Indianapolis, IN, ⁴Massachusetts Gen. Hosp., Cambridge, MA, ⁵Dana-Farber Cancer Inst., Boston, MA

Abstract Body:

Background

VTE is a significant secondary cause of mortality in cancer patients, with up to 20% experiencing a VTE during their cancer treatment, constituting a 5-7 times increased risk as compared to the non-cancer population (Razak et al, *Cancers* 2018). The leading clinical predictor, 'Khorana score' is based on few clinical factors and has been challenging to translate into a clinically effective biomarker. Germline variants are known to be significant factors for VTEs in patients without cancer. In large GWAS studies, the predictive value of polygenic risk scores (PRS) was comparable to well-known genetic risk factors such as factor V Leiden and prothrombin G20210A mutations (Klarin et al, *Nature Genetics*, 2019). Here, we investigate the utility of a non-cancer VTE PRS to clinically stratify VTE risk in cancer patients and compare to existing clinical risk models.

Methods

The study was conducted in a discovery cohort of 5,760 patients with solid tumors sequenced at Dana-Farber Cancer Institute (DFCI) and treated with anti-neoplastic therapy. The VTE phenotype for the 5,760 patients was abstracted using ICD-10 codes. For validation, we performed manual chart review on a subpopulation of 806 patients with pancreatic cancer sequenced at DFCI. Targeted tumor sequencing was used to impute a VTE PRS from external GWAS data of ~420,000 individuals. Predictive accuracy was quantified in a cause-specific way in a time-to-event analysis and benchmarked against the clinically established Khorana score (Khorana, *Blood* 2008) for cancer-associated thromboembolism. Associations were then validated in an independent cohort of 927 patients sequenced after 2020 to evaluate predictive shift.

Results

In a univariate analysis, the VTE PRS alone yielded comparable concordance ($c=0.55$ [0.54-0.56]) to the clinical Khorana score ($c=0.56$ [0.54-0.58]). Combining these predictors increased the cause specific concordance ($c=0.57$ [0.56-0.58]), indicating independent information from the germline predictor. This is furthermore corroborated on the level of effect sizes. Importantly, we find that the PRS predictor remains highly significant (cause-specific HR=1.2, $p=1.3 \times 10^{-7}$) after controlling for known clinical factors (cancer type, cancer stage, ECOG performance status, chemotherapy medication, stationary hospital stay, metastasis status, gender, age at start of treatment and genetic ancestry), whereas the Khorana score was no longer significant (HR=0.99 [0.91-1.1], $p=0.88$). A germline VTE PRS could improve stratification of VTE risk in patients with cancer.

Cancer Posters - Wednesday

PB1122. Germline sequencing in Brazilian pancreatic carcinoma patients.

Authors:

L. Munhoz Rodrigues¹, S. Maistro², L. Antônio Senna Leite², M. del Pilar Estevez Diz², U. Ribeiro Jr.¹, R. Guindalini³, M. Folgueira¹; ¹Faculdade de Med. da Univ.e de Sao Paulo, Sao Paulo, Brazil, ²Inst. do Cancer do Estado de Sao Paulo, Sao Paulo, Brazil, ³Oncologia D'Or, Bahia, Brazil

Abstract Body:

Background: Hereditary susceptibility is scarcely known in pancreatic cancer patients in Latin America, which presents a multiethnic population. We evaluated an unselected cohort of Brazilian pancreatic carcinoma (PC) patients to detect the spectrum and frequency of germline mutations in cancer predisposing genes. **Methods:** Patients from Instituto do Cancer do Estado de Sao Paulo (Sao Paulo, located in the southeastern region of Brazil), with histopathological diagnosis of non-endocrine PC were included between 2018-2021. Genomic DNA was obtained from peripheral blood for Next Generation Sequencing using a panel of 113 cancer predisposing genes. Copy number variation (CNV) was assessed by CNV-Atlas and confirmed by Multiplex Ligation-dependent Probe Amplification. **Results:** A total of 180 participants were evaluated, with mean age 61 years (27-87), among whom, 17% with young age (≤ 50 years) and 108 women (60%). Regarding risk factors, 106 (59%) participants reported cases of any cancer in first-degree relatives, 101 (56%) reported a history of smoking and 39 (22%) of alcohol abuse, 125 (70%) reported previous overweight or obesity, 38 (21%) reported diabetes for at least one year before cancer diagnosis and 26 (14%) had a history of occupational exposure. No participants reported Ashkenazi Jewish ancestry and 69 (38%) participants self-declared black or brown - “pardo” skin color. Sixteen participants (9%) had more than one diagnosis of primary cancer and 110 (61%) presented with advanced disease (clinical stage III or IV). We observed that 28 (16%) participants carried pathogenic/likely pathogenic variants, in the following genes: *CHEK2* (n=5), *ATM* (n=4), *BRCA1*, *BRIP1*, *FANCM*, *MTIF*, *MUTYH*, *PALB2* (each gene in two patients) and *BRCA2*, *CDKN2A*, *FANCE*, *MRE11*, *MSH2*, *RAD51C*, *RECQL4*, *SDHA* (each gene in one patient), as well as deletion of 2 exons of *ATM* and duplication of 13 exons of *CHEK2* (each alteration in one participant). Among these, two patients carried two gene variants and one patient carried one variant and one CNV. **Conclusions:** The use of multigene panel in this unselected and multiethnic group of Brazilian PC patients revealed that 16% were carriers of pathogenic germline variants or CNVs, mainly in *CHEK2* and *ATM*.

Cancer Posters - Thursday

PB1123. Germline sequencing of DNA damage repair genes in two hereditary prostate cancer cohorts reveals rare risk-associated variants

Authors:

G. Foley¹, J. Marthick¹, S. Lucas¹, K. Raspin¹, A. Banks¹, J. Stanford², E. Ostrander³, L. FitzGerald¹, J. Dickinson¹; ¹Univ. of Tasmania, Hobart, Australia, ²Fred Hutchinson Cancer Res Ctr, Seattle, WA, ³NHGRI (NIH), Bethesda, MD

Abstract Body:

Rare, inherited variants in DNA damage repair (DDR) genes play an important role in prostate cancer (PrCa) susceptibility. Here, two independent high-risk familial PrCa datasets were interrogated to identify novel, rare DDR variants that contribute to disease risk. Massively parallel sequencing data from Australian and North American familial PrCa datasets were examined for rare, likely deleterious variants in 35 DDR genes. Putative high-risk variants were prioritised based on frequency (minor allele frequency <1%), mutation type (nonsense, missense, or splice), segregation with disease, and *in silico* predicted deleteriousness. Six prioritised variants were genotyped in a total of 1,963 individuals (700 familial and 459 sporadic PrCa cases, 482 unaffected relatives, and 322 screened controls) and M_{QLS} association analysis was performed. Statistically significant associations between PrCa risk and rare variants in *ERCC3* (rs145201970, $p=2.57 \times 10^{-4}$) and *BRIP1* (rs4988345, $p=0.025$) were identified in the combined Australian and North American datasets. A variant in *PARP2* (rs200603922, $p=0.028$) was significantly associated with risk in the Australian dataset alone, while a variant in *MUTYH* (rs36053993, $p=0.031$) was significantly associated with risk in the North American dataset. Our study implicates several rare germline DDR variants in familial PrCa risk, indicating that additional genes in DDR pathways should be considered when evaluating inherited genetic risk. Understanding the functional and/or biological effects of these variants may have wide-reaching implications on the burden of PrCa, especially in their roles as potential gene-based therapeutic targets. Further, we provide evidence that a proportion of rare DDR variants will elude screening confined to early-onset or high-grade familial disease, with implications for the selection of gene-based therapies targeting DDR pathways in PrCa patients.

Cancer Posters - Wednesday

PB1124. Germline variants in the Ah Receptor in Colombian smoker patients with squamous cell carcinoma of the head and neck.

Authors:

N. Trujillo¹, C. I. Vargas C.¹, Á. A. Herrera H.¹, S. Guauque-Olarte², C. Fong³, L. Cifuentes C.⁴; ¹Univ. Industrial de Santander, Bucaramanga, Colombia, ²Univ. Cooperativa de Colombia, Envigado, Colombia, ³Univ. Cooperativa de Colombia, Santa Marta, Colombia, ⁴Univ. Cooperativa de Colombia, Pasto, Colombia

Abstract Body:

Head and neck squamous cell carcinoma (HNSCC) evolves from the mucosal epithelium in the oral cavity, pharynx and larynx, and collectively represents the 7th most common cancer by incidence worldwide. Colombia by 2020 reported 3.148 new cases and at least 1343 deaths associated to this neoplasm. The strongest risk factor for developing HNSCC is Tobacco consumption. The Aryl hydrocarbon Receptor (AhR) encoded by the AHR gene, induces the activation of xenobiotic-metabolizing enzymes. However, interindividual variation in the activity of these enzymes involved in the detoxification of tobacco carcinogens can contribute to cancer susceptibility. We aimed to identify genetic variants in the AHR gene in Colombian smoker patients with HNSCC, and to establish their current effect on the structure - function of the protein product. **Materials and Methods:** This study included the analysis of 23 blood samples from HNSCC smoker patients. The AHR gene coding sequence and its exon-intron boundaries were sequenced through Sanger's method. We determined the presence and localization of variants using BLAST and SW ChromasPro. Also, in silico structural, and functional predictions of the protein were performed by using bioinformatics tools like VEP, SIFT, POLYPHEN, FATHMM, Mutation Taster, PROVEAN and Human Splicing Finder. **Results:** We reported for the first time genetic variants in the AHR gene in HNSCC colombian patients. Also, we identified variants not previously reported for the Latin American population. Some of the variants have been classified as having unknown clinical significance, while others have not been previously reported. Through in silico analysis some variants were found to possibly affect the protein structure, and therefore the function of the Ah Receptor. Allele frequencies were establish for each variant according to the 1000 Genomes Project, GnomAD, and ExAC databases. **Conclusion:** The findings represent a first approach to identify SNPs in the AHR gene in Colombian population. This study contributes to the understanding of the genetic susceptibility to HNC in Colombia. **Financial Support:** CONADI-UCC (INV2085).

Cancer Posters - Thursday

PB1125. GLUT10 is a biomarker for poor prognosis and a predictor of vitamin C combination therapy in breast cancer

Authors:

Y-C. Lee, H-L. Chou, T-T. Nguyen; Academia Sinica, Taipei, Taiwan

Abstract Body:

Breast cancer is the most common malignancy and the leading cause of cancer mortality among women worldwide. Treatment failure and breast cancer mortality are primarily caused by cancer heterogeneity and metastasis. Metastasis cancer cells adapt to the environmental changes during the metastatic cascade through selection and metabolism reprogramming. Thus, the discovery of new markers and development of treatments targeting metabolism reprogramming will benefit breast cancer patients at high risk of metastasis. Here we report the identification of the increased expression of glucose transporter 10 (GLUT10) is associated with poor survival in all subtypes of breast cancer patients. Furthermore, we show that GLUT10 expression enhances cancer progression through promoting mitochondrial function and HIF-1-mediated pathways in a glucose concentration-dependent manner. GLUT10 transports the dehydroascorbic acid, the oxidize form of ascorbic acid (vitamin C) more efficiently than glucose. Notably, this GLUT10-induced breast cancer progression can be disrupted by vitamin C supplementation to inhibit mitochondrial function and enhance HIF-1 degradation. Our study reveals that GLUT10 is a crucial regulator of metabolism reprogramming and breast cancer metastasis, serving as a biomarker and an actionable therapeutic target for breast cancer.

Cancer Posters - Wednesday

PB1126. Going beyond the atlas: Mapping the tumor landscape with complete genomic signatures

Authors:

K. Kennedy¹, J. Dahl¹, M. Graybill¹, T. Morozova¹, J. Zawistowski², J. Blackinton³, J. West⁴; ¹BioSkryb Genomics Inc, Durham, NC, ²BioSkryb Genomics, Inc., Durham, NC, ³BioSkryb Genomics, Durham, NC, ⁴BioSkryb, Inc., Durham, NC

Abstract Body:

Glioblastoma multiforme (GBM) represents an aggressive malignancy with dismal outcome. Despite recent advances in tumor biology, there are limited data capable of linking tumor landscape with genomic signatures to improve patient outcomes. Current tissue atlas methods capably identify cellular location and phenotype in tumor sections, however, they woefully underrepresent the totality of the genomic and transcriptomic landscape, frequently focusing on a pre-defined panel of genes or transcripts. One powerful combination capable of revealing such data is the CellCelector platform from ALS paired with ResolveOME to reveal the complete genome and transcriptome of a single cell. Here, we present an unbiased mapping approach that simultaneously allows for the complete assessment of the tumor genome and transcriptome at the single cell level in a highly heterogenous and deadly tumor type. In this study, GBM tissues were digested *in-situ* and single cells selected for analysis using the CellCelector platform from ALS. For this pilot project, a total of 88 cells were evaluated in an unbiased survey across the landscape of the tumor. Single cells were selected distanced 10uM apart and importantly, no pre-defined stains were utilized to ensure random cell sampling. Single cells were processed using ResolveOME, enabling simultaneous evaluation of the complete genome and transcriptome. Whole genome and whole transcriptome sequencing was performed targeting 70M PE reads and 2M PE reads respectively. After sequencing, genomic and transcriptomic data were processed using the BaseJumper platform to identify cell type, cellular function, and differential gene expression in relation to genomic heterogeneity. We observe substantial heterogeneity between cells that can be organized into clear lineage tracing relationships between both spatial arrangement and mutational signature. This enables an improved understanding of the development of the tumor, and importantly, key insights into potential treatments.

Cancer Posters - Thursday

PB1127*. HDM2 differentially modulates the molecular phenotype of lung tumor cells of varying p53 genotypes

Authors:

Y. Wang, C. Li, K. Ramos; Texas A&M Inst. of BioSci.s and Technology, Houston, TX

Abstract Body:

Retrotransposons such as the Long Interspersed Nuclear Element-1 (LINE-1) represent the most powerful remodeling force of the human genome. LINE-1 is the only autonomous retrotransposon remaining in the human genome and is strongly linked to the poor prognosis of non-small cell lung cancers. Previous studies by our group identified a 4kb intronic LINE-1 insertion into the NACC2 locus of nickel-transformed human bronchial epithelial cells. This insertion led to dramatic reductions in NACC2 at both the mRNA and protein levels. The mRNA levels of HDM2, a protein repressed through NuRD and a negative regulator of p53 through polyubiquitination, were markedly increased in transformed cells. To evaluate the functionality of the HDM2/p53 genetic network, HDM2 was overexpressed in three independent clones of NCI-460 (p53^{wt}), NCI-520 (p53^{mut}), and NCI-1299 (p53^{mut}) cells, and the protein expression of critical molecular targets examined by Western blotting. HDM2 overexpression increased LINE-1 ORF-1p levels in all three clones of wild-type NCI-460 cells but decreased protein expression in all NCI-520 and NCI-1299 clones. TP53 increased in NCI 460 cells and as expected was undetectable in NCI-520 and NCI 1299 clones. The expression level of EGFR did not change irrespective of the p53 genotype, while RB decreased in NCI-H460 clones, but remained unchanged in NCI-520 and NCI-1299 clones. These findings establish the functional integrity of the HDM2/p53 axis and the strong influence of TP53 interactions with LINE-1 in defining lung cancer phenotypes. Together, these data implicate LINE-1 as a targetable pathway for precision therapeutics in lung cancer.

Cancer Posters - Wednesday

PB1128. Hemophagocytosis related to acute promyelocytic leukemia is also positive for the *PML::RARA* gene fusion

Authors:

A. García Romero¹, M. Magaña-Torres², R. González-Arreola¹, C. Borjas-Gutiérrez², J. González-García²; ¹Univ. de Guadalajara, Guadalajara, Mexico, ²Inst. Mexicano del Seguro Social, Guadalajara, Mexico

Abstract Body:

Introduction: Acute promyelocytic leukemia (APL) is characterized by the chromosomal translocation t(15;17)(q24.1;q21.2), which fuses the *PML* and *RARA* genes, raising the hybrid gene *PML::RARA* considered the direct cause of the pathology. In several types of leukemias with different chromosomal arrangements, an hemophagocytic phenomenon has been observed, where the macrophages show a great phagocytic activity of other blood cells; this phenomenon has previously been reported in association with APL on four occasions. The objective of this work was to determine the presence of the *PML::RARA* fusion in phagocytic and phagocytosed cells observed in APL. The study was carried out in a total of 22 patients with APL. Samples were taken before antineoplastic treatment. Patient's data of their clinical characteristics and blood studies were evaluated. Hemophagocytic binomials (phagocytic cell/phagocytosed cell) were identified in bone marrow smears stained with Wright; then, we performed a fluorescence in situ hybridization (FISH) study with the commercial *PML/RARA* dual color/dual fusion in order to determine the presence or absence of the *PML::RARA* gene fusion in these cells. Results: The average age of the patients was 25.6 years, 13 adults and 9 children; 14 men and 8 women. The most common clinical symptoms were cytopenia and coagulopathy. Hemophagocytic binomials were observed in all patients. A total of 548 binomials were evaluated. It was found that the most frequent combination of binomials was the one where both the phagocytic and phagocytosed cells were positive for the *PML::RARA* fusion (81.57%) (p<0.0001; Yates corrected χ^2 test). An unexpected finding was the observation of cells showing a netotic-like morphology, which sometimes appeared trapping erythrocyte cells. These cells were observed in all patients and all without exception were positive for the *PML::RARA* fusion. Conclusions: The hemophagocytic phenomenon was observed in all APL patients. The combination where both cells (phagocytic cell/phagocytosed cell) were positive for the *PML::RARA* gene fusion, was the most frequent of the four possible combinations. Almost all phagocytic cells (544/548) were positive for the *PML::RARA* gene fusion. All netotic-like cells were positive for the *PML::RARA* gene fusion. It is possible that the mutational event that gave rise to the *PML::RARA* gene fusion had occurred in a common progenitor cell of the monocyte/macrophage and myelocyte lineage.

Cancer Posters - Thursday

PB1129. Hereditary Cancer Variants & Homologous Recombination Repair Deficiency in Biliary Tract Cancer

Authors:

H. Nakagawa¹, Y. Okawa¹, T. Nakamura², S. Hirano², Y. Momozawa¹; ¹RIKEN IMS, Yokohama, Japan, ²Hokkaido Univ. Faculty of Med., Sapporo, Japan

Abstract Body:

Background: Biliary tract cancer (BTC) is a rare malignant tumor, but the incidence of BTC is high in Japan, East Asia and South America and increasing worldwide. The heritability and actionability of molecular therapies for BTC are uncertain. Although associations between BTC and *BRCA* germline variants have been reported, homologous recombination deficiency (HRD) has not been investigated in BTCs. **Methods:** We here analyzed germline variants in 27 cancer-predisposing genes (JAMA Oncology 2022) in 1,292 Japanese BTC patients, which were enrolled in Biobank Japan (BBJ) and Hokkaido University Hospital, and 37,583 controls without a personal and family cancer history. We compared the pathogenic germline variant frequency between cases and controls and documented the demographic and clinical characteristics of carrier patients. In addition, whole-genome sequencing analysis of 45 BTC tissues was performed to evaluate somatic mutations and homologous recombination deficiency status. **Results:** Targeted sequencing identified 5,018 germline variants, which were classified into 317 pathogenic, 3,611 variants of uncertain significance, and 1,090 benign variants. Seventy-one BTC cases (5.5%) had at least one pathogenic variant of the 27 cancer-predisposing genes, indicating hereditary cancer. Pathogenic germline variants in BTCs were significantly ($P < 0.00185$) enriched in *BRCA1* (OR=13.6), *BRCA2* (OR=6.5), *APC* (OR=18.2), and *MSH6* (OR =5.2). *PALB2* variants were marginally associated with BTC ($P=0.01$, OR=5.3). The mean BTC diagnosis age of the carriers was significantly younger than the non-carriers and the carriers had more personal history of breast cancer ($P=0.026$, OR=5.8) and family history of breast cancer ($P=0.047$, OR=2.5). Whole-genome sequencing analysis demonstrated that BTCs with pathogenic germline variants in *BRCA2* and *PALB2*, accompanied with loss of heterozygosity (LOH), displayed homologous recombination DNA repair deficiency phenotypes. Conversely, pathogenic germline variants without LOH in homologous recombination-related genes showed homologous recombination proficient phenotypes. **Conclusions:** This study described the heritability and the actionability of homologous recombination deficiency targeted treatments and provides possibilities for expanding therapeutic strategies such as PARP inhibitor and platinum-based drugs, and screening for BTC.

Cancer Posters - Wednesday

PB1130*. Heterozygous loss of *AURKB* in the germline associates with protection from metastasis and death from cancer

Authors:

L. Ward, W. Broom, C. Willis, A. Deaton, A. Holleman, L. Krohn, R. Hoffing, P. LoGerfo, M. Plekan, P. Nioi; Alnylam Pharmaceuticals, Cambridge, MA

Abstract Body:

Both germline and somatic genetic variants contribute to cancer formation and progression, and identifying these variants has led to the discovery of tumor suppressors and oncogenes, leading to the rational development of chemotherapies. While tumor sequencing and expression studies have been useful at understanding somatic cancer genetics, germline genetic associations from GWAS and family studies are more difficult to interpret: well-powered associations with common variants are not always easily assigned to a gene, and associations with rare variants are best powered to detect risk rather than protection. We took advantage of the unprecedented scale of the UK Biobank exome sequencing data to search for rare coding variants protective against cancer among 397,212 people. For phenotypes, we aggregated cancer at the ICD10 “block” level and used data from the cancer and death registries, inpatient hospitalizations, self-reports, and primary care diagnoses, and included BMI, smoking, and drinking behavior as covariates; for genotypes we aggregated rare (MAF < 1%) variants predicted to be loss of function (pLOF) or predicted damaging missense (CADD > 25). The strongest protective association was between *AURKB* variants (N = 2847 carriers / 397,212 participants) and ICD10 block C76-C80, which includes secondary malignant neoplasms. Looking more closely, we detect protection from having a primary tumor (C00-C97 excluding C77-C79; OR = 0.82; p = 1.8×10^{-5}), metastasis (C77-C79; OR=0.58; p = 9.5×10^{-8}), and death from cancer (OR = 0.64; p = 6.4×10^{-5}). Limiting the analysis to only 97,500 individuals with a primary malignancy diagnosed, we find that conditioned on having cancer, *AURKB* damaging variant carriers (N = 617) have a better prognosis, being less likely to experience metastasis (OR = 0.64; p = 7.9×10^{-5}) or death (OR = 0.71; p = 5.4×10^{-3}). PheWAS indicates no other phenome-wide significant associations, suggesting *AURKB* as a safe target for cancer. Furthermore, complementary TCGA data show *AURKB* overexpression and duplication associating with poorer prognosis. While small molecules inhibiting *AURKB* and other aurora kinases have showed disappointing efficacy and safety in the clinic, inhibition using other modalities such as RNAi may have therapeutic application in oncology, although additional research is needed.

Cancer Posters - Thursday

PB1131. High tumor mutational burden by whole-genome sequencing in resected non-small cell lung cancer in never smokers is associated with worse prognosis.

Authors:

L.-J. Ruel¹, Z. Li¹, N. Gaudreault¹, C. Henry¹, V. Saavedra Armero¹, D. K. Boudreau¹, T. Zhang², M. T. Landi², C. Labbé¹, C. Couture¹, P. Desmeules¹, P. Joubert¹, Y. Bossé^{1,3}; ¹Inst. universitaire de cardiologie et de pneumologie de Québec – Université Laval, Québec, QC, Canada, ²Div. of Cancer Epidemiology and Genetics, Natl. Cancer Inst., Bethesda, MD, ³Dept. of Molecular Med., Université Laval, Québec, QC, Canada

Abstract Body:

Introduction: Tumor mutational burden (TMB) is a measure of the number of somatic mutations in a tumor. In non-small-cell lung cancer (NSCLC), TMB is a surrogate biomarker of neoantigen load and immunotherapy efficacy. Data are scarce about TMB as a biomarker in never smokers with NSCLC. Using whole-genome sequencing (WGS), we aimed to 1) test whether TMB is a prognostic biomarker of survival after surgery in never smokers with NSCLC, 2) define a prognostic TMB cutoff, and 3) compare TMB derived from WGS with exome sequencing (WES) and commercial NGS gene panels.

Methods: TMB was assessed by WGS and *in silico*-reduced WES and targeted NGS panels in 93 paired tumor-normal samples from never smokers who underwent lung cancer resection with curative intent. Kaplan-Meier and multivariate Cox proportional hazards regression analyses were performed to test for association with survival after surgery and to identify the optimal prognostic TMB cutoff. TMB derived from WGS was compared to *in silico*-reduced sequencing size of WES and targeted NGS panels.

Results: Tumors of never smokers with NSCLC had low TMB scores (median of 1.10 mutations/Mb, range of 0.01-14.71). A TMB cutoff of 1.40 mutations/megabase was associated with a 5-year overall survival of 54% in the high-TMB (31% of cases) compared to 82% in low-TMB patients (log-rank $p = 0.0017$). TMB scores from WGS and WES were highly correlated (Spearman $\rho = 0.91$, $p < 2.2e-16$). TMB scores from NGS panels demonstrated high intra-individual fluctuations and identified high-TMB patients with 54% concordance in average compared to WGS.

Conclusions: In resected NSCLC of never smokers, high TMB was associated with worse prognosis. WES provided a good estimate of TMB while targeted NGS panels seem to lack adequate depth and resolution in the setting of low mutation burden. Further studies are needed to evaluate TMB as a predictive biomarker for immunotherapy in never smokers.

Cancer Posters - Wednesday

PB1132*. High-throughput functional screening of candidate causal variants from lung cancer susceptibility loci

Authors:

H. Patel¹, E. Long¹, A. Golden¹, J. Yin¹, K. Funderburk¹, J. Feng¹, R. Hung², C. Amos³, L. Song⁴, J. Shi⁵, N. Rothman⁶, Q. Lan⁶, International Lung Cancer Consortium, J. Choi¹; ¹Lab. of Translational Genomics, Div. of Cancer Epidemiology and Genetics, Natl. Cancer Inst., Bethesda, MD, ²Lunenfeld-Tanenbaum Res. Inst., Sinai Hlth. System, Univ. of Toronto, Toronto, ON, Canada, ³Inst. for Clinical and Translational Res., Baylor Coll. of Med., Houston, TX, ⁴Div. of Cancer Epidemiology and Genetics, Natl. Cancer Inst., Bethesda, MD, ⁵Biostatistics Branch, Div. of Cancer Epidemiology and Genetics, Natl. Cancer Inst., Bethesda, MD, ⁶Occupational and Environmental Epidemiology Branch, Div. of Cancer Epidemiology and Genetics, Natl. Cancer Inst., Bethesda, MD

Abstract Body:

Lung cancer (LC) is the leading cause of cancer deaths globally. While smoking is the principal cause, genetic factors also contribute to LC as shown by 12-21% heritability. GWAS have identified multiple LC risk loci including those that are distinct in the major histological types. However, functional characterization of GWAS loci is challenging because most GWAS variants are non-protein-coding and linkage disequilibrium (LD) limits fine-mapping resolution. Hence, we employed massively parallel reporter assays (MPRA) to test transcriptional activity of risk-associated variants *en masse*. We selected 2,245 variants based on the association *P* values (log likelihood ratio <1000) or LD ($R^2 \geq 0.8$) from 41 risk loci from 3 recent GWAS of Asian and/or European populations (each including >20,000 cases). MPRA library was constructed using 145-bp genomic sequences flanking the variants with each allele in both strands and tagged with 25 unique 12-bp tags. Final library containing 239,800 oligonucleotides was cloned into a luciferase plasmid (input DNA), which was transfected into lung cancer cells representing two histological subtypes (A549: adenocarcinoma; NCI-H520: squamous cell carcinoma). We also incorporated benzo[a]pyrene (BaP) exposure (major tobacco-smoke carcinogen) or DMSO to analyze the impact of smoking on variant function. BaP dosage and exposure duration were optimized based on the induction of known target genes and cell viability. Transfection efficiency was optimized to achieve 25 million transfected cells in each of 5 transfections per treatment for each cell line. Regulatory potential of variants was evaluated by tag sequencing and counting in DNA input and mRNA output. Our QC results showed high input DNA tag recovery (>98%) in MPRA mRNA and high inter-transfection correlation ($r > 0.8$) indicating reproducibility among the replicates. At FDR <0.01, we identified 509 and 525 variants (DMSO and BaP groups combined) with significant allelic transcriptional activities in A549 and H520 cells, respectively (~23% of tested variants). Moreover, we found 101 and 93 variants only significant in BaP exposed A549 and H520 cells, respectively, highlighting potential effect of tobacco smoke exposure on variant function. While 190 of the MPRA significant variants were common in both cell types, 319 and 335 variants were unique to A549 and H520, respectively, indicating distinct variant function based on the histological context. Thus, MPRA with relevant cell type and exposure prioritized functional variants, which can be further analyzed by lung-eQTL and chromatin interaction data to identify new target genes and elucidate genetic basis of LC.

Cancer Posters - Thursday

PB1133. Identification of key molecular mechanisms in IDH mutant brain tumors to enable precise risk stratification

Authors:

S. Bhattacharya¹, A. Dawood¹, H. Barseghyan², E. Vilain³, M. Bornhorst⁴; ¹Children's Natl. Hosp., Washington DC, DC, ²Childrens Natl. Med. Ctr., Washington, DC, ³Children s Natl. Med. Ctr., Washington, DC, ⁴Children s Natl. Hosp., Washington, DC

Abstract Body:

Isocitrate dehydrogenase 1 and 2 (IDH) mutations are the most prevalent genetic alterations in adult low- to intermediate grade diffuse astrocytomas, anaplastic astrocytomas, and oligodendrogliomas. Previous studies of adult IDH-mutant tumors have revealed unique tumor-specific signatures, allowing for stratification based on molecular phenotype and clinical presentation. However, very little is known about pediatric IDH-mutant tumors, resulting in fragmented clinical care. To perform precise molecular profiling of IDH-mutant brain tumors to predict patient outcomes and guide potential future therapeutic developments First, we harmonized data from nine pediatric and adult brain tumor datasets, along with our pediatric IDH-mutant tumor samples, to determine the genetic and epigenetic profiles of the brain tumors. We then performed a comprehensive and integrated analysis of genetic, epigenetic, transcriptomic and demographic data from IDH-mutant tumors to identify co-occurring somatic/germline and epigenetic changes within the tumors. Finally, we determined the impact of genomic, epigenomic and demographic parameters on patient outcomes. Using exome sequencing we identified mutations of tumor suppressors like *TP53*, *ATRX* and *NF1*, co-occurring with *IDH* mutations. Additionally, we also identified genes like *MUC3A* and *MUC16*, which has not been previously found to co-occur with *IDH* mutations. Combining the genomic, with the transcriptomic and epigenetic data, we would enable precise risk stratification that can be used to optimize treatments for all patients with IDH-mutant tumors.

PB1134. Identification of target genes and pathways involved in triple-negative breast cancer proliferation and stemness using genome-wide CRISPR screens.

Authors:

T. Li¹, G. Lu², W. Wang³, W-Y. Chan⁴, Z. Zhao¹; ¹The Chinese Univ. of Hong Kong, Hong Kong, China, ²Sch. of BioMed. Sci., Hong Kong, China, ³The Chinese Univ. of Hong Kong, Hong Kong, Hong Kong, ⁴The Chinese Univ. of Hong Kong, Shatin, China

Abstract Body:

Identification of target genes and pathways involved in triple-negative breast cancer proliferation and stemness using genome-wide CRISPR screens. Breast cancer is the leading cause of cancer death among women. Unlike other subtypes of breast cancer, triple-negative breast cancer (TNBC) is acknowledged as one of the most aggressive and refractory subtypes of breast cancer that accounts for most of breast cancer-related mortality. For decades, the therapeutic strategies of TNBC were limited to several traditional treatments, which can only eliminate the bulk tumor population. However, the remaining core population - cancer stem cells (CSCs) can develop new tumor tissues with a few cells to initiate disease relapse and invade other organs that contribute to cancer metastasis. Advanced targeted strategies - immunotherapies provide exciting prospects in TNBC treatment. However, it is paramount to identify cancer-specific antigens in advance. Genome-wide CRISPR-Cas9 screens have proven to be an exquisitely powerful method for discovering and functional annotation of genetic or epigenetic elements in biological processes. This study used two CRISPR-Cas9 screening libraries to perform high-throughput pooled screens in TNBC cell lines. One is the human membrane protein activation library, which aims to identify candidate genes encoding antigens that can serve as tumor-specific targets in immunotherapy. The other is the human epigenetic knockout library, which we hope can reveal the epigenetic “drivers” or driver genes regulated by epigenetic factors in TNBC. After weeks of consecutive culture, gene-edited cells were collected, and skewed gRNA distribution in the population will indicate essential genes in cancer cell proliferation. Non-cancer stem cells and cancer stem cells (mesenchymal-like, CD44+/CD24-; epithelial-like, ALDH1+) were separated by FACS, genes critical to stemness transformation will also be screened out. Many known TNBC-specific or promoting genes, such as *SUZ12*, *RAD51* and *PELPI*, were among the top ranks in our screening results. These coincidences confirm the biological reliability of our findings. KEGG pathway analysis showed most candidate genes were involved in cell cycle, NF- κ B, and thyroid hormone signaling pathways. The GEPIA database and Kaplan-Meier method also show that many top hits are tumor-specific and critical for patient survival. In the end, tissue microarray will be used to determine the clinical significance of candidates. Overall, our results provide essential genetic and epigenetic targets for developing TNBC treatments.

Cancer Posters - Thursday

PB1135. Identification of *USP9X* as a leukemia susceptibility gene.

Authors:

S. Sisoudiya^{1,2}, H. Li³, J. Schraw², M. Scheurer², A. Sabo³, P. J. Lupo², S. E. Plon^{1,2,3}; ¹Dept. of Molecular and Human Genetics, Baylor Coll. of Med., Houston, TX, ²Section of Hematology-Oncology, Dept. of Pediatrics, Baylor Coll. of Med., Houston, TX, ³Human Genome Sequencing Ctr., Baylor Coll. of Med., Houston, TX

Abstract Body:

Introduction: Data from the Genetic Overlap Between Anomalies and Cancer in Kids (GOBACK) Study (Lupo et al., 2019) indicated that children with multiple non-chromosomal anomalies (MCAs) were 5.9-times (95% CI 5.3-6.4) more likely to develop childhood cancer compared to children without these conditions. Based on this, we hypothesize that molecular characterization of children with MCAs and cancer can reveal novel cancer predisposition syndrome genes.

Method: Whole genome sequencing (WGS) was performed on DNA extracted from saliva samples of GOBACK families. Structural variants (SVs) were called using five callers. A consensus call was defined by greater than 50% reciprocal overlap and made by at least 2 callers. We also analyzed RNA-seq and overall survival data of 142 B-cell acute lymphoblastic leukemia (B-ALL) tumor samples in the TARGET program.

Results: SV analysis of WGS data (n = 20 trios) identified a novel 5kb *de novo* heterozygous inframe deletion in *USP9X* in a female proband with MCAs and B-ALL. Her phenotype was consistent with female-restricted X-linked syndromic intellectual developmental disorder-99 (MRXS99F). We extracted genotype and phenotype data from 42 female probands in the literature with *USP9X* germline variants, two of whom had B-ALL. The patient with the inframe deletion had anomalies similar to the pattern in subjects with loss-of-function variants. Notably, the cumulative incidence of B-ALL among female patients with germline variants in *USP9X* below the age of 8 years (14%) is significantly higher than an age- and sex-matched cohort (0.002%) from the Surveillance, Epidemiology, and End Results (SEER) database (P<0.0001, log-rank test). In sporadic B-ALL, somatic loss of function *USP9X* mutations occur, consistent with a tumor suppressor mechanism. *USP9X* encodes a highly conserved deubiquitinating enzyme. Expression analysis of high-risk sporadic B-ALL patients demonstrates that pathways such as cell cycle, TGF-beta signaling are associated with changes in *USP9X* expression. Overall survival data shows that high-risk ALL patients with lowest quartile *USP9X* expression had significantly poorer overall survival compared to patients with top quartile expression (HR = 2.00; 95% CI: 1.09 - 3.67; P = 0.02), which was validated in an independent B-ALL cohort.

Conclusion: Overall, we describe *USP9X* as a novel leukemia susceptibility gene associated with multiple congenital anomalies and B-ALL. *USP9X* also serves as a tumor suppressor in sporadic B-ALL where its low expression could be used to inform clinical management of high-risk B-ALL patients.

Cancer Posters - Wednesday

PB1136*. Identifying molecular markers of early stage ovarian cancer pathogenesis through whole genome CRISPR screening of mutant *BRCA1* fallopian tube cells.

Authors:

S. Dhungana¹, K. Ayaluri¹, F. Dezem¹, S. Chen^{1,2}, B. Davis^{1,2}, J. Plummer^{1,2}, S. Gayther^{1,2}; ¹Ctr. for Bioinformatics and Functional Genomics, Dept. of BioMed. Sci., Cedars-Sinai Med. Ctr., Los Angeles, CA, ²Applied Genomics, Computation and Translational Core, Cedars-Sinai Cancer, Cedars-Sinai Med. Ctr., Los Angeles, CA

Abstract Body:

An accumulation of genetic alterations transforms normal fallopian tube cells into high-grade serous ovarian cancers (HGSOC). A lack of understanding of the earliest stage molecular mutations in disease development continues to be an impediment for the prevention and care of the disease. Somatic *TP53* mutations are almost ubiquitous HGSOCs, acting as a driving factor for the dysfunction of critical biological processes involved cell division and apoptosis. *BRCA1* mutations predispose to HGSOC and usually occur in conjunction with *TP53* alterations. *BRCA1* functions in the DNA damage repair pathway and it is the breakdown of this process that leads to characteristic accumulation of gross interstitial alterations throughout HGSOC development. In the current study, we created early stage models of fallopian tube epithelial cells carrying both *TP53* and *BRCA1* pathogenic mutations and then used whole genome CRISPR screening of 19,500 genes targets in these models to identify genes associated with early stage neoplasia. We performed this negative selection CRISPR screen in FTE cells that were *BRCA1* wild-type (FT282^{*BRCA1:WT*}) *BRCA1* heterozygous (FT282^{*BRCA1:+/-*}) and *BRCA1* homozygous (FT282^{*BRCA1:-/-*}). Using the ‘Model-based Analysis of Genome-wide CRISPR/Cas9 Knockout’ (MAGeCK) method we identified genes that were enriched and depleted in FTE cells engineered to express different *BRCA1* mutations including several known cancer genes including *PAWR*, *AMOTL2*, *MDM2*, *MYH9*. We next integrated transcriptomic and proteomic profiling in these cell lines to further substantiate the genes found from MAGeCK analysis including: *PAWR*, a regulator of *WT1* (master transcription factor of HGSOC) that downregulates the anti-apoptotic protein *BCL2*; *MYH9*, which plays role in cytokinesis, cell shape and regulates *TP53* stability and localization; *AMOTL2*, which inhibits the *Wnt*/beta-catenin signaling pathway and plays role in polarity, proliferation, and migration; *C16ORF72*, a identified binding partner for *HUWE1*, which is a DNA damage response gene with a role in ubiquitin mediated degradation of *TP53*; and the *Myc* oncogene which is frequently amplified in ovarian and other cancer type. In conclusion, this highly novel study to screen the entire repertoire of coding genes in a single assay has identified multiple target genes that represent new candidates for the early stage detection and diagnosis of HGSOC, chemoprevention and targeted treatments and provides unique opportunities to identify common vulnerabilities for the three most frequent oncogenic alterations in fallopian tube epithelium.

Cancer Posters - Thursday

PB1137. Identifying strong instrumental variables for pleiotropic assessment in Mendelian randomization: CALGB/SWOG 80405 (Alliance).

Abstract Body:

Integrating genotype, gene expression, and clinical outcome data by Mendelian randomization (MR) technique provides potential opportunities for uncovering causal mechanisms underlying disease etiology. In this context, fulfilling MR assumptions on genetic variants as instrumental variables (IVs) are essential steps to yield unbiased results. Therefore, here we proposed an approach for selecting valid IVs to perform MR analysis. This approach allows for multiple IVs selected from expression quantitative trait loci (eQTL) analysis. We used a predictive model to assess if the accumulated effects of selected *cis*-eQTLs on gene expression can control unobserved sources of variability in investigating gene expression and outcome relationships. The predictive model accounts for linkage disequilibrium and interconnectivity among genes since it is a multivariable polygenic model. If the predicted gene expression significantly affects the outcome, the accumulated effect of IVs is strong. We considered no pleiotropy for the IVs with a *p*-value > 0.01 in GWAS analysis and potential pleiotropic effect for the IVs with a *p*-value < 0.01. To test the latter's pleiotropy, we simultaneously estimated the effects of IVs and gene expressions on the outcome. If only the effect of IVs were significant in the model, it was an indicator of the pleiotropic action of the IVs.

We used tumor RNA-seq and germline genotype data from 1,284 patients with metastatic colorectal cancer treated either with cetuximab or bevacizumab monoclonal antibodies through a randomized phase III trial (CALGB/SWOG 80405). Cetuximab targets epidermal growth factor receptor (EGFR) and bevacizumab vascular endothelial growth factor (VEGF). We found genes causally associated with the overall survival (OS) and IVs that have both direct and indirect effects on OS, specific to each treatment. For instance, we found *WDR62* (*p*-value: 0.639 vs. 0.019) and *SCD5* (*p*-value: 0.056 vs. 0.47) genes with unfavorable putative causal effects on OS in patients treated with cetuximab and bevacizumab, respectively. *SCD5*, as a key regulator of energy metabolism, highlighted the possible risk of dyslipidemia in the use of vascular endothelial growth factor (VEGF) inhibitors. *WDR62* has shown the oncogenic role across a series of human tumors, including colorectal cancer. We replicated the findings using a replication set for each treatment, which proved the power of the proposed approach in providing

Hlth., Univ. of Helsinki, Helsinki, Finland, ⁵Dept. of Clinical Genetics, HUSLAB, HUS Diagnostic Ctr., Univ. of Helsinki and Helsinki Univ. Hosp., Helsinki, Finland, ⁶Dept. of Med. Genetics, Univ. of Helsinki, Helsinki, Finland, ⁷Dept. of Clinical Genetics, Helsinki Univ. Hosp., Helsinki, Finland, ⁸Breast Surgery Unit, Comprehensive Cancer Ctr., Helsinki Univ. Hosp., Helsinki, Finland, ⁹Univ. of Helsinki, Helsinki, Finland, ¹⁰Finnish Cancer Registry and Cancer Society of Finland, Helsinki, Finland

Abstract Body:

Polygenic risk scores (PRS) for breast cancer are effective for stratifying women for their breast cancer risk. They show potential for risk-stratified screening, but there is limited evidence on the impact of PRSs on interval and screen-detected breast cancer in population-based data. Similarly, although family history and pathogenic variants (PV) are applied for risk-tailored screening in selected individuals, limited data about their utility on a national level exists. In Finland, women are biennially screened nationwide with mammograms between ages 50 and 69. Using FinnGen, combining the national Mass Screening Registry for breast cancer (780,091 screening invitations 1992-2019) with imputed genotypes and the Finnish Cancer Registry, we perform a comprehensive assessment of the impact of a genome-wide PRS (PRS-CS, 1,079,089 variants), Finnish-enriched pathogenic variants, and family history on breast cancer detection within and outside the screening program for 117,252 screening-aged women (12,965 cases).

The higher the PRS, the higher was the positive predictive value (PPV) of breast cancer screening: at age 50, the PPV in the highest vs lowest PRS deciles were 24.1% and 6.0%, and at age 60, 49.0% and 14.7%. Similar PPVs were detected for carriers of PVs and for family history, and combinations of these three risk factors led to PPVs up to 55.2%. No excess of benign breast lesions was detected with any of the risk factors. All performed similarly for in situ and invasive cancers. A high PRS (>90%) conferred a particularly high risk for bilateral breast cancer (HR 4.85, 95%CI 3.28-7.17), with similar risks for PVs and positive family history. At all ages, women with a high PRS with a negative screening finding had an elevated risk of being diagnosed with an interval breast cancer, and a screen-detected cancer in the next screen. This indicates that women with high PRS could benefit from more frequent screens. The proportion of women with a lymph node-positive breast cancer at diagnosis was similar for the risk factors (range 41.8-42.9% for interval-detected, 29.2-32.3% for screen-detected).

Our findings demonstrate benefits of risk-based screening in breast cancer. Risk-tailored screening has long been employed for subgroups of women with family history and/or PVs. Our real-life data provide evidence that it would be beneficial to use PRSs - the risk factor most common of the three - together with PVs and family history for optimal risk-based screening. Although these risk factors were compelling for risk stratification within the Mass Screening Registry, the optimal strategies for a cost-effective, risk-tailored breast cancer screening remain to be studied.

Cancer Posters - Thursday

PB1139. Implementation of new ClinGen/CGC/VICC recommendations for classification of oncogenicity of somatic variants using AI

Authors:

Y. Einhorn, O. Shani; Genoox, Palo Alto, CA

Abstract Body:

Introduction: The ClinGen, CGC and VICC recently published new recommendations for the classification of pathogenicity of somatic variants in cancer, in order to create a set of standards when classifying the oncogenicity of a somatic variant. While the detailed evaluation criteria will increase classification consistency between different labs, the process is time-consuming and holds some computational challenges. Here, we present a novel AI-based oncogenicity classification engine for somatic variants based on these new recommendations and integrated it into Franklin (franklin.genoox.com), an open-access platform for variant interpretation.

Methods: An AI oncogenic classification engine was developed and integrated into Franklin for implementing the new recommendations and removing their computational and technical challenges. We evaluated the classifications against the dataset which was classified by experts during the process of creating these recommendations, which included 94 variants in 10 cancer-related genes.

Results: Comparing the results shows high concordance without any strong conflict between the experts and Franklin. 100% (34/34) of the Oncogenic/Likely-Oncogenic variants were classified as Oncogenic/Likely-Oncogenic, 100% (7/7) of the B/LB variants were classified as B/LB/VUS-Leaning-Benign (VUS-B). 74% (23/31) of the VUS variants were classified as VUS, VUS-Leaning-Oncogenetic, or VUS-B. Of the 8 VUS conflicts, 2 were classified as B/LB and 6 were classified as Oncogenic/Likely-Oncogenic, suggesting that there might be additional evidence to be considered.

Conclusions: Herein we demonstrated how Franklin can aid in following the new oncogenic classification recommendations, a task that is challenging, and time-consuming. To the best of our knowledge, this is the only solution that currently exists today.

Cancer Posters - Wednesday

PB1140. Implementation, utilization, and diagnostic outcomes of a technology-enabled telehealth-based program for individuals to access multi-cancer early detection testing

Authors:

S. Weissman; Genome Med., South San Francisco, IL

Abstract Body:

Background: Multi-cancer early detection (MCED) is a novel method to screen for many different cancers by detecting circulating tumor DNA in blood. Upon its commercial availability in 2021, we established two nation-wide telehealth programs that rely on digital tools to provide access to MCED in an efficient and scalable manner: 1) a patient-initiated program (PIP) and 2) an employer benefit program (EBP). Qualification for MCED was assessed via a digital tool for both programs, but the EBP required a consultation with a genetic counselor (GC) for individuals <50 years of age.

Purpose: We investigated the implementation, utilization, and diagnostic outcomes of a technology-enabled telehealth program that provides access to MCED.

Methods: We performed a chart review of consecutive patients who presented for MCED from June 2021 - April 2022 in two separate programs - 1) an EBP for individuals aged 50 or older and those that were 18-49 years of age and had a GC consultation to determine eligibility based on personal and family history; 2) a PIP for individuals aged 40 or older through an automated questionnaire that assessed eligibility based on cancer risk factors. We extracted patient sex, age, risk criteria met, personal cancer history, test completion, and MCED results.

Results: 99% (4909/4963) of people completed the screening process by finishing the questionnaire or having a GC consultation. 59% (2919/4909) and 41% (1990/4909) came through the PIP and EBP, respectively. 59% were male (n=2896) and the mean age was 54 (SD=12). Overall, 78% (3810/4909) qualified for MCED. Of those, 78% (2960/3810) qualified based on age alone (50 or older). The remaining individuals (n=850) qualified because of a family history of cancer (790, 93%), smoking history (128, 15%), HIV infection (9, 1.1%), and/or previous solid organ transplant (5, 0.6%). Through the EBP, 23% (459/1990) of individuals met with a GC and of those, 55% (253/459) qualified for MCED. To date, 76% (n=2910) of individuals completed MCED, 12% (n=462) have testing pending, and 11% (n=438) never completed or canceled testing. 18 of the 2910 individuals with a completed test had a cancer signal detected (0.61%); mean age was 63 years (SD=8.7) and the majority were male (78%; 14/18). 50% (9) were diagnosed with cancer, 22% (4) were likely false positives, and 5 (28%) are still undergoing a clinical work-up.

Conclusion: MCED testing offered through a nation-wide telemedicine program had high utilization and completion of both the digital tool and testing. This suggests that a tech-enabled telehealth model can be used successfully to provide access to MCED with minimal barriers.

PB1141. Inference on the genetic architecture of breast cancer risk

Authors:

Y. Yasui¹, W. Letsou², F. Wang³, C. Im⁴, Y. Sapkota⁵, Z. Wang², S. Mirzaei Salehabadi¹, J. Baedke⁶, W. Moon⁵, Q. Liu⁴, L. Robison⁶, J. Martinez⁷; ¹St Jude Children's Res. Hosp., Memphis, TN, ²St. Jude Children's Res. Hosp., Memphis, TN, ³St. Jude Children's Res. Hosp., Memphis, TN, ⁴Univ. of Alberta, Edmonton, AB, Canada, ⁵St Jude Children's Res. Hosp., Memphis, TN, ⁶St. Jude Children's Res. Hosp., Memphis, TN, ⁷The Polytechnic Univ. of Catalonia, Barcelona, Spain

Abstract Body:

What are the major determinants of women's risk of developing breast cancer? Rare mutations such as those in the *BRCA1/2* genes, common alleles identified by genome-wide association studies, or non-genetic factors? The largest population-based twin study of cancer, the Nordic Twin Study of Cancer (NTSC), with 3,933 breast cancer cases among 21,054 monozygotic and 30,939 dizygotic female twin pairs, provided exceptional data from which we can draw inferences regarding this question. Specifically, there were three key observations in NTSC: (#1) the average lifetime breast cancer risk, approximately 8%, does not differ by twin zygosity; (#2) the mean time interval between diagnoses when both twins develop disease (i.e., the disease concordance) also does not differ by twin zygosity; but, (#3) conditioned on one twin's developing disease, the incidence rate in the co-twin is approximately 1% per year if the pair are monozygotic and 0.5% per year if they are dizygotic. Assuming that non-genetic risk factors are shared similarly between twins regardless of their zygosity, we can draw two conclusions from these observations. First, (#1) and (#3) imply that the major determinant of risk is in the germline DNA: conditioned on the development of any breast cancer in one twin (not limited to "familial breast cancer"), the incidence rate in the co-twin is several-fold higher than the average risk (about 8% in lifetime) if the pair is monozygotic, and only half as much higher if dizygotic. Second, the two-fold difference in the conditional incidence rate between zygositys (#3) seemingly conflicts with the equality of the mean inter-twin disease intervals in disease concordance between zygositys (#2). This can be resolved, however, if rare variants, not common variants, in the germline DNA elevate the risk. That is, the two-fold difference in the conditional incidence rate between zygositys reflects the 50:50 chance of a dizygotic co-twin's carrying or not carrying one of the high-risk rare variants, and only when (like monozygotic twins) both twins carry the variant and develop disease (disease concordance), the inter-twin disease interval can be calculated (hence the equality of the mean interval between zygositys). These conclusions are consistent with the hypothesis of Peto and Mack, which states that only a subgroup of women carry the risk and that this risk is high, and that of McClellan and King, which states that breast cancer risk is defined by genetic heterogeneity with many rare underlying mutations. Our presentation details the deductive reasoning that derives these conclusions and draws a critical inference regarding breast cancer etiology.

Cancer Posters - Wednesday

PB1142*. Integrating GWAS and 3D chromatin interactome data to identify multi-cancer risk genes in hormone-related cancers.

Authors:

S. Rivera^{1,2}, J. Beesley¹, H. Sivakumaran¹, M. Moradi Marjaneh^{1,3}, K. Hillman¹, S. Nair¹, S. Edwards^{1,2}, J. French^{1,2}; ¹QIMR Berghofer Med. Res. Inst., Brisbane, Australia, ²Queensland Univ. of Technology, Brisbane, Australia, ³UK Dementia Res. Inst. at Imperial Coll., London, United Kingdom

Abstract Body:

Breast, endometrial, ovarian and prostate are hormone-related cancers that account for over 15% of all cancer deaths. To date, GWAS has identified 150 breast, 16 endometrial, 37 ovarian and 167 prostate cancer-associated genetic variants. In this study, we observed that those variants are often in close proximity suggesting common mechanisms underlying these cancers. We identified 45 multi-cancer risk regions (MCRRs) defined as genomic regions that contain variants associated with risk of two or more hormone-related cancers. Disease-associated variants frequently fall in DNA regulatory elements, such as enhancers, that can lie up to 1Mb from their target gene promoter. Therefore, we hypothesized that within MCRRs, genetic variants associated with different cancer types modulate the expression of common target genes through altered tissue-specific regulatory elements. To enrich for chromatin interactions between gene promoters and enhancers within MCRRs in relevant cell types, we performed promoter capture HiC (PCHiC) in twelve immortalised 'normal' and cancer cell lines. To identify MCR genes we integrated PCHiC interactions and risk-associated SNPs within MCRRs. We identified 78 candidate MCR genes associated with at least two hormone-related cancers. This list includes established cancer driver genes such as MYC and CCND1, but also >20 genes with little or no reported role in cancer. One example is MLLT10, a candidate breast and ovarian cancer risk gene. MLLT10 encodes a transcription factor that interacts with DOT1L, which methylates H3K79, a histone mark associated with active transcription. Reporter assays show risk SNPs induced MLLT10 promoter activity, suggesting increased MLLT10 contributes to cancer risk. CRISPR-based functional studies are currently underway to elucidate the role of MLLT10 in breast and ovarian cancer development. We anticipate that some of the identified multi-cancer risk genes may provide new drug targets for future prevention or treatment of hormone-related cancers.

Cancer Posters - Thursday

PB1143. Integrative data analysis to uncover genes and pathways underlying the aggressiveness of lung cancer brain metastasis and the overall prognosis

Authors:

R. Asakereh^{1,2}, Q. Zhang^{1,3}, P. Shooshtari^{1,2,4}, ¹Univ. of Western Ontario, London, ON, Canada, ²Children's Hlth.Res. Inst., Victoria Hosp., London Hlth.Sci. Ctr., London, ON, Canada, ³Univ. Hosp., London Hlth.Sci. Ctr., London, ON, Canada, ⁴Ontario Inst. for Cancer Res., Toronto, ON, Canada

Abstract Body:

Introduction. Recent advances in cancer diagnosis and treatment have resulted in better management of the mortality caused directly by tumors at primary sites. However, this on the other hand, has increased the proportion of observed metastatic cases among cancer patients. In particular, we observe a relatively high portion of brain metastasis with primary lung cancer. The ability to predict the prognosis of the primary tumor and the prediction of how rapidly the metastasis may occur, would result in providing better treatment decisions. As a step towards this goal, we need to identify the specific molecular mechanisms underlying fast/slow metastasis in different patients. Current studies in this area have several drawbacks, including neglecting the heterogeneity of the tumor cells, and/or focusing on a limited number of genes rather than a whole transcriptome analysis. In our study, we have addressed these drawbacks and uncovered several genes and molecular processes affecting the prognosis of the lung tumor brain metastasis.

Methods. We have collected a dataset which contains the spatially profiled gene expression of three different organs (lung, brain, and lymph nodes) in 35 patients using Nanostring Digital Spatial Profiler. We followed a data integration method based on Multi-Omics Factor Analysis (MOFA) to discover the molecular sources of heterogeneity in the patients and applied robust statistical tests to identify the factors that contribute to prognosis differences between patients. Then we identified a set of highly relevant genes and performed KEGG pathways analysis to identify the underlying pathways.

Results. Our analysis indicated that there are three major categories of pathways likely to be implicated in lung cancer patients with fast brain metastasis. They include (a) immunity-related pathways, (b) stemness related pathways such as focal adhesion and ECM receptor interaction, and (c) metabolic pathways such as Warburg effect and oxidative phosphorylation. The tumor associated immune related pathways are twofold: (1) the impaired immune system in tumor suppression such as neutrophil extracellular traps; and (2) the enhanced ability of the tumor cells to escape the immune surveillance, such as antigen processing and presentation.

Conclusions. Our analyses predict target pathways underlying the brain metastasis in lung cancer patients and establish a means for the prediction of the lung tumor prognosis using molecular experiments.

Cancer Posters - Thursday

PB1144. Investigating the link between cholesterol-lowering genes and risk of skin cancers

Authors:

J. Ong, J-C. Dusingize, C. M. Olsen, M. Law, N. Pandeya, R. E. Neale, D. C. Whiteman, S. Macgregor; QIMR Berghofer Med. Res. Inst., HERSTON, Australia

Abstract Body:

Epidemiologic studies have yet to resolve whether alterations in serum lipids levels influence skin cancer risk. The evidence from observational studies and clinical trials are not concordant. To clarify whether there is genetic evidence supporting a potential causal link, we adopted a series of Mendelian randomization (MR) approaches to evaluate the effects of genetically predicted low-density lipoprotein-cholesterol (LDL-C) levels on the risk of developing several types of common skin cancers, namely cutaneous melanoma, basal cell carcinoma (BCC) and squamous cell carcinoma (SCC).

In our study, we considered two different approaches. The first approach utilizes an array of summary-data based MR techniques, where we relied on LDL-C GWAS summary statistics identified from the Global Lipids Genetics Consortium (GLGC) and GWAS summary statistics for melanoma, BCC and SCC directly obtained from the latest European GWAS meta-analyses of more than half a million participants. The second approach is based on conventional two-stage-least square estimates. Here we calculated the polygenic risk scores (PRS) for LDL-C and performed a 2SLS MR analyses within the UK Biobank, including a stratified analysis specifically on statin-free users. The MR association between the KC PRS and each cancer site was estimated using logistic regression adjusted for standard covariates such as age, sex and genetic principal components.

Based on the pooled estimate derived from the 77 LDL-associated variants, there was limited evidence of an effect of genetically-predicted LDL-C on the risk of developing skin cancer (OR, 95% CI: 0.99, 0.92-1.05 for melanoma, 1.03, 0.96-1.10 for BCC and 1.06, 0.97-1.16 for SCC). In supplementary analyses, the ORs and their 95% CI were 1.03, 0.98-1.07 for melanoma, 1.01, 0.99-1.03 for BCC and 1.01, 0.96-1.07 for SCC. Results did not change when we restricted our analyses to variants in lipid-lowering drug targets gene regions or when we evaluate statin-free users within the UK Biobank cohort. Taken together findings from both summary-based and individual-level MR analyses, our study does not support a potential role of LDL-C-lowering genetic variants on the risk of developing skin cancer.

PB1145. Isolated multinodular goiter in a family with DICER1 heterozygous germline variant

Authors:

P. Dalal^{1,2}, G. Leone^{1,2}, R. Rabenn³, A. Parikh⁴, L. Ponsky⁵, C-H. Wu¹; ¹Dept. of Genetics and Urology, Case Western Reserve Univ. and Univ. Hosp., Cleveland, OH, ²Northeast Ohio Med. Univ., Rootstown, OH, ³Univ. Hosp., Cleveland, OH, ⁴Univ Hosp. Case Med Ctr., Cleveland, OH, ⁵Dept. of Urology, Case Western Reserve Univ. and Univ. Hosp., Cleveland, OH

Abstract Body:

Background

Germline pathogenic variant of DICER1 (OMIM *606241, 14q32.13) is a monogenic cause of multinodular thyroid goiter 1, with or without Sertoli-Leydig cell tumors (OMIM #138800) and pleuropulmonary blastoma (PPB) (OMIM #601200). The inheritance pattern is autosomal dominant with incomplete penetrance. The other manifestations include GLOW (OMIM #618272) and embryonal rhabdomyosarcoma 2. GLOW encompasses global developmental delay, lung cysts, overgrowth and Wilms tumor. Embryonal rhabdomyosarcoma (OMIM #180295) presents with uterine cervix embryonal rhabdomyosarcoma and variant carriers also presented with multinodular goiter, Sertoli-Leydig cell tumors, and Wilms tumor. Most tumors onset before the age of 40, with PPB presenting infants and children less than 6 years. 32% of women and 13% of men with a DICER1 variant will be diagnosed with multinodular thyroid goiter and/or have undergone a thyroidectomy by age 20. We present a family with confirmed DICER1 pathogenic variant c.5528-2del who presents with development of thyroid goiters.

Case Report

A 44 year old female is referred to genetics with a history of total thyroidectomy due to development of multinodular goiters in adolescence. Family history is significant for lung cancer in the paternal grandmother, colon cancer in her maternal mother, and lymphoma in her brother. The patient is otherwise healthy without other concerning signs or symptoms. The patient's 14-year-old son has a past medical history of aortic dilation, autism, cardiac murmur, and multinodular thyroid goiter. The patient's 12-year-old daughter with the same paternity has a past medical history of confirmed nontoxic, multinodular goiter. Both children plan to undergo a thyroidectomy. The mother, the 14-year-old son, and the 12-year-old daughter have a heterozygous DICER1 c.5528-2del variant. This variant has not been reported in any literature or database before and is isolated to these three individuals. Serial workups for other DICER1 syndromes for these 3 individuals are negative.

Discussion

We present a family with confirmed DICER1 variant of c.5528-2del who presents with development of only thyroid goiters without other typical DICER1 presentations. We would like to present this specific variant, c.5528-2del, to the genetic community as a likely association with isolated multinodular thyroid goiter. Our report may be useful for future genotype-phenotype correlations of DICER1. The family plans to actively monitor for the development of other DICER1 presentations by following with multidisciplinary care.

Div., Univ. of Oxford, Oxford, United Kingdom

Abstract Body:

Somatic mutations in normal tissues can reveal the evolution of the genomic landscape during life and provide insights into the mutagenic processes that may contribute to cancer development. Although we now have a comprehensive perspective on the landscape of somatic mutations in cancers, due to technological limitations, we are still in the process of understanding the diversity of somatic mutation patterns in normal cells. Here, as part of a wider survey of human tissues, we have whole genome sequenced 342 laser-microdissected normal epithelial crypts from the small intestines of 39 individuals, and examined the somatic mutational burden, mutational signature exposure, and cancer driver mutation landscape. We find the frequent presence of single-base substitution mutational signatures SBS2 and SBS13, thought to be caused by the APOBEC family of cytidine deaminase enzymes.

APOBEC mutagenesis is a common source of mutations across the broad spectrum of human cancer types. However, it is unusual in previous studies of normal human tissues; in particular, the common presence of APOBEC mutational signatures in the small intestine differs from other segments of the gastrointestinal tract including oesophagus, stomach and colon, where it is rare. APOBEC3A/B are previously thought to be the major contributing enzymes of APOBEC mutagenesis, but bulk and single-cell RNA sequencing data of small and large intestine didn't indicate any elevated expression of APOBEC3A/B in the small intestine. We extract mutational signatures with extended context, and find APOBEC mutations are enriched in APOBEC1/3A motif. Together with the fact that the small intestine has a much higher APOBEC1 expression level than colon, this indicate that the common RNA editing enzyme APOBEC1 might have also contributed to the elevated APOBEC mutagenesis level in the small intestine.

Through sampling multiple crypts from the same individual together with phylogenetic reconstruction, we find that APOBEC mutagenesis is episodic in vivo, can happen throughout life (from as early as 4 years of age), but only a single or a very small number of episodes are found during the lifetime of an individual in any single crypt. Localised clusters of SBS2/13 mutations (kataegis) are also commonly found. Crypts with SBS2/13 often have immediate crypt neighbours without SBS2/13, suggesting that the underlying cause of SBS2/13 is controlled by cell-intrinsic factors rather than due to a widely distributed microenvironmental exposure. Overall, our findings substantially further define the features of this biologically important and distinctive mutational process.

PB1147. Leveraging network architecture and transfer learning for precision oncology

Authors:

S. Yi; The Univ. of Texas at Austin, Austin, TX

Abstract Body:

Leveraging multi-omics and network biology holds great promise for the next generation of precision oncology; yet, due to tumor heterogeneity, this is challenging. Towards this end, here we are presenting our two recent efforts, leveraging network architecture and transfer learning for improved precision oncology. In the first study, we built comprehensive cancer-specific miRNA regulatory networks across 30 cancer types to systematically analyze the effect of mutations on miRNA related pathways. 3,518,261 mutations from 9,819 samples were mapped to miRNA-gene interactions (mGI), and mutations in miRNAs versus in their target genes show a mutually exclusive pattern in almost all cancer types. We find that driver mutations play their roles by altering RNA binding energy and the expression of target genes. We provide this data resource (mGI-map) through a user-friendly, open-access web portal. Together, our results will facilitate novel non-coding biomarker identification and therapeutic drug design. The second effort deals with rational drug combination design. Numerous studies have been conducted to produce clinically relevant pharmacological response forecasts by integrating modern machine learning algorithms and several data types. Insufficient patient numbers and lack of knowledge of the molecular targets for each drug under study limit their use. As a proof of concept, we use single-cell RNA-seq based transfer learning to contextualize patients' tumor cells in terms of their more similar cell lines with known susceptibility to drug combinations. Our objective is to maximize the translational potential of in-vitro assays for identifying synergistic drug combinations and prioritizing them for clinical use. Consistent findings in a cohort of breast cancer patients corroborated our understanding of the disease's molecular subtypes. To aid in creating personalized treatments and data-driven clinical trials, we identified the most prevalent match options and prioritized synergistic combinations based on tumor compositions at various resolution levels.

PB1148. Leveraging somatic cancer mutation data to predict the pathogenicity of germline missense variants

Authors:

B. Haque^{1,2}, M. Curtis^{1,2}, A. Pan², G. Costain^{1,2,3,4}; ¹Dept. of Molecular Genetics, Univ. of Toronto, Toronto, ON, Canada, ²Genetics and Genome Biology, The Hosp. for Sick Children, Toronto, ON, Canada, ³The Ctr. for Applied Genomics, The Hosp. for Sick Children, Toronto, ON, Canada, ⁴Div. of Clinical and Metabolic Genetics, The Hosp. for Sick Children, and Dept. of Paediatrics, Univ. of Toronto, Toronto, ON, Canada

Abstract Body:

Background: Germline missense variants are often classified using current guidelines as having uncertain clinical significance. New scalable and easy-to-implement strategies are needed to generate supporting evidence for pathogenicity that can improve the interpretation of rare missense variants. We hypothesized that publicly available somatic cancer mutational data from tumor sequencing studies can be used to develop and test a new method of predicting the pathogenicity of germline missense variants. **Methods:** Somatic cancer missense mutations were extracted from the Cancer Hotspots database, and then annotated with *in silico* tools and public databases (e.g., ClinVar, gnomAD) using computational pipelines. Cancer mutations were identified that had been reported and classified in the ClinVar database as germline missense variants related to rare Mendelian disorders. By assessing the relationship between somatic cancer and germline variants in shared amino acid residues, a statistical model can be developed to estimate pathogenicity of novel missense variants. **Results (preliminary):** Among the 2,456 cancer mutations from Cancer Hotspots, 698 were reported as germline variants in ClinVar. The odds ratio for these germline variants having a pathogenic or likely pathogenic classification was 24.30 (95% CI, 20.78-28.41, $p < 0.001$), compared to all other germline missense variants in these same genes that are not in Cancer Hotspots. These and other data will be used as a training set for a supervised learning model for estimating the probability of pathogenicity of novel missense variants. **Conclusion:** Germline missense variants that are also known to be somatic cancer driver mutations are enriched for pathogenic/likely pathogenic classifications. These findings support the use of somatic cancer data as novel supporting evidence for germline variant classification to facilitate improved diagnosis of rare disorders.

PB1149. Liquid biopsy for the detection of actionable human variants in the blood of cancer-diagnosed dogs: Opening the door to comparative oncology and therapeutic development.

Authors:

I. Chorny, K. M. Kruglyak, J. A. Tynan, P. Nakashe, G. E. Hernandez, L. M. McLennan, J. M. Rafalko, J. Chibuk, A. L. McCleary-Wheeler, A. Flory, D. S. Grosu, D. W. Y. Tsui; PetDx, La Jolla, CA

Abstract Body:

Introduction: Characterizing actionable variants in humans and dogs can expand the knowledge base of comparative oncology and support the development of novel treatments for the benefit of both species. Blood-based liquid biopsy testing has opened new opportunities to noninvasively profile the cancer genomes of both species and aid in these translational efforts. The purpose of this study was to examine the ability of liquid biopsy testing to identify genomic variants common in human cancers in the blood of dogs with cancer diagnoses. **Methods:** In this study, the Cancer Gene Census (CGC) in the Catalogue of Somatic Mutations in Cancer (COSMIC) database (v91) was interrogated for canine orthologs. A targeted next-generation sequencing somatic panel was then developed that incorporated a subset of the small genomic alterations from the CGC for which a canine ortholog was identified. The panel also incorporated a broader set of oncogenes and tumor suppressor genes (TSGs), including *TP53*, the most common TSG mutated in cancer. This panel was applied to plasma and tissue samples from a cohort of over 300 client-owned dogs with histologically confirmed diagnoses of a variety of cancer types. **Results:** High homology (>85%) was observed between the human and canine genomes, with even higher levels of homology (>90%) noted between human and canine oncogenes and TSGs. Approximately one third of cancer-diagnosed dogs were found to have a variant in both tissue and pre-surgical plasma that mapped to an actionable variant in the human genome or to the *TP53* gene (which is a human prognostic marker). Of those, ~10% had an ortholog of a variant targeted by current human therapies, including variants in *AKT1*, *HRAS*, *KRAS*, *NRAS*, and *PIK3CA*. **Conclusion:** This study demonstrates the technical feasibility of blood-based detection of canine orthologs of variants that are actionable in human cancers. The ability to noninvasively profile the genomic landscape of canine cancers opens the possibility of targeted treatment selection based on liquid biopsy. Many targeted therapies have received regulatory approval or are under development in human oncology; however, such therapies are lacking in veterinary medicine. Liquid biopsy is uniquely positioned to aid in large scale safety and efficacy studies to support therapeutic development to benefit both humans and dogs alike.

PB1150. Loss of function of *neurofibromin* affects *afadin* -6 in neurofibromatosis type-1.

Authors:

M. Sulaiman¹, A. Dodson², T. Helliwell²; ¹Ahmadu Bello Univ., Zaria, ZARIA, Nigeria, ²Univ. of Liverpool, Liverpool, U.K, United Kingdom

Abstract Body:

Introduction Neurofibromatosis type 1 (NF1) is a common autosomal disorder in human with incidence of 1/3000 people worldwide. The *NF1* gene is mapped to chromosome 17, (17p21). Its protein product, *neurofibromin* negatively regulate *Ras*. Therefore, loss of function of *neurofibromin* may promote cell proliferation. The *afadin* (*AF-6*) protein is a multi-domain protein that contains two potential *Ras* binding domains and is mapped to 6q27 of human chromosome. *AF-6* has also been described as a constituent of a cell-cell adhesion system named; *Nectin*, *Afadin* and *Ponsin* (NAP), which is express at adherens junctions.

Aim of the Study This study was undertaken in order to demonstrate the likely consequences of instability of chromosome 17 on chromosome 6 and the functional integrity of cell-cell junction in familiar, sporadic and plexiform neurofibromas.

Material and Methods Prior informed patient consent from familial (9 cases), sporadic (7 cases) and plexiform neurofibromas (6 cases) was obtained, and the study has an ethical approval (06/1505/137) granted by the Liverpool Research Ethics Committee. Standard immunohistochemistry method was used. Briefly, routine histological procedures (haematoxylin and eosin staining) was first carried out followed by staining using cell markers and Rabbit anti-AF-6 polyclonal Zymed (Cat # 433280 staining on both experimental and control tissues.

Result Weak to moderate membranous and nuclei immunolocalization of the AF-6 were observed in endothelial cells of all the familial and the plexiform forms. Similarly, the *AF-6* moderately localize to the membrane of the endothelial cell of 57% of the sporadic neurofibroma studied.

Conclusion From this study, we suggest that the instability of chromosome 17 (*neurofibromin*) may affect chromosome 6 (*AF-6*) in familiar, plexiform and sporadic neurofibroma with the attendant loss of cell-cell adhesion and subsequent unregulated cell proliferation

Cancer Posters - Wednesday

PB1151. Low CD2 expression in sentinel lymph nodes of early breast cancer patients is associated with postoperative tumor recurrence or metastasis

Authors:

S. Kang, H. Lee, J-H. Kim, T. Park; Ajou Univ. Sch. of Med., Suwon, Korea, Republic of

Abstract Body:

Recurrence and metastasis are associated with increased mortality and poor outcomes in early breast cancer (EBC) patients. To predict loco-regional recurrence or distant metastasis, various prediction models based on clinicopathological characteristics or genetic profiles have been suggested. However, most of those systems focused on the primary tumor, and prediction of recurrence in EBC is still limited. The sentinel lymph nodes (SLNs) are the first few lymph nodes into which a tumor drains and an important barrier for protecting against metastasis. Since the immune microenvironment plays a key role in tumor progressions and metastasis, evaluation of SLNs could provide not only the state of metastasis to the axillary lymph nodes but also additional information on recurrence of EBC. In this study, we reviewed clinical data of EBC patients who had an operation with SLNs biopsy and selected patients with loco-regional recurrences or distant metastasis during follow-up period (at least 5 years). We analyzed clinicopathological characteristics of patients and investigated immune gene expression of SLNs by using the nCounter® PanCancer Immune Profiling Panel. We further performed immunohistochemistry for the most significantly altered genes. Among 1615 cases of EBC patients, 60 cases (3.7%) revealed loco-regional recurrences or distant metastasis. A total of 24 cases (12 SLNs of patients with recurrence and matched 12 SLNs of those without recurrence) were subjected to gene expression analysis and revealed a significant decrease in the expression of 21 genes. Based on gene expression levels and fold change, we selected 6 candidate genes (CD2, BLNK, ATF2, IGF2R, CXCL16, and IFITM1). We performed immunohistochemistry in a total of 119 cases (54 SLNs of patients with recurrence and matched 65 SLNs of those without recurrence) and found CD2 and ATF2 were significantly decreased in SLNs of EBC patients with recurrence. The pattern of immune gene expression of SLNs, especially C2 and ATF2 could be an additional prognostic marker for predicting recurrences of EBC.

Biology, Genetics and Clinical Genetics, Faculty of Med., Comenius Univ., Bratislava, Slovakia, ⁴Slovak Ctr. of Scientific and Technical Information, Bratislava, Slovakia, ⁵Dept. of Molecular Biology, Faculty of Natural Sci., Comenius Univ., Bratislava, Slovakia, ⁶Inst. for Clinical and Translational Res., BioMed. Res. Ctr., Slovak Academy of Sci., Bratislava, Slovakia, ⁷Inst. of Pathological Anatomy, Faculty of Med., Comenius Univ., Bratislava, Slovakia, ⁸Medirex Group Academy n.p.o., Nitra, Slovakia

Abstract Body:

Somatic changes within short tandem repeats (STRs) result in microsatellite instability (MSI) that serves as a diagnostic biomarker for Lynch syndrome-associated tumors and a predictive biomarker for the efficacy of immune checkpoint inhibitors. Up to date, no alternative high-throughput screening strategy to gold-standard methods has been proposed. Along with advances in massively parallel sequencing (MPS) technologies and their ever-increasing cost-effectiveness, it could thus represent a new era of MSI monitoring. However, using them with the homopolymer repeats may be difficult due to technical and methodological drawbacks associated with FFPE samples and circulating cell-free DNA analyses. We designed an easy-handling MSI analysis workflow to enrich 17 homopolymer marker sites (8 - 27 bp) obtained from genomic regions associated with MSI across various malignancies. Unlike other MSI capturing strategies, we focus the sequencing on only the microsatellite regions of interest. The proposed assay was standardized for sequencing using the MiSeq platform. Sequencing data were annotated and genotyped with the bioinformatic tool Dante, not requiring mapping of reads to a reference genome. Our preliminary results clearly show that optimized PCR conditions allow to use FFPE blocks as a template, which are widely utilized in translational research settings. Although there was some variation within individual markers, this MPS-based method produced the same overall MSI status as obtained with the traditional method. We also show that biases resulting from the repetitive nature of homopolymers could be alleviated by pre-analytical optimization. We believe that this strategy could be used in practice as a straightforward and cost-effective assay. However, the analysis of cell-free DNA fragments and other laboratory and statistical methodologies are needed to improve the proposed MSI workflow's utility. The presented work was supported by the Slovak Research and Development projects (APVV-18-0319) and the OP Integrated Infrastructure within projects with ITMS codes 313011V578 and NFP313010Q927, all co-financed by the European Regional Development and Fund.

Cancer Posters - Wednesday

PB1153. Mechanistic insight into HIF1 α -Notch1 axis in chronic myeloid leukemia patients and its diagnostic implications

Authors:

V. Singh, R. Singh, R. Kushwaha; King George's Med. Univ., Lucknow, India

Abstract Body:

Chronic myeloid leukemia (CML) is potentially fatal blood cancer, but its diagnosis needs more attention in the search for molecular markers. However, this study explored the relationship of HIF1 α with the redox system, Krebs cycles, notch1, and other regulatory proteins and better understood the pathophysiology and clinical relevance in CML patients, where the molecular mechanism of this axis is still not clear. This study included CML patient samples (n-60; 60: blood; 10: bone marrow tissues) and compared them with healthy controls (n-20; blood) at the clinical and molecular levels. Here, we found that p210, p190BCR/ABL1 translocation is common in all blast crisis phases of CML. Redox factor and Krebs oncometabolite levels were upregulated, which consequentially led to upregulation and stabilization of HIF1 α that in turn lead to upregulation of their downstream genes (Notch2,4, Ikaros, SIRT1, Foxo-3a,p53, etc.). HIF1 α also downregulates ubiquitin proteasomal factors/apoptotic factors, which trigger its degradation by proline hydroxylation. the results also revealed that HIF1 α has an antagonist relationship with the notch1 pathway that plays the tumor-suppressive role in CML patients. Thus, this study has proven that Notch1 might be a potential diagnostic marker along with some other factors in CML patients. Overall this study concluded that HIF1 α /Notch1 axis plays an important role in the pathogenesis of leukemia, and might open the gate for the future diagnostic markers for CML.

PB1154. Metabolic Profiling of Primary and Metastatic Breast Cancer Cells and New Treatment Approaches.

Authors:

L. Boccuto¹, D. Ivankovic^{1,2}, B. A. Moffitt¹, B. Dyar¹, N. Khulordava¹, A. Larkins¹, J. Benjock¹, J. Spencer¹, K. Henrie¹, S. Loehr¹, M. A. Learmonth², G. M. DeRosa², A. G. Powell², Z. E. Sanders², M. A. Treaster²; ¹Clemson Univ., Clemson, SC, ²Anderson Univ., Anderson, SC

Abstract Body:

Breast cancer is the second most common type of cancer overall and the first among women, 20-30% of cases develop metastases. More than 154,000 U.S. women are estimated to have metastatic breast cancer, and about 40,000 die every year because of this disease. In preliminary studies, we noted significant abnormalities in the metabolic profile of breast cancer cells, and we demonstrated that a natural compound such as marjoram can correct such abnormalities in cancer cells without disrupting normal cells. This study aims to compare the metabolic profiles of metastatic and non-metastatic cancer cells to one of normal breast tissue, and then assess the efficacy of candidate compounds at correcting metabolic abnormalities in cancerous cells. The purpose of this study is to identify metabolic abnormalities underlying the metastatic transformation of cancer cells, novel biomarkers for early screening, new molecular targets for treatment, and to investigate the efficacy and side effects of candidate therapeutic compounds. Results gathered from the metabolic profiles of metastatic and non-metastatic breast cancer, as compared to the one from normal breast tissue, were investigated and assessed via the Biolog Phenotype Mammalian Microarray (PM-M) platform. This approach has allowed us to analyze the capacity of the cells to produce energy in different metabolic environments and after exposure to over 700 compounds, including energy sources, hormones, cytokines, and other metabolic effectors. The assay has revealed significant differences between the metabolic profiles of metastatic and non-metastatic cancer, both compared to normal breast tissue cells. We have selected the PM-M arrays with the highest number of compounds showing significant differences between metastatic and non-metastatic cancer. We have tested the efficacy of one drug commonly used for chemotherapy in metastatic breast cancer, doxorubicin (Adriamycin), and a natural compound that proved to be effective on cancer cells, marjoram. The two compounds were tested on both primary and metastatic breast cancer cells, as well as on control cells from the normal breast tissue, and their efficacy at correcting metabolic abnormalities was assessed, as well as their toxicity and metabolic side effects. By identifying biomarkers for early diagnosis or screening, new novel treatment approaches can be discovered, and the efficacy of candidate drugs can be assessed. The results of our study may lead to innovative approaches to the characterization, management, and treatment of metastatic breast cancer.

PB1155. Metagenomics and metabolomics of persistent high-risk Human Papillomavirus (hrHPV) infections and cervical cancer

Authors:

C. Adebamowo^{1,2,3}, S. Adebamowo^{1,3}, A. Adebayo⁴, P. Achara⁵, B. Alabi⁶, R. Bakare⁷, A. Famooto², K. Obende⁸, R. Offiong⁹, O. Olaniyan¹⁰, ACCME Research Group as part of the H3Africa Consortium; ¹Univ. of Maryland Sch. of Med., Baltimore, MD, ²Inst. of Human Virology Nigeria, Abuja, Nigeria, ³Greenebaum Comprehensive Cancer Ctr., Baltimore, MD, ⁴Asokoro District Hosp., Abuja, Nigeria, ⁵Federal Med. Ctr., Keffi, Nigeria, ⁶Wuse Gen. Hosp., Abuja, Nigeria, ⁷Univ. of Ibadan, Ibadan, Nigeria, ⁸Garki Hosp., Abuja, Nigeria, ⁹Univ. of Abuja, Abuja, Nigeria, ¹⁰Natl. Hosp., Abuja, Nigeria

Abstract Body:

Background: Persistent hrHPV infections is a non-oncolytic infection of the basal epithelium at the transition zone of the cervical epithelium and a necessary cause of cervical cancer. Evidence suggests significant roles for the vaginal microenvironment in establishment of persistence of the infection and progression to cervical cancer. **Methods:** We conducted shotgun metagenomics sequencing and global metabolomics profiling of the cervical secretions from 84 women. Some 68 of these women were tested and categorized based on HPV results as negative (N) or positive (P) at 3 time points: baseline, 12 months, and 24 months, using DEIA/LiPA₂₅ into NNN (13), NNP (16), NPP (10), PPP (12), PPN (15) and PNN (1), while 16 women had either invasive squamous cell carcinoma (15) or papillary adenocarcinoma (1). **Results:** There was higher diversity of bacteria and lower *Lactobacillus* abundance comparing the PPP category to the NNN category. The most frequently identified genus in PPP category were *Gardnerella*, *Prevotella*, *Atopobium*, *Ureaplasma*, *Sneathia* and *Streptococcus*. Cervical cancer samples showed significantly decreased bacterial diversity, absence of *Lactobacillus spp.*, and relatively high abundance of *Cutibacterium*. Our discriminative analysis showed that *Prevotella* prevalence and abundance discriminated between NNN and PPP categories. We found *Mageeibacillus indolicus*, a recently discovered bacteria in 4 members of the PPP group. The commonest HPV types in the cervical cancer group were types 16 and 18, while HPV 82 was the most prevalent hrHPV genotype in the other categories. The top five enriched pathways in the NNN group compared to the PPP group were: *Folate transformations II, sucrose degradation III (sucrose invertase), lipid IVA biosynthesis, super pathway of thiamin diphosphate biosynthesis III (eukaryotes)* and *Guanosine ribonucleotides de novo biosynthesis* mainly contributed by the *Lactobacillus spp.* and unclassified strata. The top enriched gene family in the NNN group: *3.1.22.4 Crossover junction endodeoxyribonuclease, 2.7.1.69 Protein-N(pi)-phosphohistidine—sugar phosphotransferase* and *1.7.1.7 GMP reductase* similarly contributed by diverse *Lactobacillus spp.* and unclassified. We identified HPV integration sites in 6/20 cervical cancer cases and 1/12 of the PPP cases. **Conclusions:** Persistent hrHPV infection was associated with vaginal dysbiosis and reduced abundance of *Lactobacillus spp.* Several bacterial genera and species, gene families and pathways whose abundance was significantly different between the different groups in this study and hold promise as potential biomarkers.

Abstract Body:

Background: Among the various genomic features of blood, methylation patterns could be useful not only for determining whether cancer is present but also for revealing its origin. The purposes of this prospective study are to evaluate the diagnostic performance of methylation-sensitive restriction enzyme digestion followed by sequencing (MRE-seq) using cell-free DNA (cfDNA) in the diagnosis of cancer and to investigate tissue-of-origin (TOO) using a deep neural network (DNN).

Patients and methods: We developed a deep-learning-based prediction model using demethylated-sequence-depth patterns from 63,266 sites through MRE-seq. One hundred and ninety-one patients with stage I-IV cancers (95 lung cancers and 96 colorectal cancers) and 126 noncancer participants were enrolled in this study.

Results: We found an overall area under the ROC curve (AUC) of 0.978 with a sensitivity of 78.1% at a specificity of 99.2% for colorectal cancer and an AUC of 0.956 with a sensitivity of 66.3% at a specificity of 99.2% for lung cancer. In colorectal cancer, the sensitivity was 76.5% in stage I, 76.2% in stage II, 78.3% in stage III, and 83.3% in stage IV at a specificity of 99.2%. In lung cancer, the sensitivity was 48.5% in stage I, 44.4% in stage II, 78.9% in stage III, and 76.0% in stage IV at a specificity of 99.2%. The true positive rates of the TOO model were 94.4% (85/90) and 89.9% (80/89) for colorectal and lung cancers, respectively.

Conclusions: The global hypomethylation pattern obtained by MRE-seq was useful in the diagnosis of cancer with high accuracy and in the determination of TOO through DNN. The role of MRE-seq needs to be validated for various solid tumors in future multicenter studies.

PB1157. Mitonuclear genotype remodels the metabolic and microenvironmental landscape of Hürthle cell carcinoma

Authors:

E. Liu¹, I. Ganly¹, F. Kuo¹, V. Makarov², Y. Dong¹, J. Park¹, Y. Gong¹, A. N. Gorelick³, J. A. Kanuf², E. Benedetti⁴, J. Tait-Mulder⁵, L. G. T. Morris¹, J. A. Fagin¹, A. M. Intlekofer¹, J. Krumsiek⁴, P. A. Gammage⁵, R. Ghossein¹, B. Xu¹, T. A. Chan², E. Reznik¹; ¹Mem. Sloan Kettering Cancer Ctr., New York, NY, ²Cleveland Clinic, Cleveland, OH, ³Massachusetts Gen. Hosp., Boston, MA, ⁴Weill Cornell Med., New York, NY, ⁵Cancer Res. UK Beatson Inst., Glasgow, United Kingdom

Abstract Body:

Hürthle cell carcinomas (HCCs) display two exceptional genotypes: near-homoplasmic mutation of mitochondrial DNA (mtDNA) and genome-wide loss of heterozygosity (gLOH). To understand the phenotypic consequences of these genetic alterations, we analyzed genomic, metabolomic, and immunophenotypic data of HCC and other thyroid cancers. Both mtDNA mutations and profound depletion of citrate pools are common in both HCC and other thyroid malignancies, suggesting that thyroid cancers are broadly equipped to survive tricarboxylic acid cycle impairment, whereas metabolites in the NADH-dependent lysine degradation pathway were elevated exclusively in HCC. The presence of gLOH was not associated with metabolic phenotypes but rather with reduced immune infiltration, indicating that gLOH confers a selective advantage partially through immunosuppression. Unsupervised multimodal clustering revealed four clusters of HCC with distinct clinical, metabolomic, and microenvironmental phenotypes but overlapping genotypes. These findings chart the metabolic and microenvironmental landscape of HCC and shed light on the interaction between genotype, metabolism, and the microenvironment in cancer.

PB1158. Modulating the immune system not to reject an allograft

Authors:

D. McDaniel, L. S. McDaniel; Univ Mississippi Med Ctr, Jackson, MS

Abstract Body:

Introduction: Organ transplantation is a major therapeutic approach in end stage disease with organ dysfunction. Mechanical devices to replace or for restoration of organ structure/function remain a challenge because many biological functions cannot be replicated. The immune system plays a central role in the recovery process including restoration of organ function after allograft transplantation. Organ or tissue chip development following tissue engineering through reprogramming of immune system criteria has been proposed as the next generation of regenerative medicine and transplantation. **Methods:** Current approaches in regenerative medicine includes cell-based therapeutics; combination of cells and scaffolds to stimulate tissue repair *in vivo* and building of tissues *ex vivo* for implantation. Training stimulatory pathways of immunity that induce macrophage polarization, antigen presentation, T cell activation and cytokine production are included. **Results:** Previously, we have shown that human recipients can tolerate their transplanted organ when infusing the donor bone-marrow cells, prior to the kidney transplantation. This is known the induction of tolerance through mixed chimerism. However, this approach required a specialized conditioning regimen to allow allograft survival with less or minimized immunosuppressants. Furthermore, during organ procurement (recovery) stimulatory signals released in the donor organ due to ischemia-reperfusion injury, encounter trained macrophages to secrete pro-inflammatory cytokines leading to allograft rejection. We reported the AIF-1-TLR2 interactions favor the induction of tolerance under blockade with anti-AIF-1 through the secretion of IL-10 by graft-infiltrating macrophages. **Conclusions:** Advances in immune modulation through reprogramming of immune system arranges the foundation to train the immunity in organ transplantation not to reject through epigenetic modification of the immune microenvironment.

PB1160. Molecular signature predicts immunotherapy resistance in gynecologic cancer patients treated with immune checkpoint inhibition.

Authors:

Y. Ni¹, H. Al-Sudani², A. Soliman³, P. G. Rose¹, H. Mahdi⁴; ¹Cleveland Clinic, Cleveland, OH, ²Einstein Med. Ctr. Montgomery, Philadelphia, PA, ³Case Western Reserve Univ., Cleveland, OH, ⁴Univ. of Pittsburgh Med. Ctr., Pittsburgh, PA

Abstract Body:

Immunotherapy with immune checkpoint inhibitors (ICI) has emerged as a promising option in other solid tumors like lung and urothelial cancers and melanoma. In gynecological (GYN) cancers, the ICI response rates range from 11-17% in the recurrent setting. Various immune signatures predictive of resistance to immune ICI have been described in multiple solid cancers, but still under-investigated in GYN cancer.

For 49 GYN cancer patients included in our study, without transcriptome signature, immune-related toxicity was the only clinical predictor of ICI treatment response ($p=0.008$). The objective clinical response was the only predictor of progression-free survival (ICI-PFS, $p=0.0008$) and overall survival (ICI-OS, $p=0.01$). Commonly used ICI marker PD-L1 expression was negatively correlated with progression-free survival (ICI-PFS) ($p=0.0019$). We performed transcriptome and signaling pathway enrichment analyses based on ICI treatment responses and the survival outcome, and further estimated immune cell abundance using 547 gene markers. Our data revealed that TGF-beta regulated signaling pathway was noted to play an important role in immunotherapy failure. Using our 6-genes TGF-beta score, we observed longer ICI-PFS associated with lower TGF-beta score (8.1 vs. 2.8 months, $p=0.046$), which was especially more prominent in ovarian cancer (ICI-PFS 16.6 vs. 2.65 months, $p=0.0012$). Further, abundant immunosuppressive cells like T-regulatory cells, eosinophils, and M2 macrophages were associated with shorter ICI-OS and correlated positively with *CD274* (PD-L1) and *CTLA4* expressions. Interestingly, patients who failed immunotherapy also have higher *CD47* expression ($p=0.03$). Higher *CD47* correlated with lower cytotoxic T-cells ($p < 0.001$) and dendritic cells ($p=0.038$) as well as lower *CD274* (PD-L1) and *CTLA4* expression but positively correlated with higher TGF- signature ($p=0.006$). With an integrated random forest prediction model, besides immunotherapy treatment cycle and toxicity, TGF-beta score and *CD47* together with *CD274* (PD-L1) expression are the top important contributors predicting immunotherapy response. Our study provides insight on the potential role of TGF-beta and *CD47* in mediating immunotherapy resistance and cross-talking to immunosuppressive environment in GYN cancer. If validated in a larger cohort, can identify patients who likely to fail ICI and benefit from targeting this pathway to enhance the response to ICI.

Cancer Posters - Wednesday

PB1161. Mosaic chromosomal alterations detected in HIV infected men and its relationship to non-Hodgkin lymphoma.

Authors:

S. Khan¹, S-H. Lin¹, W. Zhou¹, D. W. Brown¹, C. Vergara², S. Wolinsky³, O. Martinez-Maza⁴, J. Margolick², J. Martinson⁵, S. K. Hussain⁶, M. J. Machiela¹, E. A. Engels¹; ¹Natl. Cancer Inst., Rockville, MD, ²Bloomberg Sch. of Publ. Hlth., The Johns Hopkins Univ., Baltimore, MD, ³Feinberg Sch. of Med., Northwestern Univ., Chicago, IL, ⁴UCLA AIDS Inst. and Jonsson Comprehensive Cancer Ctr. at UCLA, Los Angeles, CA, ⁵Univ Pittsburgh GSPH, Pittsburgh, PA, ⁶Univ. of California Davis Comprehensive Cancer Ctr., Sacramento, CA

Abstract Body:

Men living with HIV (MLWH) are at increased risk of infection and non-Hodgkin lymphoma (NHL); however, limited clinical markers are available for identifying men most susceptible to these outcomes. Mosaic chromosomal alterations (mCAs), the age-related acquisition of large acquired chromosomal alterations in a clonal subset of leukocytes, are markers of genomic instability and associated with increased susceptibility to infections and hematologic malignancies. As mCAs have not previously been characterized in MLWH, we investigated the frequency and distribution of mCAs among MLWH as well as potential elevated risk of NHL conferred by mCAs. We scanned for mCAs in blood-derived DNA from 3,139 MLWH and 2,840 HIV- men from the Multicenter AIDS Cohort Study (MACS) using raw genotyping array intensity data. The proportion of MLWH and HIV- with autosomal mCAs was similar (121 [3.9%] vs. 102 [3.6%]); however, mosaic loss of the Y chromosome (mLOY) was less common in MLWH than in HIV- men (44 [1.4%] vs. 83 [2.9%]). Logistic regression models adjusting for age and smoking found no evidence for an association of HIV with autosomal mCAs (OR=1.19, 95% CI=0.98-1.58, P-value=0.22), but an inverse association with mLOY (OR=0.60, 95% CI=0.40-0.88, P-value=0.01). No differences in median length of mCAs (31.2 vs 35.7 Mb) or mean cell fraction impacted (7.48% vs 7.65%) were observed between HIV- and MLWH. The genomic distribution of mCAs differed at select chromosomal regions, with MLWH more likely to harbor 14q copy number neutral-loss of heterozygosity (CN-LOH) events (P-value=3.5×10⁻³) and less likely to have chromosome 1 gains (P-value=0.03) and 11 losses (P-value=0.03). A total of 177 (5.6%) MLWH developed incident NHL during follow-up, with 5 cases occurring in MLWH with autosomal mCAs and 3 occurring in MLWH with mLOY. MLWH with mCAs who subsequently developed NHL had higher median cell fractions relative to NHL-free men (7.6% vs. 2.3% in MLWH). Unadjusted Poisson regression models showed no evidence for an increased incidence of NHL among MLWH associated with autosomal mCA (IRR=0.81, 95% CI=0.29-1.78) or mLOY (IRR=1.51, 95% CI=0.37-3.97). There were no common genomic regions impacted by autosomal mCAs in the NHL cases, and positions were similar to NHL-free men in the MACS cohort. Neither autosomal mCAs nor mLOY were associated with mortality in MLWH when examined with models adjusting for age and smoking. We find no overall association between HIV and autosomal mCAs nor between mCAs and NHL risk among MLWH. Our findings suggest limited clinical utility of mCAs in MLWH, but some relationships (e.g., enrichment of 14q CNLOH in MLWH) merit further investigation.

Cancer Posters - Thursday

PB1162. Multigene deregulation 12q12 renal cancer-susceptibility locus.

Authors:

L. Andrade Costa¹, A. Souza¹, E. Zier¹, L. Jessop², T. Myers², S. Chanock², D. Mole³, L. Colli¹; ¹Univ. of São Paulo, Ribeirão Preto, Brazil, ²Natl. Cancer Inst., Bethesda, MD, ³Univ. of Oxford, Oxford, United Kingdom

Abstract Body:

Renal Cancer (RCC) is the seventh most common type of cancer in the United States, and most of these tumors do not respond to radiation and chemotherapy treatments. A Genome-Wide Association Study (GWAS) identified 13 regions related to the risk of developing RCC. In this study, we analyzed the *12q12* region, a region that has already been shown to have two SNPs increasing the expression of *BHLHE41*. However, eQTL data suggests other genes in the region could also be deregulated by those SNPs. It is well established that a region may have multiple functional SNPs, but the interaction between genes is rare. Our objective is to evaluate *12q12* gene interaction and how this could impact RCC susceptibility. For this, we are using CRISPR (CRISPRi) to inhibit the expression of two SNPs associated with the *12q12* region, rs7132434 and rs10842708, in renal cancer cell lines (UO-31 and 786-O) and analyze changes in *BHLHE41*, *SSPN*, *ITPR2*, and *RASSF8* expression. On the 786-O cell line, which is homozygous for protective alleles, the blockade of SNPs does not change the expression of any *12p12* evaluated genes. On the other hand, on UO-31 lineage (risk alleles), the inhibition of both SNPs was able to decrease the expression of *BHLHE41*, and, in a lower effect, it also decreased *SSPN* and *ITPR2* expression. Previous work has shown that *BHLHE41* and *SSPN* have an oncogenic effect on renal cancer development. Here, our project showed evidence for multiple gene deregulation impacting cancer susceptibility in renal cancer.

Cancer Posters - Wednesday

PB1163. Multi-modal characterization of ultra-rare germline genetic variants driving breast cancer risk in the indigenous Arab population

Authors:

H. Chu^{1,2}, A. Al-Sulaiman³, M. Al-Jumaan³, S. Han^{4,2}, S. Y. Camp^{1,2}, R. Gillani^{5,2,6,7}, Y. Al Marzooq³, F. Almulhim³, C. B. Vatte³, A. Alnimer³, A. Almuhanna³, E. M. Van Allen^{1,2,8}, A. Al-Ali⁹, S. H. Aldubayan^{1,2,10,11}; ¹Dept. of Med. Oncology, Dana-Farber Cancer Inst., Boston, MA, ²Cancer Program, The Broad Inst. of MIT and Harvard, Cambridge, MA, ³Coll. of Med., Imam Abdulrahman bin Faisal Univ., Dammam, Saudi Arabia, ⁴Harvard Med. Sch., Cambridge, MA, ⁵Dept. of Pediatric Oncology, Dana-Farber Cancer Inst., Boston, MA, ⁶Dept. of Pediatrics, Harvard Med. Sch., Boston, MA, ⁷Boston Children's Hosp., Boston, MA, ⁸Ctr. for Cancer Genomics, Dana-Farber Cancer Inst., Boston, MA, ⁹Coll. of Med., Imam Abdulrahman bin Faisal Univ., Dammam, MA, ¹⁰Div. of Genetics, Brigham and Women's Hosp., Boston, MA, ¹¹Coll. of Med., King Saud bin Abdulaziz Univ. for Hlth.Sci., Riyadh, Saudi Arabia

Abstract Body:

The indigenous Arab population is underrepresented in genomic studies and the germline predisposition to breast cancer in this population is largely unknown. Using a deep-learning-based variant caller, we performed systematic exome-wide characterization of germline single-nucleotide polymorphisms (SNPs) and indels from 215 unrelated Arab female breast cancer patients unselected for family history and 1290 ancestry-matched female controls. Pathogenic variants in 143 established cancer-predisposition genes were found in 15.8% (95% Confidence Interval [CI]: 11.2%-21.4%; binomial exact) of the patients with 13.02% (95%CI: 8.83%-18.27%) of the patients carrying at least one clinically actionable variant, including a founder frameshift variant in BRCA2 (c.2808_2811del, p.Ala938ProfsX21, rs80359351) previously unreported in this population which was present in 5.12% (95%CI: 2.58%-8.97%) of the patients. A gene-burden analysis of ultra-rare pathogenic and loss of function variants was then performed which showed BRCA2 to be the most significantly enriched gene after adjusting for false-discovery rate (alpha=0.05) (Odds Ratio [OR]: 82.6, 95%CI: 13.44-1739.6, q-value<0.001, p-value<0.001, Fisher's exact), followed by three nominally enriched genes BRCA1 (OR:10.19, 95%CI: 2.47-49.23, q=0.065, p=0.002), SDHB (OR >3.52, q=0.065, p=0.002), and PTEN (OR >1.73, q=0.346, p=0.02). A validated germline copy number variant (CNV) caller was used to analyze 824 cancer-related genes and identified pathogenic CNVs in 4.19% (95%CI: 1.93%-7.80%) of the patients with 2.79% (95%CI: 1.03%-5.97%) of the patients carrying germline MYC partial duplications, which was significantly associated with cancer spreading to lymph node (OR:11.30, 95%CI: 1.42-281.05, p=0.02) and metastasis (OR:11.51, 95%CI: 1.29-83.46, p=0.03). Overall, carriers of pathogenic variants in the expanded cancer genes (mean age: 43.7, standard deviation [SD]: 8.7) presented on average 5.2 years earlier than non-carriers (mean age: 48.8, SD: 10.1, p=0.004, Mann-Whitney U-test), and are almost four times (OR: 3.69, 95%CI: 1.04-13.93, p=0.045, Fisher's Exact) more likely to become metastatic than non-carriers. Collectively, our study identified a highly actionable BRCA2 founder variant in the Arab population with available first-line targeted therapeutic intervention, highlighted the major drivers of breast cancer risk and heritability in this population, and alleviated existing healthcare disparity by providing evidence for clinical actions in cancer patients from an underrepresented population.

Cancer Posters - Thursday

PB1164. Multiomic sequencing analysis with whole genome association study at chromosome 16 of wilms tumor patients.

Authors:

C-S. Chang, K. Eiko; Augusta Univ., Augusta, GA

Abstract Body:

Wilms tumor (WT) is the most common childhood renal tumor and affects approximately 1 in 10,000 children in Europe and North America. Chromosome 16q deletion (del) or loss of heterozygosity (LOH) has been associated with recurrence and adverse prognosis in WT. Through a Genome Wide Association Study (GWAS) on a biallelic test and a filtration of Minor Allele Frequency (MAF) of 0.01, we further discovered that a block of SNPs with the lowest p value of $3.45E-08$ on the SNP of rs2632824 at 16P11.2 found in this study. Therefore, we focused on searching for the genes implicated in the adverse event at this region of Chromosome 16P11.2. We performed the isoform detection of 27 WT's RNASeqs from the SRA database, together with conducting the RNA-seq analysis. Differentially expressed genes were analyzed by Tuxedo suite pipeline from each group. Through an isoform detection analysis by calculating the percent spliced in index (PSI) counts, we found the alternative splicing events mainly with an intron retention detected on genes of *C16orf58* (RUSF1) and *SLC5A2* at Chromosome 16P11.2 from the tumor group. These two genes, especially *SLC5A2*, were statistically up-regulated in the tumor group when compared with the healthy controls from SRA as well. An ITGA gene family are located in the upstream region, a series of TP53 target gene (*TP53TG*) family, *NR 158162* and *LOC390705* as well as *ENPP7P13* are located at the downstream region of Chromosome 16P11.2 that potentially indicates the importance of the risk loci previously identified by Exome-Seq data for the disease phenotype of Wilms tumor by a mechanism of the enhancer regulation from coding and no-coding RNAs at this region. These findings derived from the multiomic sequencing studies can provide a likelihood of being applied as an evidence of genetic biomarkers initiated at the quantitative trait loci for susceptibility as well as an insight of the actionable genes for a therapeutic drug target at chromosome 16P11.2 in pediatric Wilms tumor patients.

Cancer Posters - Wednesday

PB1165. Multi-omic single-cell profiling of endogenous and engineered T cells in patients undergoing CAR T cell therapy for high-grade glioma

Authors:

H. Natri¹, M-I. Chung¹, L. Peter¹, D. Alizadeh², B. Badie², C. Brown², **N. Banovich¹**; ¹Translational Genomics Res. Inst. (TGen), Phoenix, AZ, ²City of Hope Beckman Res. Inst. and Med. Ctr., Duarte, CA

Abstract Body:

Chimeric Antigen Receptor (CAR) T cell therapy has emerged as a promising approach to treating cancer, including glioblastoma (GBM) and other gliomas. T cell exhaustion due to persistent antigen exposure in the tumor microenvironment remains a major limitation to CAR T efficacy in the treatment of solid tumors. Enrichment of less differentiated memory T cells for manufacturing may enhance CAR T product proliferation, persistence, and anti-tumor efficacy. A better understanding of the cellular and transcriptional programs driving T cell fitness can inform CAR T manufacturing to improve clinical outcomes. To this end, we present a comprehensive multidimensional characterization of CAR T cells and endogenous immune cells from 62 patients with recurrent or refractory malignant glioma who participated in a Phase I study on memory enriched CAR T cells targeting a glioma-associated antigen IL13R α 2. Each patient received infusions of CAR T cells produced from T cell subsets enriched either for naive, stem-like memory, and central memory T cells (Tn/mem, n=22) or only central memory T cells (Tcm, n=40). T cells from patient leukapheresis used as starting material in CAR T manufacturing and the resulting infusion products were characterized using single-cell multi-omic profiling of gene expression, surface protein expression, and T cell receptor clonality. Annotation of clusters of 80,986 CAR T cells and 32,319 leukapheresis T cells shows that the dataset consists of a mixture of memory, activated effector, and exhausted cytotoxic (CD8+) and helper (CD4+) T cells. Single-cell data recapitulate differences in surface phenotypes observed between Tn/mem and Tcm products in flow cytometric analyses, with enrichment of cytotoxic T cells in Tn/mem products reflecting differences in manufacturing protocols. Higher expression of exhaustion markers in cells used in manufacturing was associated with poorer expansion *ex vivo*, demonstrating the quality of the patient-derived starting material as one of the drivers of CAR T fitness. Tn/mem products showed higher levels of proliferation *ex vivo* and expressed higher levels of cytotoxic markers, likely underlying higher anti-tumor efficacy. While the fitness of the patient-derived T cells remains a limiting factor in CAR T therapy, our results demonstrate that the manufacturing protocol largely drives CAR T fitness and anti-tumor efficacy. Further developing culture protocol can help reduce cell stress and improve long-term outcomes. These findings will inform strategies for improving clinical outcomes of CAR T cell therapy in GBM and other cancers.

Abdel Azeem⁹, A. El-Haddad²; ¹Natl. research centre - Egypt, Giza, Egypt, ²Children's Cancer Hosp., 57357, Cairo, Egypt, ³Natl. Res. Ctr., Cairo, Egypt, ⁴Natl. Res. Ctr., Cairo, Cairo, Egypt, ⁵Children's Cancer Hosp., 57357, Egypt, Cairo, Egypt, ⁶Children's Cancer Hosp., 57357, Egypt, Cairo, Egypt, ⁷Natl. research center, cairo, Egypt, ⁸Ain Shams Univ., Cairo, Egypt, ⁹Res. Inst. of Ophthalmology, Cairo, Egypt

Abstract Body:

Background: Retinoblastoma (RB) is the most common primary intraocular malignant tumor in children. RB is mostly caused by biallelic mutations in *RB1* and occurs in hereditary and non-hereditary forms according to the “two-hit” theory. *RB1* mutations comprise point mutations, indels, large deletions, and duplications. Genetic testing is essential for the comprehensive treatment and management of patients with RB. **Aim:** the aim was to evaluate *RB1* copy number variations (CNVs) using MLPA versus FISH assays in group of Egyptian patients with RB. **Results:** Twelve patients from the 72 patients (16.67%) showed an *RB1* deletion, abnormal methylation status, or both. The detection rate of *RB1* deletions in our cohort was 5.5% by FISH, which agreed with reported detection rates. However, the detection rate increased to 15.27% using MLPA; this assay detected partial gene deletions not detected by FISH. Two patients who had an *RB1* deletion exhibited mosaicism by FISH, one showed 30%-40% *RB1* deletion mosaicism while the other showed only 15% *RB1* deletion mosaicism. MLPA detected deletion in the 1st patient. Also, MLPA assay detected hyper-methylation *RB1* at intron 2 in two patients; one was associated with almost entire *RB1* deletion. The assay also detected hypo-methylated *RB1* at intron 2 in a patient and was associated with a partial *RB1* deletion. **Conclusion:** Our results suggested MLPA is a fast, reliable, and powerful method and should be used as a first-line screening tool for detecting *RB1* CNVs in patients with RB. Moreover, MLPA is advantageous as it evaluates the methylation status/inactivation of *RB1*, not possible by FISH.

Cancer Posters - Wednesday

PB1167. Multi-population GWAS analysis identified functional variants in ever- and never-smoking lung cancer.

Authors:

Y. Li, X. Xiao, J. Xia, J-R. Li, C. Cheng, Y. Han, G. Fernandes, S. Slewitzke, S. Rosenberg, J. Byun, C. Amos, INTEGRAL-ILCCO lung cancer consortium; Baylor Coll. of Med., Houston, TX

Abstract Body:

Introduction Remarkable differences have been identified in both clinical and molecular epidemiology studies between ever- and never-smoking lung cancer. Most of previous GWAS studies were conducted in European and Asian population, and African-American population is under-represented. A multi-population lung cancer Genome-wide Association Study (GWAS) stratified by smoking status has the potential to identify novel variants. **Method** We conducted a multi-population (European, Asian and African-American) GWAS on ~9,000,000 high-quality imputed SNPs in 44,823 ever-smokers and 20,074 never-smokers, respectively. Extensive functional analysis was conducted using approaches including functional annotation analysis, colocalization analysis, and DNA damage assay. **Results** Five independent novel loci, including *GABRA4* from ever-smoking and *LRRC4C* and *LCNLI* from never-smoking lung cancer, were identified with association effect in two or three populations ($P < 5 \times 10^{-8}$). Besides the novel findings, we also validated the lung cancer risk effect for known variants at *VTTIA* and *ACVR1B* in never-smoking women in African-American for the first time. Multiple lines of evidence were obtained suggesting the variants may potentially increase cancer risk through excessive DNA damage level (*GABRA4*) or cis-regulation of gene expression (*LCNLI*). **Conclusion** Our study highlighted the heterogeneity in genetic architecture between ever- and never- smoking lung cancer. It also demonstrated that inclusion of African population in the multi-population GWAS is crucial for better understanding of genomic and environmental variations underpinning lung cancer. This integrated study enhanced our knowledge about the complicated genetic architecture in lung cancer and has a potential to contribute to precision medicine in lung cancer treatment and prevention.

Cancer Posters - Thursday

PB1168*. Multi-stage germline exome sequencing study of 17,546 men with aggressive or non-aggressive prostate cancer identifies genes that may inform clinical gene panel testing.

Sch. of Med., Baltimore, MD, ¹⁹Monash Univ., Melbourne, Australia, ²⁰The Inst. of Cancer Res., Sutton, United Kingdom, ²¹MEB, Stockholm, Sweden, ²²Univ of Southern California, Los Angeles, CA

Abstract Body:

BACKGROUND: Gene panel testing for prostate cancer can be used to identify men at high risk of aggressive disease. However, due to restricted sample sizes of previous exome sequencing investigations and the focus on candidate genes, evidence is limited for some panel genes, likely rendering them incomplete. We conducted a large case-only exome sequencing study to define genes with rare coding variation that predispose to aggressive prostate cancer. **METHODS:** This study included 9,185 aggressive cases (6,033 died due to prostate cancer and 1,730 had metastatic disease) and 8,361 non-aggressive cases of European ancestry from 19 international studies. Stage 1 samples (n=5,545) had whole-exome sequencing, and stage 2 samples (n=12,001) had targeted exome sequencing for 1,459 genes selected based on stage 1 results and previous evidence. Gene burden analyses were meta-analyzed across stages 1 and 2, aggregating rare (MAF<1%) deleterious variants to compare carrier frequencies in non-aggressive prostate cancer cases to 1) aggressive and 2) metastatic cases using logistic regression models adjusted for age, study, and principal components of ancestry. **RESULTS:** In addition to genes previously associated with aggressive prostate cancer (*BRCA2*, *ATM*, and *NBN*), we identified robust (P<0.002) but not exome-wide significant potentially novel prostate cancer susceptibility genes *MMP19* (involved in reproduction and metastasis), with carriers having 2.8-fold higher odds of prostate cancer death (95% CI=1.53-5.05, P=8x10⁻⁴); *PKD2L2* (involved in fertility), with carriers having 3.5-fold higher odds of prostate cancer death (95% CI=1.76-7.04, P=5x10⁻⁴); and *SMPD1* (involved in converting sphingomyelin to ceramide), with carriers having 5.3-fold higher odds of metastatic disease (95% CI=1.85-14.98, P=0.002). In a focused set of 36 prostate cancer gene panel genes and previously curated candidate prostate cancer DNA repair genes, we found strong evidence (P<0.05) of association with aggressive or metastatic disease for *BRCA2*, *ATM*, *NBN*, *MSH2*, *XRCC2*, *SLX4*, *MRE11A*, *POLK*, *POLH*, and *MSH5*. We observed intermediate evidence ([P<0.2 and OR>1] or [OR>1.8] for aggressive or metastatic disease) for *CHEK2*, *MLH1*, *PALB2*, *TP53*, *BRCA1*, *RAD51D*, *BARD1*, *GEN1*, *XPC*, *FAM175A*, *LIG4*, *POLD1*, *EIL2*, and *RDM1*. Deleterious variants in the 36 genes were carried by 15.7% of aggressive and 17.7% of metastatic cases compared with 11.7% of non-aggressive cases. **CONCLUSION:** These findings support the importance of rare genetic variation in aggressive prostate cancer risk and provide evidence for additional susceptibility genes that may be beneficial to include on prostate cancer gene panels.

PB1169. Next Generation SP DNA Sample Prep and DLS Labeling Readies Optical Genome Mapping Workflows for Adoption at Scale

Authors:

H. Sadowski, K. Pham, V. Alexiadis, M. Valdez, M. Yadav, Y. Zhang, L. Anna, C. Proskow, A. Files, R. Nieto, K. Fernandez, M. White, M. Oldakowski; Bionano Genomics, San Diego, CA

Abstract Body:

Movement through the Bionano optical genome mapping (OGM) workflow from biological sample to genome-wide structural variation analysis requires the isolation of ultra-high molecular weight (UHMW) genomic DNA (gDNA) and the Direct Label and Stain (DLS) of this UHMW gDNA for analysis on the Bionano Saphyr platform. We present significant evolution of the protocols for the isolation of UHMW gDNA and the DLS labeling of that isolated DNA towards adoption of OGM at larger scale.

The Bionano Prep SP family of kits and protocols has been designed specifically for the isolation of UHMW gDNA. The next generation workflow improvements presented here make it easier to use at scale both manually and on automation platforms. We present data showing improved robustness across a broader range of difficult starting materials, including bone marrow aspirates (BMAs). We demonstrate higher molecule size and data throughput when these samples are run on the Bionano Saphyr system. We also show how these improvements are adopted onto a liquid handling platform to form the first-ever automated UHMW gDNA isolation and purification solution.

The Bionano Prep DLS chemistry has been the backbone of genome-wide structural variation detection using labeled molecules collected on the Saphyr system. We present significant improvements that pave the way for adoption at scale and automation. The improvements allow for 12 samples to be processed at a single time (versus 6), a reduction in overall assay time of nearly 50%, and the streamlining of the sample-to-answer Saphyr workflow by 1 day.

Overall, these improvements allow for processing more samples through the Saphyr system and provide for a sample-to-answer turnaround time for complex blood cancers of 4 days.

Chan Sch. of Publ. Hlth., Boston, MA, ¹³Northwestern Univ. Feinberg Sch. of Med., Chicago, IL, ¹⁴Johns Hopkins Univ. Sch. of Med., Baltimore, MD, ¹⁵The Royal Marsden NHS Fndn. Trust, London, United Kingdom, ¹⁶Karolinska Inst.t, Solna, Sweden, ¹⁷Fred Hutchinson Cancer Res. Ctr., Seattle, WA

Abstract Body:

Little is known regarding the potential relationship between clonal hematopoiesis (CH) of indeterminate potential (CHIP), which is the expansion of hematopoietic stem cells with somatic mutations, and risk of prostate cancer, the fifth leading cause of cancer death of men worldwide. We evaluated the association of age-related CHIP with overall and aggressive prostate cancer risk in two large whole-exome sequencing studies of 86,884 European ancestry men, including 3,579 prostate cancer cases and 77,760 controls from the UK Biobank and 2,770 aggressive and 2,775 non-aggressive prostate cancer cases from a case-only study, Whole-Exome Sequencing Study in Prostate Cancer (WESP). Somatic CHIP variants (SNVs and Indels) were identified based on a list of 74 genes with previously reported mutations in human hematologic cancers. Somatic variant calling was carried out using the GATK Mutect2, and only variants meeting the following criteria were included: 1) minor allele frequencies (MAF) <0.1% in the respective UK Biobank or WESP data; 2) MAF <0.5% in the Genome Aggregation Database (gnomAD); and 3) variant allelic fraction (VAF) >10%. This led to a total of 1663 variants in 61 CHIP genes identified in the UK Biobank and 360 variants in 52 CHIP genes identified in WESP. We found that CHIP, defined by carrier status of CHIP genes individually and in aggregate, was not associated with overall (aggregate OR=1.13, 95% CI=0.88-1.45, P=0.34), aggressive (aggregate OR=0.91, 95% CI=0.73-1.14, P=0.43), or metastatic (aggregate OR=0.90, 95% CI=0.57-1.42, P=0.65) prostate cancer risk or death due to prostate cancer (aggregate OR=0.84, 95% CI=0.65-1.08, P=0.18). Further, CHIP was not associated with germline genetic risk of overall prostate cancer, measured using a polygenic risk score, or carrying germline pathogenic/likely pathogenic/deleterious variants in DNA repair genes, which have previously been found to be associated with aggressive prostate cancer. While findings from this study do not implicate CHIP as a risk factor for prostate cancer, it will be important to investigate other types of CH in association with prostate cancer risk, such as loss of chromosome Y, which is common and heavily influenced by germline genetics.

PB1171. Novel Germline Pathogenic Variants of *APC* and *BMPRIA* genes in Algerian patients with Hereditary Polyposis Syndromes

Authors:

F. Cherbal¹, F. Khider¹, A-L. Boumehdi¹, A-W. Damache¹, S. Sabri¹, K. Layada², F. Zebboudj³, H. Mahfouf⁴, M. Maaoui⁵; ¹Molecular Genetics Team, LBCM, Faculty of Biological Sci., USTHB, Algiers, Algeria, ²Gastroenterology services, Univ. Hosp. Mustapha Bacha, Sch. of Med., Univ. of Algiers-1, Algiers, Algeria, ³Mohamed El Kolli Publ. Hosp., Academic Med. Oncology Services, Sch. of Med., Univ. of Algiers-1, Rouiba, Algeria, ⁴Mohamed El Kolli Publ. Hosp., Academic Med. Oncology Services, Sch. of Med., Univ. of Algiers1, Rouiba, Algeria, ⁵Bachir Mentouri Publ. Hosp. , Academic Gen. Surgery Services, Sch. of medicine, Univ. of Algiers-1, Kouba, Algiers, Algeria

Abstract Body:

Background Hereditary polyposis syndromes (HPS) are a group of rare, inherited syndromes that can be present in various age groups of patients (from children to adults). Patients diagnosed with HPS have a high risk to develop colorectal cancer (CRC) and extracolonic cancer at early age. The present study focuses on two HPS: Familial Adenomatous Polyposis (FAP) and Juvenile Polyposis Syndrome (JPS). **Methods** The patients and their families were referred from 2012 to 2019 through six main medical oncology services and gastroenterology and general surgery services of public hospitals of Algiers. Clinical and pathological information was extracted from medical records of the patients with particular attention to the age at diagnosis, gender, history of CRC and instance of extracolonic cancers. Family histories of HPS were obtained from interviews, pedigrees and chart review of the index cases. We screened by PCR-direct sequencing the entire exon 15 of *APC* gene in 44 patients with strong family history of hereditary polyposis and two patients were analyzed by NGS using a cancer panel of 30 hereditary cancer genes (Color genomics). **Results** The analysis of DNA samples by PCR-Sanger sequencing of 44 patients revealed that 16 FAP patients carried out nine (09) distinct germline pathogenic variants in the *APC* gene. Out of these nine pathogenic variants, the novel *APC* variant c.2544dup detected in young FAP female index case and her sister has never been reported in individuals with FAP. The rare germline pathogenic variant c.4728dup has been detected in two unrelated FAP patients; hence, the codon 1577 could be a new mutational hot spot in Algerian FAP families. Interestingly, the recurrent *APC* germline pathogenic variant c.3927_3931del had occurred *de novo* in two unrelated FAP patients. NGS analysis revealed a novel *APC* germline pathogenic variant c.1605dup in young FAP proband with a strong history of FAP and 16 of his relatives were FAP affected along 3 generations. Subsequently genetic testing was performed in four relatives of this index case and they were found to carry the novel pathogenic variant c.1605dup. NGS analysis also revealed a novel *BMPRIA* pathogenic variant c.1474-1G>C in young JPS patient. We performed *in-silico* analysis for this novel variant and the results showed an alteration of the wild type acceptor site and an activation of a cryptic acceptor site, respectively, most probably affecting splicing. **Conclusions** The present study will contribute to the molecular genetics characterization of hereditary polyposis syndromes in Algerian families that is relevant for clinical management in the areas of genetic testing, early diagnosis, treatment and prevention.

PB1172. Nucleotide resolution of large tandem duplications in cancer genomes

Authors:

P. Audano¹, F. Menghi¹, E. Liu², C. Beck³; ¹The Jackson Lab., Farmington, CT, ²The Jackson Lab, Bar Harbor, ME, ³The Jackson Lab. and Univ. of Connecticut Hlth.Ctr., Farmington, CT

Abstract Body:

Large scale chromosomal rearrangements are a hallmark of cancer genomes, and often lead to the amplification of proto-oncogenes or truncation of tumor suppressors. The Tandem Duplicator Phenotype (TDP) is common in breast, ovarian, endometrial, and liver cancers, and was first identified using short-read and array technologies. These experiments revealed three tandem duplication (TD) size groups associated with aberrations in *TP53* and *BRCA1* (group 1, ~11 kbp), *CCNE1* (group 2, ~231 kbp), and *CDK12* (group 3, ~1.7 Mbp) and showed TD clustering around genes; together these data suggest errors in DNA break repair underlying duplication formation. The precise mechanisms and full spectrum of variation resulting from TDs remains unknown because both the breakpoints of duplications and the sequence differences in the additional copy were not resolvable to basepair accuracy. We applied modern long-read sequencing technologies including PacBio HiFi and ultra-long ONT to a triple-negative breast cancer (TNBC) clonal pool known to harbor group 1 TDPs, MB436. In this cell line, we found long-read support for 87 of 92 validated duplications where missing validated TDs were small and in accessible loci suggesting they are missing in our clonal pool. Using standard tools, we fully assembled 75 TDs up to 495 kbp (2-7 assembled TDs per normal genome up to 27 kbp). We targeted an additional 17 large unassembled TDs resolved the duplication breakpoint as well as inter-duplication variants up to 20 kbp from breakpoints. By determining duplication breakpoints to basepair accuracy and analyzing duplicated sequence for somatic variants, we are constructing a database of mechanistic signatures and identifying mutations in duplicated genes resulting from DNA repair errors.

Cancer Posters - Wednesday

PB1173. OM2BFB: Detecting and elucidating Breakage Fusion Bridge structures in cancer genomes using Optical Mapping data

Authors:

S. Raeisi Dehkordi¹, J. Luebeck¹, N. Jing², I. Tsz-Lo Wong³, G. Xu⁴, L. Krockenberger¹, U. Rajkumar¹, A. Caplin¹, T. Xu¹, C. Coruh⁴, Q. Jin⁵, K. Ledward², K. Turner⁶, A. Pang⁷, J. Law⁴, F. Yue⁵, J. Zhao², P. Mischel³, V. Bafna¹; ¹Univ. of California San Diego, La Jolla, CA, ²Harvard Univ., Boston, MA, ³Stanford Univ., Palo Alto, CA, ⁴Salk, La Jolla, CA, ⁵Northwestern Univ., Chicago, IL, ⁶Boundless Bio, San Diego, CA, ⁷Bionano Genomics, San Diego, CA

Abstract Body:

Focal copy number amplification (fCNA) of oncogenes is a significant driver of cancer pathogenicity. Key fCNA mechanisms include Extrachromosomal DNA (ecDNA) formation and Breakage-fusion-bridge (BFB) cycles. Unlike ecDNA, BFB architectures have not been systematically explored. BFB formation starts with a telomere break, followed by anaphase bridge formation between sister chromatids. Multiple cycles of fusion bridge break to generate inverted duplications during cytokinesis, and subsequent fusions of broken ends in sister chromatids leads to rapid amplification of large (megabase sized) genomic intervals. BFBs can arise early during carcinogenesis, enable oncogene amplification and resistance to targeted therapy (e.g. HER2+ tumors), and have been implicated in neurodevelopmental disorders. These findings highlight the need for improved BFB detection and reconstruction--a challenge for short read data.

Optical Mapping technology provides physical maps that can be assembled into ultra-long OM assemblies (N50 ~ 50 Mbp), that overcome the challenge of analyzing large duplicated segments and fold-backs characteristic of BFB. We describe OM2BFB, a computational method for detection and reconstruction of BFB structures using OM data. OM2BFB rapidly filters for candidate BFBs, then enumerates candidate BFB structures and scores them using a novel likelihood formulation. In simulations, OM2BFB detected and reconstructed BFBs with nearly perfect recall.

We applied OM2BFB to 65 focal amplifications (28 samples), including cancer cell lines, and also breast cancer samples with brain metastases (PDX and primary). It detected and reconstructed 24 putative BFB structures in 16 different samples. On HCC827, the automated reconstruction including amplification of EGFR was identical to the previously manually reconstructed structure. While HER2 (chr17q) amplification dominated BFB structures (7 of 24 cases), BFB amplicons were found on 11 chromosomes, including 12 oncogenes. The structures often included translocation from other chromosomes, and other rearrangements. Telomere loss is a defining characteristic, but >90% percent of detected BFBs were closer to the centromere. Analysis of non-BFB structures revealed cases of ecDNA reintegration into chromosomes, while a few cases suggested ecDNA originating from BFB. BFB fCNA were lower in copy number (mean CN:27) and involved larger genomic segments (~2.2 Mbp) compared to ecDNA. Together, the results suggest that OM2BFB is a useful tool for elucidating the unique role of BFB in oncogene amplification.

Cancer Posters - Thursday

PB1174. Oncological biomarkers identified by NGS: characterization of the colombian population tumors from 2019 to 2022

Authors:

L. Parada Niño¹, M. Gálvez Bermudez¹, S. Bello Uyaban¹, M. Latorre Quintana¹, M. Lasso Carlosama²; ¹Gencell - Genuino Group, Bogotá, Colombia, ²Colina Clinic, Bogotá, Colombia

Abstract Body:

Justification: Cancer is one of the main causes of mortality worldwide and had an incidence of 182/1.000 habitants in Colombia, in 2020. Biotechnological advances such as next-generation sequencing (NGS), have allowed the analysis of tumor genomic profile, using liquid biopsy (cell-free circulating tumor DNA [cfDNA]) or tumor tissue, for the identification of oncological biomarkers that provide prognostic, predictive, and therapeutic information, also allowing the identification of germline variants. **Objective:** To describe the oncological biomarkers identified by NGS in liquid biopsy or tumor tissue samples, in a cross-section of Colombian patients with a histopathological diagnosis of cancer. **Methods:** Retrospective cross-sectional and descriptive observational study, in subjects with diagnosis of cancer, who had molecular testing by NGS in liquid biopsy or tumor tissue, and normalized with a germline sample, from May 2019 to April 2022. Participants have informed consent, according to the Helsinki's declaration. Using a NGS panel of less than 700 genes, genetic variants were identified including somatic and germline variants, as well as microsatellite instability status (MSI), and tumor mutational burden (TMB). **Results:** A total of 45 subjects were included, with a mean age of 62,8 years, 54,3% women, and 17,7% cases documented a family history of cancer. Molecular studies were performed for lung (20%), prostate (15.5%), breast (15.5%), pancreas (8.9%) and colon cancer (8.9%), among others. The analyses performed in liquid biopsy represented 75,55% of the cases. Clinically significant somatic variants were identified in 94% of cases, with an average of 3,6 variants per case. The most prevalent mutated genes were *TP53*, *AR*, *MAP3K1*, and *PTEN*. Tumor tissue cases represented 24,11% of the cohort. Biologically relevant somatic variants were identified in 81,8% of these tumors, where loss-of-function variants were predominant (90%). Mutations were more frequently found in *TP53*, *APC*, and *SMAD4* genes. MSI stable was identified in 100% of the cases. TMB was between 0,4 to 24,92 m/Mb for liquid biopsy and within 0,1 to 8,24 m/Mb in tumor tissue. Germline variants were reported in 6,6% of the cases, identified in *BRCA1*, *MUTYH*, *NF1*, and *BMPRIA* genes. **Conclusions:** This study provides important epidemiological data for Colombian cancer population, where NGS is an useful tool to detect biomarkers to potentially direct therapeutic schemes.

Cancer Posters - Wednesday

PB1175. Online implementation of combined polygenetic protein prediction algorithm for oncology (C3PO): Tumor mutation contributions to cancer hallmarks based on proteomics.

Authors:

G. R. G. Caryotakis, B. H. Song, T. H. West, M. H. Bailey; Brigham Young Univ., Provo, UT

Abstract Body:

The hallmarks of cancer, as defined by Hannahan and Weingberg (2011 and 2022), classify 13 essential characteristics linked to the development and progression of human cancer. Molecular contribution to cancer hallmarks can be measured using different next generation technologies, i.e., whole exome sequencing, RNA-sequencing, and high through proteomics measures using LC-MS-MS. However, little work has been done to establish the cumulative effect of tumor mutations on protein variation globally. Using 1061 samples collected by the Clinical Proteomic Tumor Analysis Consortium (CPTAC), we built a polygenic risk model to predict the genomic contribution to variable protein levels. Using genomics alone, we can correlate scores with protein data ranging from correlation coefficients of 0.03-0.90. While it may be difficult to predict all protein-levels, we reasoned that consistent changes across many proteins in a pathway might reveal biologically meaningful results. Here we outline a web tool developed in R Shiny, which provides sample-specific profiles for all 13 cancer hallmarks. Our bioinformatics approach empowers users to link any oncological genomic data to protein levels. Our tool can be used for both individual cancer types and cancer in general. When applied to the CPTAC lung adenocarcinoma (LUAD) cohort we observed distinct shifts in hallmarks that are correlated with smoking status- specifically the ‘non-mutational epigenetic reprogramming’ hallmark. Hallmark variations were mostly attributed to HDAC6, HDAC2, and SUV39H2 protein activity ($p=4.7 \times 10^{-6}$, $CI=-0.77 - -0.33$; $p=1.2 \times 10^{-3}$, $CI=0.15-0.57$; $p=3.4 \times 10^{-4}$, $CI=0.80-2.42$; respectively). Due to the modular nature of our tool, future iterations may include expanded datasets such as transcriptomic or methylomic data. Additionally, more specific cancer types can be included to improve predictions. We anticipate this will help identify prominent hallmark patterns in tumors leading to improved outcomes in modern precision medicine.

Cancer Posters - Thursday

PB1176. Ovarian sex cord stromal tumor is a likely additional phenotype of *BAP1*-Tumor Predisposition Syndrome

Authors:

M. Abdel-Rahman, M. Y. Hussein, C. Ingalls, C. Porteus, A. Ansari, L. Senter, C. M. Cebulla, L. Byrne; The Ohio State Univ., Columbus, OH

Abstract Body:

Objective: Germline mutations in the tumor suppressor gene *BAP1* are associated with the hereditary tumor predisposition syndrome, *BAP1*-TPDS (OMIM 614327), with predisposition to four main cancers: uveal melanoma, mesothelioma, cutaneous melanoma, and renal cell carcinoma. However, other cancers are likely part of the clinical phenotype. Here, we report the potential association of ovarian stromal sex cord (OSSC) cancers with *BAP1*-TPDS. **Methods:** A total of 3321 unselected cancer patients enrolled through the Total Cancer Care (TCC) Protocol, at the Ohio State University Comprehensive Cancer Center and were assessed for germline *BAP1* variants by secondary analysis of research exome sequencing. Exome sequencing was carried out through the Oncology Research Information Exchange Network (ORIEN) AVATAR program. Selected *BAP1* variants were confirmed by direct sequencing. Additionally, subjects with germline *BAP1* variants identified through routine clinical testing were enrolled in a separate protocol (NCT04792463). Cascade testing for at risk family members was then performed for P/LP or suspicious variant of uncertain significance (VUS). **Results:** We identified 15/3321 missense VUSes in the tested cohort of unselected cancer patients. Fourteen of these were located outside the ubiquitin carboxy-terminal hydrolase (UCH) domain of BAP1 (amino acids:1-240). One of these VUS (c.86T>G, p.V29G) was located in the active UCH domain of BAP1 and was identified in a female patient with an OSSC cancer. The variant is not reported in the general population and predicted deleterious by multiple computational tools. The patient had a family history consistent with *BAP1*-TPDS including multiple mesotheliomas, as well as other cancers. The ovarian tumor of this patient showed evidence of biallelic inactivation of BAP1. We reviewed our clinical cohort of germline *BAP1* P/LP patients and their positive family members. These included 100 individual (31 males and 69 females) from 50 families. We identified three with ovarian cancer; one had OSSC cancer, one had papillary serious ovarian carcinoma and the pathology was not available on the third. A literature search identified two additional OSSC cancers in patients with germline *BAP1* P/LP. Furthermore, OSSC tumors were the most common spontaneous cancer observed in murine models of germline heterozygous *BAP1* P/LP variants. **Conclusions:** Given the rarity of OSSC in general population, our results in addition to published data, strongly suggest that it is likely part of the clinical phenotype of *BAP1*-TPDS. Validation studies in independent cohorts are warranted.

Cancer Posters - Thursday

PB1177. *PALB2*-mutated human mammary cells display a broad spectrum of morphological and functional abnormalities beyond defective DNA damage response.

Authors:

R. Winqvist^{1,2}, H. Tuppurainen¹, N. Laurila¹, M. Nätyinki¹, L. Eshraghi^{1,3}, A. Tervasmäki¹, L. Erichsen⁴, C. Storgaard Sørensen⁴, K. Pylkäs^{1,2}, H. Peltoketo¹; ¹Univ Oulu, Oulu, Finland, ²Northern Finland Lab. Ctr., Oulu, Finland, ³Garvan Inst. of Med. Res., Sydney, Australia, ⁴Univ Copenhagen, BRIC, Copenhagen, Denmark

Abstract Body:

Heterozygous mutations in any of three major genes, *BRCA1*, *BRCA2* and *PALB2*, are associated with high-risk hereditary breast cancer susceptibility frequently seen as familial disease clustering. *PALB2* is a key interaction partner and regulator of several vital cellular activities of *BRCA1* and *BRCA2*, and thus it is required for DNA damage repair and alleviation of replicative and oxidative stress. Little is however known about how *PALB2*-deficiency affects cell function beyond that, especially in the three-dimensional setting, but also about its role during early steps of malignancy development. To answer these questions, we have generated biologically relevant isogenic cell lines with mutations that are comparable to certain clinically important *PALB2* defects. We show in a non-cancerous background how both mono- and biallelically *PALB2*-mutated cells exhibit gross spontaneous DNA damage and mitotic aberrations. Furthermore, *PALB2*-deficiency disturbs three-dimensional spheroid morphology, increases the migrational and invasional capacity of the cells, and broadly alters their transcriptome profiles. TGFB signaling has been enhanced in *PALB2*-mutated cells and its inhibition partially rescues the cells. Independent of DNA damage, expression of several genes associated with cell adhesion and migration has also been triggered in *PALB2*-mutated cells. The obtained results indicate comprehensive changes in cell function upon *PALB2* mutations, even in the presence of half a dosage of wild type *PALB2*, and demonstrate how *PALB2* mutations may predispose their carriers to malignancy.

Cancer Posters - Wednesday

PB1178. Pan-Cancer Analysis introduces HLF as a tumor suppressor gene and a promising biomarker for prognosis and targeted therapy in human tumors

Authors:

M. Ahmadi¹, S. Ghaderian²; ¹Shahid Beheshti Univ. of Med. Sci., Tehran, Iran, Islamic Republic of, ²Shahid Beheshti Univ. of Med. Sci., Tehran, Iran, Islamic Republic of

Abstract Body:

Hepatic leukemia factor (HLF) is considered a clock-dependent transcription factor. Even though prior research has linked the aberration of the *HLF* gene to cancer development, no pan-cancer assessments of the *HLF* gene have been published. Therefore, we employed several databases to demonstrate the possible functions of the *HLF* gene in various cancer types in this investigation. We analyzed the expression level of the *HLF* gene across TCGA cancers using the UALCAN, GEPIA2, and GSCA databases. We further evaluated the association of the *HLF* gene with the overall survival of cancer patients. We also assessed the genetic alterations, the methylation level of the promoter region, protein-protein interaction of the *HLF* gene, and the correlation between HLF expression and immune cell infiltration in various tumors utilizing the cBioPortal, DNMIVD, GeneMANIA, and TIMER2 databases, respectively. Besides, data from the GSCA database was used to investigate the possible roles of the HLF gene and the relationship between HLF expression and drug sensitivity. We determined that the *HLF* gene was downregulated in tumor tissues of a wide range of cancers compared to corresponding normal tissues. We also detected a significant association between abnormal expression of *HLF* and patient survival, genetic mutations, and immune infiltration. In addition, pathway analysis indicated that *HLF* affected Apoptosis, Cell Cycle, EMT, and PI3K/AKT signaling pathways. Finally, we showed that abnormal expression of the *HLF* gene could reduce the sensitivity to several anti-tumor agents and small molecules in the GDSC dataset. Our findings propose that lower expression of the *HLF* gene mediates carcinogenesis and cancer progression and could be recognized as a valuable biomarker for prognosis, immunotherapy, and target treatment in various cancers.

Cancer Posters - Thursday

PB1179. Pan-cancer polygenic risk distinctly contributes to prediction of heterogeneous subsequent malignancies across treatment profiles in survivors of childhood cancer.

Authors:

C. Im¹, N. Sharafeldin², Y. Yuan¹, Y. Sapkota³, Z. Wang³, M. A. Arnold⁴, G. T. Armstrong³, M. M. Hudson³, K. K. Ness³, L. L. Robison³, S. Bhatia², J. P. Neglia⁵, L. M. Turcotte⁵, Y. Yasui³; ¹Univ. of Alberta, Edmonton, AB, Canada, ²Univ. Alabama at Birmingham, Birmingham, AL, ³St. Jude Children's Res. Hosp., Memphis, TN, ⁴Univ. of Colorado, Aurora, CO, ⁵Univ. of Minnesota, Minneapolis, MN

Abstract Body:

Subsequent malignant neoplasms (SMNs) contribute substantially to late morbidity/mortality among long-term survivors of childhood cancer. Given growing evidence of common biological hallmarks for cancers including indications of a shared genetic basis (pleiotropy), we explored the impact of pan-cancer polygenic risk factors on overall SMN risk in 10,137 childhood cancer survivors. Participants in the Childhood Cancer Survivor Study and St. Jude Lifetime Cohort Study (European genetic ancestry) with genotype data, medical record-abstracted treatment exposures, and pathology-confirmed SMNs were analyzed. Top-performing published genome-wide polygenic risk scores (PRSs) for specific cancers and “any cancer” in the Michigan Genomics Initiative (MGI) study (Cancer-PRSWeb; prsweb.sph.umich.edu) were computed, where pan-cancer PRSs came from UK Biobank GWAS (N>300K). Hazard ratios (HRs) for any SMN incidence were estimated by Cox regression, with age, sex, batch/cohort, fine-scale ancestry, and primary cancer diagnosis/treatment (e.g., radiation therapy [RT], alkylating agents, anthracyclines, epipodophyllotoxins) as covariates. A total of 1,022 SMNs were observed among 922 survivors (total N=10,137; 242,962 person-years of follow-up), including subsequent breast (25.5% of SMNs, N=237) and thyroid (23.6%; N=218) cancers and basal cell carcinomas (BCCs; 21.8%, N=201). Since the top pan-cancer PRS in MGI (lassosum with 179 variants, PRS₁₇₉) performed similarly across the two cohorts and combined sample, we report combined results. PRS₁₇₉ was significantly associated with pan-SMN risk (HR per PRS SD=1.12, P=6.2x10⁻⁴). This association was consistently attenuated among survivors who received any RT (top vs. bottom PRS₁₇₉ quartiles, HR=2.13, P=4.5x10⁻⁴ if no RT vs. HR=1.19, P=0.13 if any RT), while anthracyclines enhanced risk (HR=2.79, P=1.1x10⁻³ if no RT, anthracyclines >0 mg/m²). Top PRSs for breast cancer, thyroid cancer, and BCC in MGI were significantly associated with corresponding specific SMN risks (HRs=1.29 to 1.37, P=5.9x10⁻¹⁴ to 1.5x10⁻⁴). Although these cancer subtypes were common (~60% of SMNs), pan-cancer PRS₁₇₉ remained significantly associated with pan-SMN risk (HR per PRS SD=1.11, P=4.1x10⁻³) while the three cancer-specific PRSs did not (P>0.06) in a model with all four scores. In summary, pan-cancer polygenic risk factors can predict overall SMN risk among childhood cancer survivors despite the heterogeneity of SMNs, depending on treatments received. Further research to refine pan-SMN genetic risk predictors reflecting common carcinogenic hallmarks and their effect modification by treatments is needed.

PB1180. Parent-of-origin-aware genomic analysis in the management of patients and families with genetic disease

Authors:

K. Schrader^{1,2}, V. Akbari¹, V. Hanlon², K. O'Neill², K. Dixon¹, Y. Shen², A. Sharma², J. Senz¹, Y. Wang¹, D. Chan², A. Fok², Q. Hong¹, D. Regier², A. Virani¹, L. Lefebvre¹, F. Feldman², M. Marra^{2,1}, S. Sun², S. Yip^{1,2}, P. Lansdorp^{1,2}, S. Jones^{1,2}; ¹Univ. British Columbia, Vancouver, BC, Canada, ²BC Cancer, as part of the Provincial Hlth.Services Authority, Vancouver, BC, Canada

Abstract Body:

Parent-of-origin-aware genomic analysis using Oxford Nanopore Technologies long-read sequencing combined with Strand-seq is a novel breakthrough method that enables assignment of variants to each biological parent with >99% accuracy using only the blood sample of the child. We demonstrate the analytic validity and clinical utility of this method of parent-of-origin-aware genomic analysis in *SDHD* pathogenic variant carriers with known parental segregation. Pathogenic variants in *SDHD* have parent-of-origin effects with disease penetrance for high lifetime risk for paragangliomas and pheochromocytomas that are dependent on transmission of the pathogenic variant through the male gamete. Hence knowledge of the parent-of-origin of *SDHD* pathogenic variants is essential when advising on management with significant clinical implications for lifelong surveillance. When parent-of-origin of the *SDHD* pathogenic variant is unknown, patients may undergo potentially unnecessary lifelong surveillance or forego necessary surveillance due to their uncertain risk estimate. Potentially unnecessary surveillance directly and indirectly burdens both the patient and the health care system and includes physical, practical, psychological, and other burdens. Beyond management of the patient, parent-of-origin-aware genomic analysis may help inform variant curation, recurrence risks, and efficiently direct cascade genetic testing throughout the family. While the added dimension to genetic testing will improve patient-centered care, there will be ethical considerations related to inference of a parent's germline variant status with >99% accuracy. Although obligate carrier status is not a new concept, routinely predicting carrier status with high accuracy could have significant duty-to-warn implications, especially in the setting of actionable diseases and secondary findings. These issues will need to be considered as the applications of parent-of-origin-aware genomic analysis expand and as uptake of this technology transforms precision medicine for both patients and families with genetic disease.

Cancer Posters - Thursday

PB1181. Pathogenic genetic variants from highly connected cancer susceptibility genes confer the loss of structural stability and further link with diabetes

Authors:

M. Hossain¹, N. Ferdous², M. Mohini³, E. Md. Tabassum Hossain⁴, M. Islam⁵, A. Mohiuddin²; ¹Natl. Inst. of Biotechnology, Savar, Bangladesh, ²Mawlana Bhashani Sci. and Technology Univ., Tangail, Bangladesh, ³Mawlana Bhashani Sci. and Technology, Tangail, Bangladesh, ⁴Natl. Inst. of Biotechnology, Tangail, Bangladesh, ⁵Mawlana Bhashani Sci. and Technology Univ., Savar, Bangladesh

Abstract Body:

Genetic polymorphisms in DNA damage repair and tumor suppressor genes have been associated with increasing the risk of several types of cancer. Analyses of putative functional single nucleotide polymorphisms (SNP) in such genes can greatly improve human health by guiding the choice of therapeutics. In this study, we selected nine genes responsible for various cancer types for gene enrichment analysis and found that BRCA1, ATM, and TP53 were more enriched in connectivity. Therefore, we used different computational algorithms to classify the nonsynonymous SNPs which are deleterious to the structure and/or function of these three proteins. Our study demonstrated that V1687G and V1736G variants of BRCA1, I2865T and V2906A variants of ATM, V216G and L194H variants of TP53 are major mutations with pathogenic impact and are likely to have a greater impact on destabilizing the proteins. To stabilize the high-risk SNPs, we performed mutation site-specific molecular docking analysis and validated using molecular dynamics (MD) simulation and molecular mechanics/Poisson Boltzmann surface area (MM/PBSA) studies. Additionally, SNPs of untranslated regions of these genes affecting miRNA binding were characterized. Besides, we have collected the human blood sample (n = 750) from the cancer-affected people and performed a population genetics study. We performed the PCR-RFLP method to observe the frequency of the genotype and found significantly associated with the genes BRCA1 (P = .001), ATM (P = .016), and TP53 (P = .011) of cancer affected patients. Interestingly, the metadata suggests that the genotypes are also significantly associated with diabetes patients (n = 370). Furthermore, we have found a strong relationship between cancer and diabetes from the exploration of systems biology and metadata. Hence, this study will assist in developing precision medicines for cancer types related to these polymorphisms and diabetes.

Cancer Posters - Wednesday

PB1182. Pathogenic Variants in Adult-Onset Cancer Predisposition Genes Identified by Pediatric Tumor Genomic Testing: Prevalence, Tumor Features, and Germline Testing Outcomes

Authors:

N. Oak¹, R. B. McGee¹, L. Harrison¹, K. Xu², A. K. Blake¹, R. Nuccio¹, R. Mostafavi¹, S. Lewis³, L. Taylor¹, M. Kubal¹, A. Ouma¹, S. Hines-Dowell¹, K. E. nichols¹; ¹Dept. of Oncology, St. Jude Children's Res. Hosp., Memphis, TN, ²Ctr. for Applied Bioinformatics, St. Jude Children's Res. Hosp., Memphis, TN, ³Dept. of Hematology, St. Jude Children's Res. Hosp., Memphis, TN

Abstract Body:

Background: Genomic sequencing of pediatric tumors is uncovering pathogenic variants (PVs) in adult-onset cancer predisposition genes (aoCPGs), some of which are germline in origin. Nevertheless, it remains uncertain whether aoCPG PVs contribute to pediatric tumor formation and unclear how germline aoCPG data inform the care of children with cancer. To address these questions, we examined the prevalence and spectrum of tumor aoCPG PVs, tumor molecular features, and germline testing and clinical management outcomes among children and young adults with cancer who underwent genomic testing at our institution between 2017-2019.

Results: Tumor genomic reports from 1,023 patients were queried for the presence of PVs in 25 pre-selected aoCPGs. Thirty-eight patients (4%) had 39 tumors harboring 41 PVs affecting 13 aoCPGs. Analysis of available whole genome sequencing data from 28 of these 39 (72%) tumors revealed mutational signatures consistent with defective DNA repair, including homologous recombination (HR) in tumors with *ATM*, *BRCA2*, *PALB2*, *CHEK2* PVs (n=8 of 18, COSMIC signature SBS3), mismatch repair in tumors with *MSH2*, *MSH6*, *PMS2* PVs (n=5 of 5, SBS15, SBS26), and base excision repair in tumors with *MUTYH* PVs (2 of 3, SBS36). Notably, only seven of these 15 mutation-signature positive tumors harbored genomic lesions affecting (n=6) or presumably affecting (n=1) the second aoCPG allele. We analyzed HR deficiency (HRD) using scarHRD, which incorporates information on genomic loss of heterozygosity, telomeric allelic imbalance and large-scale state transitions. Two tumors (both with biallelic *ATM* inactivation) had significantly higher HRD scores compared to tumors with monoallelic HR gene inactivation (Wilcoxon p-value=0.019, n=16) or in tumors without any HR gene PVs (p=0.012, n=212). Thirty patients completed germline analysis with 25 (83%) testing positive and 10 exhibiting consistent family histories of cancer. Despite high uptake of germline testing, only five patients' care changed based on germline findings: a young adult with *PMS2* and *AXIN2* variants for whom colon cancer screening was initiated and four children for whom germline data was used to direct donor selection for stem cell transplantation.

Conclusion: In sum, 4% of pediatric tumors harbored aoCPG PVs, with at least 36% (15 of 41 total PVs) demonstrating an associated DNA mutation signature. Among 18 tumors with HR gene PVs, only two exhibited evidence of HR deficiency. Further studies are warranted to determine whether or how aoCPG PVs contribute to pediatric tumor formation. There was unanimous parental interest in germline testing of aoCPGs despite limited direct clinical impact.

Cancer Posters - Thursday

PB1183. Phylogeny-aware detection of single-nucleotide variants and mode of evolution from cancer single-cell DNA sequencing data.

Authors:

M. Edrisi¹, M. Valecha², S. Chowdary³, S. Robledo⁴, H. Ogilvie¹, D. Posada², H. Zafar⁵, M. Li¹, L. Nakhleh¹; ¹Rice Univ., Houston, TX, ²Univ. of Vigo, Vigo, Spain, ³Indian Inst. of Technology Kanpur, Kanpur, India, ⁴Univ. of Houston, Houston, TX, ⁵Indian Inst. of Technology Kanpur, Kanpur, India

Abstract Body:

The growth of a tumor can be regarded as an evolutionary interplay between the mutations and the selective pressure in the tumor environment. Cancer evolutionary biology studies the timing and type of the mutations, how they accumulated, and the selective sweeps that occurred during this evolutionary process by reconstructing the tumor phylogenetic tree. With the advent of single-cell DNA sequencing (scDNA-seq), it is now possible to infer the phylogenetic tree of a tumor at a single-cell resolution. This promising opportunity comes with the burden of elevated error rates, allelic dropout, and nonuniform coverage in the scDNA-seq data that complicates the mutation detection required for phylogeny reconstruction. Here we report on two methods we developed: Phylovar (previously published) and MoTERNN. We developed Phylovar to overcome the challenge of mutation detection from scDNA-seq data by incorporating the evolutionary history of the cells. Later, we developed MoTERNN to infer the evolutionary pattern of tumor growth from scDNA-seq data.

In Phylovar, we followed up on phylogeny-aware mutation detection for single-nucleotide variations (SNVs), which was previously shown to be an effective approach to overcome the technical noise in single-cell sequencing protocols by the methods SCIΦ and scVILP. In this approach, the phylogeny of single cells plays the role of a nuisance parameter constraining the SNV detection method. Despite being accurate, these methods are not scalable to the extensive genomic breadth of single-cell whole-genome and whole-exome sequencing data. Phylovar extended the phylogeny-guided variant calling approach to sequencing datasets containing millions of loci while being as accurate as its preceding methods.

In MoTERNN, we focused on determining the mode of evolution of tumor cells from their inferred evolutionary history and SNV profiles acquired from scDNA-seq data. Here, we employed recursive neural networks that capture tree structures to classify the evolutionary history of tumor cells into one of four evolutionary modes—linear, branching, neutral, and punctuated. We trained our model, MoTERNN, using simulated data in a supervised fashion and applied it to the phylogenetic tree obtained from scDNA-seq of a triple-negative breast cancer patient. It is worth mentioning that we used Phylovar to obtain this phylogenetic tree and the SNV profiles of the cells as the input to MoTERNN. MoTERNN identified a punctuated mode of evolution for this patient which was in agreement with the results of the original study.

Cancer Posters - Wednesday

PB1184. Potential misrepresentation of inherited breast cancer risk by common germline alleles.

Authors:

W. Letsou¹, F. Wang¹, W. Moon¹, C. Im², Y. Sapkota¹, L. Robison¹, Y. Yasui^{1,2}; ¹St. Jude Children's Res. Hosp., Memphis, TN, ²Univ. of Alberta, Edmonton, AB, Canada

Abstract Body:

Hundreds of common variants have been found to confer small but significant differences in breast cancer risk, supporting the polygenic additive model of inherited risk. This widely accepted model is at odds with twin data indicating highly elevated risk in a subgroup of women. Using a novel closed-pattern-mining algorithm called Chromosome Overlap, we provide evidence that rare variants or haplotypes may underlie the association of breast cancer risk with common germline alleles. Our method consists in iteratively pairing chromosomes from affected individuals and looking for noncontiguous patterns of shared alleles without exhaustive enumeration. We applied Chromosome Overlap to haplotypes of genotyped SNPs from 9,011 female breast cancer cases from the UK Biobank (UKBB) at three topologically associating domains containing well-established common-allele “hits” for breast cancer risk near *FGFR2*, *CCND1*, and *CASC16*. A total of 181,034 UKBB women of “white British” ancestry were used to assess the discovered haplotypes, and 55,346 cases and controls of European ancestry in the Discovery, Biology, and Risk of Inherited Variants in Breast Cancer (DRIVE) case-control study were used for replication. To account for differences between the UKBB Axiom Array and the DRIVE OncoArray, imputation and phasing for all samples was done using the TOPMed Imputation Server at UKBB genotyped SNPs. After using Chromosome Overlap to mine closed haplotype patterns among case chromosomes on 50–60 SNPs within ~100 kb of (but not necessarily including) the three GWAS hits, we found three respective strongly linked common haplotypes ($LD\ r^2 \geq 0.7$, $D' \geq 0.99$) with similar effect sizes (hazard ratios: 1.2–1.3); to find rare haplotypes, we performed a second phase of the analysis in adjacent ~400-kb regions containing ~100 SNPs each on chromosomes carrying the common haplotype. Out of twenty rare (frequency < ~0.1%) risk haplotypes of large effect identified in UKBB at $p < 1.0 \times 10^{-5}$, four (hazard ratio: 4.22–20.2) were subsequently replicated in DRIVE (odds ratio: 2.13–11.9) at $p < 0.05$. This level of replication was found to be robust by permutation analysis. Because we had low power to detect such rare haplotypes and were limited to UKBB genotyped SNPs, our successful replication of four of them suggests there could be many similar haplotypes which underlie the association of other GWAS hits with disease risk. Our results are also consistent with the genetic heterogeneity of breast cancer risk and suggest a novel type of “synthetic association” wherein common risk alleles on a rare risk haplotype may misrepresent disease risk through their tagging of many “false positive” haplotypes.

Cancer Posters - Thursday

PB1185. Potential subtype-informative genetic risk variants and genes identified from a case-case analysis for breast cancer

Authors:

X. Sun^{1,2}, X. GUO³, A. Reiner¹, G. Watt¹, J. Bernstein¹, X. Shu¹; ¹Mem. Sloan Kettering Cancer Ctr., New York, NY, ²Zhejiang Chinese Med. Univ., Hangzhou, China, ³Vanderbilt Univ. Med. Ctr., Brentwood, TN

Abstract Body:

Background: Breast cancer, comprised of subtypes with distinct pathological and molecular features, is highly heterogeneous. Compared to overall breast cancer, the understanding of genetic architecture for the subtypes have lagged. **Methods:** We obtained summary statistics data of genome-wide association studies (GWAS) conducted in intrinsic-like breast cancer subtypes, including luminal A-like, luminal B-like, luminal B/Her2-negative-like, Her2-enriched-like and triple negative breast cancer (TNBC) from the Breast Cancer Association Consortium (BCAC, total 106,278 cases and 91,477 controls). We applied linkage disequilibrium score (LDSC) regression to infer single-nucleotide variant (SNV) based heritability for each subtype and calculated estimates of pairwise genetic correlations among the subtypes. We then conducted case-case comparisons among the intrinsic-like breast cancer subtypes using the newly developed case-case GWAS (CC-GWAS) approach. The conditional and joint multiple-SNV analysis was further conducted for the identified variants, as well as a gene-based analysis across the genome using MAGMA. **Results:** LDSC analysis revealed a moderate to high genetic correlation among the five intrinsic-like subtypes (ranging from 0.52 to 0.88). We identified 13 significant risk loci from the pairwise case-case comparisons across the five intrinsic-like subtypes ($P < 5 \times 10^{-8}$) and additional 8 loci with a suggestive association ($P < 5 \times 10^{-7}$), all in close proximity to previously reported breast cancer susceptibility loci (<500 Kb). Among them, 12 loci were independent from previously reported breast cancer susceptibility variants in the conditional analysis (Bonferroni corrected $P < 0.05$). Eight of the 12 loci were identified from the comparisons between TNBC and luminal A-like cancers, followed by TNBC versus luminal B/Her2-negative-like (n=1) and Her2-enriched-like versus luminal A-like (n=1). Two loci identified from the comparisons between TNBC and luminal A-like were also found in the comparisons of TNBC versus luminal B-like (8q22.3) and TNBC versus luminal B/Her2-negative-like (11q22.3). The gene-based analysis also identified 32 significant risk-associated genes after the Bonferroni correction, of which 19 genes were specific to TNBC when compared to luminal A-like cancer. **Conclusion:** This study showed the complexity in the heterogeneity of breast cancer genetic susceptibility and provided new insights into the etiology of breast cancer especially for TNBC.

Cancer Posters - Thursday

PB1187. Prevalence of mutations in hereditary cancers of Czech patients.

Authors:

M. Koudová¹, L. Cerna¹, S. Chvojka¹, M. Sekowska¹, M. Urbanova¹, M. Bittoova¹, F. Zembol¹, B. Honysova¹, H. Dohnalova¹, A. Puchmajerova¹, D. Stejskal²; ¹GENNET s.r.o, Prague 7, Czech Republic, ²GENNET s.r.o., Praha 7, CZ

Abstract Body:

Introduction: Czech patients fulfilling clinical criteria for hereditary cancer (HC) are tested by NGS panel CZEKANCA (PMID: 29649263, Seq-Cap EZ Choice, Roche) that includes 226 genes associated with HC. Methods: Total 7286 DNA samples - patients (4729) and healthy relatives (2557) were tested. The most indications were for the breast, ovarian and colorectal HC. We have developed a bioinformatic pipeline using local installation of Ensembl genomic database for annotation and own variant database CheckBase for data handling and clinical reporting. Clinical interpretation was prioritised according to primary indication, revision based on IACR* standards, ACMG guidelines (PMID: 25741868) and the HGVS genetic nomenclature. Detection of exon deletions and duplications and larger gene rearrangements was performed by analyzing the coverage of NGS data on the target areas of the CZEKANCA panel. Positive results were validated by direct sequencing and CNV findings by MLPA. Results: Clinical important variants (class 5 and 4)* were detected in 20,1% samples and VOUS (class 3)* in 15,6% samples. The most variants were detected in genes BRCA1 (18%), BRCA2 (12%), CHEK2 and MUTYH (7%), NBN (6%), ATM and PALB2 (4%), NF1 (3%), MLH1, FH, FANCA, FANCM (all 2%). Conclusion: These results highlight the importance of extending the examination to other cancer susceptibility genes, because *BRCA1/2* gene mutations are responsible only for 1/3 of the heritable mutations in HC.

Cancer Posters - Wednesday

PB1188*. Prevalence of suspected pathogenic or likely pathogenic germline *TP53* variants in population sequencing databases: A genotype-first analysis.

Authors:

K. De Andrade¹, N. Strande², J. Kim¹, J. Haley², J. Hatton¹, M. Frone¹, P. Khincha¹, G. Thone², U. Mirshahi², J. Dove², A. Levine³, D. Stewart¹, D. Carey², S. Savage¹; ¹Natl. Cancer Inst., Rockville, MD, ²Geisinger, Danville, PA, ³Simons Ctr. for Systems Biology, Inst. for Advanced Study, Princeton, NJ

Abstract Body:

Pathogenic or likely pathogenic (P/LP) germline *TP53* variants are associated with Li-Fraumeni syndrome (LFS), a hereditary cancer predisposition disorder characterized by early-onset cancers. While the true prevalence of LFS is unknown, population-based studies suggest that the prevalence of P/LP germline *TP53* variants in the general population may be higher than previous estimates based on ascertainment of severely affected families. Genotype-first approaches can overcome selection biases present in most traditional phenotype-based studies. Analysis of individuals unselected for specific traits allows the detection of carriers of germline variants that would not otherwise be identified. We identified suspected germline *TP53* variants in two electronic health records (EHR)-linked sequencing cohorts, UK Biobank (n=200,600) and Geisinger healthcare system (n=175,449). Variants with allele fraction \geq 30% in exonic regions were classified based on ClinVar and InterVar. A total of 56 individuals from Geisinger (56/175,449; 0.03%) and 22 from UK Biobank (22/200,600; 0.01%) were detected with suspected P/LP germline *TP53* variants; including 35 females and 43 males. Median age at first visit was 64 years for females (range 18-80) and 62 years for males (range 22-80). Sixty-six individuals were cancer-free at least until the age of 60. Forty-seven individuals were diagnosed with a first cancer (median age at diagnosis 67 years; range 22-84) and 15 had developed multiple primaries on analysis of last available EHR data. Hematologic cancers were the most common first diagnoses. There were 54 unique P/LP variants, with p.R181H being the most frequent (9/78; 11.5%). Three of the nine p.R181H carriers had been diagnosed with cancer (bladder, prostate, and thyroid). We corroborate conservative population-based prevalence estimates of P/LP germline *TP53* variants in the range of 1:5,000 individuals of predominant European ancestry. However, the median ages at cancer diagnosis in the UK Biobank and Geisinger cohorts were 30 years higher than in LFS cohorts. This survival bias suggests that most of the *TP53* variants detected in our study may be associated with low cancer penetrance. Despite using an allele fraction cut-off \geq 30%, the relatively high number of hematologic cancers suggests there could be some somatic *TP53* variants occurring due to clonal hematopoiesis of indeterminate potential whose allele fractions resemble that of germline origin. Genotype-first analyses are valuable in identifying suspected P/LP germline *TP53* variants associated with variable cancer penetrance and with non-traditional LFS phenotypes.

Cancer Posters - Thursday

PB1189. Primary myelofibrosis and progression to acute myeloid leukemia in a young patient with variant in *CARL*

Authors:

A. Tamayo Palacio¹, N. Huerta Bolfeta¹, C. Afanador², G. C. Ramirez², S. Villa-Perez³, L. Gaviria Jaramillo³, G. Vasquez Palacio⁴; ¹Hosp. Infantil de México Federico Gómez, Ciudad de México, Mexico, ²Laboratorio Integrado de Med. Especializada LIME, Facultad de Med., Univ. de Antioquia, Medellín, Colombia, ³Hosp. San Vicente Fundación, Medellín, Colombia, ⁴Laboratorio Integrado de Med. Especializada LIME, Facultad de Med., Univ. de Antioquia, Medellín, Colombia

Abstract Body:

Introduction: Myeloproliferative neoplasms (MPNs) are clonal disorders characterized by increased proliferation of erythrocytes, megakaryocytes and mature granulocytes. Among the Philadelphia negative (Ph-) myeloproliferative neoplasms are Polycythemia Vera, Primary Myelofibrosis and Essential Thrombocythemia. In recent years, somatic mutations have been identified in the JAK2, MPL and CALR genes, which are associated with the progression of Ph- MPNs and are currently considered fundamental markers for the diagnosis of these neoplasms.

Case report: We present the case of a 35-year-old female patient with no relevant history, who was initially treated in Panama for abnormal uterine bleeding, severe anemia (Hb 3 g/dL) and pancytopenia. Gynecological alterations were excluded and the patient decides to return to her hometown. At the San Vicente Fundación Hospital, in Medellín, Colombia, the bone marrow (BM) biopsy showed findings suggestive of myelofibrosis and cells suggestive of blasts and immunohistochemistry was compatible with acute myeloid leukemia (AML) associated with grade 3 fibrosis. Myelogram: 9% blasts, hypercellular cord with dysplastic changes in erythroid and myeloid lines. Infectious causes were excluded and molecular studies were requested for BCR-ABL, JAK2, MPL and CALR. Negatives for BCR-ABL1, MPL and JAK2 (V617F), it also presented a 5bp deletion in exon 12 (rs56241661) in JAK2, and an 11bp deletion in exon 9 in CALR

Materials and methods: Clinical evaluation of the patient, bone marrow biopsy, immunohistochemistry, immunophenotype, qRT-PCR for BCR-ABL1, JAK2 and capillary electrophoresis in MPL and CALR. Discussion: CALR located at 19p13.2, codes for the calreticulin protein, which has functions in calcium homeostasis, chaperone activity in protein and glycoprotein folding, apoptosis and immunogenic cell death. Variants in CALR have been correlated with the origin of MPN, especially primary myelofibrosis (PMF) and essential thrombocytosis (ET); currently being the second most important marker in these pathologies. The 11 bp deletion in CALR is a frameshift variant affecting the KDEL domain, which is essential for the retention of calreticulin in the endoplasmic reticulum. The variant identified in JAK2 needs further study. Therefore, the detection of the variant in CALR, still awaiting the sequencing result, is remarkable for the assessment of prognosis, the course of the disease and its management.

Cancer Posters - Wednesday

PB1190. Prognostic Value of Bile Acid Transporter SLC10A1 Expression in Hepatocellular Carcinoma

Authors:

H. Chen; West Windsor-Plainsboro High Sch. South, West Windsor, NJ

Abstract Body:

Background/Objectives: Hepatocellular carcinoma (HCC) is the most common primary liver malignancy that occurs predominantly in patients with underlying chronic liver disease and cirrhosis. Emerging data have implicated that the expression and function of hepatic bile acid uptake transporter NTCP (sodium-taurocholate co-transporting polypeptide) are altered in hepatocellular carcinoma. NTCP, encoded by the SLC10A1 gene (solute carrier family 10 member 1), is a key transport protein involved in the enterohepatic recirculation of bile acids. We aimed to systematically analyze SLC10A1 expression and its prognostic role in HCC using various open databases. Methods: SLC10A1 expression in HCC was assessed using UALCAN and GEPIA database. The promoter *methylation* levels were also examined by *UALCAN*. Correlation between SLC10A1 expression and patient survival was evaluated with OncoLnc. SLC10A1 genetic alterations in HCC were explored using cBioPortal. Results: SLC10A1 expression is significantly down-regulated in the clinic-pathological characteristics (cancer stages, patient's race, gender, age, weight, tumor grade, nodal metastasis status, and histological subtypes) examined in HCC patients compared to normal counterparts. SLC10A1 promoter methylation level in HCC was higher than that in normal liver tissue. Clinically, low expression of SLC10A1 was correlated with shorter overall survival in HCC patients ($P= 0.0038$). Among HCC cases with SLC10A1 genetic alterations, mutations were the most common type of alteration (data from TCGA Liver Hepatocellular Carcinoma, PanCancer Atlas). Conclusions: These observations indicate that SLC10A1 may function as a potential tumor suppressor gene. In HCC patients, SLC10A1 expression levels may also serve as a prognostic predictive marker.

Cancer Posters - Thursday

PB1191*. Proteome studies of breast, prostate, ovarian, and endometrial cancers implicate plasma protein regulation in cancer susceptibility.

Authors:

I. Gregga¹, B. Prins², A. Butterworth², P. Pharoah³, S. Gayther⁴, A. Manichaikul⁵, H. Im⁶, S. Kar², J. Schildkraut⁷, H. Wheeler⁸; ¹Loyola Univ. Chicago, Chicago, IL, ²Univ. of Cambridge, Cambridge, United Kingdom, ³Univ Cambridge, Cambridge, United Kingdom, ⁴Cedars Sinai Med. Ctr., Los Angeles, CA, ⁵Univ Virginia, Charlottesville, VA, ⁶Univ. of Chicago, Chicago, IL, ⁷Emory Univ., Augusta, GA, ⁸Loyola Univ Chicago, Chicago, IL

Abstract Body:

Predicting protein levels from genotypes for proteome-wide association studies (PWAS) may provide insight to the mechanisms underlying cancer susceptibility. Here, we focused our PWAS analysis on breast, endometrial, ovarian, and prostate cancers and their subtypes using GWAS summary statistics from several large consortia comprising 237,483 cases and 317,006 controls. We applied three sets of plasma protein prediction models to the cancer summary statistics, performing PWAS to identify protein-cancer associations. In the Atherosclerosis Risk in Communities (ARIC) study, there were 1,276 protein prediction models trained in 7,213 European American individuals available to use as our discovery set. We used additional protein prediction models from INTERVAL (592 proteins trained in 3,301 European individuals) and TOPMed-MESA (300 proteins trained in a population of 975 European, Chinese, African, and Hispanic individuals) to follow up associations discovered with the ARIC models. We found 93 significant protein-cancer associations at an FDR threshold of 0.05 with the ARIC models. Our top 19 ARIC results are significant at a more stringent $p < 5.6E-06$, accounting for multiple testing, and 9 of these proteins had models available to test in our additional model sets. Seven were significant in INTERVAL and/or TOPMed-MESA with the same direction of effect ($p < 5.5E-07$): MSMB-prostate, PLG-prostate, TNFRSF6B-prostate, GSTM1-breast, ARL3-prostate, SERPINA3-prostate, and LAYN-breast. LAYN is associated with breast, ER-positive breast, and prostate cancer at $FDR < 0.05$, suggesting pleiotropy. To further support our results, we applied Bayesian colocalization analysis to the cancer GWAS and ARIC cis-pQTL summary statistics, focusing on our top findings. Testing both one causal variant and multiple-causal variant model assumptions, we found colocalized SNPs for MSMB-prostate (Posterior Probability, PP=1), PLG-prostate (PP=1), LAYN-breast (PP=0.88), SERPINA3-prostate (PP=0.65), and GSTM1-breast (PP=0.62). SNPs in LAYN, SERPINA3, and GSTM1 did not reach genome-wide significance for cancer in the original GWAS, highlighting the power of PWAS for novel locus discovery. In summary, we have identified several loci that likely act through plasma protein regulation to affect cancer susceptibility. PWAS and colocalization are promising methods to identify the molecular mechanisms associated with common variant risk alleles underlying complex traits.

Cancer Posters - Wednesday

PB1192. Rare germline variants in Deubiquitylating enzymes (DUBs) in young women with breast cancer

Authors:

L. Grimaldo¹, A. Mohar², N. Reynoso-Noverón³, L. Sánchez-Zamorano⁴, L. Gómez-Flores-Ramos⁵; ¹The Natl. Inst. of Publ. Hlth.of Mexico, Mexico City, Mexico, ²Inst. of BioMed. Res., Natl. Autonomous Univ. of Mexico, Mexico City, Mexico, ³Res. division, Natl. Cancer Inst., Mexico, Mexico, ⁴Population Hlth.Res. Ctr., Natl. Inst. of Publ. Hlth., Mexico, Mexico, ⁵CONACYT, Mexico; Population Hlth.Res. Ctr., Natl. Inst. of Publ. Hlth., Mexico City, Mexico

Abstract Body:

Breast cancer in young women (BCYW) represents nearly 20% of cases of BC in Mexico and Latin America. Studies reveal that BCYW exhibit a higher genetic susceptibility and a specific genomic signature compared to older women. The evidence shows that deubiquitylating enzymes (DUBs) participate in tumorigenesis, have oncogenic or tumor suppressor activity, and are proposed as therapeutic targets. Whether they contribute to BCYW is unclear. This study aimed to search for rare germline variants in DUBs and describe their pathogenic potential. We analyzed whole-exome 100X data from a clinical cohort of 115 BCYW (women diagnosed with BC <40 years old) using the cloud-based platform PeCanPie. We identified three novel mutations in DUBs. First, *CYLD rs773205473* (c.1274T>A; p.Ile425Lys), a missense mutation located in exon 13, the C-terminal USP domain, is responsible for its DUB activity. The *CYLD rs773205473* is classified as pathogenic according to the Varsome database. *CYLD* regulates cell proliferation and apoptosis pathways, acting as a tumor suppressor gene implicated in the epithelial-mesenchymal transition in BC. The second variant, *USP6 rs149134900* (c.4029T>A), is a stop gain mutation located in exon 29 in its USP domain. The SNV *USP6 rs149134900* is classified as likely-pathogenic/VUS according to Varsome. *USP6* can initiate tumorigenesis by inducing the production of matrix metalloproteinases following NF-kappa-B activation. It is a protooncogene associated with the aneurysmal bone cyst, nodular fasciitis, pancreatic adenocarcinoma and BC development. Finally, *USP7 rs753160107* (c.3203-6C>T) is an intronic variant located in the C-terminus domain and classified as benign in Varsome. *USP7* forms a complex with DAXX that regulates the intrinsic MDM2 ligase activity, consequently regulating p53 through proteasomal degradation. None of the variants we report are in the Clinvar database, and their global population MAF is <0.0001. This is the first time *CYLD rs773205473*, *USP6 rs149134900*, and *USP7 rs753160107* are reported in Mexican YWBC, making them potentially relevant for early-onset BC. The three patients carrying DUBs rare variants were diagnosed with BC before the age of 30 with Luminal-B invasive ductal carcinoma. All of them had a family history of cancer.

PB1193. Rare variant association study in lymphoid cancers

Authors:

S. Ralli^{1,2}, S. J. Jones¹, S. Leach¹, A. Brooks-Wilson^{1,2}; ¹Canada's Michael Smith Genome Sci. Ctr., BC Cancer, Vancouver, BC, Canada, ²Simon Fraser Univ., Burnaby, BC, Canada

Abstract Body:

Genetic factors have been identified in lymphoid cancer using genome-wide association and familial studies, with effect sizes ranging from small for common variants to large for rare variants. However, a substantial fraction of the heritability remains unexplained for lymphoid cancers, leading to the question of 'missing heritability,' which might be attributed to rare variants with small effect sizes. We aim to identify genes and pathways with rare germline variants associated with lymphoid cancers using exome sequencing.

Forty multiple-case lymphoid cancer families were exome sequenced, and one affected individual with the earliest age of onset or rarest type of lymphoid cancer was chosen from each family. The ethnicities for lymphoid cancer cases were determined by PCA using KING, and 38 affected individuals of European ethnicity were selected for the association study. Non-Finnish Europeans from gnomAD exomes (N = 56,885) or ExAC (N=33,370) were the controls. High-quality rare deleterious variants with a read depth ≥ 10 were selected from cases and controls for the rare variant association study to be carried out by TRAPD under a dominant model at gene and pathway levels. TRAPD performs a Fisher's exact test to analyze if there is a significantly higher burden of rare deleterious variants in cases than controls for each gene and pathway.

Analysis of genes with two or more rare variants identified five putatively pathogenic germline variants observed in four genes, *INTU*, *PEX7*, *EHHADH*, and *ASXLI*, associated with lymphoid cancers.

Reactome's innate and adaptive immune systems showed rare variant association at the pathway level. Identifying the pathways and genes related to lymphoid cancers will enable us to understand the biology of these cancers and potentially design new prevention and treatment avenues.

PB1194. Relative involvement of human papillomavirus constitutional genomic instability: Cellular sequela syndromes.

Authors:

E. McGhee, K. Kemp, J. Vadgama; Charles R. Drew Univ. of Med. and Sci., Los Angeles, CA

Abstract Body:

Persistent infections involving high-risk human papillomavirus (HPV) in perinatal transmission is being established as an etiological agent for constitutional genetics in Mendelian syndromes. Recent data indicates that several polymorphisms of key regulators from DNA damage pathways are associated with Mendelian Syndromes. The long arm of chromosome 11q has received much attention as a high frequency of epigenetic deletions of various sites, observed in HPV-long term infection that led to cervical cancer, which is the fourth most common cancer in women, and the fourth leading cause of cancer death indicating the presence of putative tumor suppressor genes, and its potential association with Jacobsen syndrome. To better understand the importance of HPV and constitutional genomic instability, we investigated genetic and epigenetic alterations of tumor suppressor genes such as the ATM and p53 genes in human keratinocytes transfected with HPV16 E6/E7 oncoproteins (16-MT). In this study we examined epigenetic changes and chromosome imbalances, using target CRISPR, NGS, FISH, and arrayCGH. We used several genetic probes, mapping to terminal regions of 11q where the ATM gene is located, genomic instability of chromosomes 13, 14, 15, 20, and 22 are highly methylated regions seen in HPV infected human cells indicating an association with Robertsonian syndrome. This study show that the ATM gene located on chromosome 11q is deleted in these human cells, relating to chromosome deletions, that are recurrent abnormalities in cervical cancer, implicating the loss of tumor suppressor genes as a significant mechanism that drive cells to become genomic unstable, and a possible association to Jacobsen syndrome. Our findings suggest that a delivery detection system involving perinatal transmission of HPV, such as gene editing- CRISPR/Cas9 may be effective in targeting HPV proteins in human cells and may also provide therapeutic benefits.

PB1195. Resolving clone- and haplotype-specific copy number variation and DNA methylation in heterogeneous tumors with nanopore sequencing.

Authors:

S. Aganezov, J. Beaulaurier, E. Harrington, S. Hickey, S. Juul; Oxford Nanopore Technologies, New York, NY

Abstract Body:

Large-scale somatic genomic copy number variations (CNV) accumulate during cancer progression, resulting in a tumor comprised of collections of cells, or clones, with distinct CNV profiles. Untangling intra-tumor heterogeneity and inferring clone- and haplotype-specific CNV profiles is important for cancer research and can help inform treatment.

We present a computational workflow to infer clone- and haplotype-specific cancer CNV profiles by processing long nanopore reads obtained with high-throughput bulk sequencing of a tumor and matching normal sample. The workflow first identifies and phases heterozygous germline single nucleotide polymorphisms (SNPs) in the normal sample. Nanopore reads from the tumor sample are then haplotagged with presence/absence of the phased germline SNPs. Both the overall and the haplotype-specific read counts from the tumor are then tallied over fixed-size bins tiled across the reference genome. Finally, we use the state-of-the-art HATCHet matrix factorization algorithm to process the total- and allele-specific read counts and get integer clone- and allele-specific copy number profiles, as well as the clonal cellular fractions of the tumor sample.

To test the proposed approach, we have nanopore sequenced to ~100x average read-depth coverage a COLO829 tumor and a COLO829BL matching normal cell lines. Previous NGS-based bulk and single-cell analyses of the COLO829 cell-line have revealed it to be highly aneuploid and heterogeneous. We show that the proposed nanopore-based workflow identifies clone- and haplotype-specific cancer CNV profiles in concordance with previously published results, with regions of heterogeneity in full agreement with earlier bulk and single-cell studies. Inferred CNV profiles and their clonal fractions are further supported by observed allele-frequencies of somatic SNPs. We demonstrate the stability of the obtained results across lower tumor sample sequencing coverage levels, with CNVs remaining consistent down to 30x tumor coverage, putting the proposed approach on par with the industry standard NGS-based experiments. Notably, because of the unique ability of long nanopore reads to retain single-molecule methylation signals, we were further able to identify haplotype-specific differentially methylated regions both within the tumor sample, as well as in a tumor vs normal comparison, thus shedding light on acquisition/loss of DNA modifications during tumor growth.

These results demonstrate the ability to resolve clonal and subclonal CNVs in structurally aberrant heterogeneous cancers, while also revealing the previously inaccessible allele-specific tumor methylation.

Cancer Posters - Thursday

PB1196. Revisiting tumor evolution in multifocal hepatocellular carcinoma with different clonal origins

Authors:

X. Tang¹, Y. Shao², H. Wang¹, D. Li³, K. Ding⁴; ¹State Key Lab. of Genetic Engineering and Collaborative Innovation Ctr. for Genetics and Dev., Sch. of Life Sci., Fudan Univ., Shanghai, China, ²Dept. of Cardiothoracic Surgery, The First Affiliated Hosp. of Chongqing Med. Univ., Chongqing, China, ³Hepatobiliary and Pancreatic Cancer Ctr., Chongqing Univ. Cancer Hosp., Chongqing, China, ⁴Med. Genetic Inst. of Henan Province, Henan Provincial People's Hosp., Henan Key Lab. of Genetic Diseases and Functional Genomics, Henan Provincial People's Hosp. of Henan Univ., People's Hosp. of Zhengzhou Univ., Zhengzhou, China

Abstract Body:

Multifocal hepatocellular carcinoma (MF-HCC) accounted for more than half of HCCs with uncharacterized molecular mechanisms. A full delineation of the dynamic changes of tumor heterogeneity and clone/subclone components longitudinally could enhance understanding of the formation and development of MF-HCC. Here, we investigated the clonal evolution of MF-HCCs by inferring the order of occurrence of critical genomic events. Whole-exome was sequenced in 74 tumor samples from spatially distinct regions in 36 resected foci and adjacent non-cancerous tissues in ten MF-HCC and one MF-preneoplastic patient. Inter-focal tumor samples showed a significantly higher heterogeneity than that intra-tumoral samples. Early intrahepatic metastasis was evident when the cell number was about 10^4 - 10^5 size of the primary site. Furthermore, MF-HCCs showed a more aggressive developing history in spending approximately 150-300 days from initiation to the metastatic time, significantly shorter than the previously reported 5-10 years cost. We also illustrated the mutational footprints in the preneoplastic lesions of multicentric occurrence and uncovered dominant preneoplastic clones in multicentric carcinogenesis. The portrayed tumor heterogeneity and distinct evolutionary narratives provide significant implications for the personalized drug development and therapeutic strategies for MF-HCC.

Cancer Posters - Wednesday

PB1197. Rewired phospho-signaling networks by genetic variants in Clear Cell Renal Cell Carcinoma

Authors:

S. Mao, M. Wei; Shanghai Jiao Tong Univ., Shanghai, China

Abstract Body:

Clear cell renal cell carcinoma (RCC), the most common type of renal cancer, has been considered insensitive to traditional therapies such as chemotherapy and radiation. Despite the discoveries of novel agents targeting cellular pathways and advance in immunotherapy, response to these treatments has been noticed to be effective in only a small part of patients with late-stage cancers. Therefore, continuous development of new methods to identify biological candidate targets will provide critical clues for future improved therapeutic strategy design. Phosphorylation has been known to provide signal transduction and impact protein-protein interactions, especially in the field oncogenic pathology. Genetic variations exert influence on the phosphorylation sites of proteins so that the phospho-signaling networks were affected in human body. Here, we hypothesized that human missense single nucleotide variants (SNVs) in the phosphorylation sites that were differentially phosphorylated in RCC could modulate kinase signaling interactions and altered the process of RCC. In this study, we first summarized a list of 794 candidate functional phosphorylation sites based on previous literatures. Then, we analyzed 691,052 single nucleotide substitutions from the exome sequencing data of 314 ccRCC patients from the UK Biobank dataset. The phosphorylation associated SNVs (pSNVs) were defined as harmful SNVs that occurred in sites on our list. Our results demonstrated that there were 1012 pSNVs in 280 RCC-associated phosphorylation sites and the significances of these functional pSNVs were evaluated by comparison to the gnomAD SNV frequency data. Significance scores were calculated by assigning various weights to the genes with multiple pSNVs altered kinase binding motifs or replaced central phospho-residues. Genes with frequent pSNVs and significance scores broadly expressed and enriched in functions of RNA splicing, hypoxia and cell cycle regulation signaling, resulting in rewired proteins. The most significant genes (CDK4, MAPK3 et. al) were also shown to have potential associations with RCC. In addition, we evaluated the prognosis prediction effects of pSNVs and constructed a machine learning model based on the DNA sequencing and clinical data of ccRCC samples in the Cancer Genome Atlas (TCGA) database. This model was tested using UKBiobank data set and an independent data set including 880 Chinese ccRCC patients. In sum, our findings successfully identify multiple candidate cell signaling genetic factors contributing to ccRCC development and provide important clues to future mechanistic and translational studies of RCC.

PB1198. Risk of cancer in persons with a single Fanconi anemia gene variant: A population-based study of MyCode Cohort

Authors:

B. Altintas¹, J. Kim¹, J. Haley², DiscovEHR Collaboration, D. Carey², D. Stewart¹, L. McReynolds¹; ¹Natl. Cancer Inst., Rockville, MD, ²Geisinger, Danville, PA

Abstract Body:

Fanconi anemia (FA) is a bone marrow failure and cancer predisposition syndrome. The risk of malignancies in heterozygous carriers of a single pathogenic FA gene variant has been a question in the field. Our group previously studied the relatives of patients with FA enrolled in the National Cancer Institute (NCI) cohort. Now, we investigate a population-based cohort using a genome-first approach to quantify the cancer risk in heterozygous individuals, potentially identify unrecognized patients with FA and uncover new phenotypes.

We analyzed exome sequencing data from 175,449 individuals enrolled in the MyCode Cohort of Geisinger. Variants in 22 FA genes were identified and annotated by using ANNOVAR, snpEFF and ClinVar. We determined pathogenicity based on ClinVar classification when available, and InterVar classification when there was no ClinVar entry. Phenotypes were extracted from the linked electronic health record (EHR) system and the tumor registry at Geisinger using ICD-10 codes.

At least one FA single nucleotide variant was identified in 7,132 individuals (4.06%). The most frequently affected genes were *FANCN/PALB2* (0.9%), *FANCM* (0.5%), *FAND1/BRCA2* (0.4%) and *FANCA* (0.3%). The rate of heterozygous carriers of a copy number variant within or encompassing one of the FA genes was 0.34%; most commonly in *FANCA* (0.15%).

We identified 28 potentially unrecognized patients with FA; 16 were female and 12 were male. Current median age of these patients was 67 years (range: 32-82). None of these patients had a diagnosis of FA available in the EHR. There were seven male patients with truncating variants in *FANCB*; one of them had adenocarcinoma of an unknown primary at age 68 years, another patient developed adenocarcinoma of the prostate at age 64 and mucinous adenocarcinoma of the head of the pancreas at age 69 years. These patients had no report of an expected early onset cytopenia or congenital abnormalities. We also identified four patients with two *PALB2* variants who were older than 40 years and had no severe phenotype. Three of these patients had no reported phenotype, one patient had developed adenocarcinoma of the prostate at age 53 years. Medical records will be reviewed for confirmation of phenotypes or lack thereof. The validation of genotypes in patients with biallelic variants and the estimation of cancer risk in heterozygous carriers are ongoing.

Our data highlight the power of the genotype-first approach in identifying undiagnosed patients with FA and uncovering novel phenotypes that will aid to properly manage their disease. The high numbers of carriers in this study will allow us to better estimate the cancer risk and validate findings from the NCI cohort.

Cancer Posters - Wednesday

PB1199. Serum biomarkers are altered in UK Biobank participants with mosaic chromosomal alterations.

Authors:

A. Hubbard, W. Zhou, D. W. Brown, S-H. Lin, S. J. Chanock, M. J. Machiela; Natl. Cancer Inst., Rockville, MD

Abstract Body:

The age-related clonal expansion of cells harboring mosaic chromosomal alterations (mCAs) is indicative of clonal hematopoiesis. mCAs can be detected from raw genotype intensity data of blood-derived DNA and have been associated with disease, specifically elevated risk of infection and hematologic cancers. The biological mechanisms linking mCAs to disease risk are poorly understood. Studies of clinical serum biomarkers in individuals with mCAs could provide new insight into molecular mechanisms linking mCAs to elevated disease risk. We investigated the association of 30 serum biomarkers with autosomal mCAs, mosaic loss of the Y chromosome (mLOY) and mosaic loss of the X chromosome (mLOX) in 415,144 cancer-free participants aged 38 to 73 years from the UK Biobank. Log-transformed serum biomarker measurements were regressed against each type of mCA with stratification by sex and adjustment for potential confounders including age, age-squared, and smoking. In total, 12,103 participants had autosomal mCAs, 36,921 had mLOY and 10,246 had mLOX. Our analysis did not provide evidence for a relationship between autosomal mCAs or mLOX and C-reactive protein, a common marker of inflammation, but did demonstrate a strong inverse relationship with mLOY ($p=2.07 \times 10^{-11}$). There was not a clear association between mCAs and hormones except for testosterone, where we observed an overall inverse relationship with expanded autosomal mCAs driven by females ($p=0.009$). We also noted a positive relationship between testosterone and mLOY ($p=5.44 \times 10^{-55}$). While there was no evidence of an association between autosomal mCAs or mLOX and glucose or HbA1c, both displayed strong inverse associations with mLOY ($p < 1.96 \times 10^{-10}$) supporting prior inverse associations reported between mLOY and type 2 diabetes. Our analysis identified inverse relationships between autosomal mCAs, and several lipid biomarkers ($p < 3.80 \times 10^{-5}$). The observed lipid associations remained statistically significant with larger observed effect sizes when restricted to expanded autosomal mCAs (cell fraction $> 10\%$). Conversely, several lipid biomarkers demonstrated a positive relationship with mLOX ($p < 5.92 \times 10^{-4}$) and mLOY ($p < 1.85 \times 10^{-42}$). Our results suggest common clinical serum biomarkers associated with disease risk are altered in individuals with mCAs, although associations vary by type of mCA. Future studies with serial biomarker measurements are needed to disentangle whether these observations reflect causal relationships.

Cancer Posters - Thursday

PB1200. Sex differences in the Lung Adenocarcinoma transcriptome: Analysis of TCGA LUAD and GTEx lung tissue.

Authors:

C. Printzis¹, L. Pesce^{1,2}, B. Stranger^{1,2}; ¹Ctr. for Genetic Med., Northwestern Univ., Feinberg Sch. of Med., Chicago, IL, ²Dept. of Pharmacology, Northwestern Univ., Feinberg Sch. of Med., Chicago, IL

Abstract Body:

Lung cancer is one of the leading causes of death among all cancer deaths, and its mortality, morbidity, and incidence are associated with biological sex. Despite the prevalence of lung cancer and well-known environmental risk factors, there is still much to be learned about the underlying genetic mechanisms and tumor biology. We have characterized sex differences in the transcriptomes of Lung Adenocarcinoma (LUAD) from male and female-derived tumors of The Cancer Genome Atlas (TCGA) and determined the functional impact of those differences. We compared these patterns to those observed in lung tissue from the Genotype-Tissue Expression (GTEx) project. While performing this analysis, we learned several lessons about how transcriptome heterogeneity affects the ability of methods like Surrogate Variable Analysis (SVA) to estimate unknown bias without removing the biological signal of interest. In addition to observing how hidden factor adjustments affect differentially-expressed (DE) gene discovery, we performed simulations to evaluate our ability to avoid false positives while maximizing true discoveries when the effect, batch, and noise are defined. If an effect is heterogeneous, indicating that only a portion of the samples display the effect, we observed that all SVD-related corrections remove all effects. Given the inherent heterogeneity of cancer, these methods produce a large fraction of false negatives. We observed that SVA consistently reduced true positive discoveries to a few percent and often to zero except for the largest uniform differences. We analyzed 516 transcriptomes from TCGA LUAD (N = 238 males; N = 278 females) and 578 from GTEx lung, (N = 395 males; N = 183 females). We identified 798 sex-DE genes in LUAD without use of SVA, and 50 with SVA. In GTEx lung, we identified 213 sex-DE genes without SVA, and 500 with SVA. The 50 DE genes from LUAD with SVA tend to be homogeneous sex-DE genes and are mostly chromosome X genes, e.g., XIST. The sex-biased regulation appeared to be different between healthy lung tissues and lung cancer as indicated by the low replication rate across the two sets. Gene set enrichment analysis of sex-DE genes revealed different enrichments between TCGA and GTEx, as well as between male- and female-derived tumors.

Cancer Posters - Wednesday

PB1201. Shared predisposition to cancer and metabolic disorders using large-scale genomic data

Authors:

V. Pascat¹, L. Zudina², A. Ulrich², A. Demirkan², Z. Balkhiarova², J. Maina³, P. Igor², P. Froguel⁴, M. Kaakinen², I. Prokopenko²; ¹Université de Lille, Lille, France, ²Univ. of Surrey, Guildford, United Kingdom, ³Univ. of Lille, NYERI, Kenya, ⁴UMR 8199, Lille, France

Abstract Body:

Common **metabolic conditions**, such as **type 2 diabetes (T2D)** and **hypertension**, are related to a higher risk of comorbidities and notably to several **cancers**, such as rare **pancreatic** and common **postmenopausal breast, prostate, and colorectal**. These diseases' pathophysiology and comorbidity are related to shared biological processes leading to hyperinsulinemia, hyperglycemia, hyperlipidemia, inflammation. However, the **shared genetic effects** between these diseases **have not been studied systematically**. We dissected the genetic variability shared between T2D, hypertension, and the four aforementioned cancers through standard **polygenic scores (PGS)** and then **clustering of respective disease outcomes and endophenotypes associated DNA variants** to define implicated biological pathways. We finally assessed the causality of these associations by doing multivariate **Mendelian Randomization (MR)**. We constructed PGSs using 2,254 variants, effects of which were evaluated on 39 endophenotypes by hierarchical clustering, giving us five biological process groups. Variants were given weights using Z-scores from published Genome-Wide Association Studies (GWAS). We constructed PGSs and tested their effects in 487,410 individuals from the UK BioBank, including 18,676/8,201/1,425/11,825/40,619 people diagnosed with postmenopausal breast/colorectal/pancreatic/prostate cancer/T2D respectively. We applied two-sample MR to investigate the role of T2D, hypertension, and the different pathways from cluster analysis in cancer risk. We found that **breast, colorectal and pancreatic genetic factors** are directly significantly associated with the **risk of T2D** while **prostate cancer** genetic variants are **inversely associated with T2D** (Pval < 0.05/4). Reciprocally, **PGS based on T2D variants** is significantly associated with a **decreased risk of prostate cancer** (Pval < 0.05/7). Upon clustering, PGSs highlighted the role of **higher adiposity in susceptibility to pancreatic cancer**. No relevant association was found after multiple correction between hypertension and cancers. MR showed a **direct causal relationship of colorectal cancer with T2D's metabolic syndrome and insulin resistance cluster** (OR_{mr} = 1.16, SE = 0.11, Pval = 3.01e-3), and highlighted a **protective causal relationship between adiposity and breast cancer**. This association was driven by **BMI, mediated by a later age at menarche** (OR_{mr} = 0.75, SE = 0.10, Pval = 8.00e-6). This study provides evidence for the complex shared genetic predisposition between metabolic disorders and cancers, with shared biological pathways highlighting the role of adiposity.

PB1202. Single cell RNA sequencing reveals global cellular landscape of appendiceal cancer

Authors:

L. Bui¹, A. Gutierrez¹, X. Cao², J. wang³, F. Meng³, M. Feng³, L. Arvanitis³, R. Mannan³, M. Raof³, N. Banovich¹; ¹Translational Genomics Res. Inst., Phoenix, AZ, ²Beckman Res. Inst., City of Hope, Duarte, CA, ³City of Hope, Duarte, CA

Abstract Body:

Appendiceal cancer is a rare cancer with approximately 1-2 cases per 1 million individuals. Appendiceal cancer develops from the cells of the appendix and contains two types: epithelial and neuroendocrine appendiceal cancer. Appendix epithelial malignancy starts from the lining cells of the appendix that can lead to the accumulation of mucins, which may result in appendix rupture and spread inside the abdominal cavity. Epithelial appendiceal cancer includes invasive adenocarcinomas (low-grade or high-grade mucinous vs. non-mucinous), and appendiceal mucinous neoplasm (low-grade or high-grade). Classification of appendiceal cancer grades can only be done on tissue specimen by a pathologist and diagnosing appendiceal cancer at early stages is challenging due to the lack of a reliable blood or urine test. To comprehensively characterize the cell types, transcriptional profile, and molecular mechanisms driving cellular remodeling in epithelial appendiceal cancer, we performed a single-cell RNA sequencing (scRNA-seq) study on 12 appendix samples (nine cancerous samples from four different classification grades and three healthy controls). Using unsupervised clustering and cell type specific markers, we identified 24 distinct cell types from more than 85,000 cells and studied the changes in transcriptomic profiles of these cell types between cancerous and healthy samples. The cancerous epithelial cells from all different classification grades exhibit tumor characteristics with high expression of the tumor marker CEACAM6. Consistent with the histology classification of the appendix biopsy, we identified a highly expressed MUC5B+/MUC5AC+ cell cluster in the mucinous goblet-cell adenocarcinoma samples. Interestingly, a MUC5B+ cell type is present in low-grade mucinous adenocarcinoma, but not in the low-grade mucinous neoplasm samples, suggesting differences in cellular components of these two malignancy types at early stage. Cancer-associated-fibroblasts (CAFs), the hallmarks of cancerous mesenchymal phenotypes, are found in all cancerous samples, but not in the healthy controls. Additionally, we observed high expression levels of cytotoxic and exhaustion markers in the cancerous CD8+ T cells and NK cells. Taken together, our study provides an insight into the genetic control of appendiceal cancer at the single cell level and valuable resources for the development of biomarkers for appendiceal cancer classification.

Cancer Posters - Wednesday

PB1203. Single cell transcriptomics of Pituitary Neuroendocrine Tumors (PitNETs)

Authors:

M. Brunner, F. Santoni, J. Meylan-Merlini, M. Messerer, R. Daniel, M. Hegi, M. Muriset; CHUV, Lausanne, Switzerland

Abstract Body:

The pituitary gland, a master controller of hormones production and secretion, is a main component of the endocrine system. Unlike neoplastic formation in other organs, Pituitary Neuroendocrine Tumors (PitNETs) are almost exclusively benign adenomas. PitNETs have been extensively characterized by DNA sequencing, bulk RNA and DNA methylation in order to link those features with tumor invasiveness, prognosis and possible relapses. Here, we present the single cell transcriptome analysis on 7 independent tumors for a total of 37440 single cells: a bi-hormonal (GH-PRL) tumor, two corticotropic (POMC) macro-adenomas and 4 non-secreting adenomas.

Characterization of all tumors showed heterogeneous cell populations; on top of tumorigenic cells, structural cells (endothelial and fibroblasts) and immune cells can be detected. In the two most invasive tumors we identified an unexpected small population of proliferative cells (MKI67+, TOPA2+, BIRC5+, PBK+). Intriguingly, BIRC5 and PBK, two genes already known to be implicated in different type of carcinomas, were highly expressed in this cluster, suggesting a possible link between PitNETs and other types of tumors of various origin. In two non-secreting adenomas we identified a group of cells expressing autophagy related genes, supporting the recent hypothesis that autophagy is an important mechanism for tumor homeostasis. This cluster overlaps with a cluster of specialized cells expressing ribosomal genes and these cells are depleted of mitochondrial proteins. The anticorrelation between the expression of ribosomal and mitochondrial related mRNA is observed in all of our tumors suggesting a recurrent structural configuration to optimize energy balance and transcriptional activity. Our results give new perspectives on the comprehension of the structural composition and the dynamic progression of pituitary tumors.

Cancer Posters - Thursday

PB1204. Single Sample Gene Set Enrichment Analysis (ssGSEA) to Identify Dysregulated Pathways in a Biomarker Matched Pilot Study of Mantle Cell Lymphoma.

Authors:

H. Hill, Y. Liu, P. Jain, K. Chen, M. Wang; Univ. of Texas MD Anderson Cancer Ctr., Houston, TX

Abstract Body:

Mantle cell lymphoma (MCL) is a rare, incurable type of non Hodgkin lymphoma (NHL) that is disposed to to repeated relapses, therapeutic resistance and disease progression. Identification of novel therapies and combinations of drugs is essential in overcoming the cycle of relapse and resistance.

The MCL MATCH trial (NCT04872413) aims to identify therapeutic agents which are personalized to a patient's somatic aberrations. The trial utilizes targeted gene expression profiling (GEP) and in-vitro cell viability drug screening to identify potentially efficacious treatments in patients who have developed resistance to Bruton's tyrosine kinase inhibitors (BTKi).

GEP of single patient tumor samples is a unique challenge; most studies of gene expression use differential expression between multiple samples of different phenotypes. Here we utilized single sample GSEA (ssGSEA) on our first enrolled patient sample with a targeted gene panel (Nanostring Technologies, Seattle, WA) that interrogated pathways relating to the biological hallmarks of cancer. ssGSEA relies on gene count list ranking within a sample and leverages a permutation test and statistical correction for multiple testing to evaluate significance. The normalized enrichment score (NES) represents the degree to which the genes in a sample are coordinately up or down regulated within a sample.

We found that two pathways were significantly enriched in the sample: Cell Cycle (NES = 2.68, False Discovery Rate (FDR) q-value = 0.00) and DNA damage repair (NES = 2.20, FDR q-value = 0.00). Combined with in-vitro drug screening and evidence from published literature, ssGSEA could serve as a clinically viable technique to match personalized treatments in a precision medicine trial.

Cancer Posters - Wednesday

PB1205. Single-cell identity and state coupled with genome-wide SNV and CNV in primary breast cancer with ResolveOME profiling.

Authors:

J. Zawistowski¹, I. Salas-Gonzalez¹, T. Morozova¹, T. Tate¹, K. Kennedy¹, D. Arvapalli¹, S. Velivela¹, J. Blackinton¹, J. Marks², E. S. Hwang², G. Harton¹, V. Weigman¹, J. West¹; ¹BioSkryb Genomics, Inc., Durham, NC, ²Duke Univ. Med. Ctr., Durham, NC

Abstract Body:

The molecular events governing the transition from ductal carcinoma in situ (DCIS) to invasive breast cancer are still being elucidated, whereby precise definition of these events has the potential provide a therapeutic window of intervention. To simultaneously expose both genomic and transcriptomic underpinnings in primary breast cancer samples and to ascertain intratumoral heterogeneity we utilized ResolveOME to profile single cells from tumor biopsies of DCIS/invasive ductal carcinoma (IDC). While earlier single-cell methods have importantly unified assessment of copy number variation (CNV) and transcriptomics, they do not yield complete and uniform genome-wide coverage for single nucleotide-level data, made possible with ResolveOME's employment of primary template-directed amplification. As input into ResolveOME, we stratified singulated mastectomy samples by epithelial cell adhesion molecule (EpCAM) surface marker expression with FACS. The genomic arm of ResolveOME followed by analysis with BaseJumper software cataloged genome-wide single nucleotide variation (SNV) in 24 single cells expressing either high or low levels of EpCAM, including the identification of oncogenic *PIK3CA* N345K, while identifying cooccurring DCIS/IDC prototypical chromosomal loss of 11q, 13q and 16q/17p harboring tumor suppressor loci. Concurrently, the transcriptomic arm of ResolveOME enabled the calling of cell identity with the Human Cell Atlas transcriptional database, revealing monocytic and fibroblastic infiltration in the biopsy samples in addition to the expected cells of epithelial identity. The coupling of SNV data and transcriptome data critically unveiled phenotypic cell state heterogeneity, whereby an epithelial cell with both *PIK3CA* N345K and associated chromosomal losses manifested with a stemness/fibroblastic gene expression signature characteristic of the EpCAM low clade of patient cells. We are currently expanding ResolveOME profiling to additional DCIS/IDC patient tumors to comprehensively define driver and regulatory SNV while simultaneously distinguishing between infiltration of non-epithelial cell types from instances of epithelial morphing of physiological cell state within a biopsy. Furthermore, we are defining cell lineage at both the CNV and SNV level as additional single cells are sequenced for each patient sample. These data collectively highlight the molecular complexity and heterogeneity even among a small number of biopsied cells, and underscore the criticality of the interplay of DNA/RNA tiers of information when positing oncogenic mechanisms.

PB1206. Single-cell methylation and 3C sequencing in prostate tumors shows substantial epigenome reprogramming

Authors:

T. Li, Y. Zhang, K. Abuhanna, R-R. Huang, H. Ye, P. Boutros, C. Luo; Univ. of California, Los Angeles, Los Angeles, CA

Abstract Body:

Prostate cancer is associated with genomic rearrangements and genome-wide epigenomic reprogramming. In addition, prostate cancer tumors have substantial clonal heterogeneity that contributes to relapse following primary treatment. Recent single-cell RNA sequencing studies have revealed diverse transcriptomic programs in the tumor microenvironment associated with prostate cancer progression. However, prostate tumor cell-type heterogeneity at the epigenomic level remains poorly understood. We therefore investigated regulatory abnormalities in prostate cancer by simultaneously profiling methylation and chromatin conformation (3C) in primary prostate tumor samples. We demonstrate that methylation and 3C show concordance in resolving distinct tumor and non-tumor cell populations. Differential methylation analysis between cell types revealed heterogeneity in genome-wide methylation patterns. Finally, we used 3C maps to identify structural variants in tumor subpopulations, and identified novel chromatin loops induced by these variants.

PB1207. Single-cell multi-omic characterization of MPAL phenotypes reveals patient heterogeneity associated with poor treatment outcomes

Authors:

C. Hayford¹, V. Kennedy², C. D'amato¹, Y. Xue¹, A. George¹, I. Clark³, C. Peretz², E. Tran², K. Fontanez¹, A. Abate², C. Smith²; ¹Fluent BioSci., Watertown, MA, ²UCSF, San Francisco, CA, ³Berkeley, Berkeley, CA

Abstract Body:

Mixed Phenotype Acute Leukemia (MPAL) is a heterogeneous hematologic malignancy associated with poor patient prognosis, characterized by the presence of both myeloid and lymphoid phenotypes. While clinical data suggests that MPAL patients respond better to lymphoid therapy, treatment is not standardized and responses are often variable. Single-cell characterization of MPAL phenotypes provides a method to understand nuances of patient heterogeneity that may contribute to variable treatment responses. Here, we use the Fluent BioSciences' PIPseq T20 3' Single Cell RNA Kit in combination with a curated panel of BioLegend TotalSeq-A antibodies to characterize a single MPAL patient using both gene and cell surface marker expression. We observe significant intra-patient variability at both the RNA and protein levels, with both healthy immune cell types and malignant blasts separating into distinct clusters. Protein expression overlays on the gene expression space reveal MPAL blasts are HLA-DR and CD45, and healthy immune cells display canonical markers. Differential gene expression analysis identifies multiple Zinc finger genes highly expressed in MPAL blasts, while standard cell surface markers complement differentially expressed genes for the healthy immune cells. Interestingly, surface protein expression identifies further heterogeneity in the MPAL blast population, with a subset of cells exhibiting elevated CD30 expression. Identification of heterogeneity within a set of patient blasts provides a mechanism for discovery of potential resistant cell populations that arise after therapy with a single agent. Together, these results provide insight into the potential of single-cell multi-omic characterization to aid in the discovery of new phenotypes, and serve as a complement to traditional genomic and histological approaches prevalent in the field.

PB1208. Single-cell sequencing of genomic DNA: Assessing clonal populations of tumor cells in endometrial cancer

Authors:

E. Velazquez Villarreal¹, L. D. Gibbs¹, D. Mahinbakht¹, D. M. Da Silva¹, L. D. Roman¹, D. W. Craig², J. D. Carpten¹; ¹Univ. of Southern California, Los Angeles, CA, ²USC, Keck Sch. of Med., Los Angeles, CA

Abstract Body:

Introduction: Tumor clonal populations have been studied using high-resolution sequencing technologies in some tumor types but have been less explored in Endometrial Cancer (EC). This lack of knowledge exists particularly among underrepresented minority patients, where the disease burden is high. This study sought to assess the clonal populations of four ECs (two African Americans, one Hispanic/Latino, and one Caucasian). **Methods:** EC samples represented different histologies. We used single-cell whole genome sequencing of genomic DNA and performed bulk whole-exome sequencing of the same four tumor samples. The 10x ChromiumTM single-cell copy number variation (scCNV) assay was used with frozen tumor sections to collect and sequence single nuclei. Hierarchical clustering and visual inspection of the generated heatmaps were applied to each tumor sample. **Results:** scCNV data was generated for approximately 300 cells per tumor. We assessed on average five different tumor clonal populations based upon scCNV per sample. We were also able to identify somatic mutations from whole exome sequencing data and identified clones that also harbored these mutations. We were able to identify the presence of oncogenic mutations including PTEN, PIK3CA, and TP53 in heterogeneous clonal populations. **Conclusions:** Overall, our study reveals the impact of analyzing tumors using high-resolution single-cell sequencing to assess aberrations in different clonal populations within each tumor sample, which could help to make more precise treatment decisions in cancers that represent significant health disparities.

PB1209. *SMARCA4* Schwannomatosis: a known cancer susceptibility gene, a new phenotype.

Authors:

F. Chan-Pak-Choon^{1,2}, C. Nogué³, A-S. Chong³, C. Roca³, R. Austin⁴, T. Robertson⁵, K. van Spaendonck-Zwarts⁴, H. Mar Fan⁴, B. Rivera^{3,6}, W. Foulkes^{1,2,6}; ¹Dept. of Human Genetics, McGill Univ., Montreal, QC, Canada, ²Lady Davis Inst. and Segal Cancer Ctr., Jewish Gen. Hosp., Montreal, QC, Canada, ³Molecular Mechanisms and Experimental Therapy in Oncology Program, Bellvitge BioMed. Res. Inst. (IDIBELL), L'Hosp. et de Llobregat, Barcelona, Spain, ⁴Genetic Hlth. Queensland, Royal Brisbane and Women's Hosp., Brisbane, Australia, ⁵Pathology Queensland, Faculty of Med., Royal Brisbane and Women's Hosp., Brisbane, Australia, ⁶Gerald Bronfman Dept. of Oncology, McGill Univ., Montreal, QC, Canada

Abstract Body:

Schwannomatosis (SWNT) is a disorder characterized by a predisposition to multiple benign spinal, peripheral and intracranial nerve sheath tumors (schwannomas (SWNs)). Of the 13-25% of SWNT cases that are familial, 48% are caused by germline *SMARCB1* mutations, and 38% by *LZTR1* mutations. The established molecular mechanism of SWNT consists of a germline *SMARCB1* or *LZTR1* mutation, loss of heterozygosity (LOH) of chromosome 22q (loss of wildtype *SMARCB1* or *LZTR1* and *NF2*), and finally a somatic *NF2* mutation which collectively lead to the inactivation of *SMARCB1* or *LZTR1* and *NF2*. Recently, a variant in *DGCR8*, another gene on chromosome 22q, was reported in one kindred and an unrelated individual with SWNs and multinodular goiters.

We report a family, where the proband presented with a spinal SWN at age 30y whilst her mother (deceased) had had 4 peripheral SWNs (right and left arms) at age 50y followed by a glioblastoma (GBM) at age 54y. All the tumors, except for the GBM, showed loss of BRG1 (*SMARCA4*) in 70-80% of cells and loss of INI1 (*SMARCB1*) in the complementary 10-20% of cells. The GBM showed retention of BRG1 and INI1. Whole exome sequencing of the proband's germline (GM) revealed a likely pathogenic (LP) variant, *SMARCA4* (NM_001128844.2):c.1752_1755del, p.(Lys585Argfs*27) (ClinVar ID: 873514). The GM variant was confirmed in all SWNs and the GBM. Furthermore, we identified LOH at the *SMARCA4* locus along with 12-23 Mb of chromosome 19p in all SWNs (acting as the second hits), but not in the GBM. Methylation analyses are ongoing. No LOH on chromosome 22 or alterations within the 22q SWN genes were detected in the germline nor the tumors, suggesting that the SWNs were caused by a deficient *SMARCA4*, and not by the loss of chromosome 22.

SMARCA4 deficiency has not been reported in SWN patients. GM *SMARCA4* mutations are known to cause SCCOHT, AT/RTs and be associated with uterine sarcomas and infantile pulmonary teratoid tumors. Our findings suggest that there might be other mechanisms by which SWNs are formed - possibly pertaining to *SMARCA4* and *SMARCB1* being key members of the SWI/SNF complexes that regulate essential cellular processes, such as those involved in neuronal differentiation.

Funded by CIHR grant (FDN-148390) to WF and Gershman Scholarship to FCPC.

PB1210. Splicing analysis of endometrial cancer GWAS risk loci: splicing-associated variants reveal *NF1* and *SKAP1* as candidate susceptibility genes.

Authors:

D. Glubb, T. O'Mara, A. Spurdle, D. Canson; QIMR Berghofer Med. Res. Inst., Brisbane, Australia

Abstract Body:

Alternative splicing contributes to the development of many common traits, including cancer. Indeed, splicing analysis of genome-wide association study (GWAS) variants has revealed both likely causal variants and genes at several cancer GWAS risk loci. However, splicing is not well studied in GWAS even though it may explain the functionality of GWAS variants at ~10% of loci.

To assess GWAS variants for splicing effects, we have developed a prioritization workflow using a combination of SpliceAI and HEXplorer splicing prediction tools, supplemented by splicing quantitative trait locus (sQTL) annotations from the Genotype Tissue Expression Project. Application of this workflow to a set of candidate causal variants from 16 endometrial cancer GWAS risk loci revealed four single nucleotide polymorphisms (SNPs) at two risk loci (17q11.2 and 17q21.32) that were predicted to generate alternative transcripts.

Three SNPs at the 17q11.2 risk locus were predicted to increase inclusion of alternative exons in *NF1* transcripts. The exon inclusion associated with the protective (A) allele of rs7502834 was predicted to generate a truncated NF1 protein with altered C-terminal domain. This prediction was supported by an association of the protective allele with expression of the corresponding alternative *NF1* transcript in subcutaneous adipose. This splicing is expected to reduce expression of the canonical *NF1* transcript, and is consistent with a previous transcriptome-wide association study (TWAS) that found decreased NF1 expression in subcutaneous adipose associated with decreased endometrial cancer risk. Notably, *NF1* haploinsufficiency is protective for obesity, a well-established risk factor for endometrial cancer.

At the 17q21.32 locus, the risk allele (A) of rs2278868 was predicted to generate a nonsense-mediated decay *SKAP1* transcript through exon skipping and expression of this transcript in whole blood was associated with the risk allele. This finding was also consistent with a TWAS association of decreased *SKAP1* expression in whole blood and increased endometrial cancer risk. As SKAP1 regulates T-cell receptor signaling and enhances conjugation of T-cells and antigen-presenting cells, decreased *SKAP1* expression may reduce T-cell activity and, consequently, impact endometrial tumor immune surveillance.

In summary, our workflow revealed potentially causal GWAS variants that increase alternative splicing of two genes, with tissue-specific effects that may explain their associations with endometrial cancer risk. This approach could be applied to other datasets to prioritize GWAS variants, and their splicing target genes, for causality.

Cancer Posters - Wednesday

PB1211. t(6;9)(p22;q34) translocation with DEK-NUP214 fusion identified in one patient with chronic myeloid leukemia

Authors:

Y. Zhang¹, D. Jeyakumar², L. Lee², K. Dang³, J. Tso³, L. Yang³, J. Chan⁴, X. Zhao¹, F. Quintero-Rivera⁵; ¹Dept. of Pathology and Lab. Med., UC Irvine Hlth., Orange, CA, ²Div. of Hematology/Oncology, Dept. of Med., UC Irvine Hlth., Orange, CA, ³Dept. of Pathology and Lab. Med., Cytogenetics and Genomics Lab., UC Irvine Hlth., Orange, CA, ⁴Dept. of Pathology and Lab. Med., Univ. of California Irvine, UCI Hlth., Irvine, CA, ⁵Dept.s of Pathology and Lab. Med., and Pediatrics, Div. of Genetic and Genomic Med., Univ. of California Irvine, UCI Hlth., Irvine, CA

Abstract Body:

Chronic myelogenous leukemia (CML) is a clonal hematopoietic disorder characterized by t(9;22)(q34;q11.2) translocation, that results in the generation of a shortened chromosome 22 (Philadelphia-Ph⁺ chromosome), and BCR-ABL1 fusion oncogene which leads to the production of a constitutively activated BCR-ABL1 tyrosine kinase. The unregulated tyrosine kinase activity of BCR-ABL1 fusion protein contributes to the immortality of leukemic cells. Cytogenetics clonal evolution in CML, the occurrence of additional chromosomal abnormalities in addition to the Ph⁺ chromosome, is associated with disease progression and is considered a parameter that defines the accelerated-phase (AP) of CML. Translocation (6;9)(p22;q34) is one of the recurrent cytogenetics findings in acute myeloid leukemia (AML), and myelodysplastic syndrome, and is usually associated with poor prognosis. Here we present, a 50-year-old male who was transferred to our hospital for leukocytosis with blasts on peripheral blood. Patient has insomnia, chest tightness with intermittent dry coughs, fever and chills for the past 3 months. Peripheral blood flow cytometry showed markedly left-shifted granulocytosis with basophilia and circulating blasts (8%). Bone marrow biopsy showed markedly hypercellularity with left shifted myeloid hyperplasia and increased myeloid blasts (9-10%) and mild to moderate reticulin fibrosis, consistent with CML-AP. The presence of BCR/ABL1 (p210) fusion transcript was confirmed by RT-PCR. Chromosome analysis identified a translocation between chromosomes 9 and 22 in all the 20 metaphase cells examined, consistent with a clinical diagnosis of CML. In addition, ten of these cells (a subclone), exhibit secondary anomalies, including a reciprocal translocation between chromosomes 6 and 9 at breakpoints 6p22 and 9q34, resulting in the formation of a chimeric fusion gene between DEK (6p22) and NUP214/CAN (9q34), which was confirmed by concurrent FISH studies. A targeted NGS panel detected both fusions, BCR/ABL1 (VAF % 43.4), and DEK/NUP214 (VAF % 21.2), consistent with the cytogenetics/FISH results. Patient has been treated with dasatinib, cytoreduced with hydroxyurea two weeks prior to his transfer to our institution. Translocation (6;9) is extremely rare in CML patients, only one single CML patient has been reported to carry this t(6;9) translocation previously (PMID: 21156248). How this t(6;9) translocation affects the treatment and prognosis of CML is not clear given its association with a poor prognosis in patients with AML, however, more data is needed to verify this correlation.

PB1212. Targeting mutant HLA-bound cancer peptide demonstrated in vivo efficacy in delaying tumour growth in a low mutational burden aggressive ovarian cancer

Authors:

T. Nguyen-Dumont¹, G. Ho¹, J. Chang¹, J. Wu¹, H. Barker², P. Eggenhuizen¹, J. Steen¹, J. Bedo², C. Vandenberg², P. Hertzog³, S. Grimmond⁴, T. Papenfuss², C. Scott², M. Southey¹, E. Segelov¹, P. Faridi¹, J. Ooi¹; ¹Monash Univ., Clayton, Australia, ²Walter Eliza Hall Inst., Melbourne, Australia, ³Hudson Inst., Clayton, Australia, ⁴The Univ. of Melbourne, Melbourne, Australia

Abstract Body:

Ovarian carcinosarcoma (OCS) are rare, aggressive cancers with poor prognosis due to limited effective treatments. OCS tumorigenesis is not driven by somatic mutation, but via reprogramming of gene expression. Therefore, the tumour mutation burden (TMB) is often low, and they are relatively non-responsive to single agent immunotherapy.

We have established a paired OCS patient-derived xenograft (PDX) model, SFRC01177 from baseline chemo-naïve and post-chemotherapy specimens in Nod-SCID-Gamma (NSG) major histocompatibility complex (MHC)^{null} mice. These mice are deficient in MHC class I/II expression to reduce acute graft-versus-host disease following injection of human peripheral mononuclear cells. The tumour is refractory to cisplatin and to 1 million human leukocyte antigens (HLA)-match CD8 T-cell injection consistent with expected tumour phenotype.

Whole genome/exome sequencing was performed on the baseline and recurrent tumours. Despite a low TMB of < 4 mutations/Mb, a total of 14,419 variants of mutant peptides ranging from 8 to 16 amino acid length were identified: 13,170 in the baseline and 10,998 in the recurrent tumour with 9,750 shared. Immunoprecipitation of the tumour HLA-complexes with their bound peptides followed by tandem mass spectrometry have identified over 2,300 HLA-bound peptides: 2,215 in the baseline and only 317 in the recurrent tumour with 239 shared. The analysis of the HLA-peptide motifs suggested that down-regulation of tumour cell MHC class I/II may account for this reduction. By combining the genomic and the immunopeptidomic data, a mutant HLA-bound neoepitope was identified. Neuropeptide W E100Q homologous to COSV61585942 (known immunogenic peptide; reported over 5 times in colon cancer) was associated with high areas under the curve in both the baseline and recurrent tumours. *Ex vivo* pulse neuropeptide W E100Q with HLA-matched dendritic and CD8 T-cells demonstrated delayed in OCS tumour *in vivo* growth and increased CD8 T-cells intra-tumour infiltration.

In summary, we can identify potential immunogenic mutant neoepitope using an integrated multi-omics approach in a TMB-low tumour. High affinity T-cell receptor discovery against this peptide is currently underway.

Cancer Posters - Thursday

PB1213. Telomeric nuclear organization of urinary circulating cells in bladder cancer (BC): A new method uncovers unreported markers.

Authors:

O. Doumbia¹, O. Samassekou¹, H. Berthé^{1,2}, M. Goita¹, S. Bamba³, M. Keita¹, I. Sissoko^{1,4}, G. Landoure^{1,5}, M. Traoré¹, A. Kassogue^{1,4}, A. Diarra^{1,6}, C. Traoré^{1,7}; ¹Univ. of Sci. Techniques and Technologies of Bamako (USTTB), Bamako, Mali, ²Urology Dept. of CHU Point G, Bamako, Mali, ³USTTB, Bamako, Mali, ⁴Urology Dept. of CHU Kati, Kati, Mali, ⁵Neurology Dept. of CHU Point G, Bamako, Mali, ⁶Urology Dept. of Hosp. " Mère-Enfant le Luxembourg", Bamako, Mali, ⁷Pathology Dept. Of CHU Point G, Bamako, Mali

Abstract Body:

Background: Bladder cancer is one of the most common cancers and the first cause of death by cancer in urology worldwide and the same epidemiological trend is observed in Mali. The poor prognosis of patients with bladder cancer could be due to the presence of aggressive forms associated with genomic instability which can be determined by the 3D telomeric nuclear organization of cancer cells studies. Biomarkers are lacking to predict therapeutic response.

Objectives: To assess the nuclear organization of telomeres in the urinary circulating cells of patients suffering from bladder cancer.

Methodology: We enrolled patients at diagnosis and recorded their clinical data. We carried out cytological preparation from their urine samples. Then, we did the 3-Dimensional (3D) fluorescence in situ hybridization by using the Cy3 labeled peptide nucleic acid probes specific for telomere. Thereafter, we captured 3D images of the cancer and the normal cells, and assessed the parameters (total number of telomeric signals, average intensity of telomeric signals, Total number of telomeric aggregates, nuclear distribution index, nuclear volume and telomeric distance from the center of the nucleus) defining the telomeric nuclear organization of cancer and normal cells by the 3D telomere analysis.

Results: We found that more than 90% of patients were diagnosed at late stage of the disease and the median survival rate was less than 180 days after the diagnosis, we observed a difference between all of the telomeric parameters of cancer and normal cells. For instance, cancer cells had more telomeres and telomeric aggregates, but had shorter telomeres than normal cells. The nuclei of tumor cells were twice as large as those of normal cells. The telomere nuclear distribution index, which corresponds to the cell proliferation index, was also twice higher in cancer cells compared to normal cells. Also, the telomeres of cancer cells had a more central nuclear location than those of normal cells. Furthermore, we found that cancer cells were more heterogeneous than normal cells. Finally, we found a correlation between the telomeric profile and patient prognosis.

Conclusion: We profiled, for the first time, the telomeric nuclear organization of bladder cancer cells and found that their alteration is associated with patient prognosis. The potentiality of finding a predictive biomarker for this disease might improve the abysmal survival rate of the patients in Mali.

Cancer Posters - Wednesday

PB1215. The effect of weight-loss on the colorectal transcriptome and its relation to colorectal cancer risk.

Hlth., Baltimore, MD, ¹⁶Div. of Human Nutrition and Hlth., Wageningen Univ. & Res., Wageningen, Netherlands, ¹⁷Sch. of Translational Hlth.Sci., Univ. of Bristol, Bristol, United Kingdom

Abstract Body:

Colorectal cancer is the second most common cause of cancer-related death. Obesity is a modifiable risk factor for this disease, although the mechanisms underpinning this effect remain largely unknown. Recent research has highlighted that weight-loss may lead to changes in tumourigenic biomarkers in normal colorectal tissue. However, further research is needed to characterise how adiposity influences colorectal tissue biology, and to investigate how these changes may in turn impact colorectal cancer susceptibility. As part of an exploratory single arm intervention study, we analysed gene expression microarray data from colorectal biopsies performed in eight individuals before and after an eight-week low-energy diet intervention. We used a permutation approach to identify colorectal tissue-specific gene expression changes resulting from the intervention. In addition, we performed ingenuity pathway analysis (IPA) to determine pathways which were up- or downregulated following weight-loss. We then performed Mendelian randomization (MR) to evaluate the potential causal effect of changes in the identified genes on site-specific colorectal cancer risk (GECCO/CCFR/CORECT consortium comprising 52,775 cases, 45,940 controls). We identified 499 genes which were differentially expressed following the weight-loss intervention (Perm-P < 0.05, fold change > 1.4). In the IPA, several pathways related to cancer development were identified as being differentially regulated following weight loss, including colony formation of colorectal cancer cell lines (5% false discovery rate (FDR)-adjusted P = 5.53 x 10⁻⁵), upper gastrointestinal tract tumour development (FDR-P = 7.09 x 10⁻⁵), senescence of epidermal cells (FDR-P = 3.86 x 10⁻⁴), BEX2 signalling pathway (FDR-P = 2.32 x 10⁻³), role of BRCA1 in DNA damage response (FDR-P = 1.95 x 10⁻²) and CDK5 signalling (FDR-P = 3.63 x 10⁻²). In MR analyses, there was evidence for a potential causal effect of expression of six of the differentially expressed genes on increased colorectal cancer risk (FDR-P < 0.05). Our analysis provides potential insight into the colorectal-tissue specific effects of weight-loss and identifies putative causal mechanisms linking adiposity and colorectal cancer.

Cancer Posters - Wednesday

PB1217. The role of senescent tumor cells in cancer progression

Authors:

T. Park, S. Park, Y. Choi; Ajou Univ. Sch. of Med., Suwon, Korea, Republic of

Abstract Body:

Senescent cells in cancer tissue, including senescent fibroblasts and macrophages, have been reported to increase the malignant potency of cancer cells by secreting senescence-associated secretory phenotype (SASP). Otherwise, Senescence of tumor cells has been believed to inhibit tumor growth by halting the massive proliferation and increasing the chances of immune clearance. In particular, senescent tumor cells (STCs) have been thought that they rarely exist in carcinomas because oncogene-induced senescence needs to be overcome for protumorigenic cells to become malignant. However, recent studies have revealed that a considerable number of STCs are present in cancer tissue, even in metastatic sites. In fact, STCs are widely involved in cancer progression by leading to collective invasion and building a cytokine barrier to protect nonsenescent tumor cells from immune attack. Furthermore, therapy-induced STCs can induce tumor progression and recurrence by increasing stemness. However, obscure causative factors and their heterogeneity in various cancers make it difficult to establish the physiological role of STCs. Here, we present the pathophysiology and role of STCs in cancer progression.

Cancer Posters - Thursday

PB1218. The Role of Tumor Microenvironment and Tumor-Active Pathways in the Progression of Glioma

Authors:

F. Bayram¹, P. Ata², V. Oğlin², M. Ziyal²; ¹Marmara Univ., Istanbul, Turkey, ²Marmara Univ. Sch. of Med., Istanbul, Turkey

Abstract Body:

Many pathways are effective in glioma formed because of differentiation of glial cells. Proliferation related Hippo pathway is one of them. Objective of our study is to express genes of *LATS2* (*Large Tumor Suppressor Kinase 2*), which effects metastasis, *WWTR1* (*WW Domain Containing Transcription Regulator*) that changes proliferation, and downstream *CYR61* (*Cysteine-rich angiogenic inducer 61*), which alters cell adhesion in HGG&LGG tissues and microenvironment via Hippo pathway. Five LGG (age: 47.2±17.9) and eight HGG (age: 60±10.06) patients who were operated in Marmara University Training and Research Hospital, Department of Neurosurgery were included. mRNA isolation and cDNA synthesis were performed. SYBR green with RT-qPCR method was used, expressions of genes were analyzed in BioRad CFX 96 device. *ACTB* (*B Actin*) gene was used as internal control. Fold increase of genes in HGGs compared to LGGs was analyzed with $2^{-\Delta\Delta C_t}$ method. When gene expressions of LGG&HGG samples were analyzed, expression values of *CYR61* were found 3.09 times higher in HGGs. Expressions of *LATS2* and *WWTR1* were not significant. When expressions of GBM tumor and tumor microenvironment were compared, it was found that expression of *LATS2* in tumor decreased, while *CYR61* and *WWTR1* increased. No statistically significant results were obtained. *CYR61* leads glioma by providing epithelial-mesenchymal transformation. This finding, which was found in our study, shows that tumor has capacity to transform into GBM. Gene expression analyzes in tumor microenvironment as well as in the tumor should be an important analysis tool that can provide information about clinical course

Cancer Posters - Wednesday

PB1219. The use of *TNF- α* polymorphic forms as a possible risk assessment tool for the management of breast cancer among Nigerian women.

Authors:

N. Alamukii^{1,2,3}, A. Odetunde⁴, C. P. Babalola^{5,6}, A. G. Falusi⁴, R. I. Nwuba¹; ¹Univ. of Med. Sci., Ondo, Nigeria, ²Dept. of Zoology, Faculty of Sci., Univ. of Ibadan, Nigeria, Ibadan, Nigeria, ³Consortium for Advanced Res. Training in Africa, Nairobi, Kenya, ⁴Genetics and Bioethics Res. Unit, Inst. for Advanced Med. Res. and Training (IAMRAT), Coll. of Med., Univ. of Ibadan, Nigeria, Ibadan, Nigeria, ⁵Dept. of Pharmaceutical Chemistry, Faculty of Pharmacy, Univ. of Ibadan, Nigeria, Ibadan, Nigeria, ⁶Chrisland Univ., Abeokuta, Nigeria

Abstract Body:

Introduction: Early diagnosis is a key factor in management, treatment and survival of breast cancer among Nigerian women. There is therefore a need for more research on suitable risk assessment tool for cancer prevention as well as early diagnosis. Tumour Necrosis factor alpha (*TNF- α*), an important cytokine in development of breast cancer is thus a likely marker for the detection of breast cancer. The single nucleotide polymorphisms (SNPs) of *TNF- α* were genotyped to determine their possible use as risk assessment tool for breast cancer among women. **Methodology:** A case-control study of 200 consenting women recruited from the University College Hospital, Ibadan was carried out. Blood samples were collected from participants for extraction of genomic DNA. Each allele of *TNF- α* SNPs were genotyped through allele specific polymerase chain reaction on extracted DNA of participants. The *TNF- α* (488 G/A, 238 G/A, 308 G/A, 380 G/A, 859 C/T and 1032 C/T) were genotyped. Sequencing of *TNF- α* isolates was done using a Nanopore sequencer. The *TNF- α* level was quantified by ELISA. **Results:** Of 12 alleles genotyped, 4 alleles showed significant association with reduced risk for breast cancer: *TNF- α 488G* (OR-0.24, CI-0.08-0.74), *TNF- α 380G* (OR-0.51, CI-0.51-0.93), *TNF- α 308A* (OR-0.33, CI-0.14-0.78), and *TNF- α 1032C* (OR-2.08, CI-1.18-3.65). The *TNF- α* level was significantly lower in cases compared to controls. *TNF- α 488G*, *308A* and *1032C* were associated with TNF α levels in cases while *TNF- α 488G*, *238A* and *1032T* were associated with *TNF- α* levels in controls. The observed results also showed non-linkage of *TNF- α* SNPs, indicating that each SNP is inherited independent of one another. Sequence analysis confirms the presence of SNPs in the expression of *TNF- α* . **Conclusion:** The *TNF- α 488G*, *308A*, *1032C* variants might be possible predictors for breast cancer among Nigerian women, hence, might be used as possible indicators for risk assessment of breast cancer among Nigerian women.

PB1220. Transcriptome Wide Association Study identifies novel candidate risk genes for testicular germ cell tumors

Authors:

E. Ugalde Morales¹, R. Wilf², J. Pluta², B. Weathers², M. Damra², P. Kanetsky³, A. Monteiro³, K. Almstrup⁴, K. Nathanson^{5,6}, F. Wiklund¹, for the Testicular Cancer Consortium; ¹Department of Med. Epidemiology and Biostatistics, Karolinska Inst.t, Stockholm, Sweden, ²Div. of Translational Med. and Human Genetics, Dept. of Med., Perelman Sch. of Med., Univ. of Pennsylvania, Philadelphia, PA, ³Dept. of Cancer Epidemiology, Moffitt Cancer Ctr. and Res. Inst., Tampa, FL, ⁴Dept. of Growth and Reproduction, Copenhagen Univ. Hosp. - Rigshosp.et, Copenhagen, Denmark, ⁵Div. of Translational Med. and Human Genetics, Dept. of Med., Perelman Sch. of Med., Philadelphia, PA, ⁶Abramson Cancer Ctr., Perelman Sch. of Med., Univ. of Pennsylvania, Philadelphia, PA

Abstract Body:

BACKGROUND

Testicular germ cell tumors (TGCT) are highly heritable. GWAS has been successful in identifying 78 independent susceptibility loci for testicular germ cell tumors. However, so far the GWAS data have not been integrated with gene expression data sets to identify causal genes, and novel genes associated with risk.

AIM

To identify candidate genes for which expression is associated with the genetic risk of TGCT.

METHODS

Study design: We conducted a transcriptome-wide association study (TWAS) using the FUSION method, which leverage GWAS summary data and heritable gene expression models trained on independent data sets. **Data:** We used summary statistics from the most recent TGCT GWAS meta-analysis and pre-computed expression prediction models from the Genotype-Tissue Expression (GTEx) version 8 and The Cancer Genome Atlas (TCGA) databases. **Prediction models:** We considered normal testis from GTEx as our primary target tissue (n=322; 12,669 genes), followed by TGCT from TCGA (n=149; 421 genes) and three principal multi-tissue features derived from 22 GTEx tissues, testis included, based on the FUSION sparse canonical correlation analysis (sCCA) summarizing shared regulatory features across tissues (7,128 genes). Models were built based on cis-SNPs from the 1000 genomes LD reference panel located in a 1 Mb window of each gene. Only genes with nominally significant SNP heritability were included in the TWAS analysis.

RESULTS

We tested for 20,218 gene-disease associations and found 168 genes associated at false-discovery rate less than 1%, 98 of which surpassed Bonferroni correction. The 168 genes were mapped to 59 non-overlapping genomic regions. In a joint-conditional analysis performed for each locus, 88 (52%) genes remained as independent hits. GWAS analyses conditioned on the predicted expression showed 48 (55%) genes located at 43 unique loci that could explain, to a large extent, cis-GWAS signals. Of the 48 plausible TGCT causal genes, 27 were novel, i.e., did not harbor any GWAS significant cis-SNP. Using a Bonferroni adjusted gene permutation test to adjust conservatively for enhanced GWAS signals, four novel genes (*BOD1L1*, *CRYL1*, *ARID3B*, *RP4-539M6.14*) and three genes at known TGCT risk loci (*UCK2*, *HEATR3*, *USP36*) were further prioritized.

CONCLUSIONS

We identified candidate TGCT predisposition genes at novel and known loci that are likely to be mediated by gene expression changes, mainly in the testis tissue. Functional analyses are planned to provide additional evidence of key molecular alterations potentially driving the disease onset.

PB1221. Transcriptome-wide association study identifies new breast cancer susceptibility genes in Latinas.

Authors:

P. Middha¹, L. Kachuri², A. C. Y. Mak¹, D. Hu¹, S. Huntsman¹, L. H. Kushi³, C. Haiman⁴, E. M. John², G. Torres-Mejia⁵, E. G. Burchard¹, S. L. Neuhausen⁶, L. Fejerman⁷, E. Ziv¹; ¹Univ. of California, San Francisco, San Francisco, CA, ²Stanford Univ., Stanford, CA, ³Kaiser Permanente Northern California, Oakland, CA, ⁴Univ. of Southern California, Los Angeles, CA, ⁵Natl. Inst. of Publ. Hlth., Cuernavaca, Mexico, ⁶City HOPE, Duarte, CO, ⁷Univ. of California, Davis, Davis, CA

Abstract Body:

Background: Genetic susceptibility to breast cancer has been studied extensively in European ancestry populations, but few studies have addressed genetic susceptibility in non-European women. Latinas are a genetically diverse population with contributions from European, African, and Indigenous American ancestries. Genome-wide association studies (GWAS) have identified unique variants in this population, particularly at the 6q25 locus. We conducted a transcriptome-wide association study (TWAS) to identify novel genes associated with risk of breast cancer in Latinas. Methods: We used individual level GWAS data from 2,396 Latina cases and 6,505 Latina controls from studies in Northern California (San Francisco Bay Area Breast Cancer Study, Northern California Breast Cancer Family Registry and Kaiser Permanente Genetic Epidemiology Research on Aging Cohort), Southern California (Multi-ethnic Cohort) and Mexico (CAMA study). We analyzed the association between genetically predicted whole blood (WB) gene expression and breast cancer risk using newly developed TWAS models based on 784 Mexican American individuals. We also conducted parallel analyses using breast mammary tissue (BT) TWAS models from GTEx v8. All analyses were adjusted for age, ancestry, and study. Associations with false discovery rate (FDR) probability <0.05 were considered statistically significant. Results: We tested 9,084 genes from models generated from WB from Latinos and 14,654 genes from models generated from GTEx BT. At FDR<0.05, we identified 10 genes from WB and 9 genes from BT models. Three of the genes were significantly associated with breast cancer risk in both the WB models and BT models. Lower expression of *MIB2* ($p^{\text{FDR}} = 4.6 \times 10^{-13}$ (WB) and 4.93×10^{-11} (BT)) and *SLC35E2B* ($p^{\text{FDR}} = 1.60 \times 10^{-5}$ (WB) and 2.48×10^{-5} (BT)) was associated with decreased risk of breast cancer. Higher expression of *PDGFA* was associated with decreased risk ($p^{\text{FDR}} = 2.86 \times 10^{-25}$) in GTEx BT reference models, but increased risk ($p^{\text{FDR}} = 1.74 \times 10^{-8}$) in the ancestry-specific WB model. Conclusion: This is the first TWAS investigating the relationship between genetically predicted gene expression and breast cancer risk in Latinas. By leveraging gene expression prediction models from whole blood from Latinos and combining these gene expression models that are tissue specific (breast), we have identified ten novel genes associated with breast cancer risk in Latinas. Of these, *MIB2* is a strong candidate for a mechanistic role in breast carcinogenesis. *MIB2* is involved in Notch signaling which plays an important role in breast carcinogenesis via its mismatched receptor-ligand interaction.

PB1222*. Transcriptome-wide association study identifies novel susceptibility genes for childhood acute lymphoblastic leukemia in Latinos

Authors:

L. Kachuri¹, S. Jeon², A. Mak³, A. DeWan⁴, C. Metayer⁵, X. Ma⁴, E. Ziv³, E. G. Burchard⁶, N. Mancuso⁷, C. W. K. Chiang⁷, J. L. Wiemels⁷, A. J. de Smith⁷; ¹Stanford Univ., Stanford, CA, ²Keck Sch. of Med., USC, Pasadena, CA, ³UCSF, San Francisco, CA, ⁴Yale Sch. of Publ. Hlth., New Haven, CT, ⁵Univ. of California Berkeley, Berkeley, CA, ⁶Univ. of California San Francisco, San Francisco, CA, ⁷Univ. of Southern California, Los Angeles, CA

Abstract Body:

Acute lymphoblastic leukemia (ALL) is the most common childhood malignancy. In the USA and globally children of Latin American origin have the highest risk of ALL, with incidence rates up to 40% higher than in predominantly European ancestry populations. There is accumulating evidence that genetic factors may underlie this striking disparity in risk.

To identify novel ALL susceptibility genes we conducted a transcriptome-wide association study (TWAS) in 1878 cases and 8441 controls from California, self-identified as Latino/Hispanic, using whole blood gene expression prediction models developed in Mexican American adolescents (n=784).

Comparative analyses were conducted using whole blood transcriptome models trained in predominantly European ancestry individuals in GTEx. Statistically significant (FDR<0.05) associations between genetically predicted transcript levels and ALL risk were detected at two novel loci: 19q13.33 (*FCGRT*, OR=1.61, p=2.0x10⁻⁵) and 20p11.23 (*CRNKLI*, OR=0.41, p=2.4x10⁻⁵). We also replicated established ALL risk genes in 7p12.2, 10p12.2, and 14q11.2. *CRNKLI* and *FCGRT* were missed using GTEx TWAS models due to the absence of ancestry-specific expression quantitative trait loci (eQTLs) - variants that are common in admixed populations with Indigenous American ancestry, but rare in other ancestry groups.

Next, we performed TWAS using a meta-analysis that incorporated additional non-Latino White participants (total n=3040 ALL cases, 65,872 controls). Using models trained in Mexican Americans yielded 16 genes with FDR<0.05, five of which were novel (*CRNKLI*, *FCGRT*, *REEP3*, *PGM2*, *CACNBI*). Applying TWAS models trained in a sample that included additional African American and Puerto Rican youths (n=2733) identified 19 genes, including two novel associations (*STOX1*, *INPP4B*). Only 9 known ALL risk genes achieved FDR<0.05 using GTEx, however, effect sizes were directionally concordant across populations for most significantly associated genes. Five novel genes (*FCGRT*, *CRNKLI*, *REEP3*, *PGM2*, *INPP4B*) colocalized with posterior probability (PP)>0.85 indicating strong evidence for shared genetic mechanisms of ALL susceptibility and regulation of gene expression. Given the proposed role of early-life immune dysregulation in ALL etiology, *FCGRT*, which encodes the Fc region of the immunoglobulin G receptor, is a strong mechanistic candidate due its role in transferring humoral immunity across the placental barrier.

In summary, our first TWAS of childhood ALL in Latino/Hispanic participants underscores the value of ancestrally diverse studies for unravelling mechanisms of disease susceptibility across populations.

Cancer Posters - Wednesday

PB1223*. Uncovering gene fusions with 3D genomics: from clinical validation to actionable insights for undiagnosable solid tumors

Authors:

A. Schmitt¹, K. Sikkink¹, K. Galbraith², M. Perez-Arreola¹, M. Movahed-Ezazi², G. Jour², M. Snuderl²; ¹Arima Genomics, San Diego, CA, ²New York Univ., New York, NY

Abstract Body:

Identifying gene fusions in tumor biopsies is critical for understanding disease etiology, however, clinical NGS panels often fail to yield clear genetic drivers. One challenge is that RNA-seq does not perform well in FFPE tissue blocks due to RNA degradation, low transcript abundance, and/or RNA panel design. To overcome this, we developed a novel DNA-based partner-agnostic approach for identifying fusions from FFPE tumors using 3D genomics based on Arima-HiC technology, in some cases with target enrichment (Capture-HiC), and NGS. Using this approach, we have profiled 108 FFPE tumors across tumor types. We first performed clinical validation of the Capture-HiC approach by re-analyzing 29 FFPE tumors comprising 34 actionable gene fusions detected by the RNA-based NYU FUSION SEQer CLIA assay. We observed a 91% concordance (31/34) between Capture-HiC and RNA panels, and are currently re-testing the 3 discordant fusions. We then analyzed 63 FFPE tumors using genome-wide HiC, including 36 CNS tumors, 10 gynecological sarcomas, and 12 solid hematological tumors (lymphoma / plasmacytoma). These tumors had no genetic drivers from prior CLIA-validated DNA and RNA panels. Amongst these, HiC analysis identified previously undetected fusions in 71% (45/63) of tumors. To attribute clinical significance to the fusions detected, we compared the genes implicated in our fusion calls with NCCN and WHO guidelines, and OncoKB, and assigned which tumors had a therapeutic level biomarker (e.g. *PD-L1*, *NTRK*, *RAD51*), or a diagnostic / prognostic biomarker (e.g. *MYBL1* in glioma). We found 39.7% (25/63) of tumors had fusions involving a therapeutic level biomarker and a further 12.7% (8/63) had fusions involving a diagnostic or prognostic biomarker, indicating an overall diagnostic yield of 52.4%. The remaining 19% (12/63) had fusions of potential clinical significance, according to OncoKB. To highlight examples, we identified a novel *PD-L1* rearrangement in a pediatric glioma that was not detected by DNA or RNA panels. Our finding was confirmed by PD-L1 IHC, and the patient was put on pembrolizumab off-label after tumor recurrence and has exhibited a complete response. We also identified *MYBL1* fusions in two glioma cases that were previously missed by RNA panels. In one case, our *MYBL1* fusion spared the patient unnecessary chemo post resection. Together, our findings demonstrate clinical validation, and highlights the utility for 3D genome profiling to increase diagnostic yield by finding clinically actionable fusions as a reflex test and as a frontline test in tumors without available NGS fusion assays (e.g. solid hematological tumors).

PB1224*. UNISON: a software toolkit for streamlined detection of clonal hematopoiesis of indeterminate potential in large-scale sequencing studies

Authors:

S. Tian, G. Jenkinson, A. Ferrer, H. Yan, S. Baheti, T. Lasho, J. Morales Rosado, M. Patnaik, K. Lazaridis, E. Klee; Mayo Clinic, Rochester, MN

Abstract Body:

Clonal hematopoiesis of indeterminate potential (CHIP) is a premalignant state, in which leukemia associated genes acquire somatic mutations in peripheral blood, at a variant allele frequency (VAF) above 2%; yet the individual does not meet the diagnostic criteria for a hematologic neoplasm. CHIP represents a risk factor for various hematologic malignancies and cardiovascular diseases. The $\geq 2\%$ VAF cutoff was set arbitrarily, which considers the limitation of standard NGS in detecting small clones and the rarity of clinical consequences associated with mutations at lower VAFs. For example, individuals with CH at $\geq 1\%$ VAF also have a significantly increased risk of developing acute myeloid leukemia. Accurate detection of CHIP highly depends on sequencing platform and depth. At $\sim 100\times$ coverage, typically for WES, most CHIPs with 2-5% VAFs can't be reliably detected. Deep targeted panel sequencing can reach a lower VAF of 0.5-1%, but it is costly to survey CHIP prevalence in large cohort studies. Currently, no bioinformatics pipeline has been developed for CHIP detection. Rather, a few generic callers have been used, such as GATK HaplotypeCaller, VarScan and MuTect(2). Popular variant calling algorithms often lose power on variants with low VAFs. Further, variant refinement is another key step to enhance CHIP discovery. Empirical filtering strategies are commonly applied, in which the thresholds are not necessarily well justified across all attributes. To systematically address these challenges, we present UNified SOmatic calling of Next-generation sequencing data, or UNISON for short, for streamlined CHIP discovery. UNISON takes raw sequencing reads or analysis-ready bam as input, and integrates variant calling and CHIP prediction in a seamless framework. It implements a meta-caller, which includes Mutect2 and Vardict, plus a hypersensitive in-house caller (VarTracker), and a pre-trained XGBoost classifier for predicting CHIP based on discriminative genomic features and other attributes. Analysis of feature of importance in XGBoost classifier revealed distinct features contributing to CHIP prediction through WES vs. WGS, and for SNVs and INDELS, respectively. UNISON was further assessed on 27 subjects that were sequenced by WES ($\sim 150\times$) and by ultra-deep ($\sim 1,000\times$) CHIP panel for orthogonal validation. UNISON with WES reaches the lowest VAF of 1.27%, agreeing with ultra-deep CHIP panel in 79.5% of the calls. Finally, applying UNISON to Mayo Biobank WGS data has demonstrated its robustness in discovering the most frequent CHIP genes and in surveying CHIP prevalence, mutation pattern and phenotypic associations at the population scale.

PB1225. Unraveling the mechanisms behind the malignant behavior of mast cell tumors using laser capture microdissection mediated RNA sequencing on canine models.

Authors:

A-S. Vander Plaetsen¹, K. Deserranno¹, S. De Vos², W. De Spiegelaere², H. de Rooster², D. Deforce¹, F. Van Nieuwerburgh¹; ¹Ghent Univ. - Lab. of Pharmaceutical Biotechnology, Ghent, Belgium, ²Ghent Univ. - Faculty of Vet. Med., Ghent, Belgium

Abstract Body:

Mast cell tumors (MCTs) are the most frequently diagnosed form of canine skin cancer. They are a diverse class of mast cell malignancies, which are also present in human patients with benign or poor prognosis. Therefore, based on the remarkable resemblances in terms of both biological and clinical features, dogs may serve as an attractive model to study MCTs in humans. Currently, in dogs, MCTs are resected with wide margins, histopathologically graded post-resection, and, depending on post-resection histopathology results, the need for adjuvant therapy is determined. This a posteriori grading requires surgeons to apply large surgical margins, resulting in increased morbidity and risk of complications, even in less aggressive MCTs and delays optimal adjuvant therapy in aggressive MCTs. Therefore, a molecular biomarker that can be used to classify tumors up-front would be of value to personalize patient care. Unfortunately, comprehensive basic and translational knowledge on the molecular characteristics of the MCTs and their correlation with the current canine grading systems and possible metastatic disease is lacking.

The goal of this research is to study the transcriptome across all MCT grades. Furthermore, transcriptome analysis of specific cells in the tumor microenvironment (TME) and in the draining lymph nodes will be performed to elucidate the underlying molecular pathways. Laser capture microdissection sequencing (LCM-seq) is an ideal method to isolate these specific cells from tissue slides based on histological features. Subsequently, cell type specific RNA sequencing can be performed to evaluate the transcriptome. A major advantage of this LCM-seq technology, in contrast to for example flow cytometry-based methods, is the fact that tissue sections can be kept intact and information about the spatial position of each captured cell in the TME is preserved, allowing both archival formalin-fixed paraffin-embedded tissue blocks and cryosections to be evaluated. A cost-effective miniaturized full-length RNA sequencing strategy capable of handling a limited input number of cells will be established based on the recent Smart-seq3xpress protocol. The full-length transcript information will be used to assess differential gene expression and isoform variation in mast cells and cancer-associated fibroblasts (CAFs) in the TME. In addition, further optimization of our RNA sequencing strategy would also allow for long non-coding RNA (lncRNA) biomarker screening.

Cancer Posters - Thursday

PB1226. Unravelling RecQ helicase function in genome stability using Strand-seq

Authors:

Z. Hamadeh¹, V. Hanlon¹, P. Lansdorp²; ¹BC Cancer Res. Ctr., Vancouver, BC, Canada, ²BC Cancer Agency, Vancouver, BC, Canada

Abstract Body:

Helicases are a highly conserved family of motor proteins responsible for interacting with and unwinding canonical and non-canonical DNA and RNA structures. The RecQ class of helicases, known to suppress illegitimate recombination, are implicated in aging and cancer with three of the five human RecQ helicases directly linked to premature aging syndromes characterized by strong cancer predisposition. While no human disease has been associated with the RECQL5 helicase, loss of this gene in cells is known to result in elevated double strand breaks (DSBs) and sister chromatid exchange events (SCEs), a phenotype of genome instability similar to what is observed in RecQ helicase-linked diseases of strong cancer predisposition. Until recently, studying SCEs has been limited to cytogenetic assays that map at megabase resolution. We used single cell template strand sequencing (Strand-seq) to map SCEs as changes in template strand orientation before and after loss of RECQL5 at kilobase resolution. We generated over 20 single and double knockout models for RECQL5 as well as BLM, WRN and RECQL1 helicases using CRISPR-Cas9 in the human haploid cell line, KBM7, and mapped SCEs to the genome using custom bioinformatic approaches to improve resolution and accuracy of SCE detection. We performed enrichment analysis to show SCEs are frequently occurring near actively transcribed genes with guanine quadruplexes and common fragile sites further supporting the role of these helicase genes in suppressing inappropriate recombination at specific genomic elements. We also developed novel bioinformatic approaches to generate genotype-specific call sets for copy number alterations (CNAs), inversions, and translocations. Uncovering the role of DNA helicases in DNA repair and replication pathways is critical for understanding their significance in cancer and aging. Strand-seq offers a unique method to study helicases by mapping the location of SCEs arising in their absence.

PB1227. Using human genetics to evaluate the causal role of circulating inflammatory markers in risk of adult cancer.

Authors:

J. Yarmolinsky¹, J. Robinson¹, K. Tsilidis², A. Dehghan², M. Johansson³, D. Mariosa³, M. Gunter³, B. Kiemeny⁴, G. Davey Smith¹, R. Martin¹; ¹Univ. of Bristol, Bristol, United Kingdom, ²Imperial Coll. London, London, United Kingdom, ³Intl. Agency for Res. on Cancer, Lyon, France, ⁴Radboud Univ. Med. Ctr., Nijmegen, Netherlands

Abstract Body:

Tumour-promoting inflammation is a “hallmark” of cancer and laboratory and epidemiological studies have reported links between various inflammatory markers and cancer risk. The causal nature of these relationships and, thus, the suitability of these markers as intervention targets for cancer prevention is unclear. We meta-analysed 6 genome-wide association studies of circulating inflammatory markers comprising 59,969 participants of European ancestry. We then used combined *cis*-Mendelian randomization and colocalisation to evaluate the causal role of 75 circulating inflammatory markers in risk of 32 adult cancers in 347,300 cancer cases and up to 1,015,204 controls. Genetic instruments for inflammatory markers were constructed using genome-wide significant ($P < 5.0 \times 10^{-8}$) *cis*-acting SNPs (i.e. ± 250 KB from the gene encoding the relevant protein) in weak linkage disequilibrium (LD, $r^2 < 0.10$). Effect estimates were generated using inverse-variance weighted random-effects models and standard errors were inflated to account for weak LD between variants with reference to the 1000G Phase 3 European panel. We find strong evidence for effects of genetically-proxied circulating adrenomedullin on breast cancer risk (OR:1.19, 95%CI:1.10-1.29, $P=2.02 \times 10^{-5}$, $H_4=84.3\%$), interleukin-23 receptor on pancreatic cancer risk (OR:1.42, 95%CI:1.20-1.69, $P=6.72 \times 10^{-5}$, $H_4=73.9\%$), antithrombin on triple-negative breast cancer risk (OR:3.62, 95%CI:1.70-7.70, $P=8.30 \times 10^{-4}$, $H_4=72.7\%$), and macrophage migration inhibitory factor on bladder cancer risk (OR:1.14, 95%CI:1.05-1.23, $P=1.43 \times 10^{-3}$, $H_4=76.1\%$), among other findings. Our comprehensive analyses represent the largest human genetics evaluation of circulating inflammatory markers in risk of adult cancers to date. Our findings highlight various novel inflammatory markers implicated in cancer development and suggest pharmacological targeting of these markers as a potential strategy for primary cancer prevention.

PB1228. Utility of hereditary cancer panel testing in individuals with a known familial variant.

Authors:

E. Weltmer¹, K. O'Brien¹, R. Johnson¹, C. Terhaar¹, Y. Fesko²; ¹Quest Diagnostics, San Juan Capistrano, CA, ²Quest Diagnostics, Secaucus, NJ

Abstract Body:

Accurate reporting of a familial pathogenic or likely pathogenic (P/LP) variant allows an individual to receive targeted testing for the familial variant. However, families and individuals with P/LP variants in 2 different genes have also been reported. The incidence of such findings has not been well-described, particularly in those who already have a known familial P/LP variant. This study aims to describe the percentage of individuals positive for at least one P/LP variant on hereditary cancer panel testing whose clinical history mentioned a P/LP variant in a different gene than was identified through panel testing. This information would add to the understanding of the utility of panel testing for individuals with a known familial P/LP variant. We performed a retrospective analysis of results from hereditary cancer panel tests that were positive for a P/LP variant between June 2016 and March 2022. Our analysis focused on panels representing broad cancer phenotypes such as breast, colon, and multi-cancer phenotypes. Panels targeting a specific syndrome (eg, Lynch syndrome and hereditary breast/ovarian cancer syndrome) were excluded. Cases were reviewed for clinical history of a familial P/LP variant that was either confirmed (genetic test result or genetics family letter specifying gene and variant provided) or suspected (gene provided via verbal report only). Results from 8 hereditary cancer panel tests were included in our analysis: 2 panels of genes associated with breast cancer, 2 associated with colorectal cancer, 1 associated with endocrine cancers, and 3 associated with multiple cancer types. A total of 1,233 of these tests were positive for a P/LP variant, and 151 (12.2%) of these had a familial variant in the clinical history. Among the 151 cases where a familial P/LP variant was mentioned in the clinical history, 8% (12/151) were negative for the familial variant but positive for a P/LP variant in a different gene, 2% (3/151) were double heterozygotes for both the familial variant and a P/LP variant in a different gene, and 90% were positive for only the familial variant. Although targeted testing would have been sufficient for 90% (136/151) of the individuals in our cohort, it would have missed a clinically significant variant in 10% (15/151). These data demonstrate that testing for genes in addition to those specifically noted in an individual's family history may provide opportunities to identify additional at-risk individuals and more appropriately manage those who have additional risks due to a P/LP variant in another gene.

Cancer Posters - Wednesday

PB1229*. Utilizing Electronic Health Records (EHR) and Tumor Panel Sequencing to Demystify Prognosis of Cancer of Unknown Primary (CUP) patients

Authors:

I. Moon^{1,2}, J. LoPiccolo², S. Baca², K. Kehl², A. Gusev²; ¹Massachusetts Inst. of Technology, Cambridge, MA, ²Dana-Farber Cancer Inst., Boston, MA

Abstract Body:

Background:When a standardized diagnostic test fails to locate the primary site of a metastatic cancer, it is diagnosed as a cancer of unknown primary (CUP). This type of cancer represents about 3-5% of all cancers. Due to the hidden nature of primary sites for CUP tumors, oncologists often resort to empiric treatments and patients with CUPs typically have very poor outcomes. Therefore, there is great need for an accurate method to identify the primary site of CUP and empower more informed clinical decision making.

Methods:We used the next generation sequencing (NGS) data collected in routine clinical care as part of the AACR project GENIE (n = 34,567). We trained a gradient boosted decision tree algorithm we call “Boosted Cancer Type” or “BCT” to classify 22 primary cancer types using molecular features abstracted from the NGS data. We validated the model using cross-validation on primary and metastatic cancers with known primary (CKP) as well as germline Polygenic Risk Scores (PRS) among a cohort of 833 patients with CUP. Finally, among 159 patients with CUP who received palliative treatment as their first therapy and had clinical outcomes available, we evaluated whether concordance between BCT predicted sites and first palliative treatment was predictive of improved survival using a multivariable Cox Proportional Hazard regression with the clinical covariates.

Result:BCT achieved high performance on held-out test data consisting of 7,289 primary and metastatic tumor samples from 22 known cancer types (weighted F1 : 0.789). Applying BCT to 838 patients with CUP, we showed that patients with a BCT predicted site have a higher germline risk for the corresponding cancer, providing evidence that CUPs are genetically correlated with known cancers. Furthermore, BCT identified subtypes with significant prognostic differences, which were significantly correlated with relative median survival in their corresponding CKPs (Spearman’s rho 0.810, p-value : 0.015). Importantly, patients with CUP who received first palliative treatments concordant with their BCT predicted sites showed better 5-year survival than those assigned to discordant treatments (H.R. 0.32, 95% C.I. 0.17 - 0.62, p-value : < 0.001).

Conclusion:We demonstrated accurate primary site classification from routinely collected, multi-center NGS panels. BCT stratified patients with CUP into significantly different survival groups, and first palliative treatment concordant with the BCT predictions were predictive of improved survival. BCT thus offers the potential for meaningful clinical decision support for managing patients with CUP.

Cancer Posters - Thursday

PB1230. Variants in *FANCM* confer risk to estrogen receptor-negative breast cancer among Latinas

Authors:

J. Nierenberg¹, A. Adamson², L. Fejerman³, S. B. Gruber², C. A. Haiman⁴, D. Hu⁵, S. Huntsman¹, E. M. John⁶, L. H. Kushi⁷, R. Lee¹, G. Torres-Mejia⁸, C. Patrick⁹, C. Ricker¹⁰, Y. Shieh¹¹, L. California Davis, Davis, CA, ⁴Univ. of Southern California, Los Angeles, CA, ⁵Univ California San Francisco, San Francisco, CA, ⁶Stanford Univ. Sch. of Med., Stanford, CA, ⁷Kaiser Permanente Northern California, Oakland, CA, ⁸Inst. Natl. de Salud Pública, Cuernavaca, Mexico, ⁹City of Hope, Duarte, CA, ¹⁰USC Norris Comprehensive Cancer Ctr., Los Angeles, CA, ¹¹Weill Cornell Med. Coll., New York, NY, ¹²Latin American Sch. of Oncology, Tuxla Gutierrez, Mexico

Abstract Body:

Introduction: Genetic testing for pathogenic variants in breast cancer susceptibility genes is currently used to identify women at high risk of breast cancer, who may benefit from intensive screening and preventive interventions, for cascade testing in families, and to inform the use of targeted treatments. However, most evidence supporting this testing is from studies of European ancestry participants. We investigated the impact of known and suspected breast cancer susceptibility genes among over 8,500 Latinas from California and Mexico.

Methods: We conducted a pooled case-control analysis of breast cancer in Latinas from the San Francisco Bay Area, Los Angeles, and Mexico (4,178 cases and 4,344 controls). This included cases from high-risk studies (age below 50 years, family history, or bilateral breast cancer) and from general population studies. Genetic assays included whole exome sequencing on 1,043 cases and 1,188 controls and a targeted panel of 800 genes on the remainder of the samples. We tested the association of loss of function (LoF) variants (frameshift, truncating, or splice site) in each gene with overall, estrogen receptor (ER) positive (+), and ER negative (-) breast cancer, using ancestry-adjusted SKAT-O analyses. We calculated odds ratios for breast cancer with the presence of LoF variants in each gene, using ancestry-adjusted logistic regression models. Our alpha threshold for novel genes was $0.05/20,000=2.5 \cdot 10^{-6}$.

Results: We saw a strong association of LoF variants in *FANCM* with ER- disease ($p=3.7 \cdot 10^{-7}$, OR [CI]: 6.7 [5.8-7.5]) and a nominal association with overall breast cancer risk. Among known susceptibility genes, three were strongly associated with breast cancer, *BRCA1* ($p=5.9 \cdot 10^{-7}$, OR [CI]: 12.3 [11.1-13.4]), *BRCA2* ($p=9.2 \cdot 10^{-11}$, OR [CI]: 7.1 [6.4-7.7]), and *PALB2* ($p=1.2 \cdot 10^{-8}$, OR [CI]: 6.5 [5.8-7.2]). We also found nominally significant associations with other genes, including *CHEK2*, *RAD51D*, and *TP53*.

Discussion: In addition to confirming the role of several accepted breast cancer susceptibility genes in Latinas, we found that LoF variants in *FANCM* were strongly associated with ER- breast cancer risk among Latinas from California and Mexico. *FANCM* is involved in homologous recombination repair like other breast cancer susceptibility genes and has previously been proposed as a possible susceptibility gene for ER- disease, but is not routinely tested in clinical practice. Our results suggest that *FANCM* should be added to breast cancer gene panels, especially among Latinas.

Cancer Posters - Wednesday

PB1231. Whole genome CpG-resolution DNA methylation profiling of HNSCC reveals previously ignored heterogeneity among HPV(+)tumors and clinical implications

Authors:

T. Qin¹, S. Li¹, L. Henry¹, E. Chou¹, L. Rozek², M. Sartor^{1,3}; ¹Dept. of Computational Med. and Bioinformatics, Univ. of Michigan Med. Sch., Ann Arbor, MI, ²Dept. of Environmental Hlth.Sci., Sch. of Publ. Hlth., Univ. of Michigan, Ann Arbor, MI, ³Dept. of Biostatistics, Univ. of Michigan, Sch. of Publ. Hlth., Ann Arbor, MI

Abstract Body:

Background: DNA methylation is an important epigenetic modification and has been widely studied as a source of biomarkers for cancers. Methylation alterations have been reported in head and neck squamous cell carcinoma (HNSCC), however, most of the findings were based on array data with limited coverage and resolution, and the methylation differences have mainly been explored by HPV status ignoring the high heterogeneity of this disease. *Methods:* In this study we employed whole genome bisulfite sequencing (WGBS) to assay the methylation landscape of a well-studied HNSCC cohort (n=36), already characterized by gene expression, copy number alterations (CNAs), and mutations. We investigated the methylation changes between fine-scaled HNSCC subtypes, including two HPV(+) subtypes. To interpret and validate the findings, we performed integrative pathway analysis to identify the gene sets with both differential methylation and expression, and applied Methylation-based Inference of Regulatory Activity (MIRA) analysis to examine differences in regulatory potential of relevant DNA-binding proteins between the subtypes. *Results:* The previous observation of genome-wide hypermethylation in the HPV(+) patients as compared to HPV(-) was found to be dominantly present in the immune-strong (IMU) subtype of HPV(+) tumors, but not in the keratinized (KRT) subtype (99% vs. 1% of significant regions). The genes formerly reported to be associated with hypermethylation in HPV(+) patients were also found to be more hypermethylated and/or carry more hypermethylated regions among IMU subtype. Notably, the methylation levels of repetitive elements were significantly higher in IMU than in KRT and HPV(-) patients, indicating that the IMU subtype is more genomically stable, in line with the fact that IMU subtype has better prognosis. This was confirmed by the significantly negative correlation between patient-wise methylation values and genomic instability scores based on CNAs. Differential methylation pathway analysis recapitulates most gene expression differences between the IMU and KRT subtypes. Among the KRT and HPV(-) patients, the MIRA analysis identified higher regulatory potential of keratinocyte CTCF-binding that positively correlated with an expression-based keratinization score. *Conclusion:* Hypermethylation in the IMU subtype may explain the higher chance of HPV integration and less favorable prognosis in the KRT subtype. Together, these findings suggest the importance of fine-scale subtype analysis in such a heterogenous disease, and reveal previously unidentified epigenomic alterations and clinical implications in subtypes of HPV(+) HNSCC.

Complex Traits Posters - Thursday

PB1232. A catalog of genetic predictors impacting lifelong medication use patterns in hyperlipidemia, hypertension and type 2 diabetes

Hosp., Boston, MA, ¹⁷Dept. of Publ. Hlth., Clinicum, Faculty of Med., Univ. of Helsinki, Helsinki, Finland

Abstract Body:

Little is known about the genetic determinants of medication use in the prevention of cardiometabolic diseases. Using the nationwide Finnish drug purchase registry with follow-up since 1995 we performed genome-wide association analyses of longitudinal patterns of medication use in hyperlipidemia, hypertension, and type 2 diabetes (T2D) in up to 193,933 individuals in the FinnGen. In meta analyses of up to 567,671 individuals combining FinnGen together with drug purchasing data in the Estonian Biobank and prescription data in the UK Biobank (UKBB), we discovered 333 independent genetic loci ($p < 5 \times 10^{-9}$): 74 with leading associations for hyperlipidemia, 181 for hypertension, and 78 for T2D medication patterns. Fine-mapping revealed 494 95% credible sets (CS) associated with the total number of medication purchases, longitudinal changes in medication combinations, or discontinuation of medication, including 46 CS in 40 medication use associated loci that have not been previously associated with the underlying treatment targets. Of the 333 independent medication loci, 158 were also associated with coronary artery disease (CAD) with shared effect directions in a novel CAD meta-analysis combining FinnGen, UKBB, and the CARDIoGRAMplusC4D consortium ($n=811,555$). Combining the genome-wide associations on CAD and the medication patterns to a novel multi-trait polygenic risk score (PRS) improved the prediction of CAD beyond a state-of-the-art CAD PRS (21% higher R^2) in an independent sample (UKBB, $n=343,676$). We also show that the PRSs for low-density lipoprotein, systolic blood pressure, and T2D are strongly associated with the medication use behavior. In summary, we demonstrate novel medication pattern-based strategies for identifying cardiometabolic risk loci and provide new genome-wide tools for medication-based prevention of cardiovascular diseases.

Complex Traits Posters - Wednesday

PB1233. A comparative PRS-PheWA of 14 autoimmune disorders, and their genetic relationship.

Authors:

A. Topaloudi, P. Jain, M. Martinez, P. Paschou; Purdue Univ., West Lafayette, IN

Abstract Body:

Autoimmune diseases (ADs) are a group of more than 80 heterogeneous disorders that occur when there is a failure in the self-tolerance mechanisms triggering self-attacking autoantibodies. Most of the autoimmune disorders are polygenic and associated with genes in the human leukocyte antigen (HLA) region. However, additional non-HLA genes are also found to be associated with different ADs, and many times they are implicated in more than one disorder. Previous studies have observed associations between various health-related and lifestyle phenotypes and ADs. A way to calculate an individual's genetic liability to a phenotype is through Polygenic risk scores (PRS), estimated as the sum of the risk alleles weighted by their effect sizes in a genome-wide association study (GWAS). Here, for the first time, we conducted a comparative PRS-PheWAS analysis for 14 different ADs (Celiac Disease, Crohn's Disease, Inflammatory Bowel Disease, Juvenile Idiopathic Arthritis, Multiple Sclerosis, Myasthenia Gravis, Primary Sclerosing Cholangitis, Psoriasis, Rheumatoid Arthritis, Systemic Lupus Erythematosus, Type 1 Diabetes, Ulcerative Colitis, Vitiligo Early Onset, Vitiligo Late Onset) and 3,281 outcomes available in the UK Biobank that cover a wide range of lifestyle, socio-demographic and health-related phenotypes. Additionally, we further explored the genetic relationships of the selected ADs by estimating the genetic correlation and performing cross-disorder GWAS meta-analyses for the identified AD sub-groups. In total, we observed 554 outcomes significantly associated with at least one disorder PRS, and 300 outcomes were significant after variants in the HLA region were excluded from the PRS calculations. From the genetic correlation followed by the genetic factor analysis we observed five genetic factors and the cross-disorder meta-analyses in each factor revealed genome-wide significant pleiotropic loci. Overall, our analyses indicate potential factors associated with genetic risk for ADs, some of which have been reported previously, and also novel observations that need to be further explored.

Complex Traits Posters - Thursday

PB1234. A comprehensive coronary artery disease risk prediction framework incorporating genetic and nongenetic risk factors.

Authors:

S-F. Chen^{1,2}, H. J. Sadaei¹, L. Sang-Eun¹, N. Wineinger^{1,2}, A. Torkamani^{1,2}; ¹Scripps Res. Translational Inst., La Jolla, CA, ²Scripps Res., La Jolla, CA

Abstract Body:

Coronary artery disease (CAD) is the leading cause of mortality and morbidity worldwide. With the polygenic inheritance of CAD, the findings from large-scale genome-wide association studies led to a proliferation of polygenic risk scores (PRSs), which variably demonstrated the potential implications of genetic studies to aid in clinical prevention and treatment development. However, the current utility of current PRS models is confined to the identification of at-risk populations in the top percentiles of genetic risk. Despite the known heterogeneous risk factors mediating CAD risk from a broad spectrum of genetic and environmental risk factors, there have been limited efforts to blend these factors into a comprehensive risk prediction model. A major goal of CAD risk prediction should be to develop schemes integrating genetic risk factors and be able to recommend appropriate medical interventions with higher therapeutic responses to reduce the burden of disease. Herein, we performed deep phenotyping on biobank data to ascertain diseases and curated all accessible nongenetic risk factors from individualized profiling of laboratory tests, diagnosis, interview, and lifestyle from self-reported or electronic health records. All accessible PRSs for expected medical measurements and predisposition of comorbidity were also calculated from whole-genome genotyping data. To improve generalizability and reduce bias from a single contributing model, we aggregated the performance by leveraging the learnability of numerous state-of-art machine-learning (ML) algorithms. Multiple risk prediction models for contributing risk factors were combined into a meta-estimator predicting the 10-year CAD cumulative incidence. To capture gene-by-environment interactions, the ensemble framework was built upon decision-tree-based algorithms capable of discovering the non-linear interplay between predictors. We also interpreted the feature importance with Shapely additive explanations value, which can isolate important contributing risk factors at an individual level and imply preventative interventions. Our preliminary results outperformed contemporary risk calculators not only with higher predictive accuracy but also delivering the risk assessment in an actionable text. With increased adoption and connectivity of personal digital health data sources, this framework provided an opportunity to promote personal or clinical utility. Altogether, the final model will be able to suggest and prioritize conforming consequential decisions to facilitate substantial personalized care and precision medicine.

Complex Traits Posters - Wednesday

PB1235*. A comprehensive genetic map of cytokine responses to pathogens in 1063 Lyme patients reveals novel regulatory mechanisms underlying diseases.

Authors:

J. Botey-Bataller^{1,2}, H. D. Vrijmoeth^{1,3}, J. Ursinus^{4,3}, B-J. Kullberg¹, C. van den Wijngaard³, H. t. Hofstede¹, C-J. Xu^{1,2,5,6}, M. G. Netea^{1,7}, J. W. R. Hovius⁴, L. A. B. Sch. and the Helmholtz Ctr. for Infection Res., Hannover, Germany, ⁶Dept. of Gastroenterology, Hepatology and Endocrinology, Hannover Med. Sch., Hannover, Germany, ⁷Dept. for Genomics and Immunoregulation, Life and Med. Sci. Inst. (LIMES), Univ. of Bonn, Bonn, Germany, ⁸Dept. of Med. Genetics, Iuliu Hatieganu Univ. of Med. and Pharmacy, Cluj-Napoca, Romania

Abstract Body:

Inter-individual variability of immune responses determines the susceptibility to certain infectious diseases or chronic conditions. To tackle this, we established a cohort of 1063 Lyme Borreliosis patients and measured the *ex vivo* cytokine responses to various stimuli before and after antibiotic treatment. We characterized the effect of the disease course on the responses and found that IL-10 responses were increased after antibiotic treatment and negatively correlated with antibody levels against *Borrelia*. This confirms the detrimental role of IL-10 in mounting an adaptive response against *Borrelia*. We characterized the effect of genetic variation through cytokine quantitative trait loci (cQTL) mapping. 45 independent loci showed a genome-wide significant association ($P < 5 \times 10^{-8}$), of which 44 are novel loci. The identified cQTL showed consistency between before and after treatment in terms of allelic effect size and direction. Among the newly identified cQTL, the *CFH* locus is associated with cytokine responses to *Candida albicans* and *Borrelia*. We captured the cis-regulating cQTL at the *IL10* and *IL6* loci. The *KL* locus, which codes for the anti-aging protein Klotho, was found significant for IL-6 and IL-1 β responses. Of note, the strongest cQTL signal was found to be the *TLRI-6-10* locus, which was reported in our early study in Health. Interestingly, we found that it regulates IL1-Ra production in response to *Borrelia* but not to Pam3Cys, which was validated in Pam3Cys stimulation RNA-seq data of 95 samples in an independent cohort. Adding to this, we assessed the causal variants by fine-mapping. This yielded a single non-synonymous variant, rs5743618, as the only significant in stimulations before treatment and multiple signals as causal for stimulations after treatment. Genes identified from cQTL were significantly enriched (GSEA, $P < 2 \times 10^{-3}$) in response to *Borrelia* stimulation based on RNA-seq data. Furthermore, cQTL were functionally enriched in open chromatin peaks of immune-cell populations based on ENCODE and Roadmap epigenomics data ($P < 1 \times 10^{-4}$). In total, four cQTL were colocalized and/or causally linked to the genetic regulation of immune-mediated diseases, adding new perspectives to their aetiology. In summary, we provide an expanded list of genetic determinants associated with variability in immune responses. In the clinical context, knowing the genetic predisposition towards different responses will help in better patient stratification and more tailored treatments.

Complex Traits Posters - Thursday

PB1236. A *Drosophila* platform to validate and assess pathogenicity of LMNA variants identified from dilated cardiomyopathy patients.

Authors:

Z. Han, H. Liu, Y. Fu, J. van de Leemput; Univ. of Maryland Sch. of Med., Baltimore, MD

Abstract Body:

LMNA is one of the most sequenced genes in humans - its variants associated with at least 18 different diseases. Yet, hundreds of *LMNA* variants remain classified as "variant with conflicting interpretations" or "variant with uncertain significance" in ClinVar, making it one of the top priority genes in need of a functional validation system to unravel its variant-to-clinical significance classifications. Here, we developed a highly efficient *Drosophila* platform to provide *in vivo* functional analysis for *LMNA* variants associated with dilated cardiomyopathy (DCM). We found that cardiac-specific silencing of *LamC*, the fly homolog of human *LMNA*, leads to a typical DCM phenotype (dilated heart tube, reduced myofibrils, reduced contraction, abnormal function), which can be completely rescued by expressing wildtype human *LMNA*, but not by mutant *LMNA* carrying the established pathogenic DCM variants, in these flies, *i.e.* our "gene replacement" approach. Using this platform, we screened 13 *LMNA* variants: 6 pathogenic variants without *in vivo* evidence, 4 variants with conflicting interpretations, and 3 variants of uncertain significance. The fly heart data validated and (re-)classified the variants as 8 pathogenic and 5 benign variants, demonstrating the effectiveness of this *Drosophila* platform in providing the much-needed "variant-level" cardiac functional validation, even for genes with complex interpretations like *LMNA*.

Complex Traits Posters - Wednesday

PB1237. A genome wide association study of chronic spontaneous urticaria risk and heterogeneity.

Authors:

D. Chang, C. Hammer, C. Holweg, S. Selveraj, N. Rathore, M. I. McCarthy, B. L. Yaspan, D. F. Choy; Genentech, South San Francisco, CA

Abstract Body:

Chronic spontaneous urticaria (CSU) is a dermatologic condition characterized by spontaneous, pruritic hives and/or angioedema that persist for six weeks or longer with no identifiable trigger. Mast cell and basophil degranulation are key factors in CSU etiology. One mediator of this degranulation is autoantibody associated FcεRI/IgE crosslinking, though additional mechanisms are likely involved. Existing therapeutic options for CSU patients such as antihistamines and omalizumab (an anti-IgE monoclonal antibody) relieve symptoms in some patients, while others remain symptomatic, suggesting additional mediators can be targeted therapeutically. Investigating the genetics of CSU may provide clues to other CSU-associated pathways, but to date, only candidate gene studies in small cohorts have been carried out with limited replication. The aim of this study was to carry out a genome-wide association study (GWAS) of CSU risk and heterogeneity. In our CSU risk GWAS of 679 CSU patients and 4,446 controls, we identified two significantly associated loci. The strongest association maps to position 56 of HLA-DQα ($P=1.69 \times 10^{-9}$), where the arginine residue was associated with increased CSU risk ($OR=1.64$). The second association signal ($P=1.57 \times 10^{-8}$, $OR_{C-allele}=1.44$) colocalized with expression-quantitative trait loci in whole blood for *ITPKB* ($P=1.90 \times 10^{-8}$, $\beta_{C-allele}=0.095$), a secondary messenger in calcium signaling ($\text{probability}_{\text{colocalization}} > 0.90$). We also investigated the genetics of CSU heterogeneity as measured by the Chronic Urticaria (CU) index - an assay that tests for basophil histamine releasing factors e.g. serum IgG autoantibodies. Comparing 455 CU-index low to 187 CU-index high patients, we found that the CSU risk associated arginine residue at position 56 of HLA-DQα was also associated with high CU-index ($P=6.15 \times 10^{-5}$, $OR=1.86$), while the *ITPKB* association was not associated with CU-index ($P=0.64$). Further analyses revealed three autoimmune polygenic scores (hypothyroidism, type-1 diabetes, and vitiligo) are associated with CSU risk and CU-index ($P < 2.34 \times 10^{-3}$, $OR > 1.72$). In summary, this GWAS identifies a role for calcium signaling in CSU pathology and provides a genetic basis for autoimmune mechanisms in risk and clinical presentation of CSU.

Complex Traits Posters - Thursday

PB1238. A genome-wide association study in Peruvians suggests new risk loci for Alzheimer disease

Authors:

F. Rajabli¹, M. Cornejo-Olivas², N. Custodio³, M. Soto-Añari⁴, R. Montesinos⁵, D. Reyes-Dumeyer⁶, J. Cedeno⁶, J. Rivero¹, P. R. Mena¹, L. D. Adams¹, P. G. Whitehead¹, K. L. Hamilton-Nelson¹, J. Martin¹, A. Griswold¹, M. L. Cuccaro¹, J. M. Vance¹, G. W. Beecham¹, M. A. Pericak-Vance¹, G. Tosto⁶; ¹John P. Hussman Inst. for Human Genomics, Univ. of Miami Miller Sch. of Med., Miami, FL, ²Neurogenetics Res. Ctr., Inst. Natl. de Ciencias Neurológicas, Lima, Peru, ³Unidad de diagnóstico de deterioro cognitivo y prevención de demencia, Inst. Peruano de Neurociencias, Lima, Peru, ⁴Univ. Católica San Pablo, Arequipa, Peru, ⁵Unidad de diagnóstico de deterioro cognitivo y prevención de demencia, Lima, Peru, ⁶Taub Inst. for Res. on Alzheimer's Disease and the Aging Brain, Coll. of Physicians and Surgeons, Columbia Univ., New York, NY, ⁷Neurogenetics Res. Ctr., Inst. Natl. de Ciencias Neurológicas, Lima, Peru, ⁸Dept. of Anatomy, Physiology & Genetics, Uniformed Services Univ. of the Hlth.Sci., Bethesda, MD, ⁹Daniel Alcides Carrion Natl. Hosp., Callao, Peru

Abstract Body:

Background Increasing racial/ethnic diversity in genetic studies is critical for defining the genetic architecture of Alzheimer disease (AD). Native American (NA) populations are substantially underrepresented in AD genetic studies. The Peruvian (PE) population, with up to ~80% of NA ancestry, provides a unique opportunity to assess the role of NA ancestry in AD. We performed the first genome-wide association study (GWAS) in the PE population to identify novel AD susceptibility loci and characterize the known AD genetic risk loci in the PE population. **Methods** The PE dataset includes array-genotype and phenotype data from 630 individuals (180 cases; 450 controls), all imputed to the NHLBI TOPMed v5 haplotype reference panel. We performed genome-wide association analyses with a generalized linear mixed-model using the SAIGE software. The model included genotype, sex, age, and principal components (population substructure) as fixed effects and genetic relationship matrix as a random effect. **Results** We identified the *APOE* gene as a genome-wide significant with an effect size comparable to the effect size found in non-Hispanic white (NHW) populations ($OR=3.35$ (2.31-4.87), $P=4.6 \times 10^{-10}$) (GIF=1.04). Variants at four additional loci reached suggestive significance ($P < 10^{-5}$): *PPCS* ($P=4.6 \times 10^{-6}$), *NFASC* ($P=1.6 \times 10^{-7}$) on chromosome 1, *DGKB* ($P=2.6 \times 10^{-7}$) on chromosome 7, and *KDM4C* ($P=1.4 \times 10^{-6}$) on chromosome 9. Follow-up ancestry-aware analysis at the *DGKB* locus showed increased NA ancestry among the risk allele carriers. The high frequency of the risk allele in NA ancestry increased the power to detect association and suggests that the signal at the *DGKB* locus was driven by the NA ancestry. In addition to the *APOE* locus, two more known AD loci, *BINI* ($P=0.03$) and *ECHDC3* ($P=0.04$), showed nominal significance. **Conclusions** Our PE GWAS generalized the association was seen in NHW individuals of *APOE*, *BINI*, and *ECHDC3* with AD risk and identified four novel suggestive susceptibility loci. *DGKB* (Diacilglicerol kinase beta) gene is a promising candidate that plays a key role in cellular processes and has been implicated in AD risk in a Caribbean Hispanic GWAS study.

Complex Traits Posters - Wednesday

PB1239. A genome-wide association study of lifetime estrogen exposure in Korean postmenopausal women

Authors:

M. Yuk, Y. Kwak, S. Yang, J. Lee, J. Youn, N. Song; Coll. of Pharmacy, Chungbuk Natl. Univ., Cheongju, Korea, Republic of

Abstract Body:

BACKGROUND: Estrogen exposure is a principal index for women's health. Abnormal estrogen exposure can induce several age-related diseases such as cardiovascular disease, osteoporosis, endometrial cancer, and ovarian cancer. There are plenty of studies about the age at menarche or menopause but not enough for estimated lifetime estrogen exposure (ELEE) even though epidemiological studies have reported that ELEE is associated with women's health. To identify novel genetic loci for ELEE and to replicate previously identified loci by genome-wide association studies (GWAS), we conducted GWAS in three cohorts of Korean postmenopausal women and meta-analyses.

METHODS: Among study participants of the Korean Genome and Epidemiology Study including the Health EXAminee (HEXA, N=38,401) study, the CARdioVascular disease Association Study (CAVAS, N=5,046), and the Ansan and Ansung study (N=2,877) with genome-wide single-nucleotide polymorphism (SNP) data, we included women who experienced natural menopause for this study (N=18,535 in HEXA, N=2,827 in CAVAS, and N=1,434 in Ansan and Ansung study). ELEE was calculated by subtracting the age at menarche from the age at menopause. To identify SNPs associated with ELEE, multivariable linear regression model was used adjusted for age and age at menarche and the results of three GWAS were meta-analyzed. We selected 40 menopause, menarche, and sex hormone susceptibility SNPs ($P < 5 \times 10^{-8}$) in East Asian population from the GWAS catalog for replication study.

RESULTS: Among 37 SNPs satisfying nominal genome-wide significance level ($P < 5 \times 10^{-8}$) in HEXA study, 12 SNPs were replicated in CAVAS or Ansan and Ansung study ($P < 0.05$). In meta-analysis, we found 26 novel SNPs ($P < 5 \times 10^{-8}$). The strongest association with ELEE was observed in the SNP rs13438 (*HI-10*, Beta (SE)=-0.4705 (0.0560), $P=4.63 \times 10^{-17}$) and rs60527165 (*HMCES*, Beta (SE)=-0.4896 (0.0586), $P=7.31 \times 10^{-17}$). The most frequent genetic association on ELEE was mapped to two genes, *SLC44A4* (rs660594, rs644774, rs494620, rs2242665, rs2242664, and rs3130482) and *PRRC2A* (rs3763295, rs2857693, rs2736171, rs2242657, and rs1046089). In replication study, 8 out of 40 previous GWAS-identified SNPs ($P < 5 \times 10^{-8}$; rs13438, rs365132, rs353493, rs2269475, rs28797500, rs3814226, rs2277339, and rs28403619) were replicated to be associated with ELEE.

CONCLUSION: We replicated 8 GWAS-identified susceptibility SNPs for ELEE and identified 26 novel SNPs for ELEE in the current GWAS. The new and replicated genetic variants for ELEE could facilitate identification of population with the longer duration of lifetime estrogen exposure for women's health.

Complex Traits Posters - Thursday

PB1240. A genome-wide association study of mammographic density phenotypes among pre-menopausal women of European ancestry.

Ctr., Seattle, WA, ²⁴Div. of Epidemiology, Population Hlth.Sci., Weill Cornell Med., New York, NY, ²⁵Princess Margaret Comprehensive Cancer Ctr., Toronto, ON, Canada

Abstract Body:

Background: Several genetic variants have been found to be associated with mammographic density, a strong risk factor for breast cancer. However, most prior studies consisted of post-menopausal women, and genetic factors associated with mammographic density may differ across the lifespan. In particular, our understanding of the genetic influence of breast composition during adolescence, pregnancy, and breastfeeding is very limited. Methods: We utilized existing genotype and breast composition data from four studies, including a study of young women with magnetic resonance measurements of breast water (N=851), and studies of pre-menopausal women with digitized mammograms from the Breast Cancer Association Consortium (BCAC, N=6,322). Measurements of breast density within each study were transformed and standardized to improve comparability across studies. We performed a GWAS meta-analysis in up to 7,173 women for three mammographic density phenotypes: percent density (PD), dense area (DA), non-dense area (NDA), and adjusting each study for age at breast composition measurement, BMI, and principal components. Results: We identified one region, 8p11.23, associated with NDA at a genome-wide significant level (p-value = 1.01×10^{-10} for lead SNP, rs16885613). This variant has been identified in previous mammographic density and breast cancer GWAS with the same directions of effect. We did not identify any statistically significant findings for the DA and PD GWAS. However, we observed suggestive significance for associations with MD phenotypes, including 19q13.31 with NDA (p-

ASHG 2022 Annual Meeting Poster Abstracts

value = 1.59×10^{-7} for lead SNP, rs56681946) and 4q13.3 with DA (p-value = 1.10×10^{-7} for lead SNP, rs62314947). When restricting the analysis to the young women only, we observed no genome-wide significant associations. Conclusion: Despite the high heritability of mammographic density (approximately 0.60-0.70), very little is known about the genetic variants and biological mechanisms influencing breast tissue composition in early life. Additional analyses in larger and more diverse sample sizes of young and/or pre-menopausal women are warranted to better elucidate genetic factors associated with breast tissue composition, including mammographic density, over the life course.

Complex Traits Posters - Wednesday

PB1241. A Haptoglobin (HP) Exon Deletion Polymorphism Alters the Effect of *APOE* Alleles on Alzheimer's Disease in Individuals of European Ancestry with *APOEε4*

Hussman Inst. for Human Genomics, Univ. of Miami, Miami, FL, ⁸Dept.s of Med. (BioMed. Genetics), Neurology, Ophthalmology, Biostatistics, and Epidemiology, Boston Univ. Sch.s of Med. and Publ. Hlth., Boston, MA, ⁹Vanderbilt Memory & Alzheimer's Ctr., Vanderbilt Univ. Med. Ctr., Nashville, TN, ¹⁰Dept. of Population & Quantitative Hlth.Sci., Case Western Reserve Univ. Sch. of Med., Cleveland, OH

Abstract Body:

Haptoglobin (HP) is an antioxidant of apolipoprotein E (APOE) — the strongest risk gene for sporadic Alzheimer's disease (AD). The *HP* gene has two functional alleles, *HP2* and *HP1*, which contains a two-exon deletion that changes its protein structure conformation. We hypothesize that this structural variant is associated with AD. To investigate this, we imputed the *HP* genotypes for 12,418 cases and 11,684 controls from the Alzheimer's Disease Genetics Consortium (ADGC), respectively within each cohort of 29 European ancestry cohorts, using a custom reference panel. We then evaluated the effects of *HP* genotype and *APOE* genotype on AD status, both individually and their interaction, using a logistic regression model, adjusting for sex, age, and the first 3 ancestry-based principal components. In this model, we included the *APOE ε2*, *ε3*, and *ε4* alleles by encoding them additively (i.e. 0, 1, and 2) as a continuous variable — *APOEε2-3-4* — to capture both the protective effect of *APOEε2* and the detrimental effect of *APOEε4*. We found *HP* influences AD risk through interactions with *APOE*. Among *APOEε4* carriers (i.e. individuals with *APOEε24*, *ε34*, or *ε44*, n=9,949), *HP2* additively decreased AD risk (OR=0.83 per allele, p=0.031). Furthermore, the interaction of *HP* and *APOEε2-3-4* among *APOEε4* carriers also showed that each copy of the *HP2* allele leads to an increase in AD risk from *APOEε2-3-4* (OR=1.18 per allele, p =0.025). In contrast, among *APOEε2* carriers (n=2,515) the *HP2* allele increased the AD risk (OR=1.40 per allele, p=0.071), while the *HP2* allele led to a decreased change of the risk in *APOEε2-3-4* (OR=0.75 per allele, p=0.035). Analyses of *APOEε3* carriers did not show any significant effects of the *HP* alleles or any significant *HP/APOE* interactions. We also analyzed age at AD onset with a Cox proportional hazard regression model. Significant effects were found for *APOEε2-3-4*, and the *HP2* effect was marginally significant (p=0.07). The directions of these effects (positive/negative) are congruent to our findings in logistic regression models. *HP* impacts AD risk and modifies the effect of *APOE*. These findings suggest the *HP* genotypes should be considered where *APOE* adjustment and stratification is needed for AD risk determination. Though the precise mechanism still awaits investigation, *HP* is known to bind directly to *APOE* and our results may suggest a possible differential anti-oxidative ability of *HP* proteins for distinct *APOE* proteins that impact their function.

PB1242. A large-scale genome-wide association meta-analysis of polycystic ovary syndrome in over 540,000 women provides insights into biological mechanisms

Authors:

K. Actkins¹, L. M. E. Moolhuijsen², F. Day³, T. Karaderi⁴, B. H. Mullin⁵, J. Zhu⁶, N. Pujol-Gualdo⁷, C. K. Welt⁸, L. K. Davis⁹, International PCOS Consortium; ¹NIH, Research Triangle Park, NC, ²Univ. Med. Ctr. Rotterdam, Rotterdam, Netherlands, ³Cambridge Univ., Cambridge, United Kingdom, ⁴Univ. of Cambridge Sch. of Clinical Med., Cambridge, United Kingdom, ⁵Univ. of Western Australia, Perth, Australia, ⁶Boston Children's Hosp., Boston, MA, ⁷Univ. of Tartu, Tartu, Estonia, ⁸Univ. of Utah Sch. of Med., Salt Lake City, UT, ⁹Vanderbilt Univ Med Ctr., Nashville, TN

Abstract Body:

INTRODUCTION: Women with polycystic ovary syndrome (PCOS) often exhibit adverse cardiometabolic profiles in addition to suffering from poor reproductive outcomes and increased testosterone levels. Symptom variation exhibited by patients has been attributed to the complex genetic architecture of PCOS, where symptoms can present as reproductive or metabolic features. To identify novel genetic associations involved in the etiology of the syndrome, we performed the largest genome-wide association (GWA) meta-analysis of PCOS to date in women of diverse ancestral origins. **MATERIAL AND METHODS:** We conducted a fixed-effect, inverse-variance weighted meta-analysis in 11,653 PCOS cases and 423,614 controls from 13 cohorts of European (86.5%), East Asian (10%), African (2.2%), and Hispanic (1.3%) ancestry. (1) Age-adjusted, and (2) age and body mass index (BMI)-adjusted models were used in all-ancestries combined and European only meta-analyses. Results were then meta-analyzed with a previously published European GWA meta-analysis, bringing the total to 21,570 PCOS cases and 523,971 controls. Secondary analysis included annotation of genome-wide identified variants using Summary-data-based Mendelian Randomization (SMR) in relevant tissues from the Genotype-Tissue Expression project and a genetic risk score (GRS) analysis within the UK Biobank using PRS-CS. **RESULTS:** In total, 21 loci were identified in the all-ancestries meta-analysis, of which 8 loci were novel. For the first time, a genetic association in the *FTO* region was identified, supporting reported epidemiological associations between PCOS and BMI. Using SMR, we identified several potential effector genes acting through reproductive tissues, including the DNA-repair *NEIL2* gene located at 8p23.1 in ovarian and pituitary tissues. Similar to the previous GWA meta-analysis, risk alleles were linked to genes involved in regulating reproductive hormonal pathways, including *FSHB*, *SHBG*, *INHBB* and *TEX41*. PCOS GRS was significantly associated with cardiovascular, metabolic, and mental health outcomes, such as coronary artery disease and depression, in both men and women. **CONCLUSION:** The current study identified novel PCOS-associated genetic variants, providing new insights into biological mechanisms involved in PCOS etiology, and highlighting disease implications for women as well as men within the genetic risk spectrum of PCOS.

Complex Traits Posters - Wednesday

PB1243. A Mendelian randomization study of genetic liability to Post-traumatic stress disorder and risk of Ischemic Stroke.

Authors:

O. Soremekun¹, C. Musanabaganwa², A. Maddalena³, T. Chikowore⁴, M. Uddin⁵, S. Fatumo⁶; ¹MRC/UVRI & LSHTM, Entebbe, Uganda, ²Med. Res. Ctr., Rwanda Biochemical Ctr., Rwanda, Rwanda, ³Dept. of Epidemiology and Biostatistics, Imperial Coll., London, United Kingdom, ⁴16MRC/Wits Dev.al Pathways for Hlth.Res. Unit, Dept. of Pediatrics, Faculty of Hlth.Sci., Univ. of the Witwatersrand,, Johannesburg, South Africa, ⁵Coll. of Publ. Hlth., Univ. of South Florida, University of South Florida, FL, ⁶UVRI P.O.Box 49, Entebbe-Uganda., Entebbe, Uganda

Abstract Body:

Background:Observational studies have shown an association between post-traumatic stress disorder (PTSD) and ischemic stroke (IS) but given the susceptibility to confounding it is unclear if these associations represent causal effects. Mendelian randomization (MR) facilitates causal inference that is robust to the influence of confounding.**Methods:** Using two sample MR, we investigated the causal effect of genetic liability to PTSD on IS risk. Ancestry specific genetic instruments of PTSD and four quantitative sub-phenotypes of PTSD, including hyperarousal, avoidance, re-experiencing, and total symptom severity score (PCL-Total) were obtained from the Million Veteran Programme (MVP) using a threshold P-Value (P) of $< 5 \times 10^{-7}$, clumping distance of 1 Megabase (Mb) and $r^2 < 0.01$. Genetic association estimates for IS were obtained from the MEGASTROKE consortium (Ncases = 34,217, Ncontrols = 406,111) for European ancestry individuals and from the Consortium of Minority Population Genome-Wide Association Studies of Stroke (COMPASS) (Ncases = 3,734, Ncontrols = 18,317) for African ancestry individuals. We used the inverse-variance weighted (IVW) approach in our primary analysis and performed MR-Egger and the weighted median methods as pleiotropy-robust sensitivity analyses.**Results:** In European ancestry individuals, we found evidence of an association between genetic liability to hyperarousal, avoidance, and PCL-Total and IS risk (odds ratio (OR)1.06, 95% Confidence Interval (CI) 1.000 to 1.125, P = 0.031 for hyperarousal; OR 1.05, 95% CI 1.016 to 1.085, P = 0.004 for avoidance; OR 1.03, 95% CI 1.010 to 1.041, P = 0.001 for PCL-Total). In African ancestry individuals, we found evidence of an association between genetically liability to PCL-Total and IS risk (OR 0.95 (95% CI 0.913 to 0.988, P = 0.01) but no association was observed for PTSD case control, hyperarousal, avoidance, or re-experiencing. Similar estimates were obtained with MR sensitivity analyses. **Conclusion:** This study provides genetic support for a casual effect of some PTSD traits on IS risk in European ancestry individuals. Except in PCL-Total, no MR evidence was found in some PTSD traits and risk of IS in African ancestry individuals. These findings warrant further investigations in larger genetic cohorts especially in African ancestry individuals.

Complex Traits Posters - Thursday

PB1244. A multi-ancestry genome-wide association study identifies two novel loci associated with increased risk of diabetic macular edema.

Authors:

A. Stockwell¹, M. Chang¹, W. Forrest¹, L. Orozco¹, S. Selvaraj¹, N. Creps¹, A. Mahajan¹, L. Macri², A. N. Neerajan², M. McCarthy¹, M. van der Brug², S. Scales¹, B. Yaspan¹; ¹Genentech, South San Francisco, CA, ²Character BioSci.s, San Francisco, CA

Abstract Body:

Diabetic retinopathy (DR) is a common complication of diabetes. Approximately 20% of DR patients have diabetic macular edema (DME), characterized by fluid leakage into the retina. While there is an accepted genetic component to DR and DME risk, currently there are few replicable loci. Focusing on the DME subtype could increase power to find novel loci associated with DME risk.

We conducted a multi-ancestry, common variant (MAF $\geq 1\%$) genome-wide association study to assess DME risk in 1,195 DME patients and 4,703 controls using an additive model, adjusted for genetic ancestry, age, and sex. Ancestry specific cohorts were analyzed separately. An additional cohort of 307 DME cases and 900 controls was used to replicate genome-wide significant results using METAL. Patient samples were obtained from Roche/Genentech clinical trials and Character Biosciences.

We identified two novel loci reaching the pre-specified GWAS significance threshold of $p \leq 5E-8$. The strongest association in our discovery dataset was rs2239785 (OR=1.71; $P=5.05E-23$), a missense variant (K150E) in *APOLI* previously associated with chronic kidney disease (CKD) in African Americans. The frequency of this SNP was highest in African American DME patients (EAF=0.76), more than twice of European DME patients (EAF=0.31). The population attributable risk percent in the African American cohort is 5.16 for the *APOLI* locus, a substantially increased compared to those of European descent (1.85). This is due to the G1 and G2 haplotypes at *APOLI*, unique to individuals of African descent, and also well-established to associate with CKD. The second genome-wide significant peak was rs10402468 (OR=1.58; $P=4.6E-13$), intronic within *BABAMI* and a cis-eQTL with *PLVAP* and *ANKLE1* in vascular / endothelium tissues. We replicated both rs2239785 (OR=1.41; $P=0.003$) and rs10402468 (OR=1.31; $P=0.03$) in an independent cohort.

In our multi-ethnic GWAS, we report two novel loci for risk of DME, one of which, *APOLI*, is a major risk factor in African Americans with diabetes for developing DME complications. Our lead SNP at *APOLI*, rs2239785, is polymorphic in multiple ancestries; however, unique variation of African descent on the same haplotype identified in CKD patients substantially increases its overall risk on a population level.

Complex Traits Posters - Wednesday

PB1245. A multi-ethnic genome-wide association study in type 1 diabetes.

Authors:

D. A. Michalek¹, C. Tern¹, W-M. Chen^{1,2}, W. Zhou^{3,4,5}, T1DGC, S. Onengut-Gumuscu^{1,2}, S. S. Rich^{1,2}; ¹Ctr. for Publ. Hlth.Genomics, Univ. of Virginia, Charlottesville, VA, ²Dept. of Publ. Hlth.Sci., Univ. of Virginia, Charlottesville, VA, ³Analytic and Translational Genetics Unit, Dept. of Med., Massachusetts Gen. Hosp., Boston, MA, ⁴Stanley Ctr. for Psychiatric Res., Broad Inst. of MIT and Harvard, Cambridge, MA, ⁵Program in Med. and Population Genetics, Broad Inst. of Harvard and MIT, Cambridge, MA

Abstract Body:

Background: Type 1 diabetes (T1D) is an autoimmune disorder in which pancreas produces little or no insulin from the destruction of pancreatic β -cells. To date, GWAS meta-analyses and fine mapping studies have identified over 80 loci associated with risk of T1D. **Objective:** Utilize a multi-ethnic GWAS approach in T1D cases, controls and families for discovery of novel genetic variants associated with the risk and age-at-onset of T1D. **Methods:** The T1DGC data included 3,222 families (11,476 individuals, majority of European ancestry), 891 unrelated African ancestry (AFR, 409 T1D cases, 482 controls) and 308 unrelated Admixed (AMR, 153 T1D cases, 155 controls) individuals. All samples were genotyped on the Illumina CoreExome BeadChip array. A total of 430,930 SNPs passed quality control metrics and were used for imputation (TOPMed), and HLA region gene and amino acid alleles were imputed on the four-digit multi-ethnic HLA reference panel. 13,965,323 variants (MAF > 0.01) were obtained from imputation, including 20,425 HLA region variants (MAF > 0.005). HLA region variants were analyzed using HLA-TAPAS. GWAS for the T1D risk was conducted based on a logistic mixed model using SAIGE and GWAS for the age-at-onset of T1D was performed based on a survival model using GATE. **Results:** Five loci were significantly associated with T1D risk and/or age-at-onset, including the MHC (T1D risk: rs9273364, $P = 4.73 \times 10^{-322}$; age-at-onset: rs9273368, $P = 1.13 \times 10^{-290}$; both in *HLA-DQB1*), *INS* (rs3842753, T1D risk: $P = 1.06 \times 10^{-29}$; age-at-onset: $P = 3.01 \times 10^{-26}$), *PTPN22* (T1D risk: rs6679677, $P = 6.22 \times 10^{-15}$; age-at-onset, $P = 1.38 \times 10^{-14}$), *SH2B3* (T1D risk: rs10774624, $P = 1.40 \times 10^{-11}$; age-at-onset, $P = 2.22 \times 10^{-10}$), *ERBB3* (T1D risk: rs11171747, $P = 2.40 \times 10^{-8}$) and *RAB5B* (age-at-onset: rs773107, $P = 2.15 \times 10^{-8}$). A new locus, *NRPI* (rs722988, $P = 2.18 \times 10^{-8}$) on 10p11.22 was identified and reached the genome-wide significance in AFR, AMR only meta-analysis. Fine mapping across ancestry groups in the HLA region revealed *HLA-DQA1*03:01* as the most significant HLA allele in AFR and AMR ($P > 10^{-8}$) and *HLA-DRB1*03:01* in EUR ($P > 10^{-8}$). **Conclusions:** Inclusion of subjects with diverse genetic ancestry allowed us to identify new genome regions associated with risk and progression of T1D. Age-at-onset analyses pinpointed five regions harboring variants that may accelerate or delay onset of T1D. Further fine mapping studies can help us identify new targets that can be exploited to delay T1D progression and improve patient outcome.

Complex Traits Posters - Wednesday

PB1246. A nationwide approach to understand the role of health, socioeconomic and genetic information in predicting COVID-19 vaccination uptake

Authors:

A. Ganna¹, B. Jermy², T. Hartonen¹, P. Vartiainen¹, M. Daly³, H. Ollila², S. Ripatti⁴, M. Perola⁵; ¹Inst. for Molecular Med. Finland, Helsinki, Finland, ²Univ. of Helsinki, Helsinki, Finland, ³Massachusetts Gen. Hosp., Boston, MA, ⁴Inst. for Molecular Med. Finland FIMM, Helsinki, Finland, ⁵Finnish Inst Hlth & Welfare, Helsinki, Finland

Abstract Body:

The high prevalence of people unvaccinated for COVID-19 is a key issue in public health. Identifying individuals likely to decline vaccinations can help to reduce the disease burden. Here, we aim to identify potential predictors of COVID-19 vaccination uptake by combining nationwide registries covering disease history, drug purchases, environmental, socioeconomic and demographic information for the entire Finnish population (5.5 million individuals). We considered 2,994 predictors measured before 31.12.2019 and vaccination uptake between 27.12.2020 and 31.10.2021. To identify genetic predictors, we performed a GWAS of vaccination uptake in a subset of 247,600 individuals (8% unvaccinated) part of the FinnGen study.

Among the strongest phenotypic predictors were speaking a mother tongue other than Finnish or Swedish (OR \approx 1.27, P-value $<$ 2.2e-16), having ever received social assistance (OR \approx 1.08, P-value \approx 4.0e-4), having ever been in an assisted living facility (OR \approx 1.11, P-value \approx 1.0e-3) and having had an Hepatitis C infection (OR \approx 1.23, P-value \approx 2.5e-3). We combined individual predictors within consistent phenotypic categories and used LASSO to predict vaccination uptake. We showed that income in 2019, job occupation, drug purchase history, and place of residence were the most predictive categories. For example, a model trained using income information from year 2019 obtained an AUC of 0.687 (95% CI: 0.684-0.689) which is approximately 16% higher than a baseline model (age and sex). Each of the individual categories were outperformed by a model combining all predictors, obtaining an AUC of 0.774 (95% CI: 0.772-0.776).

We observe a strong genetic correlation with a GWAS of participation in optional components of UK Biobank ($r_g = -0.35$, $p_{val} = 6 \times 10^{-7}$) indicating shared underlying effects between participation in scientific studies and vaccination uptake. Higher genetic risk for COVID-19 is correlated with not taking the vaccine ($r_g = 0.22$, $p_{val} = 0.0378$). A polygenic risk score predicting vaccination status obtained an AUC of 0.578 (95% CI: 0.567-0.589). Replication in Estonia Biobank is ongoing.

We provide a comparative, nationwide framework to identify the most important predictors of COVID-19 vaccination. Socio-economic information such as job occupation were the strongest predictors of vaccination uptake, more than health and genetic information. Genetic signal was low ($h^2_{SNP} \sim 1\%$), yet genetic correlations could be used to identify unmeasured behavioral correlates of vaccination uptake. Data-driven identification of subpopulations to target with information campaigns can help in resource allocation and in reducing the COVID-19 burden.

Complex Traits Posters - Thursday

PB1247. A novel missense variant in melanopsin associated with delayed sleep phenotype: A whole genome sequencing study.

Authors:

J. Brzezynski, A. Kaden, C. Johnson, S. Smieszek, C. Polymeropoulos, G. Birznieks, M. Polymeropoulos; Vanda Pharmaceuticals Inc., Washington, DC

Abstract Body:

Melanopsin (*OPN4*) is a blue light-sensitive opsin-type G-protein coupled receptor (GPCR). It is highly expressed in photosensitive retinal ganglion cells which mediate responses to light, including regulation of sleep, circadian photoentrainment, and pupillary light response. Consequential variants in *OPN4* were previously associated with increased risk of developing seasonal affective disorder.

We have conducted a rigorous observational research study in suspected delayed sleep-wake phase disorder (DSWPD) patients with the aim of detecting consequential variants that may be associated with the delayed sleep phenotype. Altogether, 119 participants were consented and 76 participants provided samples for whole genome sequencing (WGS).

We report a carrier of rs143641898 *OPN4*:NM_033282:exon4:c.C502T:p.R168C, a rare missense variant (gnomAD MAF 0.0002, predicted damaging). R168C is a highly conserved variant and is part of the E/DRY motif found in nearly all GPCRs (positive charge to polar, increased hydrophobicity).

Interestingly, this variant was tested using an *in vitro* expression system as part of a study aiming to determine the functional phenotypes of missense human *OPN4* variants. This variant was shown to be incapable of binding retinal chromophore, suggesting that it renders the *OPN4* protein non-functional. Additionally, introduction of R168C in *OPN4* abolished responses to light. This carrier is a 61-year-old White male manifesting delayed sleep symptoms since high school, meeting the DSWPD diagnostic criteria. Their Dim Light Melatonin Onset (DLMO) was 23:25 (based on a salivary threshold of 3 pg/mL), which also supports the delayed phenotype. We do not detect this variant in our healthy super control set of WGS samples (n = 300), nor in our control set of WGS samples (n = 1900). In this WGS study of suspected DSWPD patients, we report one other rare stop gain variant within the *OPN4* gene (*OPN4*:NM_033282:exon6:c.847_848insGGTAGC;p.W283delinsWX).

The identification of consequential *OPN4* variants such as R168C that lead to the disruption of protein function and melanopsin-based light perception will help identify patients with an increased risk of sleep disturbances and circadian dysfunction.

Complex Traits Posters - Wednesday

PB1248. A pan cancer immunogenomic atlas and its applications for immune checkpoint blockade immunotherapy

Authors:

J. Yang, Q. Liu, Y. Shyr; Vanderbilt Univ. Med. Ctr., Nashville, TN

Abstract Body:

A low response rate is the major challenge for existing immune checkpoint blockade (ICB)-based cancer immunotherapies. A number of biomarkers have been reported to be associated with the likelihood of patient responses to ICB, including the expression of target ligands such as *PD-L1*, co-inhibitory receptors such as *PDCDI*, tumor mutational burden (TMB), tumor infiltration lymphocytes, T cell repertoire. However, these biomarkers showed variable performance in different cohorts. And most published signatures were only evaluated on limited cohorts and showed ungeneralizable performance across different cohorts. In addition, establishing a cohort with adequate sample size requires multiple years of multi-center efforts. Therefore, it is still a lack and a challenge for evaluation of efficacy of known biomarkers and the discovery of new signature(s) in a large-scale study. Here we developed Cancer-Immu (<http://bioinfo.vanderbilt.edu/database/Cancer-Immu/>) to prioritize genomic features associated with ICB response, containing 3,652 samples for 16 cancer types. Cancer-Immu provides two analysis strategies, meta-analysis and pan-cancer analysis. Meta-analysis reveals consistent signatures across multiple tumor/study cohorts, while pan-cancer analysis enhances our ability to detect and analyze rare features by aggregating samples across cohorts/tumor types. Furthermore, Cancer-Immu enables linking dynamic features with immunotherapy response. Cancer-Immu also allows users to upload and analyze their own data independently or to co-analyze with existing data simultaneously. Based on these data and methods, we not only identified known features such as TMB, *IFNG*, *PDCDI* and *LAG3* expression, but also novel biomarkers such as proportions of M1 macrophage, expression of *IL21*, *ZBED2*, *CCL19*, CTL pathway and CXCR3 binding pathway. Multiple genes and pathways related to ICB response are involved in macrophage activity, T cell cytotoxicity and recruitment, suggesting the potential role of interaction between T cells and macrophages in cancer immunotherapy. Single-cell RNA sequencing confirmed that *IFNG* from T cells induced *IRF1* expression of M1 macrophage, TAM, and tumor, promoting T cell chemo-attractants CXCL10 and/or CXCL11 secretion in those cells. The secretion of CXCL10/11 further recruited T cells and enhanced anti-tumor immunity through CXCR3-CXCL10/11 axis. Overall, Cancer-Immu provides a comprehensive resource for identifying predictive genomic features of immunotherapy response, and presents an easy way for known biomarker assessment, novel signature discovery, and signature-of-interest validation.

Complex Traits Posters - Thursday

PB1249. A polygenic score-based approach improves discrimination between familial, idiopathic, and pathologic short stature in a cohort of pediatric patients presenting for evaluation

Authors:

J. Shelley¹, M. Shi², B. Schuler¹, S. Van Driest¹, J. H. Simmons¹, J. Mosley³; ¹Dept. of Pediatrics, Vanderbilt Univ. Med. Ctr., Nashville, TN, ²Dept. of BioMed. Informatics, Vanderbilt Univ. Med. Ctr., Nashville, TN, ³Dept. of Med., Vanderbilt Univ. Med. Ctr., Nashville, TN

Abstract Body:

Introduction: Short stature in children may be an early manifestation of systemic disease or related to a benign, genetic predisposition to shorter height. A child's anticipated height is estimated by mid-parental height (MPH), an average of the parental heights. Children with short stature who have a low MPH are classified as having "familial short stature" (FSS). Children shorter than their MPH without underlying disease are classified as having "idiopathic short stature" (ISS), while those found to have underlying disease have a pathologic form of short stature (PSS). Height is a highly polygenic trait. We tested whether a polygenic score (PGS) for height could discriminate among children classified as FSS, ISS, and PSS.

Methods: We used summary statistics from the GIANT-UKB meta-analysis of adult height to create a PGS comprising 4,803 independent SNPs (r -square=0.01, MAF>1%) associated ($p < 5 \times 10^{-5}$) with height. We curated a cohort of pediatric patients referred for an evaluation of short stature from a clinical DNA biobank linked to an electronic health record (BioVU) to identify children with ISS, FSS and PSS. Wilcoxon signed-rank tests were used to test for differences in the PGS values across diagnoses and c -statistics were used to measure discrimination.

Results: From the cohort of 535 children, 73 were diagnosed with ISS, 44 with FSS, and 39 with PSS. 37.2% were female and median age was 9.5 (IQR: 6.6, 12.5) years. PSS was most commonly due to autoimmune disease, genetic syndrome, or hypopituitarism. The respective median (IQR) z -scores for MPH and PGS were (-0.74 [-1.50, -0.45], -0.92 [-1.49, -0.40]) for the FSS group, (0.06 [-0.68, 0.62], -0.90 [-1.61, -0.33]) for ISS and (0.39 [0.17, 0.73], 0.06 [-0.53, 0.78]) for PSS. There was a significant difference in the PGS values between PSS and both FSS (difference=0.98 standard deviations, $p = 2.7 \times 10^{-5}$), and ISS (difference=0.96, $p = 3.6 \times 10^{-6}$). There was no difference in the PGS values between FSS and ISS ($p = 0.73$). The PGS significantly discriminated both FSS from PSS (c -statistic: 0.76 [95% CI: 0.65, 0.87]) and ISS from PSS (0.77 [0.67, 0.86]), but not FSS and ISS (0.52 [0.42, 0.57]).

Conclusion: A PGS for height differed significantly among these short stature phenotypes. Consistent with classification based on MPH, children with pathological short stature were not genetically predisposed to lower height. However, children diagnosed with idiopathic short stature were frequently predisposed to shorter height based on the PGS, inconsistent with their MPH estimates. This suggests that some of these children likely have familial short stature. A PGS could improve classification of some short stature subtypes.

Complex Traits Posters - Wednesday

PB1250. A second wave SARS-CoV-2 variant in Quebec is associated with persistent infection.

Authors:

D. Fournelle^{1,2}, E. Brunet-Ratnasingham^{1,3}, F. Mostefai^{1,2}, R. Poujol², J-C. Grenier², N. Chomont^{1,3}, S. Moreira⁴, D. E. Kaufmann^{1,3}, M. Craig^{1,5}, J. Hussin^{1,2}; ¹Univ. de Montreal, Montreal, QC, Canada, ²Montreal Heart Inst., Montreal, QC, Canada, ³Ctr. de recherche du CHUM, Montreal, QC, Canada, ⁴Laboratoire de santé publique du Québec, Montreal, QC, Canada, ⁵Ctr. de recherche du CHU Sainte-Justine, Montreal, QC, Canada

Abstract Body:

We are still living in the SARS-CoV-2 pandemic over two years after its start. In the Canadian province of Québec, the second wave of infections occurred between the end of August 2020 and the end of March 2021. This was an interesting period of viral diversity owing to imposed travel restrictions that created competition between multiple pockets of local strains prior to the introduction of international variants of concern such as Alpha, Delta and Omicron. The height of the second wave in Quebec was characterized by two now defunct variants (B.1.160 and B.1.1.176) that accounted for just under 50% of sequenced cases in the province. The B.1.160 variant has a mutation to the S protein (S477N) that is known to strengthen binding to receptor ACE2. In Québec, a substrain of B.1.160 also developed a T20I mutation on the S protein. Case studies from patients infected with the Quebec specific B.1.160, showed that this specific variant had the potential to cause infections that persisted for several months, including periods during which the virus was not detectable by PCR tests. We analyzed 4 time points and found that the second and third time points, taken a little before 5 months of infection, have several mutations that completely disappear by the fourth time point, taken over 6 months after the first sample was collected. The patient also acquires 2 different mutations on codon 484 of the S protein, both associated with immune escape and present in VOCs Beta, Gama and Omicron. This longitudinal analysis shows that mutational patterns of intra-host mutations in our patient are in line with the presence of a viral reservoir. This raises the question of whether some cases of long COVID were due to lingering infections that could not be detected by PCR tests.

Complex Traits Posters - Thursday

PB1251. A single nucleus transcriptomics study of alcohol use disorder in postmortem brain tissue

Authors:

S. Clark¹, L. Y. Xie², K. A. Aberg², E. J. C. Van den Oord²; ¹Texas A&M Univ., College Station, TX, ²Virginia Commonwealth Univ., Richmond, VA

Abstract Body:

Alcohol use disorder (AUD) is a chronic and debilitating brain disorder. Gene expression studies offer promising opportunities to better understand the underlying pathogenic processes. As cells differ in their function, gene expression will typically vary across cell types. When studying bulk tissue, failure to account for this cellular diversity has a detrimental impact on the ability to detect disease associations. We therefore assayed the transcriptomes of 32,531 individual nuclei extracted from the nucleus accumbens (NAc) of 9 donors with AUD and 9 controls. We obtained 241,497 high quality reads per nucleus. Our study identified 17 clearly delineated cell-types. We detected 26 transcriptome wide significant association signals (q value < 0.1) that mainly involved a group of medium spiny neurons with both D1 type and D2 type dopamine receptors, microglia and oligodendrocytes. The alcohol related pathways detected for each cell type were consistent with the functions of those cells reported in the literature. Thus, for neurons we observed pathways for alcohol related neurodegeneration, disruption of circadian rhythms, alterations in glucose metabolism, and changes in synaptic plasticity. For microglia we found neuroinflammation and immune related pathways and for oligodendrocytes disruptions in pathways related to myelination. This identification of the specific cells from which the association signals originate is key for designing proper followup experiments and, eventually, for developing new and targeted clinical interventions.

Complex Traits Posters - Wednesday

PB1252. A Systematic Multi-omics Approach Identifies miRNA and Proteomic Dysregulation in Human Post-traumatic Stress Disorder

Authors:

J. Wang, R. Wilson, H. Li, T. Lam, A. Nairn, Traumatic Stress Brain Research Group, J. Krystal, R. S. Duman, H. Zhao, M. Girgenti; Yale Univ., New Haven, CT

Abstract Body:

Post-traumatic stress disorder (PTSD) is a severe psychiatric disease with a prevalence of ~7% in the general population. However, despite its prevalence, our understanding of the molecular determinants is limited and examination of postmortem brain tissue from donors with PTSD across genomic layers is necessary to better understand the etiopathology of this disorder. Here we present findings from the first genome-wide microRNA (miRNA) expression profile followed by proteomic analysis in postmortem PTSD brain. We identified 124 differentially expressed miRNAs that organized into PTSD-associated co-expression modules. We confirmed regulatory relationships between several differentially expressed miRNAs and their putative target proteins and protein co-expression modules. Integrative analysis identified miRNA hsa-mir-589 as a core regulating miRNA in the translational process of disease-associated protein modules for PTSD. In addition, we identified significant enrichment of genetic risk genes for other neurodegenerative and psychiatric disorders within these PTSD co-expression modules, suggesting a shared molecular pathology. Our findings support a role for miRNA dysfunction in the pathological alterations of PTSD and provide a novel framework for future studies integrating small RNA transcriptomics with proteomic profiling.

Complex Traits Posters - Thursday

PB1253. A trans ancestry genomics based approach to study the interplay between the immune system, infectious type, and HLA type, ancestry and sepsis outcome

Authors:

K. Chhugani, T. Ramesh, Y. Chang, B. Nadel, Y. Patel, A. Wong-Beringer, S. Mangul; Univ. of Southern California, Sch. of Pharmacy, Los Angeles, CA

Abstract Body:

Sepsis is a life threatening, dysregulated host response to infection that is a major cause of mortality worldwide. Sepsis has complex pathobiology which relates to the infectious agent and host immune response. The outcome of sepsis is the result of a complex interaction between pathogens and host immune defense during the course of infection. Current research approaches usually over simplify the interactions between pathogens and innate and adaptive immune systems. We developed and benchmarked transcriptomic based bioinformatics methods to accurately infer the features of the innate and adaptive immune system and virulence of infectious agents. We performed extensive benchmarking of the developed method based on the most comprehensive gold standard dataset available. We combined publicly available transcriptomics data into the largest trans-ancestry retrospective sepsis cohort with a rich set of clinical phenotypes. Our cohort will include over 3705 individuals diagnosed with sepsis across 33 individual studies. We focused on the identification of immune features like cell type composition and sepsis type respectively, associated with the severity of the infection and poor outcomes in sepsis and studying the complex interplay between the immune system and the infectious type (viral or bacterial), facilitating insights on clinical severity scores and survival status of patients. To achieve this goal, we assembled a large scale multicentre and trans-ancestry retrospective sepsis (MCMERS) cohort, including individuals diagnosed with sepsis from publicly available datasets. We compared the cell type composition of samples derived from survivors and non-survivors groups using our recently developed tool (GEDIT). Our results suggest that the relative abundance of various immune cells (e.g. Mast cells, Neutrophils) were significantly different across survivors and non-survivors (p -value $<10^{-4}$). The advanced set of genomic and immunological features which was inferred across a large scale heterogeneous population with available information about genetic ancestry and HLA type makes this study uniquely positioned to provide new insights into the complex immune response to sepsis. Results from our study will improve our understanding of the relationship between the immune system and infectious type (viral or bacterial) across individuals of diverse ancestry backgrounds.

Complex Traits Posters - Thursday

PB1254. Accurate identification of causal variants of intracellular LDL uptake via Bayesian modeling of base editor reporter screens

Authors:

J. Ryu^{1,2}, S. Barkal^{3,1}, T. Yu⁴, L. Pinello^{2,1,5}, R. Sherwood^{1,3}; ¹Harvard Med. Sch., Boston, MA, ²Massachusetts Gen. Hosp., Charlestown, MA, ³Brigham and Women's Hosp., Boston, MA, ⁴Brigham and Women's Hosp., Boston, MA, ⁵Broad Inst., Cambridge, MA

Abstract Body:

Since its first application as a genome editing tool, CRISPR-Cas9 has been harnessed to precisely alter the genome and epigenome. CRISPR base editors that induce single-nucleotide transitions have emerged as powerful tools to test the phenotypic impacts of disease-associated variants in the human population. However, base editing often results in incomplete efficiency at the target base as well as bystander edits within a window of around 5 bp. This variability in editing efficiency and genotypic outcomes hinders the identification of causal variants in high-throughput base editor screens. We, along with other studies, have recently developed base editor reporter techniques to address this problem by incorporating a target site surrogate (reporter) sequence with the same spacer and PAM sequence as the endogenous target site into the guide RNA (gRNA) construct. As the gRNA introduces base edits in both the endogenous target site and the reporter sequence, the overall editing pattern in the endogenous target site can be inferred. To utilize the reporter editing pattern to improve the resolution of base editor screens, we have built a novel computational method that explicitly models the data generation process using the observed editing rate and pattern of the reporter sequence. We have employed this model to analyze base editor reporter screen data from two screens measuring the effects of over 10,000 gRNAs on uptake of fluorescent LDL-cholesterol. These screens include a saturation tiling screen of LDLR and a survey of LDL-cholesterol GWAS-associated variants. Our computational method shows better performance in inferring the correct effect sizes of coding and noncoding variants compared to previous approaches. Our approach has four major advantages over previous screen analysis methods based solely on gRNA counts: 1) flexible normalization to account for the different editing activity of each gRNA; 2) accurate identification of causal edits at individual nucleotides based on the reporter editing patterns; 3) interpretable and statistically robust model estimates of the posterior distribution of phenotype change induced by each variant rather than the log fold change across conditions; 4) flexibility to adapt to various experimental setups such as cell sorting methods as the model directly reflects the experimental procedure that generated the read counts. Moreover, the model improves sensitivity in screens without reporter data by accurately accounting for the editing rate of each guide. This work provides a novel and widely applicable approach to improving the power of base editor screens.

Complex Traits Posters - Wednesday

PB1255. Activity-dependent transcriptional program in glutamatergic neurons enriched for genetic risk for schizophrenia.

Authors:

Y. Ma¹, J. Bendl¹, B. J. Hartley¹, J. F. Fullard¹, R. Abdelaal¹, S-M. Ho¹, R. Kosoy¹, P. Gochman², J. Rapoport², G. E. Hoffman¹, K. J. Brennand³, P. Roussos¹; ¹Icahn Sch. of Med. at Mount Sinai, New York, NY, ²NIMH, Bethesda, MD, ³Yale Sch. of Med., New Haven, CT

Abstract Body:

Converging evidence from large-scale genetic and post-mortem studies highlight the role of aberrant control of synaptic plasticity in schizophrenia. To better understand the molecular mechanisms of activity-dependent regulome contributing to risk for psychiatric disorders, we profiled the epigenomic and transcriptomic changes following membrane depolarization in human induced pluripotent stem cell (hiPSC)-derived glutamatergic neurons from individuals with children-onset schizophrenia patients and healthy controls. Multi-omic data integration associated global patterns of chromatin accessibility with gene expression and reconstructed the maps of enhancer-promoter interactions in glutamatergic neurons. Within one hour of KCl-induced depolarization, glutamatergic neurons displayed substantial changes in the expression of genes regulating synaptic function. Consistently with increased density of schizophrenia risk variants in activity-dependent enhancers, dysfunction of many of those genes was previously likewise linked to neurodevelopmental disorders. Furthermore, network analysis revealed multiple co-expressed modules consisting of both schizophrenia- and activity-associated genes whose key drivers might represent novel targets for advanced diagnosis and therapy. Overall, our framework offers an alternative approach to studying the schizophrenia-related mechanisms but also adds to mounting evidence that sequence variation within activation-dependent regulatory elements contribute to the genetic risk for schizophrenia.

Complex Traits Posters - Thursday

PB1256. Advancing rare disease research through web-based recruitment: the 23andMe Systemic Sclerosis Research Study

Authors:

K. Kukar¹, C. Wong¹, M. Moreno¹, J. Matthews¹, L. Babalola¹, W. Fahy², M. Ehm², J. Reid², S. Shringarpure¹; ¹23andMe, Inc, Sunnyvale, CA, ²GlaxoSmithKline, Brentford, United Kingdom

Abstract Body:

Rare diseases affect fewer than 200,000 individuals in the United States. Due to the low prevalence, it is challenging for scientists to find enough research participants to study rare disease genetics. Here, we demonstrate how rare disease study cohorts can be built through web-based recruitment using various patient-engagement approaches, with the example of the 23andMe Systemic Sclerosis Research Study. Systemic sclerosis (SSc) is a rare autoimmune disease characterized by vascular abnormalities, fibrosis of the skin and internal organs and the production of autoantibodies, for which there is no cure. In 2020, 23andMe Inc. launched the 23andMe Systemic Sclerosis Research Study, aimed at enrolling 1000 individuals who self-reported a diagnosis of systemic sclerosis¹. The goals were to learn more about the genetics of people living with the disease to help lead to the development of better treatments. Consenting participants were asked to provide a saliva sample for genetic analysis and complete surveys about their disease over a three year period. We used various methods to engage participants, including online advertisements, blog posts, and a collaboration with the Scleroderma Research Foundation. Within 18 months, 1594 eligible individuals enrolled in the study. Of the enrolled participants, 94% were female. The self-reported ethnicities of the enrolled participants are: 75% White or European, 5% American Indian or Alaska Native, 4% Black or African, 3% Asian, less than 1% Middle Eastern and Native Hawaiian or Pacific Islander, and 12% other. 95% of enrolled participants reported being diagnosed by a rheumatologist, and 94% reported undergoing an autoantibody blood test before diagnosis. We found this cohort to have many clinical features similar to other SSc cohorts. The median age-of-onset was 35 years for Raynaud's phenomenon, and 38 years for non-Raynaud's symptoms. Limited cutaneous SSc was the most commonly reported subtype (43%), with diffuse cutaneous SSc reported by 27%, CREST syndrome by 6%, and the remaining participants (24%) reported being unsure of their disease subtype. Among symptoms reported by participants, digital ulcers (48%) were most common, followed by interstitial lung disease (30%), pulmonary arterial hypertension (14%), and renal crisis (3%). The results from this study show that participant-powered research can help build cohorts to advance the study of rare diseases, and that web-based research models can replicate findings from other clinical cohorts. 23andMe will share data from this study through dbGaP to enable further SSc research.¹ Individuals with morphea or linear and guttate sub-types were ineligible.

Complex Traits Posters - Wednesday

PB1257. Age differences in preadipocyte proportions and expression profiles link to obesity and insulin resistance.

Authors:

A. Kar¹, M. Alvarez¹, H. Huang^{1,2}, S. T. Lee¹, M. Deal¹, K. L. Mohlke³, J. S. Sinsheimer^{1,2,4}, K. H. Pietiläinen^{5,6}, M. Laakso⁷, P. Pajukanta^{1,2,8}; ¹Dept. of Human Genetics, David Geffen Sch. of Med. at UCLA, Los Angeles, CA, ²Bioinformatics InterDept.al Program, UCLA, Los Angeles, CA, ³Dept. of Genetics, Univ. of North Carolina at Chapel Hill, Chapel Hill, NC, ⁴Dept. of Computational Med., David Geffen Sch. of Med. at UCLA, Los Angeles, CA, ⁵Obesity Res. Unit, Res. Program for Clinical and Molecular Metabolism, Faculty of Med., Univ. of Helsinki, Helsinki, Finland, ⁶Obesity Ctr., Endocrinology, Abdominal Ctr., Helsinki Univ. Central Hosp. and Univ. of Helsinki, Helsinki, Finland, ⁷Dept. of Med., Univ. of Eastern Finland and Kuopio Univ. Hosp., Kuopio, Finland, ⁸Inst. for Precision Hlth.at UCLA, Los Angeles, CA

Abstract Body:

Obesity and related cardiometabolic diseases (CMD) display well-established age effects in epidemiological studies. However, mechanisms underlying age effects have remained largely elusive. We hypothesized that adipose tissue contributes to these CMD-related age effects in a cell-type-specific way. To this end, we first estimated the main adipose cell-type proportions in bulk adipose expression data using Bisque from 53 monozygotic (MZ) BMI-discordant twin pairs utilizing single nucleus RNA-seq (snRNA-seq) data as a reference from 6 of the 106 twins. Next, we divided each BMI discordant MZ twin pair to lower and higher BMI groups and compared cell-type proportions by age in each non-related group. In the lower BMI individuals, the younger individuals (mean age=30.4, SD=4.8) had significantly higher preadipocyte proportions ($p=0.00252$) than the older ones (mean age=64.8, SD=4.0). Noteworthy, as preadipocytes generate adipocytes, their proportions are essential for metabolically healthy adipose tissue functions. No such age-dependent preadipocyte proportion difference was seen in the higher BMI individuals. We replicated these findings in the adipose bulk RNA-seq data from the METSIM cohort ($n=335$, mean age=54.1, SD=4.9), where we similarly estimated bulk preadipocyte proportions using snRNA-seq data from 84 METSIM men. As in the twins, among the normal weight men (BMI<25), the men in the youngest age quartile had higher preadipocyte proportions than the men in the oldest age quartile ($p=0.0435$). No such age-dependent difference in preadipocyte proportions was observed in the overweight or obese METSIM men. Next, we found that 50 of the 151 preadipocyte marker genes are DE by age using snRNA-seq data. The 50 genes are significantly enriched (FDR<0.05) for multiple tissue and organ developmental pathways using WebGestalt. Of the 50 genes, 12 are correlated with adipocyte cell volume (adjP<0.05) and 10 with adipocyte cell weight (adjP<0.05) in the twins, and 21 were significantly correlated with insulin sensitivity using the Matsuda index in METSIM (Q-value<0.05). Our results show that preadipocyte proportions differ by age in normal weight individuals and that obesity reduces this metabolically favorable age-dependency in younger individuals' preadipocyte proportions. We also identify 50 preadipocyte marker genes DE by age and enriched for developmental pathways, of which 42% are correlated with insulin sensitivity. Our results suggest that adipose cell-type specific factors likely contribute to age differences in obesity-related CMDs.

Complex Traits Posters - Thursday

PB1258. Altered expression levels of *TASIR1*, *TASIR3* genes among SARS-CoV-2 variants

Authors:

M. Ergoren¹, Q. Hoti¹, G. Akan², G. Tuncel², T. Sanlidag²; ¹Sch. of Med., Near East Univ., Nicosia, Cyprus, ²DESAM Res. Inst., Near East Univ., Nicosia, Cyprus

Abstract Body:

Background: The most common symptoms of COVID-19 are fever, cough, shortness of breath, headache, ache of joints and etc. But latest scientific and medical records showed that patients with proven COVID-19 have developed a loss of smell (anosmia), and loss of taste (hypogeusia and ageusia). These symptoms are usually temporary and might manifest in absence of any other clinical symptoms but a chronic loss of smell and taste is occurring in many patients. Also, prior studies suggested that smell and taste receptors were associated with pathogenic detection and immunity. We aim to evaluate the expression profile of genes that are related to taste, smell and, appetite receptors in COVID-19 patients and their correlation with SARS-CoV-19 Delta and Omicron BA.1 variants of concerns (VOC). **Method:** Expressions of *TASIR1*, *TASIR3*, *TAS2R38*, *OR51E1*, *LEPR*, *GHRL* were detected in 100 SARS-CoV-2 RT-qPCR test result's positive patients (50 SARS-CoV-2 Delta, 50 Omicron BA.1 variants) and 100 SARS-CoV-2 RT-qPCR test result's negative samples as a control group. **Results:** The expression levels of *TASIR2* and *TASIR3*, genes were significantly decreased in COVID-19 patients who were infected with Delta variants compared to control group as well as in COVID-19 patients who were infected with Omicron BA.1 variants ($p < 0.05$). Also, *TAS2R38* gene expression level significantly lower when compared to control group ($p < 0.05$). Moreover, we found that *TASIR2* gene expression was positively correlated with *TASIR3*, and *TAS2R38* ($r=0.655$, $p=0.001$, $r=0.301$ $p=0.025$, respectively). **Conclusion:** We observed that *TASIR2*, *TASIR3* and *TAS2R38* gene expression were decreased in Delta variant which is the most disruptive and symptomatic variant caused of hospitalizations, and deaths compared to other variants. The results of our study provides a clue for loss of taste in especially in Delta variant may be cause of *ACE2* is expressed in the taste buds then the replication of SARS-CoV-2 in infected gustatory cells in the taste bud can generate inflammation and eventually destroy the cells. This direct cell damage may cause malfunction of the gustatory system.

Complex Traits Posters - Wednesday

PB1259. Alzheimer Disease plasma biomarker pTau-181 in individuals of diverse admixed ancestral backgrounds

Authors:

A. Griswold^{1,2}, F. RAJABLI¹, T. Gu¹, C. Garcia-Serje¹, J. Arvizu¹, C. Golightly¹, P. Whitehead¹, K. Hamilton-Nelson¹, L. Adams¹, M. Contreras¹, J. Sanchez¹, S. Tejada¹, P. Mena¹, T. Starks³, M. Hussman Inst. for Human Genomics, Univ. of Miami, Miami, FL, ²Dr. John T Macdonald Fndn. Dept. of Human Genetics, Univ. of Miami, Miami, FL, ³Maya Angelou Ctr. for Hlth.Equity, Wake Forest Univ., Winston-Salem, NC, ⁴Neurogenetics Res. Ctr., Inst. Natl. de Ciencias Neurologicas, Lima, Peru, ⁵Dept. of Internal Med., Univ. Central Del Caribe, Bayamon, PR, ⁶Dept. of Population & Quantitative Hlth.Sci., Case Western Reserve Univ., Cleveland, OH, ⁷Cleveland Inst. for Computational Biology, Cleveland, OH

Abstract Body:

Background. Plasma proteins, including phosphorylated threonine-181 of Tau (pTau181) can be used as readily available and inexpensive biomarkers for differential diagnosis and preclinical detection of Alzheimer disease (AD). However, most measurements of these analytes are from individuals of non-Hispanic, European ancestry. Given differences in AD risk depending on both genetics and environmental factors, generalizability of these previous findings is not assured in diverse ancestry individuals. This study evaluates the utility of plasma pTau181 in discriminating clinically diagnosed AD from cognitively intact, age-matched controls in genetically admixed cohorts. **Methods.** We measured plasma pTau181 with Simoa chemistry with the pTau181 AdvantageV2 assay on the Quanterix HD-X. Our cohorts consisted of 642 African Americans (162 AD and 480 cognitively intact controls), 906 Puerto Ricans (385 AD and 521 controls), 149 Peruvians (49 AD and 100 controls), 60 Cubans (26 AD and 34 controls), 246 individuals of non-Hispanic, European ancestry (22 AD and 224 controls), and 58 autopsy confirmed AD cases of European ancestry with plasma isolated from EDTA blood tubes. Samples were randomized, measurements performed in duplicate, and non-parametric Kruskal-Wallis tests used to detect differences in biomarker concentrations between cases and controls overall and in each cohort. Receiver operating characteristic (ROC) area under the curve (AUC) were generated to test the predictive ability of pTau181 levels in each cohort. **Results.** Overall pTau levels in AD cases was higher than controls ($2.51 \pm 1.84 \text{ pg/mL}$ vs $1.12 \pm 3.24 \text{ pg/mL}$, $p_{\text{corr}} = 1.59 \times 10^{-76}$) and this was observed in all cohorts: African Americans ($2.30 \pm 1.14 \text{ pg/mL}$ vs $1.15 \pm 2.99 \text{ pg/mL}$, $p_{\text{corr}} = 2.0 \times 10^{-27}$); Puerto Ricans ($2.33 \pm 1.82 \text{ pg/mL}$ vs $1.44 \pm 1.21 \text{ pg/mL}$, $p_{\text{corr}} = 8.2 \times 10^{-32}$); Peruvians ($2.63 \pm 1.64 \text{ pg/mL}$ vs $2.13 \pm 1.42 \text{ pg/mL}$, $p_{\text{corr}} = 0.02$); Cubans ($2.09 \pm 1.16 \text{ pg/mL}$ vs $1.35 \pm 0.67 \text{ pg/mL}$, $p_{\text{corr}} = 0.02$); and European ancestry ($2.40 \text{ pg/mL} \pm 0.78 \text{ pg/mL}$ vs $1.54 \text{ pg/mL} \pm 1.44 \text{ pg/mL}$, $p_{\text{corr}} = 0.02$). ROC analyses showed that European and African Americans had higher predictive value (AUC = 0.78) than in Hispanic cohorts (AUC = 0.73 in Puerto Ricans, 0.70 in Cubans, and 0.62 in Peruvians). **Conclusion.** This study suggests pTau181 as an AD biomarker is generalizable across ancestries, though the predictive value may differ depending on background. Ultimately, combining genomic and biomarker data, including pTau181 and other AD related plasma biomarkers such as A β 40 and A β 42, from diverse individuals will increase understanding of genetic risk and refine clinical diagnoses in individuals of diverse ancestries.

Complex Traits Posters - Thursday

PB1260. Alzheimer's disease genetic risk and plasma biomarker profiles in the Midwestern Amish

Authors:

D. Dorfsman^{1,2}, M. B. Prough¹, L. J. Caywood¹, J. E. Clouse¹, S. D. Herington¹, S. H. Slifer¹, L. D. Adams¹, R. A. Laux^{3,4}, Y. E. Song^{3,4}, A. Lynn^{3,4}, M. Fuzzell^{3,4}, S. L. Pericak-Vance^{1,2}, W. K. Scott^{1,2}; ¹John P. Hussman Inst. for Human Genomics, Univ. of Miami Miller Sch. of Med., Miami, FL, ²Dr. John T. Macdonald Fndn. of Human Genetics, Univ. of Miami Miller Sch. of Med., Miami, FL, ³Dept. of Population and Quantitative Hlth.Sci., Case Western Reserve Univ., Cleveland, OH, ⁴Cleveland Inst. for Computational Biology, Case Western Reserve Univ., Cleveland, OH, ⁵Case Western Reserve Univ. Sch. of Med., Cleveland, OH, ⁶Univ. Hosp. Cleveland Med. Ctr., Cleveland, OH

Abstract Body:

At least two-thirds of dementia cases are attributable to Alzheimer's disease (AD), a neurodegenerative disorder characterized by progressive loss of brain integrity. AD is complex, meaning the risk of occurrence depends on both inherited and environmental exposures. AD research has predominantly focused on identifying genetic variation that elevates risk. The discovery of risk-decreasing variants suggests that AD variability is also explained by genetic factors that reduce risk, highlighting an alternate strategy that prioritizes the discovery of protective variation. Studies of the aged and unimpaired have found genetic + AD pathology signatures to be diverse. The aim of this study is to explore the combined utility of whole-genome-sequence (WGS) derived AD genetic risk scores (GRS) and plasma-biomarker measures of AD pathology, to better understand how they differ within the cognitively impaired (CI) and unimpaired (CU). The study sample is drawn from the Midwestern Amish population, an endogamous population isolate with a shared lifestyle, resulting in increased genetic homogeneity with few environmental confounders. Variant calls from 1,055 WGS were obtained via the Illumina sequencing platform using GATK best practices. 312 clinically diagnosed (140 CI, 172 CU) subjects aged ≥ 75 have plasma measurements of pTau181 and total Tau. GRS were calculated using genome-wide effect sizes, including APOE, reported in Kunkle et al. (2019). By multivariate logistic regression, the best-fitting model using significant univariate results confirmed that increased GRS ($p = 0.0015$, OR = 1.83), pTau181 ($p = 0.003$, OR = 1.51), and age ($p = 0.018$, OR = 1.06) were significantly associated with cognitive impairment (CI). Further examining the CI group using multiple linear regression we find that the increasing GRS is associated with increased pTau181 ($p = 0.045$, $\beta = 0.22$), adjusting for age. Among the unimpaired, we did not observe an association between GRS and pTau181 ($p = 0.53$, $\beta = 0.015$), adjusting for age. These results indicate that there might be distinct genetic + biomarker signatures among CI and CU groups. While elevated genetic risk is associated with increased AD biomarker in the CI, we do not see the same trend in the CU. This may be explained by differences in the GRS composition that promote pathology, or by the presence of other genetic factors that actively mitigate or resist pathology. These findings will inform our efforts to characterize subgroups defined by unique genetic risk + AD pathological signatures to aid the discovery of genetic variation associated with preserved cognitive function.

Complex Traits Posters - Wednesday

PB1261*. Alzheimer's disease pathology drives distinct homeostatic and active microglia phenotypes revealing clues to early pathogenic transcriptional switches

Authors:

S. Jayadev¹, K. Prater², K. Green³, W. Sun⁴, S. Mamde¹, A. Sotelo¹, C. Smith³, K. Chiou⁵, I. Heath⁶, S. Rose¹, C. D. Keene¹, R. Kwon¹, N. Snyder-Mackler⁵, E. Blue¹, B. Logsdon⁷, J. Young¹, G. A. Ctr., Seattle, WA, ⁵Arizona State Univ., Phoenix, AZ, ⁶SAGE, Seattle, WA, ⁷Cajal NeuroSci., Seattle, WA, ⁸Univ. of North Carolina, Raleigh, NC

Abstract Body:

Microglia contribute to Alzheimer Disease (AD) progression and mediate a significant portion of AD genetic risk. Single cell transcriptomics have demonstrated that microglia adopt a spectrum of functional states. However, identifying human microglia AD molecular profiles to elucidate disease mechanisms has been limited by small numbers of microglia relative to other central nervous system cells. We report a novel approach that vastly enriched the population of microglia that can be studied for single-nucleus RNAseq (snRNAseq). Using fluorescence activated nuclei sorting followed by snRNAseq we analyzed more than 127,000 microglia from 12 AD and 10 control autopsy brain cortex resulting on average 5790 microglia per individual and 10 microglia subtypes. Beyond established subtypes such as “inflammatory” or “senescent”, the data revealed three distinct subpopulations characterized by enrichment for endolysosomal pathways with unique immunometabolic profiles. One of these three is previously unrecognized and is increased in AD cases. This endolysosomal subtype is unique in the increased expression of cytosolic DNA/RNA recognition molecules, interferon response factors (IRFs) and AD GWAS genes. We provide immunohistochemical evidence for microglia with this phenotype including accumulation of cytoplasmic DNA and aberrant lysosomal vesicles. Single-Cell Regulatory Network Inference and Clustering analysis demonstrated cluster enrichment of specific transcriptional networks within microglia subtypes and further identified apical transcription factor networks that could act as molecular switches that specify functional heterogeneity. To study the dynamics of microglia transcriptomic transitions between states, we employed the Monocle trajectory inference method. We map the progression of “homeostatic” microglia through several phenotypes and end-states. We analyzed the homeostatic microglia population and find a uniquely AD subtype differentially enriched for cellular motility and calcium regulation. Taken together our data nominate candidate genes and pathways that signify early drivers of microglia reactivity in AD. We report that the interferon signature associated with AD may relate to microglial accumulation of cytoplasmic nucleic acids and endolysosomal dysfunction. Our study demonstrates the value of deeply profiling microglia populations in each sample to allow for identification of novel and AD specific microglial subtypes including those that likely reflect early disease microglial changes.

Complex Traits Posters - Thursday

PB1262. An emirati cohort of autism spectrum disorders.

Authors:

N. Nassir¹, A. Albanna^{1,2}, A. Abou Tayoun^{2,1}, A. Ahmed¹, M. Verano¹, N. Karuvantevida³, C. Walsh⁴, M. Uddin⁵; ¹Mohammed bin rashid Univ. of medicine and Hlth. Sci.s, Dubai, United Arab Emirates, ²Al Jalila Children's Specialty Hosp., Dubai, United Arab Emirates, ³MBR Univ., DHCC, United Arab Emirates, ⁴Children s Hosp Boston, Boston, MA, ⁵Mohammed Bin Rashid Univ. of Med. and Hlth.Sci., Dubai, United Arab Emirates

Abstract Body:

Autism spectrum disorder (ASD) is a complex neurodevelopmental disorder that encompasses clinical (characterized by social impairment and repetitive behavior) and genetic heterogeneity, including rare *de novo* or inherited mutations or chromosomal rearrangements. Whole exome sequencing has emerged as a fundamental tool in the detection of susceptibility variants and causative genes underlying genetic causes of diseases, but identification of all causative variants remains elusive. We aim to identify clinically relevant variants in the ASD cohort from an ethnically homogenous population of the United Arab Emirates. We have conducted short read based whole-exome sequencing in 29 parent-offspring trio samples from the Emirati population. The analysis pipeline consists of genome alignment using BWA-MEM, Genome Analysis Toolkit GlobalHaplotyper (GATK), and annotation using Annovar. The variants were classified by the GenomeArc Analytics platform following the ACMG guidelines. We identified 121 *de novo* variants and observed that VOUS were frequently observed, in about 96% of our cases. We detected 4 likely pathogenic rare *de novo* variants impacting genes, *GLI2*, *LZTR1*, *DMWD*, and *CAPZA2*, which were validated using Sanger sequencing. We also identified novel *de novo* variants in *BRSK1* and *MAST3* genes. *BRSK1* is a part of brain-specific kinase family of genes, of which *BRSK2* is previously associated with neurodevelopmental disorders. *MAST3* is a part of microtubule associated serine-threonine kinase family of genes, whereas *MAST1* is conclusively associated with neurological diseases. The analysis of *de novo* variant containing genes showed enrichment in pathways such as the development of spinal cord and neuronal differentiation, suggesting an important role in ASD pathogenesis. Expressed early in brain development, both *BRSK1* and *MAST3* are expressed in neurons and oligodendrocytes, whereas *GLI2* is expressed in astrocytes. Our study supports the utility of whole-exome sequencing in the identification of disease-causing variants and novel ASD candidate genes, which aid in facilitating precision genetic diagnosis and its integration into novel therapeutic approaches and management of ASD patients.

PB1263. An integrated genomic and phenotypic analysis of sleep traits in autism spectrum disorder

Authors:

J. Weissenkampen¹, A. Ghorai¹, J. Zhang¹, D. Rader², R. Sebro³, T. Brodtkin¹, L. Almasy⁴, M. Bucan¹; ¹Univ. of Pennsylvania, Philadelphia, PA, ²Univ of Pennsylvania, Philadelphia, PA, ³Mayo Clinic Florida, Jacksonville Beach, FL, ⁴Children`s Hosp. of Philadelphia, Philadelphia, PA

Abstract Body:

Autism spectrum disorders (ASD) are highly heritable, yet quite heterogeneous, neurodevelopmental disorders characterized by impaired social interactions and stereotyped behavior. Variability is typical within cognitive, executive, emotional, and sleep-related phenotypes. Sleep disturbances are common in individuals with ASD and may share an underlying neurological basis with ASD. We recruited ASD individuals and their family members (370 participants) and assessed: quantitative ASD-related traits (using questionnaires), three consecutive weeks of actimetry data, and whole genome sequence (WGS) data. Forty-eight sleep, wake, and activity measures were derived from actimetry data using two different algorithms. Five-fold cross validation least absolute shrinkage and selection operator (LASSO) identified measures associated with ASD status in the training set (area under the curve (AUC): 0.84), which were then further validated in the test set (AUC: 0.78). In addition to sleep traits, LASSO identified several physical activity traits associated with ASD. The link between physical activity and ASD traits was further confirmed through polygenic risk score (PRS) in the Simons Foundation Powering Autism Research (SPARK) collection (~3,200 participants). Conditional logistic regressions stratified by family show strong correlations between ASD and walking PRS ($p = 0.022$) and most active 10 hour period activity level PRS ($p = 0.020$). PRS deciles for walking were also significantly correlated with reported sleep problems ($p < 0.002$). Significant genetic correlation was observed between walking and ASD ($p = 0.04$). An unbiased, machine learning approach identified not only sleep traits, but physical activity traits associated with ASD status in our sample and the SPARK collection. These traits may be studied further to investigate common neurological correlates between them and ASD. Furthermore, interventions targeting these traits may also potentially alleviate some sleep disturbances in autistic individuals.

Complex Traits Posters - Thursday

PB1264. An unprecedented level of complexity in the schizophrenia-associated 3q29 region of the human genome with unique segments that increase the risk for non-allelic homologous recombination.

Authors:

F. Yilmaz¹, U. GURUSAMY², T. Mosley³, Y. Mostovoy⁴, R. Purcell³, T. Shaikh⁵, M. E. Zwick⁶, P-Y. Kwok⁴, C. Lee¹, J. G. Mulle⁷; ¹The Jackson Lab. for Genomic Med., Farmington, CT, ²Univ. of California, San Francisco, San Francisco, CA, ³Emory Univ., Atlanta, GA, ⁴Cardiovascular Res. Inst. and Inst. for Human Genetics, Univ. of California San Francisco Sch. of Med., San Francisco, CA, ⁵Univ. of Colorado Anschutz Med. Campus, Aurora, CO, ⁶Dept. of Genetics, Rutgers Univ. – New Brunswick, New Brunswick, NJ, ⁷Dept. of Psychiatry, Robert Wood Johnson Med. Sch., Rutgers BioMed. and Hlth.Sci., Rutgers Univ., New Brunswick, NJ

Abstract Body:

Structural variations (SVs) contribute to genomic variation within the general population, but can also lead to genomic disorders (e.g., 3q29 deletion syndrome) by disrupting and changing the copy number of dosage-sensitive genes. Non-allelic homologous recombination (NAHR) between highly identical paralogous copies of segmental duplications (SDs) in the 3q29 region of the human genome can cause a ~1.6 million base pairs (Mbp) deletion or duplication and results in 3q29 deletion or duplication syndrome. Patients with the 3q29 deletion or duplication syndrome have neurodevelopmental and psychiatric phenotypes. However, the risk factors and underlying structures that contribute to NAHR at this locus are not well understood. To characterize the complex 3q29 region, we used long-read sequencing and optical mapping techniques. We resolved the haplotypes for the 3q29 region in 16 probands with 3q29 deletion syndrome, two probands with 3q29 duplication syndrome, and 161 individuals from 26 populations, including African, American, European, East Asian, and South Asian, from the 1000 Genomes Project. Within these sample cohorts, we identified a total of thirty-six distinct 3q29 haplotypes. Our results show that 3q29 haplotype prevalence varies significantly between populations. For instance, the H8 haplotype is observed only in individuals of African origin, while the H5 haplotype is enriched in East Asians (p-value = 5.7397e-06). Strikingly, the difference between the largest (859 kbp) and the shortest 3q29 haplotype (287 kbp) is ~580 kbp. Optical mapping data analysis of the 3q29 Project patients enabled us to resolve breakpoints in 89% of probands with 3q29 deletion or duplication syndrome, localizing these for the first time to a 5 kbp segment within complex SDs, which may indicate increased risk for NAHR, and long-read sequencing data helped to characterize breakpoints at the sequence level and refine the breakpoint junction to a 373 bp interval. Furthermore, breakpoint analysis allowed us to categorize breakpoints into three deletion and two duplication classes. We also identified large inversions ranging in size from 2.03 Mbp to 2.13 Mbp in three individuals, but contrary to previous studies of other genomic disorder loci, we did not observe these in the parental chromosome of origin for the 3q29 deletion. The results demonstrate extraordinary variation in the human 3q29 region among individuals from diverse populations. Pinpointing the breakpoints to a 5 kbp putative risk segment within SDs informs future in vitro functional studies, and helps to elucidate the underlying structures and variations that may play a crucial role in disease etiology.

Complex Traits Posters - Wednesday

PB1265. Analysis of 3,273 undiagnosed neurodevelopmental disorder trios reveals over-transmission of polygenic risk and a female protective effect

Authors:

E. Wigdor¹, Q. Huang¹, V. Chundru¹, K. E. Samocha^{2,3}, M. E. Hurles⁴, H. C. Martin¹; ¹Wellcome Sanger Inst., Hinxton, United Kingdom, ²Massachusetts Gen. Hosp., Boston, MA, ³Broad Inst. of MIT and Harvard, Cambridge, MA, ⁴Wellcome Sanger Inst., Cambridge, United Kingdom

Abstract Body:

Work in the Deciphering Developmental Disorders (DDD) study revealed an excess of rare, inherited, likely damaging coding variants (RVs) among probands without a genetic diagnosis compared to controls. Moreover, these variants are over-transmitted to probands from unaffected parents, suggesting they are pathogenic but incompletely penetrant. Using the two largest datasets of undiagnosed neurodevelopmental disorders (NDDs), we tested whether polygenic scores (PGS) modify penetrance of RVs. Further, we explored the relationship between sex and diagnostic status with NDD-associated PGS within families.

In a meta-analysis of 3,273 European-ancestry trios from DDD and Genomics England (GEL), we tested whether unaffected parents over-transmitted NDD-associated PGS to undiagnosed NDD probands. We found nominally significant over-transmission of the DDD-derived NDD PGS in 1,573 GEL probands (SD=0.05, $p=0.02$). In the meta-analysis, probands over-inherited PGS for schizophrenia (SCZ; SD=0.07, $p=2.9 \times 10^{-3}$), but transmission of educational attainment (EA) and cognitive performance (CP) PGS did not differ from expectation. However, unaffected parents (N=6,546) had lower PGS for EA (OR=0.73, $p=1.2 \times 10^{-128}$) and CP (OR=0.80, $p=5.2 \times 10^{-60}$) than controls (N=28,214), and higher PGS for NDDs (OR=1.1, $p=6.8 \times 10^{-8}$) and SCZ (OR=1.1, $p=1.2 \times 10^{-3}$). As expected, these differences were also seen between probands and controls ($p<2.2 \times 10^{-4}$), confirming common variants contributing to EA and CP play a role in NDD risk, but suggesting probands' and unaffected parents PGS do not necessarily differ for these traits.

To explore whether PGS modify the penetrance of RVs, we compared PGS between i) unaffected parents with and without RVs, and ii) RV-transmitting parents and their offspring. We did not find any significant differences.

We then investigated the relationship of sex and diagnostic status with PGS within families. Undiagnosed probands (N=1,203) had lower PGS for EA than diagnosed probands (N=3,273, OR=0.89, $p=8.5 \times 10^{-4}$), consistent with a liability threshold model. Undiagnosed male probands had nominally significantly lower PGS for NDDs than undiagnosed female probands (OR=0.87, $p=0.02$). Similarly, unaffected fathers had lower PGS for SCZ (OR=0.93, $p=0.01$) and NDDs (OR=0.91, $p=0.01$) than unaffected mothers. Both findings are consistent with a female protective effect for NDDs.

Our results confirm the role of polygenic background in NDDs but find no evidence it modifies penetrance of RVs in these disorders. Larger sample sizes, more powerful PGS and better delineation of which RVs confer risk is needed to better understand the genetic architecture of NDDs.

Complex Traits Posters - Thursday

PB1266. Analysis of adipose and liver expression profiles from dual-tissue transcriptomic cohort discovers 10 serum biomarker candidates for NAFLD.

Hosp., Kuopio, Finland, ¹⁶Bioinformatics InterDept.al Program, UCLA, Los Angeles, CA, ¹⁷Inst. for Precision Hlth., David Geffen Sch. of Med. at UCLA, Los Angeles, CA

Abstract Body:

Non-alcoholic fatty liver disease (NAFLD) is a global health problem that remains grossly underdiagnosed due to the lack of proper diagnostic tools in primary care. NAFLD comprises a heterogeneous spectrum, from simple steatosis to severe endpoints such as liver fibrosis and non-alcoholic steatohepatitis (NASH). To address the current challenges in NAFLD diagnosis, we leverage a dual-tissue transcriptomic cohort of morbidly obese Finnish individuals with RNA-seq data available from both subcutaneous adipose tissue (n=262) and liver (n=267), coupled with gold-standard liver histology-based diagnosis of steatosis, fibrosis, and NASH. We aimed to identify serum biomarker candidates (SBCs) for NAFLD secreted from the adipose tissue because we hypothesize that obesity-induced inflammatory dysfunction of adipose tissue hampers the efficient storage of fat in subcutaneous fat depots, which initiates ectopic fat deposition into the liver in metabolically unhealthy obese individuals. We discover 947 genes that are differentially expressed (DE) in adipose tissue for steatosis, fibrosis, or NASH, and designate 645 of these as adipose aware DE genes by removing genes also DE in the liver. From these, we then select genes that 1) encode for proteins secreted to serum, 2) are highly expressed in adipose tissue, and 3) are expressed >10x higher in adipose tissue than in liver, resulting in 10 SBCs for NAFLD. Using best subsets regression, we find that the adipose expression of the key SBCs, coiled-coil domain containing 80 (*CCDC80*) and superoxide dismutase 3 (*SOD3*), explains a significant proportion of variance in fibrosis ($p=1.97 \times 10^{-3}$) and NASH ($p=3.50 \times 10^{-4}$) compared to all pairs of genes in genome-wide permutations. Noteworthy, *SOD3* has been implicated for NAFLD in mice. Next, we investigate the cellular functions of *CCDC80* and *SOD3* via siRNA knockdown in human preadipocytes differentiated to adipocytes, followed by RNA-seq at four adipogenesis timepoints. We find that *CCDC80* knockdown increases the expression of the master regulator of fatty acid biosynthesis,

ASHG 2022 Annual Meeting Poster Abstracts

sterol regulatory element binding transcription factor 1 (*SREBF1*), as well as the key triglyceride hydrolysis enzyme, lipoprotein lipase (*LPL*) (adjP<0.05). We also observe that *SOD3* knockdown decreases the expression of satiety adipokine, leptin (*LEP*) (adjP<0.05). Thus, *CCDC80* and *SOD3* may contribute to NAFLD pathogenesis by modulating key functions of healthy adipose tissue. Overall, our findings have a great translational potential to improve patient health, by discovering 10 new adipose aware SBCs for NAFLD that can be further tested in independent NAFLD cohorts and ultimately in primary care.

Complex Traits Posters - Wednesday

PB1267. Analysis of both shared and specific associations among various autoimmune disorders greatly helps the identification of the causal gene(s) and the functional mechanisms

Authors:

W. Yang, X. Dang, Y. Wang; Univ. of Hong Kong, Hong Kong, Hong Kong

Abstract Body:

GWAS has identified hundreds of associated loci for autoimmune diseases such as systemic lupus erythematosus (SLE). However, in many cases the causal gene(s) in an associated locus is unclear. Functional annotations and gene proximity information often fall short in defining the causal gene(s). In this study, we analyzed the detailed shared and specific association signals extracted from GWAS Catalog for various autoimmune diseases, including SLE, rheumatoid arthritis (RA), multiple sclerosis (MS), Sjogren's disease (SjS), primary biliary cirrhosis (PBC) and type I diabetes (T1D). We observed widespread independent association signals for both SLE and other autoimmune disorders in more than half of the loci known to have associations for at least one of the autoimmune disorders. We conclude that this is on the one hand not surprising, suggesting a variety of mechanisms in gene expression regulation, which in many cases are likely cell type-specific and context-dependent. On the other hand, this poses challenges to functional characterizations of associated loci. We observed both shared association signals among the autoimmune diseases and specific signals to one disease or a subset of diseases, sometimes within a single genomic region. We believe that further studies of the detailed mechanisms of the associations and the shared and specific signals among the autoimmune disorders will greatly facilitate our understanding of these diseases. We argue that these valuable details have been under-explored, and in many cases, they were merely used to emphasize the validity of an association. Using examples in loci such as ETS1, CD44, TRAF3, and IRF4, we demonstrate that the comprehensive analysis of association signals from various autoimmune diseases greatly facilitate the identification of the causal gene(s) and offer a venue to better understand the mechanisms of the associations and pathogenesis of the autoimmune diseases.

Complex Traits Posters - Thursday

PB1268. Analysis of MRI-derived spleen iron in the UK Biobank identifies genetic variation linked to iron homeostasis and hemolysis

Authors:

E. Sorokin¹, N. Basty², B. Whitcher², Y. Liu¹, J. D. Bell², R. L. Cohen¹, M. Cule¹, E. L. Thomas²; ¹Calico Life Sci. LLC, South San Francisco, CA, ²Univ. of Westminster, Res. Ctr. for Optimal Hlth., London, United Kingdom

Abstract Body:

The spleen plays a key role in iron homeostasis. It is the largest filter of the blood and performs iron reuptake from old or damaged red blood cells. Despite this role, spleen iron concentration has not been measured in a large, population-based cohort. In this study, we quantify spleen iron concentration in 41,764 participants of the UK Biobank using magnetic resonance imaging, and provide the first reference range for spleen iron in an unselected population. Spleen iron is only partially correlated with other measures of iron stores including serum and liver iron. Thus, spleen iron is a novel and highly tractable trait for genetic analysis. Through genome-wide association study of spleen iron, we identify associations between spleen iron and regulatory variation at two genes, *ANK1* and *SPTA1*, encoding structural components of red blood cells. Loss in function in either of these genes is known to result in a Mendelian red blood cell disorder, hereditary spherocytosis; by contrast, the common alleles found through GWAS are associated with increased expression of *SPTA1* and *ANK1*. Opposite to rare disease-causing alleles, the common alleles are also associated with protective effects red blood cell parameters including reticulocyte volume. As genetic modifiers, these common alleles may help explain the variable expressivity and penetrance of hereditary spherocytosis that has been observed clinically. After fine-mapping, our genetic study also identifies a novel association which co-localizes with a splicing quantitative trait locus for *MS4A7*, and we show this gene is abundantly expressed in the spleen and in macrophages. In summary, we combine deep learning and efficient image processing to enable the first large-scale measurement of spleen iron, and we characterize genetic factors linked to the lytic phase of the red blood cell life cycle, as well as iron reuptake by the spleen. Our work advances understanding of iron homeostasis in the human body and illustrates the power of modern imaging-based techniques to deeply phenotype non-invasively and thereby enable discovery research in large human cohorts.

Complex Traits Posters - Wednesday

PB1269. Analysis of nascent RNA reveals distinct gene signatures for acute inflammation in cytokine stimulated keratinocytes.

Authors:

M. Patrick, M. K. Sarkar, M. T. Paulsen, I. V. Narayanan, M. Ljungman, J. E. Gudjonsson, L. C. Tsoi; Univ. of Michigan, Ann Arbor, MI

Abstract Body:

Acute inflammation (i.e. the immediate immune response to injury or infection) is challenging to investigate, due to the complex, dynamic and time-sensitive processes involved. Conventional RNA sequencing only profiles total RNA at the steady state, which is subject to varying RNA synthesis and turnover rates, thereby insufficiently capturing the mechanisms involved in early proinflammatory response. To address these issues, we applied Bru-seq (an approach that directly measures nascent RNA transcription by bromouridine labeling) to stimulated (IL-17A+TNF or IL-13) and unstimulated immortalized keratinocytes (N/TERTs). We repeated our experiments using 30 and 120 minutes of cytokine stimulation, with three samples for each condition. 378 and 652 genes were differentially expressed ($FDR \leq 0.05$, $FC \geq 1.5$ or $FC \leq 2/3$) for IL-17A+TNF after 30 and 120 minutes of stimulation, respectively, while 15 and 131 genes were differentially expressed for IL-13, compared with unstimulated controls. Interestingly, although pathways such as TNF signaling (under IL-17A+TNF stimulation) were consistently enriched across each time period ($p = 1.4 \times 10^{-19}$, $OR = 10.28$ at 30 minutes and $p = 3.2 \times 10^{-31}$, $OR = 10.93$ at 120 minutes), only 79 of the 378 (21%) IL-17A+TNF genes and 2 of the 15 (13%) IL-13 genes from 30 minutes of stimulation were also differentially expressed at 120 minutes. Indeed, different genes from the TNF signaling pathway were upregulated at each time period (e.g. *IRF1* and *NFKB1* at 30 minutes, *ICAM1* and *TNFAIP2* at 120 minutes IL-17A+TNF stimulation), suggesting different components of the pathway may be subject to dynamic regulation. Specific pathways enriched at 30 minutes but not 120 minutes include IFN-g and IL-5 signaling for IL-13 stimulation, with REL/RELB protein-protein interaction and the KLF6 transcription factor for IL-17A+TNF. We also compared the upregulated genes from our Bru-seq experiments with those upregulated in acute atopic dermatitis from our previous steady state study and found substantial overlap, including *CISH* and *NOD2* for IL-13 stimulation, *IRF1* and *IL32* for IL-17A+TNF. Our results can provide insight into the specific mechanisms involved in the early inflammatory responses in keratinocytes, which will allow us to better understand the disease onset and acute inflammation of different inflammatory skin conditions.

Complex Traits Posters - Thursday

PB1270. Analysis of poison exons caused by splice donor variants in genes associated with developmental brain disorders

Authors:

A. Hare-Harris, K. Kelchner, A. Hunter; Bloomsburg Univ., Bloomsburg, PA

Abstract Body:

The role of nonsense mediated decay (NMD) facilitated by loss of function (LOF) genomic variants in developmental brain disorders (DBD) has been well established. Whole exome sequencing (WES) studies have helped to identify pathogenic LOF variants within the coding regions of >500 genes among individuals with DBD phenotypes; however, the role of NMD facilitated by intronic variants has been largely unexplored. Genomic variants that disrupt the conserved splice donor motif can lead to NMD due to the inclusion of an intronic sequence that introduces a premature stop codon to the resulting transcript. Variants that create these 'poison exons' (PEX) have been previously identified in SCN1A in individuals with Dravet Syndrome. However, a broad survey of poison exons in other DBD genes has yet to be conducted. This study identified pathogenic splice donor variants in DBD cases that do not appear in control individuals in gnomAD v3 using publically available data from ClinVar. We developed an automated pathogenicity prediction algorithm (PEX-DETEX) to identify splice donor variants that facilitate PEX from VCF datafiles. Variants were curated using RefSeq Select and MANE transcripts (hg38). To date, approximately 5000 splice donor variants across 512 DBD genes were analyzed with PEX appearing in 62% of these genes in ClinVar and 49% of these genes in gnomAD. These results show that ClinVar is significantly enriched for PEX compared to gnomAD (# PEX in ClinVar=1894; # PEX in gnomAD=968; $p < 0.00001$) and 58 genes were found to have PEX in ClinVar cases only. Of the 166 variants reported in ClinVar cases only, 15 variants were originally classified as variants of unknown significance (VOUS). This study provides increased evidence of pathogenicity for these variants. This is the first study of its kind to develop and utilize an automated algorithm to assess the clinical implications of poison exon variants in DBD phenotypes. The inclusion of this algorithm in clinical variant curation pipelines can help to elucidate the clinical manifestation of intronic VOUS and can be extended to the analysis of other genetic causes of poison exons.

Complex Traits Posters - Wednesday

PB1271. Analysis of Relationship between Metabolic Syndrome and Genome-Wide Association Study (GWAS) of Vitamin D in Koreans: Community-Based Cohort.

Authors:

H. Kim¹, Y. Lee², J. Lee¹, J. Seo²; ¹Dept. of Family Med., Veterans Med. Ctr., Korea (ROK), Seoul, Korea, Republic of, ²Veterans Med. Res. Inst., Korea (ROK), Seoul, Korea, Republic of

Abstract Body:

Purpose It is well known that vitamin D levels are reduced in people with metabolic syndrome. However, it remains unclear whether there is causal relationship or not. The purpose of this study was to evaluate the causal relationship between vitamin D levels and metabolic syndrome risk in Korean community-based population by assessing the links between vitamin D SNPs and occurrence of metabolic syndrome. **Methods** Study subjects were selected from the Korean Genome and Epidemiology Study, KoGES, which is a large prospective cohort study project to identify the interactions between chronic diseases and genetic/environmental factors in Korea. A linear regression analysis was initially performed to step forward to verifying the association vitamin D and metabolic syndrome in Korean community-based population. Then, vitamin D related SNPs from Genome Wide Association Study catalogue, GWAS, were extracted and selected overlapped vitamin D SNPs from Korean Chip. Then, Mendelian Randomization analysis, MR that has been widely applied to assess the causal relationship between exposure and outcome was applied to see the causal influence of vitamin D in people with metabolic syndrome. Subjects with or without metabolic syndrome from community-based population were designated for the outcome dataset, and SNPs associated with vitamin D were selected for the exposure dataset. **Results** In observational study, we also confirmed that vitamin D level was significantly lower about 2 times in population with metabolic syndrome than those without it. The 580 validate vitamin D SNPs were extracted from GWAS, and then 270 SNPs were selected to perform MR study. MR analysis was performed using inverse variance weighted method with vitamin D SNPs variants. MR analysis supported that decreased vitamin D was significantly associated with increased risk of metabolic syndrome. In conclusion, we showed a significant relationship between vitamin D and metabolic syndrome in the Korean population through MR analysis, which may provide a basis for future study of mechanism related metabolic syndrome.

Complex Traits Posters - Thursday

PB1272. *APOE* genotype and rare variants of APP processing complex in autopsy-confirmed rapidly progressive Alzheimer disease.

Authors:

P. Wang¹, A. Lynn¹, K. Miskimen¹, Y. E. Song¹, C. Kim^{2,3}, M. Cohen^{2,4}, B. S. Appleby^{2,3,4,5}, J. G. Safar^{2,3,6}, J. L. Haines^{1,7}; ¹Dept. of Population and Quantitative Hlth.Sci., Sch. of Med., Case Western Reserve Univ., Cleveland, OH, ²Dept. of Pathology, Case Western Reserve Univ., Cleveland, OH, ³Dept. of Neurology, Case Western Reserve Univ., Cleveland, OH, ⁴Natl. Prion Disease Pathology Surveillance Ctr., Case Western Reserve Univ., Cleveland, OH, ⁵Dept. of Psychiatry, Case Western Reserve Univ., Cleveland, OH, ⁶Dept. of NeuroSci.s, Case Western Reserve Univ., Cleveland, OH, ⁷Cleveland Inst. for Computational Biology, Cleveland, OH

Abstract Body:

Prion disease and Alzheimer disease (AD) are distinct disorders; however, recent data suggests that amyloid beta and misfolded tau protein aggregates have self-propagating ability within brain tissue, and such distinct prion-like strains are associated with accelerated disease progression in AD. The role of genetic factors in different strains of pathogenic proteins and progression rates of AD is largely unknown. We established a rapidly progressive AD (rpAD) cohort from individuals referred to the National Prion Disease Pathology Surveillance Center with rapidly progressive dementia mimicking prion disease but subsequently confirmed as AD after neuropathological examination. Medical records were reviewed for clinical data, coronal sections of human brain tissue were obtained at autopsy, and DNA was extracted from brain tissue. Coding regions of AD risk genes, including *APOE*, *PSEN1*, *PSEN2*, and *APP* were analyzed using an Illumina Global Screening Array. Among 190 individuals with autopsy-confirmed rpAD, 53.4% were males and 80% were of non-Hispanic European (NHE) ancestry. The average age of onset was 70.2 ± 11.5 years, and the median survival was 6 months (IQR: 2-20 months). In 153 cases with *APOE* genotypes, the allele frequency of *APOE* $\epsilon 2$ was 4.25%, $\epsilon 3$ was 63.40%, and $\epsilon 4$ was 32.35%. The frequency of *APOE4* is somewhat lower than in a typical NHE AD cohort, which is consistent with findings from prion centers in Japan and Europe. In the 158 sequenced rpAD cases, we found two rare missense variants (*G206A* and *E318G*) in the *PSEN1* gene, one rare synonymous variant (*p.Ala252=*) in the *PSEN2* gene, and five rare intronic variants (*rs62222412*, *rs147490386*, *rs71317448*, *rs7283060*, *rs117873188*) in the *APP* gene. In 53 rpAD cases presenting with an early onset of disease (≤ 65 years old), 18.9% (n=10) carry a rare variant. Overall, 26 individuals had rare variants in *PSEN1* (n=9), *PSEN2* (n=2), and *APP* (n=14), and one case had variants in both *PSEN1* and *APP*. Compared to individuals with no rare variants, rare variant carriers had a younger age of onset (66.7 ± 11.8 vs 70.9 ± 11.4 , $p = 0.09$), and a longer and more variable median survival (10 months [IQR: 4-42] vs 6 months [IQR: 2-15]). We found a higher frequency of rare variants in known AD risk genes. Both rare variants in *PSEN1* are associated with a younger age of AD onset, abnormally elevated total tau and phosphorylated-tau, and decreased $A\beta$ levels. There is not yet strong evidence for the pathogenicity of the rare variants in *PSEN2* and *APP*. Our preliminary findings start to shed light on possible genetic risks associated with variable rates of progression in AD and an interplay with different strains of misfolded amyloid beta and tau proteins.

Complex Traits Posters - Wednesday

PB1273*. Assessing T-Cell Receptor Diversity and Genetic Variation in Complex Phenotypes.

Authors:

D. Ercelen, N. A. Zaitlen, M. J. Thompson; UCLA, Los Angeles, CA

Abstract Body:

Hypervariable complementary-determining regions (CDRs) in the genome determine the structure of immunoglobulins and T-cell receptors (TCRs). The genetic diversity of TCRs is critical for maintaining and developing adaptive immunity to successfully fight off infections. Nonetheless, the extent to which an individual's immune repertoire is predetermined remains contested, largely due to limitations of available profiling tools. To gain more insight on the genetic components of immune diversity, we utilized IMREP, a software tool designed to detect CDR regions with off-target reads from RNA-seq. The novelty we introduce in our study is the usage of whole exome sequencing (WES) data from the UKBiobank consortium. We focus on CDR regions as well as low coverage areas in the entire genome to maximize potential targets. Confirming the validity of our approach, we observed relatively high concentrations of alpha and beta chains, in comparison to delta or gamma chains, of TCRs. We further analyze the phenotypes generated by IMREP by running genome-wide association studies (GWAS) to identify potential genetic markers of immune diversity. We examine effects of TCR diversity on other complex phenotypes such as cancer, immune disorders, diet, location, and profession through linear and logistic regressions. GWAS on our IMREP generated TCR phenotypes found two statistically significant loci inside the intronic regions of the genes *MEOX1* (rs1724438; $p=4.63 \times 10^{-26}$) and *PLEKHB2* (rs145650663; $p=6.22 \times 10^{-44}$). These two genes have previously been shown to be related to regulatory roles in T-cells and influenza vaccine efficacy, respectively. In our regressions with complex phenotypes, we found significant correlations between the number and alpha diversity of TCR alpha chains (TCRA) and complex phenotypes such as the usage of the drug Omeprazole ($p=5.83 \times 10^{-4}$). Following these results we aim to further extract mitochondrial and ribosomal DNA from our data set, as well as microbiome information, and run similar analyses. Our results not only validate the use of IMREP on large whole exome datasets, but also suggest that immune signatures, in addition to gene environment interactions, may be partly predetermined by genetics.

Complex Traits Posters - Thursday

PB1274. Association analysis of *LHCGR* gene polymorphisms with Polycystic Ovary Syndrome in Punjabi population.

Authors:

S. Singh¹, M. Kaur¹, R. Kaur², A. Kaur³; ¹Guru Nanak Dev Univ., Amritsar, India, ²Dept. of Human Genetics, Guru Nanak Dev Univ., Amritsar, India, ³Guru Nanak Dev Univ., AMRITSAR, India

Abstract Body:

Background: Polycystic ovary syndrome (PCOS) is one of the most common endocrinopathies characterized by multiple hormonal imbalances dominated by hyperandrogenism, menstrual irregularities and/or small cysts in one or both ovaries. It is a heterogeneous disorder with the involvement of multiple gene and environmental interactions. Some polymorphisms of luteinizing hormone choriogonadotrophin receptor (*LHCGR*) gene may predispose women to develop PCOS. This study was designed to investigate the association of *LHCGR* polymorphisms with PCOS in Punjabi population since there are very few studies that have tried to understand the underlying genetic mechanisms in PCOS in North Indian population. **Methodology:** A total of 719 women comprising of 419 PCOS cases and 300 regularly menstruating women participated in the present study. Genotyping of *LHCGR* polymorphisms (rs2293275 and rs4539842) was done using polymerase chain reaction-restriction fragment length polymorphism. Restriction digestion was carried out using *RsaI* and *PvuII* enzymes for rs2293275 and rs4539842, respectively. Statistical analysis was performed using SPSS (version21, IBM SPSS, NY, USA). **Results:** The *LHCGR* variants demonstrated no significant association with PCOS cases. The genotypic frequency of SNPs rs2293275 and rs4539842 were not significantly different between PCOS cases and controls ($p=0.389$ and $p=0.805$, respectively). BMI was significantly different in both groups ($p<0.00001$). There was a significant elevation in the levels of cholesterol ($p=0.00002$) and triglycerides ($p<0.00001$) in women with PCOS as compared to controls whereas HDL levels were significantly lower in PCOS subjects ($p=0.0001$). **Conclusion:** These results suggest that none of these two polymorphisms of *LHCGR* gene was significantly associated with risk of PCOS in Punjabi population and that might be due to racial background, PCOS phenotype and the diagnostic criteria used.

Complex Traits Posters - Wednesday

PB1275. Association analysis of structural variants in whole-genome sequencing of 150K UK Biobank participants

Authors:

J. Liu¹, V. Ashton¹, J. Davitte¹, P. Gormley², R. Scott³, A. Cortes³, Y. Lo¹; ¹GSK, Collegeville, PA, ²GSK, Cambridge, MA, ³GSK, Stevenage, United Kingdom

Abstract Body:

Structural variants (SVs, insertions, deletions, and duplications over 50bp) are known to play an important role in complex traits, though are not well captured by targeted sequencing and array-based genotyping methods. The UK Biobank whole-genome sequencing (WGS) data includes over 637,000 SVs identified in ~150,000 participants using pangenome graphs implemented in GraphTyper. Using these data, we will present results from genome-wide association analysis of SVs across over 300 manually derived disease endpoints and ~500 quantitative biomarker, anthropometric and imaging phenotypes of interest. Significantly associated SVs will be assessed for their predicted functional consequences and the extent to which they are independent of known GWAS signals. The results of these analyses have the potential to highlight new drug target opportunities. SVs with direct impact on functional elements provide additional variant-to-gene-to function evidence for existing target-indication pairs, enabling us to generate better therapeutic hypotheses. The inferences from SVs will demonstrate one of the benefits of WGS over traditional GWAS approaches.

Complex Traits Posters - Thursday

PB1276. Association between a type 2 diabetes polygenic risk score and type 2 diabetes-related risk factors and complications

Authors:

B. Guo^{1,2}, Y. Cai², R. A. Smit³, L. Stalbow³, Q. Sun⁴, L. Raffield⁴, S. Raghavan⁵, J. B. Meigs⁶, C. S. Carlson², S. Rich⁷, L. R. Wilkens⁸, L. L. Marchand⁸, D. O. Stram⁹, M. Graff⁴, C. Arehart⁵, C. Gignoux⁵, K. E. North⁴, S. Buyske¹⁰, R. J. F. Loos³, C. Haiman⁹, U. Peters^{2,1}, C. Kooperberg^{2,1}, H. M. Highland⁴, B. Darst², the Population Architecture using Genomics and Epidemiology (PAGE) study; ¹Univ. of Washington, Seattle, WA, ²Fred Hutchinson Cancer Ctr., Seattle, WA, ³Icahn Sch. of Med. at Mount Sinai, New York, NY, ⁴Univ. of North Carolina at Chapel Hill, Chapel Hill, NC, ⁵Univ. of Colorado, Anschutz Med. Campus, Aurora, CO, ⁶Massachusetts Gen. Hosp., Boston, MA, ⁷Univ. of Virginia, Charlottesville, VA, ⁸Univ. of Hawai'i Cancer Ctr., Honolulu, HI, ⁹Univ. of Southern California, Los Angeles, CA, ¹⁰Rutgers Univ., Piscataway, NJ

Abstract Body:

It is estimated that >13% of the US population will have diabetes by 2030. With increasing GWAS sample sizes and advances in the development of polygenic risk scores (PRS), we can estimate genetic risk of type 2 diabetes (T2D), which may inform preventive strategies. However, it is unclear whether T2D PRS holds prognostic value for T2D risk factors or major complications, particularly across multi-ancestry populations. We investigated these questions using a PRS of 582 genome-wide significant variants identified in a previously conducted large multi-ancestry T2D GWAS of 228,499 cases and 1,178,783 controls. Regression models were used to evaluate the association between the T2D PRS and T2D-related risk factors and complications (fasting glucose and insulin, HOMA-IR and HbA1c, cardiovascular traits, and lipid traits) in an independent sample of 14,823 T2D cases and 25,278 controls from African American (AA), East Asian (EA), Hispanic (HA), and Native Hawaiian (NH) populations from the Population Architecture using Genomics and Epidemiology (PAGE) Study, with models run separately for each population and stratified by T2D status. We found improvements in the percent phenotypic variance explained (R^2) for all continuous traits and small to no improvements in the area under the curve (AUC) for the two binary traits (incident heart attack and stroke) evaluated when the T2D PRS was added to a base model of age, sex, body mass index, and the first ten principal components of ancestry. The highest R^2 improvements across continuous traits were consistently observed in HA (ranging from 0.02% to 0.99%) or EA (ranging from 0.03% to 2.89%) and typically the lowest in AA (ranging from 0% to 0.37%) among T2D controls. Relative to R^2 estimated in the base model (7.06%, 10.23%, 9.97%, and 4.18% in AA, EA, HA, and NH, respectively), the trait with the largest R^2 improvement was fasting glucose (7.41%, 10.93%, 10.96%, and 4.84% in AA, EA, HA, and NH, respectively). Compared to the R^2 estimated in the base model (1.57%, 24.89%, 18.64%, and 9.05%, in AA, EA, HA, and NH, respectively), the trait with the lowest R^2 improvement was HOMA-IR (1.58%, 24.87%, 18.66%, and 9.10% in AA, EA, HA, and NH, respectively). We are conducting additional analyses to evaluate the association between the T2D PRS and other T2D comorbidities, including retinopathy, neuropathy, kidney and liver function, and cancer. These results suggest that the T2D PRS may help identify individuals across diverse populations with a greater risk of developing T2D-related risk factors and complications, which could have important clinical and prognostic implications.

Complex Traits Posters - Wednesday

PB1277. Association between Blood Pressure-related Polygenic Risk Scores and Hypertension among White and Black Individuals Across the Life Course

Authors:

X. Sun; Tulane Univ., New Orleans, LA

Abstract Body:

Genetic information may help to identify individuals at increased risk for hypertension in early life, prior to the manifestation of elevated blood pressure (BP) values. We examined 369 Black and 832 white Bogalusa Heart Study (BHS) participants recruited in childhood and followed approximately 37 years. Multi-ancestry genome-wide polygenic risk scores (PRSs) for systolic BP (SBP), diastolic BP (DBP), and hypertension were tested for association with incident hypertension and stage-2 hypertension using Cox proportional hazards models. Race-stratified analyses adjusted for baseline age, age², sex, body mass index, genetic principal components, and BP. In Black participants, each standard deviation increases in SBP and DBP PRS (respectively) conferred 38% (P=0.009) and 22% (P=0.02) increased risk of hypertension and 74% (P<0.001) and 50% (P<0.001) increased risk of stage 2 hypertension, while no association was observed with the hypertension PRS. In whites, each standard deviation increases in SBP, DBP, and hypertension PRS (respectively) conferred 24% (P<0.05), 29% (P=0.01) and 25% (P<0.001) increased risk of hypertension, and 27% (P=0.08), 29% (0.01), and 42% (P<0.001) increased risk of stage 2 hypertension. Addition of BP PRSs to the covariable-only models generally improved C-statistics (P<0.05). Multi-ancestry BP PRSs demonstrate the utility of genomic information in early life prediction of hypertension.

Complex Traits Posters - Thursday

PB1278. Association between genomic runs of homozygosity and complex traits in the Taiwan Biobank

Authors:

Y-C. Feng¹, Y-J. Lai¹, T-T. Chen², C-Y. Chen³, T. Ge⁴, H. Huang⁵, Y-F. Lin⁶; ¹Natl. Taiwan Univ., Taipei, Taiwan, ²Natl. Hlth.Res. Inst.s, Zhunan Town, Miaoli County, Taiwan, ³Biogen, Cambridge, MA, ⁴Massachusetts Gen. Hosp., Boston, MA, ⁵MGH, Boston, MA, ⁶Natl. Hlth.Res. Inst.s, Taiwan, Zhunan Town, Miaoli County, Taiwan

Abstract Body:

Inbreeding results in elevated levels of autozygosity (homozygosity-by-descent) widely known to increase the risk of Mendelian conditions. Using high-density genotype data, earlier studies have shown that contiguous stretches of homozygous segments—runs of homozygosity (ROH)—are also common in modern outbred human populations with an impact on complex traits and diseases. The emergence of global biobanks has now made it possible to investigate the phenotypic spectrum associated with genome-wide homozygosity at the population level, especially beyond the European ancestry. Here, we leveraged the population-based Taiwan biobank (TWB) to study the distribution of ROH and its relationship with 46 health-related quantitative traits (anthropometric, biometric, and reproductive) among 93,598 unrelated individuals of Han-Chinese descent. ROHs were called using PLINK based on published recommendations (≥ 65 consecutive homozygous SNPs spanning at least 1,000 Kb) in the LD-pruned imputed genetic dataset. The total length of ROHs and the fraction of the autosome in ROHs (FROH) were calculated for each individual. Using linear mixed-effects models, we estimated the effect of FROH on phenotype (standardized within each sex) adjusting for age, sex, and the first 20 principal components with batch treated as a random factor. To account for potential confounding by socioeconomic status (SES), we performed additional analysis including education and family income as SES covariates. The longest ROH detected in TWB individuals spanned 9.8Mb containing 1,788 homozygous SNPs. FROH ranged from 0-0.04 and averaged at 0.003. After Bonferroni correction, our results suggested FROH was significantly, negatively associated with inspiratory capacity ($\beta_{\text{FROH}} = -10.7$ in phenotypic SD, $P = 1.3 \times 10^{-4}$), height (-7.8SD , $P = 1.9 \times 10^{-4}$), and total cholesterol (-7.1SD , $P = 1.2 \times 10^{-4}$). The inverse association was observed at nominal significance ($P < 0.05$) for triglyceride, red blood cell count, forced vital capacity, and number of times pregnant. However, the top associations became non-significant and attenuated after adjusting for SES; notably, the effect of FROH on the number of times pregnant became slightly stronger. Overall, these findings are consistent with previously reported associations with increased autozygosity among individuals of distant relatedness and implicate possible directional selection for these traits. We will use whole-genome sequencing data to map recessive loci within ROH tracts and extend the analysis to disease phenotypes to understand the role of ROHs in the genetic architecture of complex traits.

Complex Traits Posters - Wednesday

PB1279. Association between polymorphisms in *CD32*, *CD36*, *CD40*, *CD54* and Malaria phenotypes among under-fives in Ibadan South-west Nigeria.

Authors:

T. Olajide¹, S. A. Ademola¹, O. J. Bamikole¹, M-D. B. Olufeagba¹, B. A. Adedeji², N. O. Bukoye¹, O. K. Amodu¹; ¹Univ. of Ibadan, Ibadan, Nigeria, ²Modibbo Adama Univ., Yola, Nigeria

Abstract Body:

Background: Malaria remains one of the most prevalent infectious diseases in the world. Africa and Nigeria account for 95% and 27% of the world's malaria prevalence respectively. The significant rise from the 2019 figures can be attributed to service destruction associated with the Covid-19 pandemic. Children under age 5 years and pregnant women constitute the greater proportion of malaria-associated mortalities in the world. Cell surface receptors and messengers are factors that play important roles in parasite clearance during malaria infection. Polymorphisms in *FCGR2A*(*CD32*), *CD36*, *CD40LG*, and *ICAM-1*(*CD54*) have been associated with increased susceptibility to malaria. Methods: A total of 470 children between the ages of 6 and 59 months (247 males and 223 females) from a section of the Nigerian population were recruited into case and control groups based on WHO guidelines. The participants were examined for clinical parameters and genotyped for seven SNP variants *CD40LG* (rs1126535 and rs3092945), *FCGR2A* (rs1801274), *CD36* (rs3211938 and rs201346212) and *ICAM-1* (rs5498 and rs1799969). The results were analyzed for conformity with HWE and genotypes were tested for association with the phenotypes using logistic regression under different genetic models. Results: Packed cell volume, parasitemia, respiratory rates, and body temperature differed across the clinical groups. Genetic variants (*CD40LG* rs1126535) and (*CD36* rs3211938) deviated from HWE. Here we report that (*CD36* rs3211938) was a risk for uncomplicated malaria when two copies of the risk allele were inherited while it protects against severe malaria anemia when just a copy of the protective allele is inherited. Conclusions: *CD36* (rs3211938) is associated differentially with existing malaria phenotypes in our population. However, this study could not establish a genetic association between the other SNPs and malaria phenotypes.

Complex Traits Posters - Thursday

PB1280. Association of a genetic risk score with incident coronary heart disease in the Hispanic Community Health Study/Study of Latinos (HCHS/SOL) cohort.

Authors:

C. Hutten¹, R. A. Durazo-Arvizu¹, S. Wassertheil-Smoller², C. R. Isasi², J. Cai³, J. T. Unkart⁴, J. Sun¹, V. Persky¹, T. Sofer⁵, M. L. Daviglus¹, M. Argos¹; ¹Univ. of Illinois at Chicago, Chicago, IL, ²Einstein Coll. of Med., Bronx, NY, ³UNC at Chapel Hill, Chapel Hill, NC, ⁴SUNY Downstate, Brooklyn, NY, ⁵Harvard Med. Sch., Boston, MA

Abstract Body:

Background: Coronary heart disease (CHD) is a leading cause of death for the Hispanic/Latino population living in the United States (US). Genetic risk scores (GRS) have been used in European ancestry populations to identify those at higher risk for CHD events. **Objectives:** This study evaluates a GRS with incident CHD in a Hispanic/Latino cohort. **Methods:** The Hispanic Community Health Study/Study of Latinos (HCHS/SOL) is a prospective longitudinal study that enrolled 16,415 Hispanic/Latino adults aged 18 to 74 years from four US communities between 2008-2011 with a follow-up visit in 2014-2017. We assessed the association between a 71-SNP GRS and incident CHD among 9,030 HCHS/SOL participants with complete data and consent to conduct genetic research. Incident CHD was defined as no self-reported physician diagnosis or evidence of electrocardiographic abnormalities indicative of CHD at baseline and self-reported CHD at Visit 2. CHD events and time to events (such as incident myocardial infarction (MI)) were adjudicated through 2015, with further adjudication in progress. We considered an unweighted (sum of risk alleles), European-weighted, and Latino-weighted GRS. European and Latino weights were derived from a prior publication employing this GRS (Ke et al. 2018). Cox proportional hazards models were used to derive hazard ratios and 95% CIs for the association between the GRS and incident CHD, adjusted for a priori confounders and survey weights. **Results:** Preliminary analysis shows a trend for greater than 50% increased risk of incident CHD for those in the highest quintile of unweighted GRS compared to the lower four quintiles combined (HR 1.57, 95% CI 0.91, 2.71). The trend for incident MI events was even higher for those in the top quintile of GRS compared to all others (HR 2.08, 95% CI 0.75, 5.76). Stratified analyses to explore heterogeneity by sex showed males had a 2.5-fold increased risk of incident CHD when comparing the highest quintile of the GRS to all other quintiles (HR 2.58, 95% CI 1.29, 5.14); females showed no increased risk (HR 0.86, 95% CI 0.40, 1.84). Furthermore, stratification by European genetic ancestry showed those with greater than 67% European ancestry had a 4-fold increased risk of incident CHD (HR 4.09, 95% CI 1.87, 8.94); lower proportions of European ancestry showed no increased risk. Results were comparable using the other GRS constructs. **Conclusion:** The results highlight the need for additional studies to evaluate and optimize risk prediction of CHD based on cumulative genetic risk in the Hispanic/Latino population. Adjudication of further CHD events may confirm the increased risk of incident CHD in those with high GRS.

Complex Traits Posters - Wednesday

PB1281. Association of African Ancestry with risk for fibroproliferative diseases is consistent with selection for a Th2 favored genome in African derived populations

Informatics TLE: Div. of Epidemiology, Dept. of Med., Vanderbilt Genetics Inst., Vanderbilt Univ. Med. Ctr., Nashville, TN, ²¹Vanderbilt Genetics Inst., Div. of Epidemiology; Dept. of Med., Vanderbilt Univ. Med., Nashville, TN

Abstract Body:

Fibroproliferative diseases (FPDs) are characterized by excessive scarring and overgrowth of connective tissue resulting from overactive T-helper cell type 2 (Th2) fibrotic immune response. In contrast, **inflammatory diseases (IFDs)** are characterized by an overactive T-helper cell type 1 (Th1), a Th2 antagonist, immune response that causes excessive inflammation. Many FPDs are more prevalent in African ancestry (AA) individuals, while many IFDs are more common in European Ancestry (EA) individuals. The increased prevalence of FPDs in AA populations is hypothesized to be due to selection for alleles that intensify the Th2 immune response. However, certain Th1-driven IFDs (i.e., alopecia areata and multiple sclerosis) are more prevalent in AA individuals, contradicting a Th2-favored genome. Here we calculated global ancestry proportions from 1000 Genome Phase 3 global populations [West African (WAFR), East African (EAFR), Southern European (SEUR), and Northern European (NEUR)] using Admixture software and data from electronic health record biobanks, BioVU and eMERGE. We tested for association with eight FPDs and seven IFDs defined by phecodes. Logistic regression analyses were conducted on combined BioVU and eMERGE datasets, per phenotype, for self-identified non-Hispanic blacks and non-Hispanic whites with case/control status defined by FPD and IFD phecodes, with the primary exposure being ancestry proportions, adjusted for sex, age, and body mass index (BMI). Effect estimates are reported per 10% increase in genetically inferred ancestry proportions. We detected positive associations of AA with all FPDs, with the largest effects being observed for keloids (EAFR Odds Ratio [OR]=1.26, 95% confidence interval [CI]1.22, 1.33; WAFR OR=1.27, 95% CI 1.23, 1.35) and uterine fibroids (EAFR OR=1.29, 95% CI 1.26, 1.32; WAFR OR=1.33, 95% CI 1.29, 1.36). We also observed a negative association of AA with all IFDs, with the strongest effects for celiac disease (EAFR OR=0.47, 95% CI 0.36, 0.58; WAFR OR=0.47, 95% CI 0.36, 0.57). We detected negative associations for each FPD in EAs, with the strongest effects for uterine fibroids (SEUR OR=0.81, 95% CI 0.80, 0.82;

ASHG 2022 Annual Meeting Poster Abstracts

NEUR OR=0.74, 95% CI 0.71, 0.77) and glaucoma (SEUR OR=0.84, 95% CI 0.83, 0.85; NEUR OR=0.93, 95% CI 0.90,0.95). We also detected a positive association for EA with all IFDs, with the strongest effects for Celiac (SEUR OR=1.32, 95% CI 1.23, 1.42; NEUR OR=1.42 95% CI 1.28, 1.57)). This evidence supports the role of a Th2 favored genome that contributed to the increased frequency of FPDs while also demonstrating a potentially protective relationship between AA and IFD development.

Complex Traits Posters - Thursday

PB1282. Association of genetic predisposition and physical activity with risk of gestational diabetes mellitus in nulliparous women.

Authors:

P. Radivojac¹, K. A. Pagel², H. Chu¹, R. Ramola¹, R. F. Guerrero³, J. H. Chung⁴, S. Parry⁵, U. M. Reddy⁶, R. M. Silver⁷, J. G. Steller⁴, L. M. Yee⁸, R. J. Wapner⁹, M. W. Hahn¹⁰, S. Natarajan¹¹, D. M. Haas¹²; ¹Northeastern Univ., Boston, MA, ²Johns Hopkins Univ., Baltimore, MD, ³North Carolina State Univ., Raleigh, NC, ⁴Univ. of California, Irvine, CA, ⁵Univ. of Pennsylvania, Philadelphia, PA, ⁶Yale Univ., New Haven, CT, ⁷Univ. of Utah, Salt Lake City, UT, ⁸Northwestern Univ., Chicago, IL, ⁹Columbia Univ., New York, NY, ¹⁰Indiana Univ., Bloomington, IN, ¹¹Univ. of Texas, Dallas, TX, ¹²Indiana Univ., Indianapolis, IN

Abstract Body:

Introduction: Polygenic risk scores (PRS) for Type II Diabetes Mellitus (T2DM) can improve risk prediction for Gestational Diabetes Mellitus (GDM), yet the strength of the relationship between genetic and lifestyle risk factors has not been quantified. In this work, we assess the effects of PRS and physical activity on existing GDM risk models and identify patient subgroups who may receive the most benefits from receiving a PRS or activity intervention.

Methods: The nuMoM2b cohort was established to study individuals without previous pregnancy lasting 20 or more weeks (nulliparous) and to elucidate factors associated with adverse pregnancy outcomes. In this work, a sub-cohort of 3,533 participants with European ancestry was used for risk assessment and performance evaluation of GDM. The key factors under investigation include PRS and self-reported total physical activity in early pregnancy that was quantified as metabolic equivalent of tasks (METs). PRS were calculated for T2DM using contributions of 84 single nucleotide variants, weighted by their association in the DIAGRAM Consortium data. Prediction of the development of GDM was performed based upon clinical, genetic, and environmental variables collected in early pregnancy.

Results: A total of 3,533 women met inclusion criteria (mean age = 28.6 +/- 4.9 years), of which 132 (3.7%) received GDM diagnosis. In high-risk population subgroups (body mass index ≥ 25 or age ≥ 35), individuals with high PRS (top 25th percentile) or low activity (METs < 450) have significantly increased odds of GDM diagnosis. Participants with both high PRS and low activity have three times higher odds of GDM diagnosis than the population, while those with either low PRS or high activity do not have increased odds of GDM diagnosis.

Conclusions: In this cohort study, the addition of PRS resulted in stratified risk of GDM diagnosis among high-risk patient subgroups, suggesting the benefits of targeted PRS ascertainment to encourage early intervention.

Complex Traits Posters - Wednesday

PB1283. Association of Genetically-Predicted Placental Gene Expression and Diseases of the Cardiovascular System

Authors:

A. Pigg^{1,2}, J. Hellwege², E. Jasper², T. Edwards², D. Velez Edwards²; ¹Meharry Med. Coll., Nashville, TN, ²Vanderbilt Univ. Med. Ctr., Nashville, TN

Abstract Body:

Mother-to-child transfer of disease risk may happen in utero and influence the health of offspring throughout early life and adulthood. The placenta plays a vital role in the prenatal environment and is an important biological conduit for not only maintaining a healthy pregnancy but the health of offspring. The Developmental Origins of Health and Disease (DOHaD) hypothesis describes the implications of the prenatal environment on the offspring's risk of disease later in life like obesity, type II diabetes, psychiatric disorders, and cardiovascular disease. Several cardiovascular diseases run in families which indicates an inherited genetic risk by offspring. Gene expression in the placenta could play a role in the risk of the development of cardiovascular diseases throughout the course of life. Previous studies have described the genetic control of placental gene expression through expression quantitative trait loci (eQTL) studies. In this study, we evaluated the relationship between placental gene expression and cardiovascular diseases. We constructed genetically predicted gene expression (GPGE) models for 25,885 genetic variants associated with expression of 15,154 genes from reference placental eQTL data (Peng et al., 2018). Using these models, we investigated whether placental GPGE is associated with seven adult cardiovascular diseases (Sakaue, S. et al., 2021) using GWAS summary statistics. Predicted gene expression analyses were conducted using SPrediXcan software. We respectively identified five, two, seven, three, and one genes whose predicted expression was significantly associated ($p < 1.0 \times 10^{-5}$) with angina, cardiac valvular disease, myocardial infarction, peripheral arterial disease, and subarachnoid hemorrhage after correcting for multiple comparisons. When compared to predicted expression models from 48 adult tissues from GTEx v7, nine genes were uniquely associated in the placental models. Notable genes identified are TOMM40, CDKN2B, and MAN2A2, which were previously reported to be associated with LDL levels, BMI, type II diabetes, and coronary artery disease. These results suggest unique genetic mechanisms by which the placenta contributes to later-in-life cardiovascular disease beyond that observed through adult gene expression.

PB1285. Association of Structural Variants with Coronary Artery Disease

Authors:

K. Iyer¹, R. Guarischi-Sousa¹, S. Clarke¹, G. Jun², P. de Vries², T. Assimes¹; ¹Stanford Univ Sch Med., Palo Alto, CA, ²UTHlth.Sch. of Publ. Hlth., Houston, TX

Abstract Body:

Genome-wide association studies (GWAS) have identified several hundred susceptibility single nucleotide polymorphisms (SNPs) for coronary artery disease (CAD). Despite SNP-based GWAS revolutionizing our understanding of the genetics of CAD, the contribution of structural variants (SVs) to the risk of CAD remains largely unclear. We leveraged SVs detected from high-coverage whole-genome sequencing (WGS) data in a diverse group of participants from the NHLBI Trans-Omics for Precision Medicine (TOPMed) program. Using single variant tests, we performed an SV-based GWAS including $n=75,733$ SVs that passed QC filters and had a minor allele count ≥ 10 in 13,504 CAD cases and 45,078 controls. These tests were performed using GENESIS after adjusting for age, sex, self-identified race/ethnicity, study, sequencing center, and relatedness. Population structure was also adjusted for using the first 10 principal components derived from SV calls. We identified two statistically significant overlapping duplications near *RFPL4B* on chromosome 6q21 (DUP_6:112405701-112406900 and DUP_6:112405201-112406900 with $p=7.12E-10$ and $p=2.59E-9$, respectively). These biallelic SVs were observed to have a minor allele frequency (MAF) of 5.5% and 2.5% in our participants. Both duplications spanned over 1000 bp, and housed a candidate cis-Regulatory Element EH38E2495040 with a distal enhancer-like signature along with nine common intergenic SNPs from 1000 Genomes Phase3. These SNPs were found to be nominally associated with cardio-metabolic traits like weight circumference, body mass index (BMI), hypertension, and Type 2 diabetes (T2D) on the phenome-wide associations (PheWAS) catalog. One of the SNPs in this region - rs9387078 almost reached the PheWAS significance threshold for T2D with renal manifestations ($p=7.1E-5$) in White British participants of the UK Biobank. Our analysis also identified an association between CAD and a rare 487bp biallelic deletion (MAF: 0.08%) within *CSMD2* on 1p35.1 (DEL_1:34097323-34097810, $p=9.69E-7$), a gene previously implicated in several brain-related conditions. Two intronic SNPs - rs12031634 and rs9426003 located less than 20kb and 40kb from the deletion region were found to be significantly associated with BMI ($p=1E-10$; $p=3.2E-10$) among people of European ancestry. These two variants were found not to be in linkage disequilibrium with our deletion. Our results showcase the nature of the relationship between rare and common SVs among a highly genetically diverse population and suggest that structural variation may influence the risk of CAD through well-established cardiometabolic risk factors.

Complex Traits Posters - Thursday

PB1286. Associations between polygenic risk scores and gene expression identify core genes for bipolar disorder.

Authors:

S. Lapinska¹, T. Schwarz¹, T. Boltz², M. Bot³, R. Kahn⁴, M. Boks⁵, R. Ophoff⁶, B. Pasaniuc⁷; ¹Bioinformatics InterDept.al Program, Univ. of California Los Angeles, Los Angeles, CA, ²Dept. of Human Genetics, David Geffen Sch. of Med., Univ. of California Los Angeles, Los Angeles, CA, ³Ctr. for Neurobehavioral Genetics, Semel Inst. for NeuroSci. and Human Behavior, Univ. of California, Los Angeles, Los Angeles, CA, ⁴Dept. of Psychiatry, Icahn Sch. of Med., Mount Sinai, NY, ⁵Dept. of Psychiatry, Brain Ctr. Univ. Med. Ctr. Utrecht, Univ. Utrecht, Utrecht, Utrecht, Netherlands, ⁶Dept. of Computational Med., David Geffen Sch. of Med., Univ. California Los Angeles, Los Angeles, CA, ⁷Dept. of Computational Med., David Geffen Sch. of Med., Univ. of California Los Angeles, Los Angeles, CA

Abstract Body:

Bipolar disorder (BP) is a complex, highly heritable mental illness. Approximately 20% of BP heritability can be explained by common SNP variants, while in twin studies, the overall heritability of BP has been estimated to be over 70%. Even though BP is highly heritable, only a fraction of the genetic loci that influence the risk of developing BP has been identified and the biological mechanisms that play a key role in the development of BP are mostly unknown. A recently proposed omnigenic model suggests that the heritability of most complex traits is heavily influenced by weak trans effects that converge onto a smaller set of trait-relevant genes that seem to be at the core of the molecular pathway. Given that numerous risk variants have downstream consequences in the same pathway, we investigate the associations between polygenic risk scores (PGS) and gene expression, otherwise known as expression quantitative trait scores (eQTS), to determine how genetic effects regulate genes and pathways and provide insights into the biology of bipolar disorder.

We derive PGS for bipolar disorder from sample data composed of individuals of European ancestries collected from psychiatric hospitals and institutions throughout the Netherlands via the University of California, Los Angeles. The cohort consisted of 916 individuals diagnosed with BP, 358 controls, and 216 related individuals. We further utilized this cohort to perform bulk RNA-seq of whole blood tissue to quantify estimates for gene expression as well as identify eQTL associations.

We determined a significant correlation between PGS and covariate-adjusted expression for 195 genes (Bonferroni adjusted $P < 2.62 \times 10^{-6}$), which we refer to as eQTS genes. The overrepresented Gene Ontology categories included those related to hormone receptor binding, antigen binding, and the major histocompatibility complex. Also, of these 195 eQTS genes, 20 were located within 1MB of an existing GWAS risk loci while the remaining eQTS genes indicate potential new risk regions that regulate the expression of BP. LoF-intolerant genes ($pLI > 0.9$) comprise ~14% of all genes and are enriched in the eQTS gene set with ~44% being LoF-intolerant while only ~13% of significant TWAS are LoF-intolerant. Also, ~6% of all genes have significant overlap with transcription factors (TFs) (Fisher's exact test, $OR = 1.2$, $P < 1.6 \times 10^{-3}$) and are enriched in eQTS genes with ~15% being strongly associated with TF ($OR = 2.2$, $P < 1.8 \times 10^{-4}$). Analysis with significant TWAS genes found no significant overrepresentation with TF ($OR = 1$, $P = 0.52$). Our results demonstrate that eQTS has the ability to identify potential candidate genes that capture meaningful signals.

Complex Traits Posters - Wednesday

PB1287. Associations between polygenic risk scores, alcohol use, and differences in brain measures in the UK Biobank

Authors:

V. Thornton^{1,2}, Y. Chang¹, L. Fox¹, S. Hartz², J. Bijsterbosch², A. Anokhin¹, L. Bierut³; ¹Washington Univ. in St. Louis, St. Louis, MO, ²Washington Univ. Sch. of Med., St. Louis, MO, ³Washington Univ. Sch. of Med., St Louis, MO

Abstract Body:

Purpose: The UK Biobank offers an unprecedented resource with self-reported alcohol use, genotypes, and 936 imaging derived phenotypes (IDPs). We leverage this opportunity to explore the relationship between genetics, brain differences, alcohol use behavior to determine the direction of causality between brain and alcohol use. Our analysis includes IDPs representing global and regional gray matter volume and cortical thickness derived from T1 MRI, white matter hyperintensity lesions derived from T2 MRI, white matter integrity from diffusion MRI, and 6 independent components from rfMRI. **Methods:** Survey responses, genotyping, and MRI were all acquired in accordance with UK Biobank protocols. We performed six runs in PRSice-2 to generate polygenic risk scores for drinks per week. We then performed linear regression in R while controlling for systolic and diastolic blood pressure, waist hip ratio, BMI, income, education years, pack years, brain volume, site, sex, age, imaging date, head size, and rfMRI motion. We modelled the association between alcohol use and brain imaging, PRS and alcohol use, and PRS and brain imaging. **Results:** 102 out of 936 IDPs are significantly ($p \leq 5.34 \times 10^{-5}$ after Bonferroni correction for multiple comparisons) associated with alcohol use measured as drinks per week. These include decreased total brain volume, total grey matter volume, and total white matter volume, as well as numerous regional measures. The association between PRS for drinks per week and alcohol use in drinks per week is positive, large (Beta = 14.6) and highly significant ($p = 4.3 \times 10^{-43}$). 9 out of 936 IDPs are significantly associated with PRS for drinks per week, these do not include total brain volume. Two regions, the left fusiform and left superiorfrontal are associated with both PRS and alcohol phenotype. This is double what is predicted by chance alone. **Conclusion:** The regions associated with drinks per week PRS, alcohol use, and brain imaging show that in some regions genetics contributes to brain structure which is associated with patterns of alcohol use. However, many regions remain which are associated with alcohol use and not PRS, consistent with alcohol affecting brain structure.

Complex Traits Posters - Thursday

PB1288. Autism and Cognitive Ability CNV- Genome Wide Association study (CNV-GWAS).

Authors:

C. Poulain^{1,2}, C. Proulx^{1,2}, E. Douard^{1,2}, J-L. Martineau², Z. Saci², Z. Pausova³, T. Paus², L. Almasy⁴, D. C. Glahn⁵, G. Huguet², S. Jacquemont^{1,2}; ¹Univ. of Montréal, Montréal, QC, Canada, ²CHU Sainte-Justine Res. Ctr., Montréal, QC, Canada, ³The Hosp. for Sick Children, Toronto, ON, Canada, ⁴Univ. of Pennsylvania, Philadelphia, PA, Canada, ⁵Boston Children's Hosp., Boston, MA

Abstract Body:

Background: All rare genomic variants (including CNVs) associated with Autism Spectrum Disorder (ASD) have also been associated with Intellectual Disability (ID). Moreover, 30% of autism patients have intellectual disability. In fact, we have shown that any CNV genome-wide encompassing genes intolerant to haploinsufficiency increase ASD risk even after adjusting for their negative effects on cognitive ability. The relationship between genetic risk, cognitive ability, and ASD remains contentious in part because controls in most genetic studies were not assessed for cognitive ability. **Knowledge gap:** The specific effects of genes within CNV are not well known. Indeed, some genes seem to be more associated with ASD than ID and vice versa. **Hypothesis :** CNV impact can be assessed by genes characteristics with regressions models. **We aim** to identify rare CNVs that confer ASD risk, while carefully controlling for their effects on cognition. **Methods:** We performed an association study (CNV-GWAS) on an aggregate dataset (2 cohorts with ASD and 6 control cohorts) of ~450 000 individuals, to identify CNVs implicated in ASD. For genome-wide significant CNVs, we recomputed the association study after adjusting for cognitive ability.

Results: We replicated previous associations of 33 recurrent CNVs with ASD. We also identified 100 new regions (17 for deletion and 83 for duplication) and corresponding genes not previously associated with ASD. When adjusting for cognitive ability, 19 of the new regions (6 for deletion and 13 duplication) remain significant with ASD.

Conclusion : These datasets allowed us to detect ultra rare variants with better precision than before. This unique design including controls with cognitive assessments demonstrated that CNVs deletions and duplications remained associated with ASD even after adjusting for their effects on cognitive ability.

Complex Traits Posters - Wednesday

PB1289. Autism Spectrum Disorder (ASD) in Qatar: Whole genome sequencing of 100 affected families highlights Dominant and Recessive risk genes of ASD

Authors:

M. Abdi^{1,2}, E. Aliyev², B. Trost³, M. Kohailan^{2,1}, W. Aamer², N. Hoang³, R. Shaath^{3,2}, J. Howe³, O. Rennie³, A. Syed², J. Lakshmi², S. Hussein², S. Padmajeya², A. Hussein², I. Poggiolini², A. Akil², M. Kamal⁴, S. Scherer³, K. Fakhro²; ¹Hamad Bin Khalifa Univ., Doha, Qatar, ²Dept. of Genetics, Sidra Med., Doha, Qatar, ³Hosp. for Sick Children, Toronto, ON, Canada, ⁴Dept. of Pediatrics, Sidra Med., Doha, Qatar

Abstract Body:

Abstract:

Autism spectrum disorder (ASD) is a neurodevelopmental condition associated with reduced social and communication skills, along with restricted interests and repetitive behaviors. The prevalence of ASD among children in Qatar has been estimated to be 1.14%. Large-scale genomics studies of ASD have identified causative variants that span the entire mutational spectrum, ranging from single nucleotide variants (SNVs) to large structural variants (SVs). In outbred populations, ASD often appears to be caused by *de novo* mutations; however, in consanguineous populations, recessive biallelic variants may contribute to substantial risk of ASD. Whole genome sequencing of 104 families (total samples=402) with children clinically diagnosed with ASD (n=107) was performed at a pediatric tertiary academic center. Using an integrative genetic approach, we examine the genomes for rare SNVs, indels, and SVs, and prioritized deleterious (loss-of-function (LoF) or predicted damaging missense) variants affecting known or candidate ASD genes. In total, we discovered 13 potentially pathogenic SNVs in previously reported ASD genes, including *SCN2A*, *STAG1*, *ANK3*, *KDM5B*, *MTOR*, and *PTCHD1*. The majority were *de novo* (8/13) or X-linked (3/13), while biallelic variants were present in 2 of the families. In addition, we identified deleterious variants in 22 candidate ASD genes, including 12 *de novo* variants in genes such as *MOV10*, *NPAS3*, *CHD9*, and *HDAC7* and 10 biallelic events in genes such as *TRAPPC9*, *SYNE2*, *CDH23*, and *METTL2A*. Moreover, we identified 17 SVs (12 *de novo* and 5 biallelic) affecting ASD candidate genes, including *NIPBL*, *CSNK1A*, *ELOVL2*, *MED12L*, *CHRH1*, and *CLN3*. Overall, we identified a putative genetic risk factor in 39.2% (42/107) of ASD cases—29 dominant, 10 recessive, and 3 X-linked. Our study highlights the importance of WGS studies for providing a molecular diagnosis for ASD patients in tertiary care settings and provides a growing resource and first comprehensive look into the genetic structure underlying ASD in the middle east population.

Complex Traits Posters - Thursday

PB1290. Automated identification, GWAS, and ExWAS of enlarged perivascular space burden in human brain MRI in the UK Biobank

Authors:

N. Parikshak¹, B. Geraghty¹, S. Gelfman², V. Rajagopal³, G. Coppola¹, J. Marchini¹, GHS-RGC DiscovEHR Collaboration, Regeneron Genetics Center; ¹Regeneron Genetics Ctr., Tarrytown, NY, ²Regeneron Genetic Ctr., Tarrytown, NY, ³Regeneron Genetics Ctr., White Plains, NY

Abstract Body:

Background: Perivascular spaces (PVS) are fluid-filled compartments surrounding blood vessels in the brain. They may function in circulating interstitial fluid and clearing metabolites in order to maintain brain tissue health. Numerous visible PVS on magnetic resonance imaging (MRI) may represent pathology. Prior studies have associated PVS burden with cardiovascular risk factors, stroke, and poor cognitive function. We pursued a genetic investigation of quantitative PVS burden in a large cohort to identify new risk factors related to human disease. **Methods:** We obtained T1 MRI scans from the UK Biobank (UKB) and applied a novel image processing algorithm based on connected-component labelling to identify PVS in the centrum semiovale (CS, cortical white matter) and basal ganglia (BG). We validated the quality of segmentation by visual inspection and performed a genome wide association study with PVS counts across common (GWAS) and rare protein-coding (ExWAS) variants in 35,043 individuals. We used genetic correlations, phenome-wide associations, and gene expression data to annotate our findings. **Results:** GWAS identified 22 significant loci ($P < 5e-8$) in the CS and 16 in the BG. Comparing our PVS CS results to prior work, we found significant genome-wide signal +/-500kB of 12/21 loci of a prior GWAS of binarized high PVS burden in cortical white matter, including those near SLC13A3 and GFAP. We find that many genes near significant loci are expressed in the human cerebrovasculature. Phenotypic and genetic correlations revealed distinct signal compared to other MRI-derived traits and region-specific signals in PVS with respect to cardiovascular risk factors, stroke, and cognitive function. ExWAS identified a significant association between rare variant burden in GPR20 and increased PVS burden in the BG but not the CS ($P < 2.5e-6$, driven by missense variants with MAF < 0.01). GPR20 is highly expressed in arterial cell types and specifically in vascular smooth muscle cells of the human brain. Missense variants in GPR20 exhibited no association with blood pressure traits, a nominal association with reduced cognition, and a trend with elevated stroke risk.

Conclusion: Automated PVS quantification in large cohorts can enable large-scale genomic investigations at a biobank scale. Missense mutations in GPR20 likely modulate PVS burden via changes in vascular smooth muscle and may result in cognitive changes and elevated stroke risk. Further exploration of GPR20 and the genetics of region-specific PVS burden are warranted to understand the relationship between the human cerebrovasculature and health.

Complex Traits Posters - Wednesday

PB1291. Burden of functional variants in epilepsy patients using a deep learning approach.

Authors:

A. Girard¹, C. Moreau¹, J. Michaud², B. Minassian³, P. Cossette⁴, S. Girard¹; ¹Univ. of Quebec in Chicoutimi, Chicoutimi, QC, Canada, ²CHU Sainte-Justine Res. Ctr., Montreal, QC, Canada, ³Hosp for Sick Children, Toronto, ON, Canada, ⁴CHUM Res. Ctr., Montreal, QC, Canada

Abstract Body:

Background: Epilepsy is a neurological disease with a strong genetic component. Nevertheless, classical methods, like GWAS, are not as effective at detecting new causal loci as in other diseases. Non-coding regions have largely been ignored in the study of the disease, so far only the role of non-coding RNA was studied. We used a deep learning approach to predict the tissue specific functional effect of non-coding variants in epilepsy patients. **Methods:** Whole genome sequence data are available for 241 epilepsy patients and 388 controls. We computed the predicted expression change of variants using the deep learning algorithm ExPecto (Zhou *et al.* 2018). We used python's statsmodels to conduct logistic regressions by comparing patients and controls functional variants' burden across the genome in different sets of genes (all genes, epilepsy genes, genes intolerant to loss-of-function variants and ion channels genes). **Results:** Variants were filtered based on an expression change threshold. It corresponds to the value at which directionality prediction becomes perfect when compared to known eQTLs from GTEx. Using only variants that passed the threshold, we performed a logistic regression to compute the functional variants' burden. Preliminary results show no difference between groups. Nevertheless, we observed that the odds ratios tend to increase when we use a larger threshold. Thus, showing that non-coding regulatory regions might play a role in the underlying genetic mechanism of the disease. **Conclusion:** Deep learning algorithms are incredibly powerful tools to predict variant functional effects. Those methods are especially useful in neurology since brain tissues are hard to access. ExPecto is an important asset in our study of epilepsy, and it has the potential to be so for many other illnesses. **References:** Zhou, J. et al. Deep learning sequence-based ab initio prediction of variant effects on expression and disease risk. *Nat. Genet.* 50, 1171-1179 (2018).

Complex Traits Posters - Thursday

PB1292. Causal effects of gut-related metabolites on human psychiatric disorders.

Authors:

S. Ihejirika¹, H. Xu², K. Ye¹; ¹Univ. of Georgia, Athens, GA, ²Univ. of Georgia, ATHENS, GA

Abstract Body:

Psychiatric disorders are currently the major cause of disability globally, and the human gut microbiome has been linked to several psychiatric disorders. However, the underlying mechanism by which the gut contributes to the etiology and progression of these diseases is still largely unknown. One hypothesis is that the gut microbiome produces certain metabolites which then travel to the brain and influence brain functions. In this study, the shared genetic basis and potentially causal relationship between metabolites produced by the gut microbiome and psychiatric disorders will be investigated. Summary statistics of GWAS in European populations were downloaded and after quality control, 17 psychiatric disorders were included. These disorders are major depression, schizophrenia, Alzheimer's disease, bipolar disorder, obsessive-compulsive disorder, anxiety disorders, post-traumatic stress disorder, anorexia nervosa, autism spectrum disorder, Tourette syndrome, attention deficit hyperactivity disorder, mood disorder, sleeplessness/insomnia, opioid dependence, alcohol use/dependence, cannabis use disorder, and neuroticism. A literature review was performed to identify metabolites that are related to the abundance of specific microbes or metabolic pathways in the gut microbiota. Only circulating metabolites with existing GWAS in UK Biobank were retained in our analysis to ensure sufficient sample size for genetic correlation analysis. We will first perform a genetic correlation analysis to examine shared genetic bases for all pairs of select metabolites and psychiatric disorders. Moreover, a two-sample Mendelian randomization analysis will be conducted to determine the causal effect of select metabolites on the 17 psychiatric disorders. The findings of this study will be useful in selecting metabolites and pathways of interest, to further investigate in the role they may play in the pathogenesis of psychiatric disorders.

Complex Traits Posters - Wednesday

PB1293. Cell-type-specific activity-dependent multiomic profiling in single hiPSC-derived neurons for neuropsychiatric disorders

Authors:

S. Zhang¹, C. Li², W. Wood¹, B. V. Jamison¹, H. Zhang¹, A. Kozlova³, A. Sanders⁴, Z. Pang⁵, X. He⁶, J. Duan⁷; ¹NorthShore Univ. Hlth.System, Evanston, IL, ²Northshore Res. Inst., Evanston, IL, ³The Res. Inst., NorthShore Univ. Hlth.System, Evanston, IL, ⁴North Shore Univ Hlth.System, Evanston, IL, ⁵Rutgers Robert Wood Johnson Med. Sch., New Brunswick, NJ, ⁶Univ Chicago, Chicago, IL, ⁷Northshore Univ Hlth.system/Univ of Chicago, Evanston, IL

Abstract Body:

Neuronal activity-dependent (NAD) gene regulation plays a vital role in brain development, learning, and memory processes that are impaired in neuropsychiatric disorders. While many NAD response genes, such as FOS (Fos Proto-Oncogene, AP-1 Transcription Factor Subunit), and late-response genes, such as BDNF (Brain-Derived Neurotrophic Factor), are well-known, their cell-type-specific response to neural activity and the underlying regulatory mechanisms are not well understood. Here, we co-cultured excitatory (Ex; glutamatergic) and inhibitory (Inh; GABAergic) neurons derived from human (hiPSC) of five donors, mimicked neuronal activities using 50 mM KCl stimulation, and performed single-cell multi-omics (scRNA-seq, scATAC-seq). We also performed CRISPR/Cas9-based gene editing on a specific open (accessible) chromatin region (OCR). Our integrative analysis of scRNA-seq and scATAC-seq data identified more than 9,000 cell-type-specific, differentially expressed (DE) genes after 1 hr (early response) and 6 hrs (late response) of KCl treatment, of which approximately 50% were either Ex or Inh neuron-specific. The NAD transcriptomic changes were accompanied by substantial alterations in genome-wide chromatin accessibility, with 11-18% and 23-32% differentially accessible peaks across cell types. We found an Ex neuron-specific KCl-responsive OCR (~700 bp) that is ~50 kb upstream of the BDNF transcription starting site. It exhibited increased accessibility at 1 hr and reached its peak intensity at 6 hrs. Peak-gene linkage analysis also correlated this OCR with BDNF expression. Additional transcription factor (TF) footprinting within this OCR revealed specific binding sites of the components of AP-1 TF heterodimer such as FOS and JUN families (early response genes) at 1 hr of KCl stimulation, while the TF binding pattern at 6 hrs of KCl stimulation shifted to POU2F1/POU5F1/POU3F4 and TCF3/4 families, both have been implicated in neurodevelopmental disorders. These results were further confirmed using 18 donor lines. Finally, we deleted the OCR by CRISPR/Cas9 editing in hiPSC with ~60% editing efficiency. We observed ~42% reduction of BDNF, suggesting it is required for the NAD BDNF expression. In summary, our study identified widespread cell-type-specific NAD transcriptomic and chromatin accessibility changes in a hiPSC-derived neuronal model and novel mechanistic insight into NAD-regulated BDNF expression, which itself plays part in neurodevelopment and neuropsychiatric disorders.

Complex Traits Posters - Thursday

PB1294*. Cellular context-specific gene regulation of neuropsychiatric disorders in single human neurons

Authors:

W. Wood¹, S. Zhang², H. Zhang¹, L. Liang³, C. Li⁴, B. Jamison¹, A. Kozlova¹, A. Sanders², Z. Pang⁵, X. He⁶, J. Duan⁷; ¹NorthShore Univ. Hlth.System, Evanston, IL, ²North Shore Univ Hlth.System, Evanston, IL, ³Dept. of Human Genetics, Univ. Of Chicago, Chicago, IL, ⁴Northshore Res. Inst., Evanston, IL, ⁵Dept. of NeuroSci. & Cell Biology, Rutgers Univ., New Brunswick, NJ, ⁶Dept. of Biophysics, Univ. of Chicago, Chicago, IL, ⁷Northshore Univ Hlth.system/Univ of Chicago, Evanston, IL

Abstract Body:

Genome-wide association studies (GWAS) of neuropsychiatric disorders have identified a plethora of neuropsychiatric risk loci that affect chromatin accessibility and gene expression (Zhang, Science 2020). However, functional interpretation of possible causal variants/genes remains challenging, especially in the interaction between polygenic risk effects and the environment. Regulatory variants often act in specific biological contexts, e.g., only in stimulated cells. We hypothesize that many neuropsychiatric risk variants may alter cell-type-specific chromatin accessibility and gene expression preferentially in activated/stimulated neurons. We model neural activation by potassium chloride (KCl) stimulation in co-cultured excitatory and inhibitory neurons of ~100 hiPSC lines, then assaying activity-dependent single-cell multiomes (scRNA/ATAC-seq) by mapping activity-specific expression and chromatin QTLs. With five donor lines as the start, we identified cell-type-specific expression changes of thousands of genes (40-50%) after 1hr (e.g., FOS) or 6hrs (e.g., BDNF) post-KCl stimulation in three neuron subtypes (GABAergic inhibitory, NEFM+ or NEFM- excitatory neurons). MAGMA analysis showed that the up-regulated genes are enriched for neuropsychiatric GWAS risk, with the strongest enrichment for schizophrenia (SZ). Most neuropsychiatric risk genes showed a later response and were predominantly up-regulated except for post-traumatic stress disorder (PTSD) risk genes. Moreover, the expression dynamics of risk genes shared by different disorders tended to be conserved between cell types; for instance, risk genes shared by SZ and bipolar (CACNA1C, FURIN, MAD1L1, and SP4) were up-regulated in all cell types. Consistent with the transcriptomic landscape, KCl-stimulation also led to changes in chromatin accessibility, with 11-18% and 23-32% differentially accessible (dynamic, DA) peaks across cell types at 1hr and 6 hrs post-stimulation. sLDSC analysis further showed that DA peaks showed stronger heritability enrichment of SZ and other neuropsychiatric disorders than static peaks. Furthermore, 604 SNPs in GABAergic and 608 SNPs in excitatory neurons showed differential allelic chromatin accessibility (i.e., allele-specific open chromatin, ASoC), most of which were stimulation-specific, including 4 SZ GWAS risk SNPs that showed activity-dependent ASoC. Our study provides novel mechanistic insights into how neuropsychiatric risk variants confer disease risk, expanding the repertoire of regulatory neuropsychiatric risk variants that may affect chromatin accessibility and gene expression in activated neurons.

Complex Traits Posters - Wednesday

PB1295. Characterization of a diverse Frontotemporal Dementia cohort, enriched for Caribbean Hispanic patients.

Authors:

K. Nuytemans^{1,2}, A. Martinez¹, F. RAJABLI¹, E. Gu¹, S. Tejada¹, H. Acosta³, B. Baumel⁴, C. Camargo⁴, X. Sun⁴, J. Vance^{1,2}, M. Cuccaro^{1,2}, M. Pericak-Vance^{1,2}; ¹John P. Hussman Inst. for Human Genomics, Univ. of Miami, Miami, FL, ²Dr. John T. Macdonald Fndn. Dept. of Human Genetics, Univ. of Miami, Miami, FL, ³Caribbean Ctr. for the Study of Memory and Cognition, San Juan, Puerto Rico, ⁴Dept. of Neurology, Univ. of Miami, Miami, FL

Abstract Body:

Background: The vast majority of biomedical data currently available for any disease is derived from studies in non-Hispanic white (NHW) populations. Specifically, clinical information, genetic factors as well as biomarkers for frontotemporal dementia (FTD) have been studied predominantly in those NHW populations. To increase representation in biomedical research, we set out to enroll and characterize a diverse FTD patient cohort enriched for Caribbean Hispanic patients. **Methods:** Our current cohort consists of 89 FTD patients (30% NHW, 67% Hispanic), with continuing enrollment from the University of Miami Hospital Neurology Department in Miami, FL and the Caribbean Center for the Study of Memory and Cognition in San Juan, PR. All patients were evaluated using NACC approved Uniform DataSet (UDS) or equivalent in their preferred language. For ~65% of the cohort we also completed the NACC FTD module forms. We generated genotyping data (Illumina GDA+Neurobooster array) as well as whole genome sequencing and plasma biomarker data (Quanterix Simoa Neuroplex-3; A β 40, A β 42, and total tau) for a subset of the cohort. **Results:** Initial genetic analyses showed none of the Hispanic patients are carriers of known FTD mutations originally identified in NHW patients, including the *C9orf72* repeat expansion and reported pathogenic variants in *MAPT* or *GRN*. We did not identify a significant difference in age-at-onset or Clinical Dementia Rating scores at time of enrollment between NHW and Hispanic patients. Additionally, biomarker data on A β 40/A β 42 ratio and total tau levels in a subset of 22 FTD patients (~12/10 Hispanic/NHW) did not show significantly different levels between patients of both ethnicities. **Conclusions:** Genetic analyses of FTD in underrepresented population groups is necessary as genetic information from research in NHW is not always generalizable across race/ethnicity. We are currently working to expand our efforts to include identification of novel genetic risk factors for FTD in the Hispanic patients using whole genome sequencing, full evaluation of the Neuroplex as well as p-tau181 and NfL biomarkers in the complete cohort and comparison of clinical presentations between ethnicities. The biomedical characterization of FTD across race/ethnicity will help the understanding of disease mechanisms in all patients ultimately preventing further health disparities.

Complex Traits Posters - Thursday

PB1296. Characterization of gene expression profile and molecular pathways involved in type 2 diabetes among self-identified Hispanic American individuals

Authors:

M. Yaser¹, H-H. Chen², H. Polikowsky³, L. Petty³, M. Lee⁴, J. McCormick⁴, S. Fisher-Hoch⁴, H. Highland⁵, M. Graff⁶, J. Seo¹, K. Young¹, K. North⁶, J. Below⁷, J. Below⁸; ¹Univ. of North Carolina Chapel Hill, Chapel Hill, NC, ²Vanderbilt Univ. Med. Ctr., Nashville, TN, ³Vanderbilt Univ., Nashville, TN, ⁴The Univ. of Texas Hlth.Sci. Ctr. at Houston Sch. of Publ. Hlth., Brownsville, TX, ⁵Univ North Carolina at Chapel Hill, Chapel Hill, NC, ⁶Univ North Carolina, Chapel Hill, NC, ^{7,8}Vanderbilt Univ Med Ctr., Nashville, TN

Abstract Body:

Background In the United States, 37.3 million adults have type 2 diabetes (T2D), with longstanding disparities affecting minorities, particularly Hispanic/Latino (H/L) populations. Both environmental and genetic contributions to T2D are widely acknowledged, and while genome-wide association studies (GWAS) have identified hundreds of loci associated with T2D, the function of much of this variation is unknown. Gene expression measures can illuminate the link between genetic variation and T2D, but to-date, only a handful of studies has examined the role of gene expression to identify molecular signatures associated with T2D, particularly in those populations most burdened by disease. In this study, we characterized the differential gene expression profiles and dysregulated pathways associated with T2D among H/L. **Methods** We leveraged whole blood cells derived RNA-sequencing data in 181 T2D with T2D and 424 normoglycemic controls collected from randomly selected study participants from the Cameron County Hispanic Cohort (CCHC) to identify patterns of differentially expressed (DE) genes. We used established protocols and alignment, yielding 15,694 protein coding genes after quality control. We applied *EdgeR* to assess DE, adjusted for sex, age, BMI, and 10 probabilistic estimation of expression residual (PEER) factors, followed by functional annotation and enrichment analyses of significantly dysregulated genes. **Results** After false discovery rate (FDR<0.05) adjustment, 126 genes were DE, including 36 downregulated and 90 upregulated genes in cases compared to controls. Of this set, 15 genes illustrated fold change of >5% in cases versus controls. We observed upregulation of genes *RETN*, *HP*, *ACE* and *ITG1A* genes, previously reported associated with T2D. Interestingly, novel gene expression associations were mapped, including for upregulated *CPT1A* which has previously been associated with gestational diabetes. Amongst people with T2D we observed increased WB expression of *NPAS4*, a neuronal transcription factor that is known to regulate expression of *BDNF*, part of the hunger/satiety pathway. Although less understood, *NPAS4* is also regulates transcription in pancreatic β -cells. Pathway enrichment analyses identified pathways involved in the immune response (activation and migration of leukocytes), stress signaling, and cell secretion activities. **Conclusions** Collectively, these data demonstrate how transcriptomic studies may identify novel genes important for T2D pathogenesis, elevating our understanding of molecular pathways involved and provide candidate therapeutic targets in this understudied population.

Complex Traits Posters - Wednesday

PB1297. Characterization of sequencing-based HLA alleles in a Quebec COVID-19 biobank

Authors:

P. McClelland¹, P. Nadukkalam Ravindran¹, V. Mooser², S. Zhou¹, C. Bhérier¹, D. Taliun¹; ¹McGill Univ., Montreal, QC, Canada, ²McGill Genome Ctr., Montreal, QC, Canada

Abstract Body:

Recent genetic studies have reported associations between HLA alleles and related polymorphisms with susceptibility, severity and progression of COVID-19. However, further investigation is needed to replicate these findings in other populations and better understand the role of HLA in the pathogenesis of COVID-19. Our project aims to characterize HLA alleles in the people from the province of Quebec, Canada, and identify their role in disease progression. We performed HLA typing (class I and II) using high-depth WGS data from 2,074 participants (1,558 European (EUR), 172 African (AFR), 118 East Asian (EAS), 90 South Asian (SAS), and 104 Admixed American (AMR) inferred genetic ancestries and 32 of other origins) in the Biobanque québécoise de la COVID-19 (BQC19), which collects high-quality biosamples and clinical data of hospitalized and non-hospitalized SARS-CoV-2 PCR positive and negative individuals. In total, we identified 403 HLA alleles, which passed quality checks: 71 A, 128 B, 53 C, 11 DPA1, 39 DPB1, 10 DQA1, 21 DQB1, and 70 DRB1. Of these, 347 HLA alleles were also present in the most extensive publicly available multi-ancestry high-resolution HLA-reference panel (N = 21,546). 47 HLA alleles in BQC19 had frequencies different from the HLA-reference panel (P-value < 14×10^{-5}): 29 in EUR, 17 in EAS, and 1 in AFR. We performed logistic regression (covariates: sex, age, 1-5 PCs) to test for HLA alleles association with COVID-19 severity (cases/controls = 401/980) and hospitalization (cases/controls = 816/575) among unrelated (>3rd degree) patients who tested positive. None of the associations reached the statistical significance threshold (P-value < 12×10^{-5}) corrected for multiple-testing, however, HLA-A*32:01 showed evidence of a protective effect against hospitalization (OR = 0.42) with moderate significance (P-value = 17×10^{-5}). This replicates previous suggestive evidence of HLA-A*32:01 at increased frequencies in healthy controls compared to COVID-19 patients. When stratified by ancestry, the HLA-A*32:01 allele showed the lowest P-value = 0.003 among all alleles for association with hospitalization in Europeans. All other ancestry-stratified analyses were underpowered. We are currently building a population-specific HLA reference panel for imputing HLA alleles using genotype-array data, allowing us to explore HLA associations in large-scale biobanks with tens of thousands of genotype individuals in the province and worldwide.

Complex Traits Posters - Thursday

PB1298. Characterizing 31 cardiometabolic candidate genes for a role in early vascular inflammation and foam cell formation using CRISPR-Cas9, *in vivo* imaging and deep learning

Authors:

M. den Hoed¹, E. Mujica¹, H. Zhang¹, A. Emmanouilidou¹, E. Mazzaferro¹, M. Nyberg², C. Metzendorf¹, M. Bandaru¹, N. Cook¹, J. Campos-Costa¹, G. Alavioon¹, S. Gry Vienberg², A. Larsson³, D. Djordjevic², A. Allalou⁴; ¹Beijer Lab. and Dept. of Immunology, Genetics and Pathology; Uppsala Univ. and SciLifeLab, Uppsala, Sweden, ²Novo Nordisk A/S, Målöv, Denmark, ³Dept. of Med. Sci.; Div. of Clinical Chemistry; Uppsala Univ., Uppsala, Sweden, ⁴Dept. of Information Technology; Div. of visual information and interaction; Uppsala Univ. and SciLifeLab, Uppsala, Sweden

Abstract Body:

INTRODUCTION: Genome-wide association studies have identified hundreds of loci that are robustly associated with risk of coronary artery disease. For most loci, the causal genes remain to be functionally characterized. Cell-based model systems provide valuable insights, but cannot model the complexity of a live, intact organism, while mouse models are too costly and time consuming to characterize hundreds of genes. In addition, mice lack *CETP* and only develop atherosclerosis in an *Apoe*^{-/-} or *Ldlr*^{-/-} background. To overcome these challenges, we developed and validated image- and CRISPR/Cas9-based model systems in zebrafish larvae, which we use here to functionally characterize the role of candidate genes in early-stage vascular inflammation and foam cell formation. **METHODS:** We characterized 21 genes for a role in early-stage vascular inflammation (i.e., vascular accumulation of lipids, neutrophils and macrophages), and 21 genes for a role in early-stage foam-cell formation (i.e., vascular accumulation of lipids, oxidized LDL and macrophages) using fluorescently labelled transgenes and a lipid staining dye. From day 5 post-fertilization, zebrafish larvae were fed on regular dry food (29 genes) or on regular dry food enriched with 4% extra cholesterol (10 genes). At day 9, 10 or 11, we acquired optical sections of the vasculature and liver using a fluorescence microscopy, and whole-body images in bright field. Outcomes were quantified using deep learning. After imaging, larvae were sacrificed and homogenized for enzymatic assessment of LDLc, triglyceride, total cholesterol and glucose levels. Crispants were distinguished from controls using a fragment length analysis. **RESULTS AND DISCUSSION:** By imaging 7270 CRISPR/Cas9 founders and controls for 31 genes, we show that cholesterol challenged *adamts7* crispants have less vascular infiltration of oxLDL and macrophages than controls; while CRISPR/Cas9-induced mutations in *gucylal* and *il6r* result in more vascular infiltration by oxLDL and macrophages, even without a cholesterol challenge. In line with the effects of SGLT2 inhibitors on glucose metabolism and cardiovascular risk, mutations in *slc5a2* result in lower glucose and LDLc levels in cholesterol-challenged larvae, and in less vascular infiltration by neutrophils in unchallenged larvae. **CONCLUSION:** By systematically characterizing candidate genes for a role in a range of atherosclerosis-related traits in zebrafish larvae, we can prioritize genes for further in-depth characterization and begin to understand the mechanisms by which loci identified by genome-wide association studies influence disease risk.

Complex Traits Posters - Wednesday

PB1299. Cholesterol and LDL-C levels are elevated prior to symptom onset in Alzheimer's disease independent of APOE-4.

Authors:

B. Chase^{1,2}, R. Frigerio³, D. Maraganore⁴, C. J. Yucus⁵, S. Patel⁵, J. S. Castle⁵, A. Epshteyn¹, A. R. Sanders⁶, J. Duan⁷, K. Markopoulou^{5,2}; ¹NorthShore Univ. Hlth.System, Skokie, IL, ²Univ. of Chicago, Chicago, IL, ³NorthShore Univ. Hlth.System, Evanston, IL, ⁴Tulane Univ., New Orleans, LA, ⁵NorthShore Univ. Hlth.System, Glenview, IL, ⁶North Shore Univ Hlth.System, Evanston, IL, ⁷Northshore Univ Hlth.system/Univ of Chicago, Evanston, IL

Abstract Body:

Background: Many of the >70 Alzheimer's disease (AD) risk loci, including *APOE*, impact lipid metabolism. Polygenic risk scores of low-density lipoprotein-cholesterol (LDL-C) levels, but not high-density lipoprotein-cholesterol (HDL-C), are also associated with AD risk. Although LDL-C plasma levels are elevated in early-onset AD, their association with the strongest AD risk allele, APOE-4, and their utility as a biomarker for later-onset AD (LOAD) progression remains controversial. **Methods:** To test associations of plasma lipid levels with AD, mild cognitive impairment (MCI), and *APOE* at times 5 yr before, at, and 5 yr after symptom onset, we utilized clinical data from a community-based practice setting gathered over up to 9 yr using standardized clinical documentation support tools embedded in the electronic medical record (EMR), and retrospective lipid panel data. Patients were genotyped as part of the DodoNA study using a custom Axiom SNP array. We compared lipid levels in AD (n = 390, 93% LOAD), MCI (n = 245), and at-risk (baseline = visit 1, n = 293) cohorts to 2-3 fold more controls matched for age, sex, and statin use. Controls were from other neurological disease cohorts and lacked ICD codes for cognitive impairment, dementia or Parkinson's disease. We report nominally significant associations between lipid levels and the conditions and *APOE* at each time, controlling for age, sex, body-mass index, and race. **Results:** AD was associated with increased cholesterol [pre: β (95% CI) = 10.1 (4.6, 15.6), $p < 0.0001$; onset: $\beta = 7.1$ (1.1, 13.2), $p = 0.021$; post: $\beta = 11.1$ (4.8, 17.3), $p = 0.001$], LDL-C [pre: $\beta = 7.9$ (3.2, 12.6), $p = 0.001$; post: $\beta = 5.94$ (0.5, 11.3), $p = 0.031$] and non-HDL-C [pre: $\beta = 8.0$ (3.0, 13.0), $p = 0.002$; onset: $\beta = 6.0$ (0.3, 11.6), $p = 0.038$; post: $\beta = 9.5$ (3.7, 15.4), $p = 0.001$]. While high cholesterol and LDL-C were associated with AD 5 yr before onset, no lipids were associated with MCI at any time point. Associations of lipids with statin use, sex, and age were consistent across time and cohort. Associations with at-risk cohort membership were inconsistent. APOE-4 was associated with cholesterol [$\beta = 11.8$ (4.3, 19.4), $p = 0.002$], non-HDL-C [$\beta = 12.1$ (5.2, 19.1), $p = 0.001$] and LDL-C [$\beta = 13.2$ (6.5, 19.9), $p < 0.001$] in MCI, but only 5 yr before onset, while in AD, these associations were not seen at any time. APOE-2 had consistent negative associations with cholesterol and LDL-C. **Conclusions:** Higher LDL-C and cholesterol levels are associated with increased AD risk independent of APOE-4. Finding higher LDL-C and cholesterol levels in AD but not MCI five years prior to symptom onset suggests that plasma LDL-C and cholesterol levels may serve as a biomarker for LOAD progression.

Complex Traits Posters - Thursday

PB1300. Choroidal thickness as a biomarker for age-related macular degeneration progression: Genome-wide Association Study in Amish

Authors:

J. Cooke Bailey¹, F. RAJABLI², Y. Song¹, O. García-Rodríguez³, L. Gómez³, S. Slifer³, K. Miskimen¹, M. Nittala⁴, S. Sadda⁴, J. Haines¹, M. Pericak-Vance³, D. Stambolian⁵, W. Scott²; ¹Case Western Reserve Univ., Cleveland, OH, ²Univ. of Miami, Miami, FL, ³Univ. of Miami Miller Sch. of Med., Miami, FL, ⁴Doheny Imaging Reading Ctr., Doheny Eye Inst., Los Angeles, CA, ⁵Univ. of Pennsylvania, Philadelphia, PA

Abstract Body:

Prevalence of age-related macular degeneration (AMD), the second leading worldwide cause of irreversible blindness, continues to rise with the growth of the population over 65 years of age. Progression from early to late AMD varies substantially, and factors influencing this progression are not yet fully discerned. Choroidal thickness (CT), which is significantly heritable and inversely associated with AMD severity, is a promising, potential AMD biomarker. To identify genetic loci influencing CT change, we performed a genome-wide association study (GWAS) in the Amish Eye Study (AES). Amish are a founder population with less genetic and environmental variation than the general population. AES recruits from the three largest Amish communities in the United States: Holmes County, Ohio, Elkhart and LaGrange Counties, Indiana, and Lancaster County, Pennsylvania. For this analysis, genotype data from the Illumina MEGAex array were generated for a family-based prospective cohort of 499 Amish adults over age 65. Association between single nucleotide polymorphism (SNP) allele dosage and two year difference in CT, measured on Heidelberg Spectralis optical coherence tomography (OCT) instruments, was assessed with the GWAf program via linear mixed modeling adjusting for sex, age, spherical equivalent refraction, intraocular pressure, and population and pedigree structures. Although no loci were associated with two year difference in CT at genome-wide significance ($p\text{-value} < 5 \times 10^{-8}$), we identified six genes with SNPs generating suggestive association ($p\text{-value} < 5 \times 10^{-5}$). At four SNPs, the rare allele was suggestively associated with decreasing CT: rs17418461 ($p\text{-value} = 3.9 \times 10^{-6}$, *DABI*) and rs17535312 ($p\text{-value} = 8.6 \times 10^{-6}$, *TLL7*) on chromosome 1, and rs576371849 ($p\text{-value} = 4.8 \times 10^{-6}$, *LINC00900*) and rs116309326 ($p\text{-value} = 4.8 \times 10^{-6}$, *LINC02698*) on chromosome 11. At two SNPs, rare alleles were suggestively associated with increasing CT: rs115627559 ($p\text{-value} = 5.5 \times 10^{-6}$, *TBC1D1*) on chromosome 4 and rs35892074 ($p\text{-value} = 9.22 \times 10^{-6}$, *LRRC28*) on chromosome 15. Two known loci for advanced AMD (or appropriate proxy SNPs) were nominally significant: rs10117842 ($p\text{-value} = 0.02$, *TRPM3*) on chromosome 9 and rs20145990 ($p\text{-value} = 0.04$, *C20orf85*) on chromosome 20. *DABI*, *TLL7*, and *TBC1D* are expressed in the retina and, thus, we have identified three genes that may be associated with CT change, and, therefore, AMD progression. Follow up studies are needed to replicate these findings. Identification of novel genes associated with CT and/or AMD progression could provide insight into mechanisms underlying progression to AMD and inform future therapeutic developments.

Complex Traits Posters - Wednesday

PB1301. Classical HLA Alleles are Associated with Fasting Glucose and Type 2 Diabetes in Multiple Populations

Authors:

G. Chen¹, J. Zhou², J. Zhang³, A. Bentley³, A. Doumatey², D. Shriner⁴, C. Rotimi⁵, A. Adeyemo⁵; ¹NHGRI/CRGGH, Bethesda, MD, ²NHGRI, Bethesda, MD, ³NIH, Bethesda, MD, ⁴Natl. Inst.s Hlth, Bethesda, MD, ⁵NIH, Bethesda, MD

Abstract Body:

Introduction: Class II major histocompatibility complex (MHC-II) loci play a key role in the pathophysiology of type 1 diabetes (T1D). However, several GWAS for type 2 diabetes (T2D) have found genome-wide significant variants in both class 1 and 2 HLA genes. The relationship between classical HLA alleles and T2D has rarely been investigated in large cohorts. We investigated the association between classical human leukocyte antigen (HLA) alleles and fasting glucose (FG) and T2D in large study cohorts. **Methods:** Participants from 11 datasets were included in this study for a total of 30,376 individuals: 5,080 Africans, 9,357 African Americans, 12,045 European Americans, 697 Asian Americans, 1,907 Chinese, and 1,290 Hispanic Americans. Of these, 17.6% had T2D. Classical HLA alleles (*A*, *B*, *C*, *DP*, *DQA*, *DQB* and *DR*) were imputed using the HIBAG algorithm. Association analysis was done by study under an additive genetic model with covariates of sex, age, body mass index, and significant principal components of population structure, followed by a fixed-effects meta-analysis. P values were adjusted using the Bonferroni method. **Results:** The most significant associations with FG were with HLA-DQA1*01:02 ($P_{adj}=0.0050$), HLA-DRB1*15:01 ($P_{adj}=0.0059$) and HLA-DQB1 ($P_{adj}=0.015$) while HLA-DQA1*01:02 was associated with T2D with $p_{adj}=0.038$. These findings remained significant after adjusting for a SNP-derived PRS for FG and T2D, as well as after conditioning on the most significant SNPs within the MHC region. Haplotype analysis showed that DRB1*15:01-DQA1*01:02-DQB1*06:02 was associated with FG ($p=0.003$) and T2D ($p<0.0001$). In Africans, in whom additional data was available, this haplotype was also strongly associated with higher insulin resistance (IR) ($p<0.0001$), lower Gastric Inhibitory Polypeptide (GIP) ($p=0.0014$), and Glucagon-Like Peptide-1 (GLP-1) levels ($p<0.0001$). **Conclusions:** This study reveals that classical HLA alleles are significantly associated with higher FG and T2D in multiple populations. Our finding in Africans of an HLA haplotype associated with higher IR and lower GIP and GLP-1 levels suggests that the associations are mediated via mechanisms that result in insulin resistance and/or reduced β -cell stimulation in response to the gut sensing glucose or a meal. This work adds to a growing body of literature demonstrating some overlap in the pathophysiology and genetic architecture of T1D and T2D.

Complex Traits Posters - Thursday

PB1302. CLEC16A regulates the adipogenic and lipolytic capacity of adipocytes

Authors:

M. Bakay¹, R. Pandey², B. Strenkowski², H. Hakonarson¹; ¹Children's Hosp. of Philadelphia, Philadelphia, PA, ²Children's Hosp. of Philadelphia, Philadelphia, PA, United States, Philadelphia, PA

Abstract Body:

CLEC16A has been shown to play a role in autophagy/mitophagy processes and genetic variants in *CLEC16A* are implicated in multiple autoimmune diseases. To investigate the role of CLEC16A we have generated an inducible ubiquitous *Clec16a* knockout (KO). The global *Clec16a* KO mice (*Clec16a*^{AUBC}) exhibit a complex phenotype with marked immune dysfunction, rapidly progressing sensory neurodegeneration and severe lipodystrophy. Recently we demonstrated that JAK/STAT inhibitor therapy partially rescues the lipodystrophic autoimmune phenotype of *Clec16a*^{AUBC}. Here, we investigate CLEC16A contribution to adipocyte functions.

Methods: We generated *Clec16a*-deficient 3T3-L1 adipocytes using the CRISPR-Cas9 system and continued the exploration of *Clec16a*^{AUBC} mice for loss-of-function studies. **Results:** We established *Clec16a*-deficient 3T3-L1 cell line (Clec-KO) and confirmed the *Clec16a* deletion for DNA, RNA, and protein. The rate of cell proliferation of Clec-KO preadipocytes was significantly faster comparing to Ctrl cells. Autophagy markers (LC3 and p62) as well as mTOR activity were not affected in Clec-KO preadipocytes when comparing to Ctrl in starvation-induced autophagy. To examine the roles of CLEC16A on adipogenesis, Clec-KO preadipocytes were differentiated into adipocytes, and analyzed for lipid accumulation using Oil-Red-O staining. While Clec-KO cells showed comparable lipid droplet accumulation within the adipocytes to that of controls, secreted adiponectin levels in the conditioned media of Clec-KO were slightly decreased versus Ctrl. To further elucidate the roles of CLEC16A in adipogenesis, the mRNA levels of key transcription factors for adipogenesis such as C/EBPs and PPAR γ were analyzed: C/EBP β and C/EBP α were dysregulated; PPAR γ at terminal differentiation was significantly decreased in Clec-KO. mRNA levels of mature adipocyte marker genes such as FABP4, leptin, and Adipoq were also significantly decreased in Clec-KO cells. The mRNA levels of marker genes encoding adipocyte lipolysis, including adipocyte triglyceride lipase (ATGL), hormone-sensitive lipase (HSL), monoacylglycerol lipase (MGL), and lipoprotein lipase (LPL), were significantly elevated compared to Ctrl. **Conclusions:** Mature adipocyte differentiation was attenuated in Clec-KO adipocytes, indicating that CLEC16A is important for supporting adipogenesis. While these finding require further investigation, they concur with previous results in *Clec16a*^{AUBC} mice and suggest that adipocytes are important in regulating various biological functions, including weight gain and may play a role in lipodystrophies.

Complex Traits Posters - Wednesday

PB1303*. Clinical utility of polygenic scores for cardiometabolic disease in Arabs

Authors:

I. Shim^{1,2,3}, H. Kuwahara⁴, N. Chen⁴, M. Hashem⁵, L. AlAbdi⁶, X. Gao⁴, M. AbouElHoda⁶, H-H. Won³, P. Natarajan^{1,2}, P. T. Ellinor^{1,2}, A. V. Khera^{1,2,7}, F. S. Alkuraya⁶, A. C. Fahed^{1,2}; ¹Div. of Cardiology, Dept. of Med., Massachusetts Gen. Hosp. and Harvard Med. Sch., Boston, MA, ²Cardiovascular Disease Initiative of the Broad Inst. of Harvard and MIT, Cambridge, MA, ³Dept. of Digital Hlth., SAIHST, Sungkyunkwan Univ., Samsung Med. Ctr., Seoul, Korea, Republic of, ⁴Computational BioSci. Res. Ctr., King Abdullah Univ. of Sci. and Technology, Thuwal, Saudi Arabia, ⁵Dept. of Computational Sci., Ctr. for Genomic Med., King Faisal Specialist Hosp. and Res. Ctr., Riyadh, Saudi Arabia, ⁶Dept. of Translational Genomics, Ctr. for Genomic Med., King Faisal Specialist Hosp. and Res. Ctr., Riyadh, Saudi Arabia, ⁷Verve Therapeutics, Cambridge, MA

Abstract Body:

Background Arabs account for 5% of the world population and have a high burden of cardiometabolic disease, yet they remain underrepresented in genetic studies. What is the clinical utility of polygenic scores for cardiometabolic disease in Arabs?

Method In 5,399 Arab patients (age 54.8±14.8 years, 35.7% female), we tested the performance of European-derived polygenic scores for 3 diseases (coronary artery disease [CAD], type 2 diabetes [DM-2], and cardiomyopathy [CM]), and 7 traits (LDL cholesterol, HDL cholesterol, triglyceride, systolic and diastolic blood pressures [BP], body mass index [BMI], and height). To optimize better scores for Arabs, in a validation subset (N=2,700) we selected the score with the largest AUC or R² out of multiple candidate scores calculated using best-available methods (PRSice2, LDpred2, lassosum2, PRS-CS, and PRS-CSx). We constructed a population reference distribution (N=1,017) from ethnically matched Arabs to create ancestry-adjusted polygenic scores and define percentiles. In a testing subset (N=2,699), we studied the association of selected scores with disease, the proportion of individuals with high genomic risk, and the interplay of genomic risk and clinical risk factors. Models were adjusted for age, sex, and genetic ancestry.

Results Compared to European-derived scores, we identified better performing scores for all 10 cardiometabolic traits, some with comparable performance to Europeans despite the lack of large Arab GWAS. Optimized scores for CAD, DM-2, and CM had odds ratio per standard deviation (SD) of 1.49, 1.74, and 1.32 and AUC of 0.79, 0.73, and 0.64, respectively. Optimized scores for LDL cholesterol, HDL cholesterol, triglycerides, SBP, DBP, BMI, and height had adjusted R² of 0.04, 0.13, 0.07, 0.11, 0.04, 0.08, and 0.51, respectively, and each score SD was associated with an increase of the trait by 9.9 mg/dL, 3.5 mg/dL, 28.3 mg/dL, 2.9 mmHg, 1.8 mmHg, 1.1 kg/m², and 0.025 m, respectively. The proportion of people with more than two-fold increased genomic risk was 21% for CAD, 29% for DM-2, 5% for CM, 10.6% for obesity, 4% for hypercholesterolemia, and 7.5% for hypertension. Genomic risk for CAD was independent of conventional risk factors and the polygenic score identified individuals who had early-onset and more severe disease.

Conclusion We describe a pragmatic approach for optimizing polygenic scores for 10 cardiometabolic traits in Arabs and show a strong promise for clinical utility. This framework leverages publicly available resources - short of much-needed large GWAS in non-Europeans - and could be generalizable to other populations to advance equitable clinical implementation of polygenic scores.

Complex Traits Posters - Thursday

PB1304. Clonal behavior across multiple timepoints in clonal hematopoiesis

Authors:

T. Mack^{1,2}, K. Von Beck¹, A. Silver¹, M. Savona¹, A. Bick^{1,2}; ¹Vanderbilt Univ. Sch. of Med., Nashville, TN, ²Vanderbilt Genetics Inst., Nashville, TN

Abstract Body:

Clonal hematopoiesis of indeterminate potential (CHIP) is a common age-related condition characterized by an acquired somatic mutation in a hematopoietic stem cell that confers a growth advantage. This “driver” mutation can lead to increased proliferation relative to other hematopoietic stem cells, which results in a distinct sub-clonal blood cell population that increases risk of developing blood cancer, cardiovascular disease, and death. While DNA biorepositories have the ability to identify large cohorts of individuals with CHIP, they typically only contain blood from a single timepoint, limiting the ability to infer how CHIP clones changes over time. Additionally, clones with faster expansion rates have been linked to more detrimental outcomes, but little is known about why certain clones grow faster than others. In this study, we utilized multi-timepoint samples from 103 individuals with CHIP in Vanderbilt’s biorepository (BioVU) to characterize clonal behavior over time. We used the linked electronic health record to exclude patients with prevalent hematologic malignancy. In this cohort, the driver mutations occurred 47% of the time in *DNMT3A*, 23% of the time in *TET2*, and 9% of the time in *JAK2*. 32 of these individuals had more than one CHIP driver mutation. The mean difference in time between the two timepoints was 5.2 years (SD=2.9). Surprisingly, we observed both clonal expansion and clonal shrinkage across the timepoints with 30% of *DNMT3A*, 0.6% of *TET2*, and 46% of *JAK2* clones shrinking over time. The fastest average expansion was seen in *TET2* clones (7% growth/year) and the slowest growth in *JAK2* clones (0.6% growth/year), but there was a significant amount of variation between individuals. The average expansion rate for *DNMT3A* was 2% growth/year, and there were no differences observed between loss of function mutations, missense mutations or *DNMT3A* R882 hotspot mutations. In summary, we leverage electronic health record linked serial biospecimens to quantify clonal expansion rate on a per individual basis. We find significant individual level heterogeneity in CHIP clonal dynamics even amongst individuals with the same CHIP driver mutation. Future work will evaluate how the phenome and drug exposome affects how clones change over time.

Complex Traits Posters - Wednesday

PB1305. Collagen gene cluster expressions role on liver fibrosis in biliary atresia patients

Authors:

F. Gunadi¹, A. Makhmudi¹, K. Iskandar²; ¹Univ.s Gadjah Mada, Yogyakarta, Indonesia, ²UGM Hosp., Yogyakarta, Yogyakarta, Indonesia

Abstract Body:

Background: Liver fibrosis progression might continue even after Kasai surgery in biliary atresia. Our study associated the expressions of the collagen gene cluster, including *COL6A1*, *COL6A2*, *COL6A3*, and *COL1A1*, with liver fibrosis in patients with BA. **Methods:** We extracted total RNA from liver of BA patients and controls, followed by qPCR of *COL6A1*, *COL6A2*, *COL6A3*, and *COL1A1* genes. **Results:** Our study involved 20 patients with BA and 18 controls. A significant downregulated of *COL6A1* (ΔC_T 9.06 ± 2.64 vs. 5.42 ± 2.41 ; $p=0.0009$), *COL6A2* (ΔC_T 8.25 ± 2.07 vs. 5.77 ± 3.51 ; $p=0.02$), *COL6A3* (ΔC_T 11.2 ± 6.08 vs. 6.78 ± 3.51 ; $p=0.024$), and *COL1A1* (ΔC_T 3.26 ± 1.71 vs. 0.19 ± 2.76 ; $p=0.0015$) expressions were noted in liver of patients with BA compared to controls. In addition, there was a significant association between collagen gene cluster expressions and liver cirrhosis ($p=0.0085$, 0.04 , and 0.0283 for *COL6A1*, *COL6A2*, and *COL6A3*, respectively). **Conclusion:** Our study reveals the collagen gene cluster expressions aberrant in patients with BA, implying the role of these gene clusters in the liver fibrogenesis of BA.

Complex Traits Posters - Thursday

PB1306. Colocalization and variant-to-gene mapping nominates pleiotropic bone mineral density effector genes

Authors:

M. Conery¹, J. A. Pippin², W. P. Bone³, Y. Wagley⁴, M. C. Pahl⁵, K. D. Hankenson⁴, S. Grant¹, B. Voight³; ¹Children's Hosp. of Philadelphia/Univ. of Pennsylvania, Philadelphia, PA, ²Children's Hosp. of Philadelphia, Philadelphia, PA, ³Univ. of Pennsylvania, Philadelphia, PA, ⁴Univ. of Michigan, Ann Arbor, MI, ⁵Children's Hosp. of Philadelphia, Philadelphia, PA

Abstract Body:

53 million Americans live with reduced bone mineral density (BMD) and elevated risk of osteoporotic fractures, yet the genetic etiology of BMD and how it relates to those of other complex traits is poorly understood. Specifically, while some BMD loci, such as *3q21.1*, have been found to exhibit pleiotropy, or affect multiple phenotypes, it is unknown in general how prevalent pleiotropy is across BMD loci. To elucidate these issues, we used coloc to test for colocalization between BMD signals identified by a genome-wide association study (GWAS) and the GWAS signals of 41 related complex traits. We identified 194 BMD loci that colocalize with one or more other traits, including 58 with height and 50 with serum alkaline phosphatase levels. At colocalizing loci, we nominated possible effector genes using two approaches. First, we used ColocQuiaL to test for colocalization of the BMD associations with Genotype-Tissue Expression (GTEx) v8 expression quantitative trait loci (eQTLs). Second, to supplement the lack of bone eQTLs in GTEx, we used ATAC-seq (Assay for Transposase-Accessible Chromatin) and Capture-C datasets from human mesenchymal stem cell derived osteoblasts to nominate additional genes. We identified open-chromatin regions that contained proxies of the lead, colocalized BMD SNPs and that either overlapped the promoter of an expressed gene or interacted with one or more such promoters. The two methods nominated effector genes at 94 loci including known BMD modulating genes like *SOST* and *ALPL* as well as *FDFT1*, a target of BMD-increasing bisphosphonate therapy. We hypothesize that loci prioritized specifically by the second method mostly mediate their associations via effects on osteoblast expression of nominated genes. We conclude that these observations warrant further investigation, and we have already initiated a framework that uses CRISPR interference in hFOB1.19 cells to knockdown these nominated genes and test for effects on bone deposition with paired ALP and Alizarin Red S Assays. Our approach is implicating new osteoporosis drug targets and providing insight into the mechanisms by which BMD loci exhibit cross-phenotypic effects.

PB1307. Combining genetic risk with machine learning derived biological age improves prediction of type 2 diabetes

Authors:

J. Leiby¹, M. Shivakumar¹, M. Lee¹, D. Kim¹, E. Choe²; ¹Univ. of Pennsylvania, Philadelphia, PA, ²Seoul Natl. Univ. Hosp., Seoul, Korea, Republic of

Abstract Body:

Introduction: Chronological age is a strong risk factor for death and disease. However, individuals can age biologically at different rates. The difference between the two ages, delta age, represents an important feature related to overall health and may have implications for clinical care and disease prevention. In this study, we developed a machine learning model to calculate delta age. We performed association analyses with 108 phenotypes, corroborated by comprehensive health check-ups in a Korean population, including metabolic and lifestyle factors. Lastly, we examined how delta age can be used to stratify an individual's risk of type 2 diabetes (T2D) in combination with their genetic risk for disease. **Methods:** The target dataset in this study was the Korean GENIE cohort, consisting of physiological and genetic data. To generate biological age, we selected healthy individuals from the KOGES dataset (The Korean Genome and Epidemiology Study cohort) and used a random forest model to estimate chronological age. We used the trained model to calculate delta age in the target dataset. Association analyses were performed using logistic or linear regression with 108 phenotypes, correcting for chronological age. For T2D genetic risk, we used LDpred to estimate variant weights from BioBank Japan summary statistics and used these to calculate the polygenic risk score for T2D (PRS-T2D) in the target dataset. To validate PRS-T2D and delta age, we perform logistic regression. To determine if delta age is a significant feature to stratify risk of T2D in combination with genetic risk, we performed logistic regression for T2D within each quantile correcting for covariates and genetic principal components. **Results:** The mean delta age was -2.66 (+/- 5.15). Delta age is significantly associated with 14 phenotypes including T2D. Our models showed that including delta age as a feature to predict instance of T2D significantly increased the performance of the PRS-T2D only model from an AUC of 0.777 to 0.786. In the quantile analysis biological age remains a significant feature for detecting T2D, with an odds ratio of 1.82 ($p=1.48e-2$) in the lowest fifth quantile PRS-T2D, and 1.67 ($p=5.48e-6$) in the highest quantile PRS-T2D. **Discussion:** We used machine learning to calculate biological age and found it is significantly associated with clinically relevant phenotypes. The T2D analysis showed that delta age significantly improved prediction of disease and can be used to further stratify an individual's risk in the highest and lowest genetic risk quantiles. Replication in more diverse datasets will further support the clinical utility of biological age.

Complex Traits Posters - Thursday

PB1308. Combining polygenic and monogenic causes for improved osteoporotic fracture risk prediction.

Authors:

T. Lu¹, V. Forgetta², S. Zhou¹, B. Richards¹, C. Greenwood³; ¹McGill Univ., Montreal, QC, Canada, ²Lady Davis Inst., Montreal, QC, Canada, ³Jewish Gen. Hosp., Montreal, QC, Canada

Abstract Body:

Osteoporosis and osteoporotic fractures affect >200 million people worldwide, cause significant morbidity and mortality, and incur a heavy socioeconomic burden. Predicting bone density by polygenic risk score (PRS) has demonstrated potential utility in refining osteoporotic fracture risk prediction and management that rely on traditional clinical risk factors. However, existing PRSs do not account for rare monogenic causes, because of a lack of power to accurately estimate their effects in previous studies. Leveraging UK Biobank whole-exome sequencing data from 454,787 individuals, we developed a PRS, called ggSOS, that harnesses both common and rare variants to predict heel ultrasound speed of sound (SOS), a quantitative measure of bone density. Using a combination of SnpEff annotation and Combined Annotation Dependent Depletion (CADD) score, we first generated multiple gene burden masks based on predicted functional impacts of detected variants. Next, we assigned European ancestry individuals into a training dataset (N = 317,434) and a test dataset (N = 74,825). In the training dataset, we conducted a genome-wide association study for SOS and developed a common variant-based PRS, aggregating variants with a minor allele frequency (MAF) >0.001. We then regressed measured SOS on this PRS and conducted burden testing for 19,308 RefSeq genes using the residualized SOS, targeting rare pathogenic variants with a MAF ≤0.001. Finally, the common variant-based PRS was additively combined with significant gene burden masks to derive ggSOS, with common-rare interaction effects incorporated via forward selection.

Fourteen genes harbored rare pathogenic variants associated with SOS (p-value <2.5x10⁻⁶). These variants cumulatively affected 6.6% of individuals. Amongst 4,949 carriers in the test dataset, a one standard deviation decrease in ggSOS was associated with 1.52 (1.27-1.81)-fold increased odds of osteoporosis and 1.45 (1.25-1.69)-fold increased hazard of major osteoporotic fracture. Compared to a common variant-based PRS, ggSOS had increased C-indices for predicting osteoporosis (0.625 vs. 0.619) and major osteoporotic fracture (0.620 vs. 0.613) risks. Furthermore, ggSOS demonstrated mildly improved predictive performance in populations of African and East Asian ancestries, but not in populations of South Asian and other admixed ancestries.

In conclusion, identifying monogenic causes may assist polygenic prediction for osteoporotic fracture risk. Nonetheless, the relatively high cost of sequencing, limited number of carriers, and small magnitude of predictive power gain entail careful considerations in research and in clinics.

Complex Traits Posters - Wednesday

PB1309. Common and rare variant associations with spinal stenosis in 29,488 cases.

Authors:

J. Otto, E. Stahl, N. Lin, GHS-RGC DiscovEHR Collaboration, Penn Medicine BioBank, Regeneron Genetics Center, C. Paulding, G. Coppola, K. Praveen; Regeneron Genetics Ctr., LLC, Tarrytown, NY

Abstract Body:

Background: Chronic back pain is a common musculoskeletal problem, affecting up to 7.5-15% of individuals worldwide, and is a leading cause of global disability. Numerous medical conditions contribute to symptoms of back pain, including spinal stenosis. Genetic factors account for 21-67% of the variation in risk for low back pain, and up to 80% of the variation in risk for spinal stenosis, warranting further investigation into the specific gene regions contributing to the development of these traits.

Methods: Case-control status was defined using ICD-10 M48.0 diagnosis codes and included 29,488 cases and 774,235 controls across five cohorts (UK Biobank, Geisinger DiscovEHR, University of Pennsylvania - Penn Medicine BioBank, Mount Sinai's BioMe Personalized Medicine Cohort, and FinnGen). Cross-ancestry genome-wide and exome-wide association analyses (GWAS and ExWAS, respectively) were conducted for single common and rare variants, as well as their gene burdens using REGENIE, and results across cohorts were pooled using inverse-variance weighted meta-analysis.

Results: After correction for multiple testing, 24 genome-wide significant ($P < 5e-08$) loci were identified that included effects of common variants near novel and genes previously identified in GWAS of spinal stenosis and related conditions, such as back pain. Amongst novel loci, we observed a protective association of a missense variant (rs6330; Ala35Val) within the *NGF* gene ($OR = 0.93$; $P = 3.70e-11$). Three genome-wide significant rare variant ($MAF < 0.005$) associations were also observed, including a rare missense variant (rs28931614, Gly380Arg; $MAF = 9.47e-06$) in the *FGFR3* gene ($OR = 71.54$; $P = 1.11e-08$). Gly380Arg is a known pathogenic variant for Achondroplasia, an autosomal-dominant skeletal dysplasia disorder in which spinal stenosis is a common complication. Finally, in gene burden tests, rare ($MAF < 0.001\%$) predicted loss-of-function and deleterious missense variants in a gene involved in the regulation of skeletal development pathways were significantly associated with increased risk of spinal stenosis ($OR = 2.49$; $P = 6.40e-09$).

Discussion: The current study represents the largest investigation of genetic factors underlying spinal stenosis to date. Identified genes and variants likely represent biological pathways involved in both cause (e.g., osteoarthritis) and consequence (e.g., reported back pain) of spinal stenosis. Given *NGF*'s role in mediating chronic pain response and osteoarthritis disease progression, future studies might seek to elucidate whether the current genetic signal reflects its role in disease pathophysiology or pain outcomes.

Complex Traits Posters - Thursday

PB1310. Comparison of clinical characteristics among survivor and non-survivor of covid-19 infected patients: Scoping review and meta-analysis.

Authors:

M. Adebisi^{1,2,3}, O. Ropo⁴, A. Adebisi^{1,2,3}, A. Shekari^{5,2}, M. Enwere^{5,2}; ¹Computer Sci. Dept., Coll. of Pure and Applied Sci., Landmark Univ., Omu-aran, Nigeria, ²Covenant Applied Informatics and Communications- Africa Ctr. of Excellence (CAPIIC-ACE), Ota, Nigeria, ³Landmark Univ. SDG 3: Good Hlth.and Well-being, Omu-aran, Nigeria, ⁴Biostatistics Unit, Discipline of Publ. Hlth.Med., Sch. of Nursing and Publ. Hlth., Univ. of KwaZulu-Natal (UKZN), Durban, South Africa, ⁵Dept. of Computer and Information Sci., Coll. of Sci. and Technology, Covenant Univ., Ota, Nigeria

Abstract Body:

The Coronavirus Disease of 2019 was identified as an emerging infectious disease caused by Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV 2) and was named COVID-19 by the WHO. This study used a meta-analysis approach to explore the proportion of systemic disorder with the development of COVID-19 infection. The aim is to summarize recent evidence for the prevention of COVID-19 by published studies on patients with severe COVID-19 infection. Literature search of databases using PubMed and Web-of-Science till 4th April 2021 as search engines were adjusted to identify relevant studies. A meta-analysis of studies pooled prevalence of clinical symptoms. Random-effects models were used, heterogeneity and various meta-analyses were carried out for four systemic disorders using Stata version 16.0. Of the 599 patients included in this analysis, compared with the non-survivor patient, the pooled odds ratio (OR) of Cough, Breathlessness and Fever in survivor patients were (OR: 11.2%, 95% CI: 8.2-15.2%) and (OR: 10.5%, 95% CI: 3.8-13.8%), while that of Myalgia and dyspnoea are also crucial. There is a significant heterogeneity for clinical symptoms ($I^2 = 56\%$). Re-affirming the most prominent clinical-symptoms proportion after One and a half years of COVID-19 existence, cough, breathlessness and fever still remains the most-common symptoms in COVID-19 infected patients.

Complex Traits Posters - Wednesday

PB1311. Concordance of directional effects between sexes suggests pervasive epistasis and omnigenic regulation of complex metabolic traits in mice

Authors:

A. Miller¹, C. Pan², A. J. Lusis², D. C. Crawford¹, D. A. Buchner¹, S. M. Williams³; ¹Case Western Reserve Univ., Cleveland, OH, ²UCLA, Los Angeles, CA, ³Case Western Reserve Univ, Cleveland, OH

Abstract Body:

Epistasis in humans has proven difficult to investigate in part due to limited statistical power, relatively small sample sizes, and computational demands. The well-characterized inbred strains of the Hybrid Mouse Diversity Panel (HMDP) offer a unique and powerful alternative to systematically test for non-linear epistasis in a mammalian system. We used previously collected data from over 100 inbred strains from the HMDP that were genotyped using the Mouse Diversity Genotyping Array encompassing >20,000 polymorphic loci and phenotyped for 8 complex traits related to obesity and type 2 diabetes. Using FaST-LMM and Bonferonni significant thresholds corrected for the number of haplotype blocks, we analyzed the HMDP for both main effects (additive) and epistatic interactions that regulate these traits. In females, no main effects were detected whereas in male mice, main effect QTLs were identified for adiposity (n=58), body weight (n=22), and fat mass (n=60). Interaction effects were identified in females for fat mass (n=8) and in males for adiposity (n= 56,112), body weight (n=66,296), fat mass (n=111,749), cholesterol (n=57), and triglycerides (n=123). The numbers of interactions at first seems extraordinary but are in line with the number of QTLs discovered for main effects, given the orders of magnitude more SNP-SNP interactions assessed relative to main effects. The direction of these significant effects in males (i.e. increased or decreased trait values) were concordant with the direction of effect in females, even when the effects were not statistically significant. Between 63 and 100% of main effect directions and 79 and 100% of interaction effects showed the same direction. This concordance rate is substantially greater than the 50% expected by chance, validating these interactions. Remarkably, this shared directionality of effects between males and females was also detected for non-statistically significant main effect and interacting loci until p-values ~ 0.8. This finding is consistent with an omnigenic model, where most loci contribute to the regulation of these metabolic traits with both additive and epistatic effects. These data from a mammalian model organism support an omnigenic inheritance pattern comprised of pervasive epistasis, and indicate that interactions may be critical to understanding the inheritance of complex traits in humans.

PB1312. Considerations in developing a framework for defining clinical actionability of polygenic risk scores

Authors:

J. Hunter¹, A. Buchanan², J. Bulkley³, M. Garcia-Closas⁴, K. Goddard⁵, S. Massimino⁶, B. Powell⁷, I. Kullo⁸, ClinGen; ¹RTI Intl., Durham, NC, ²Geisinger, Danville, PA, ³Kaiser Permanente Ctr. for Hlth.Res., Portland, OR, ⁴Natl. Cancer Inst, Rockville, MD, ⁵Natl. Cancer Inst., Bethesda, MD, ⁶Kaiser Permanente Northwest, Portland, OR, ⁷Univ North Carolina at Chapel Hill, Chapel Hill, NC, ⁸Mayo Clinic, Rochester, MN

Abstract Body:

There is substantial ongoing effort to generate and validate polygenic risk scores (PRS). Here we focus on their use to identify individuals at modified risk for developing a health condition where changes in management may improve health outcomes. The ClinGen Actionability Working Group developed a standardized process for assessing clinical actionability of monogenic conditions, and is adapting this framework for PRS. We consider how assessment of clinical actionability may differ for the PRS context, which have population-scale impact, compared to rare monogenic conditions, and whether risk information is returned as primary or secondary genomic findings. For the four domains of clinical actionability, points of consideration include:

Domain 1: Severity of the Outcome. Similar to the monogenic framework, we consider the impact of the health condition on individual-level morbidity and mortality. The polygenic adaptation also accounts for population impact based on health condition prevalence.

Domain 2: Likelihood of the Outcome. As with the monogenic framework, we identify estimates of absolute or relative risk. For the polygenic adaptation, we also account for variability in risk across population groups, an important consideration for all PRS.

Domain 3: Effectiveness of the Intervention. Similar to the monogenic framework, we seek recommendations for clinical interventions in practice guidelines. Since PRS-based guidelines may not be available, we use guidelines based on risk thresholds even if not specific to monogenic or polygenic sources of risk, and evidence in primary literature. For the polygenic adaptation, we consider whether evidence of effectiveness differs across population groups. To account for the population-scale impact of implementation, we summarize cost-effectiveness evidence.

Domain 4: Nature of the Intervention. We anticipate minimal adaptation of this domain for PRS, since it is not specifically related to the underlying etiology of the condition.

We will pilot test the draft PRS clinical actionability framework using exemplar health conditions, define a protocol to identify and curate evidence, and use an iterative approach to refine the framework.

Complex Traits Posters - Wednesday

PB1313. Construction of clinically significant mutation map and their spatio-temporal single cell transcriptomics trajectories in congenital heart disease

Authors:

R. Tambi¹, S. Nandkishore¹, S. Sharafat¹, F. Kader¹, N. Nassir¹, B. Ashraf¹, N. Mohamed¹, A. Ahmed¹, R. Hameid¹, A. Alsheikh-Ali^{1,2}, R. Donato³, M. Uddin⁴, B. Berdiev¹; ¹Mohammed Bin Rashid Univ. Of Med. and Hlth.Sci., Dubai, United Arab Emirates, ²Dubai Hlth.Authority, Dubai, United Arab Emirates, ³Al Jalila Children's Hosp., Dubai, United Arab Emirates, ⁴Mohammed Bin Rashid Univ. of Med. and Hlth.Sci., Dubai, United Arab Emirates

Abstract Body:

Congenital heart disease (CHD), one of the most prevalent neonatal congenital anomalies, involves a spectrum of birth defects affecting the normal functions of heart. The genetic component of CHD plays a critical role, yet the pathophysiological mechanisms remain unknown. In this study we aim to identify putative candidate risk genes to CHD and analyze the heterogeneity of these genes across cell types using spatiotemporal heart single cell transcriptome data. We have conducted rigorous literature review and collected 16,350 single nucleotide variants (SNVs) impacting 8,308 genes in 3194 CHD cases that were reported in 31 genomic studies on CHD published between January 2000 and December 2020. We have used ANNOVAR for functional annotation and after quality control (removed 891 synonymous mutations) retained only 16206 exonic/splice site rare variants (Exac_all < 0.01) for downstream analysis. The mutations were classified as benign/likely benign (0.1%), pathogenic/likely pathogenic (P/LP - 7.0%) and variance of uncertain significance (VOUS - 92.9%) following the ACMG classification guidelines. 83% of the filtered mutations were loss of function (LOF), and rest 17% were missense. In our data, 16% of these mutations were of *denovo* origin. In order to identify the candidate risk genes, we scanned the 15306 P/LP and VOUS mutations and filtered the LOF recurrent mutations which impacted 257 genes. We identified highly constraint (pLI > 0.9) 12 LOF genes with significant enrichment of pathogenic mutations, including seven known CHD risk genes: *NOTCH1*, *ANKHD1*, *TNS3*, *ARHGEF12*, *RANBP9*, *DLC1* and *FLT4*; and five novel candidate CHD risk genes *MAG11*, *MTMR12*, *SH3RF3*, *SLC12A2*, and *EDC4*. These CHD risk genes were also found to be significantly enriched in the organ development and signaling network pathways. Our analysis from spatio-temporal single cell transcriptomics analysis show *ARHGEF12*, *MAG11* and *RANBP9* genes are highly upregulated in cardiomyocyte cell types in fetal developmental period. Our study identifies the core CHD genes and maps their cellular heterogeneity, that will require further investigation to pin point cellular level causation into the aetiology of CHD.

Complex Traits Posters - Thursday

Univ., Dhaka, Bangladesh, ⁹Dept. of Pharmaceutical Sci., North South Univ., Dhaka, Bangladesh, ¹⁰Coll. of Med., Mohammed Bin Rashid Univ. of Med. and Hlth.Sci., Dubai, United Arab Emirates, ¹¹Mohammed Bin Rashid Univ. of Med. and Hlth.Sci., Dubai, United Arab Emirates, ¹²Dept. of Biochemistry, Holy Family Red Crescent Med. Coll., Dhaka, Bangladesh

Abstract Body:

Background: Short nucleotide variations (SNVs) and copy number variations (CNVs) play a critical role into the pathogenesis of neurodevelopmental disorders (NDD) among children. In this study, we aimed to identify clinically relevant variants, genes and their phenotypic characteristics in an ethnically underrepresented homogenous NDD patients of Bangladesh.

Methods: We have conducted WES (33.05 Mb human coding regions) and genome-wide CMA (642,824 probes spanning the genome) analysis for 545 NDD patients to identify SNVs and CNVs (deletion/duplication/translocation and rearrangements). We have used human genome build GRCH38/UCSC hg38 as reference. Variant classification analysis was conducted based on the American College of Medical Genetics (ACMG) guidelines.

Results: The cohort comprises 68.12% male and 31.88% female, with male to female ratio of 2.1:1. Of the 545, 44.95% (245), 21.83% (119) and 33.22% (181) patients' genomic analysis were done using CMA, WES and combined method (CMA plus WES) respectively. The diagnostic yield by only CMA, only WES and combined for broader NDD is 14.69% (36/245), 31.09% (37/119) and 37.57% (68/181) respectively. In the full cohort, further burden test identified females are significant carriers of pathogenic CNVs in comparison to males (OR=2.5; p=1.98×10⁻⁵). In the CMA cohort, we have found 3.27% (8/245) pathogenic CNVs located at the subtelomeric regions. Autism Spectrum Disorder (ASD) subset (91) of CMA cohort shows severe social communication deficit (p=0.014) and overall ASD symptoms severity (p=0.026) among the patients carrying duplication CNV compared to the CNV negative group. Candidate gene analysis identified Critical Exon Gene (CEG) PSMC3 as a potential candidate gene for ASD. Moreover, we hypothesized that KMT2B gene duplication might be associated with intellectual disability. Our custom pathway enrichment analysis of the impacted genes of all pathogenic variants identified GO:0019787, GO:0099003, GO:1901214 and GO:0099536 pathways to be highly significant (FDR P<6.53 × 10⁻⁷), (FDR P<7.1 × 10⁻⁵), (FDR P< 5.34 × 10⁻⁷) and (FDR P<1.72× 10⁻⁴) after correction for multiple tests.

Conclusions: Our results show the utility of WES and CMA for precise genetic diagnosis and its integration into the diagnosis therapeutics and management of NDD patients. To our knowledge, this is the first genomic research using larger number of NDD patients of Bangladesh.

Crosbie^{1,3}, R. Schachar^{1,3}, S. Scherer^{1,3}; ¹The Hosp. for Sick Children, Toronto, ON, Canada, ²Deep Genomics Inc., Toronto, ON, Canada, ³Univ. of Toronto, Toronto, ON, Canada, ⁴Hosp. for Sick Children, Toronto, ON, Canada, ⁵Univ. of Calgary, Calgary, AB, Canada, ⁶Newcastle Univ., Jesmond, Newcastle upon Tyne, United Kingdom

Abstract Body:

‘Spit for Science’ is a cohort of 22,515 youth (4-18 years of age) in whom we collected neurodevelopmental traits measurements and DNA extracted from saliva. Quantitative phenotype data were collected and trait scores were generated for attention deficit hyperactivity disorder (ADHD), obsessive compulsive disorder (OCD), and response inhibition using Stop-Signal Reaction Time (SSRT, a cognitive biomarker for neurodevelopmental traits). We genotyped 7,100 unrelated individuals of European (n=5,686) and East Asian (n=1,414) ancestry using either the Illumina HumanCoreExome or Illumina Global Screening Array. Among these, 1,233 (17.5%) participants self-reported a diagnosis of a neurodevelopmental disorder (NDD; e.g. autism, OCD, ADHD), and 2,412 (34.2%) participants had either a self-reported diagnosis of NDD or high quantitative scores on NDD trait measures. We performed global and functional gene-set burden analyses, and locus association test separately for East Asian and European participants on rare (<0.5%) and less-rare (1-5%) CNVs using linear regression with different traits. We identified CNVs with clinical relevance to NDDs in 279 (3.9%) participants, and found elevated standardized T-scores for all traits in this group of participants. These CNVs included i) sex-chromosome and autosomal aneuploidies in 7 (0.1%) individuals, ii) 13 genomic loci previously implicated in NDD in 48 (0.7%) participants, and iii) CNVs affecting genes with known brain functions such as *ASTN2*, *DLGAP2*, *MACROD2*, *NRXN1*, and others. Individuals carrying these CNVs had three-fold increases in having self-reported or community diagnoses of NDD (odds ratio: 3.1, $p=10^{-5}$). Rare deletions were globally associated with inattention traits in Europeans ($\beta=0.15$, $p=0.04$). In Europeans, we found an association of ADHD and inattention traits with increased burden of rare deletions impacting genes that are highly expressed in brain or involved in nervous system development or brain function. In East Asians, ADHD and inattention were associated with less-rare deletions for synaptic and neurofunctional genes. Also, within East Asian participants, we observed an association of response inhibition (cognitive biomarker) with rare duplications in a gene linked with brain function. These results highlight the importance of assessing the prevalence and impact of rare and less rare variants in community samples to provide a baseline to improve understanding of pediatric mental health.

Complex Traits Posters - Thursday

PB1316. Coronary artery disease risk assessment in Asian Indian Punjabis using a genome wide polygenic risk score

Authors:

M. Rout; Univ. of Oklahoma Hlth.Sci. Ctr., Oklahoma City, OK

Abstract Body:

BACKGROUND: Polygenic risk score (PRS) has been shown to be highly effective in predicting coronary artery disease (CAD) risk in Western European populations. However, such studies on South Asians are scarce despite the fact that they account for 50% of the global burden of CAD. In this study, we evaluated the predictive efficacy of PRS derived from the Asian Indian (AI) ancestry-specific score (PRSAI) and European-derived PRS (PRSEU). Also, we compared these with the clinical risk score (CRS).

METHODS: The study used 4602 participants (791 CAD cases and 3790 controls) from the Asian Indian Diabetic Heart Study/Sikh Diabetes Study. Weighted PRS was constructed using 100 significant SNPs from our Punjabi/Sikh CAD GWAS and 75 SNPs identified from the European GWAS catalog. The CRS was derived using the clinical risk factors described for the Framingham risk score.

RESULTS: Ancestry-specific PRSAI showed an enhanced efficacy of over 30% in estimating the relative risk for CAD over PRSEU. In sensitivity analysis, the area under the curve (AUC) for PRSAI and PRSEU were 0.84 and 0.72, respectively, while the AUC remained unchanged on combining the PRS (AI+EU), i.e., 0.84. PRSAI also predicted the risk for increased waist to hip ratio (Beta=0.11, $p=4.1 \times 10^{-13}$) in both gender, while fasting glucose levels (Beta=0.08, 3.0×10^{-3}) were confined to females.

CONCLUSIONS: The results highlight evidence for the utility of PRS for identifying genetically predisposed high-risk individuals and attest to its broader clinical value. Also, sex differences may play a role in determining the risk for CAD, and increased fasting glucose and type 2 diabetes (T2D) are known to increase the risk of heart disease in women more than men, especially after menopause.

Complex Traits Posters - Thursday

PB1317. Cross-tissue single-nucleus RNA-sequencing reveals distinct tissue-specific expression profiles of adipocytes, depending on their residency in human adipose tissue or heart

Authors:

S. Das¹, S. Rajkumar¹, S. Lee¹, M. Alvarez¹, A. Koka¹, K. Pietiläinen², P. Pajukanta^{1,3}; ¹Univ. of California Los Angeles, Los Angeles, CA, ²Univ. of Helsinki, Helsinki, Finland, ³Inst. for Precision Hlth., David Geffen Sch. of Med. at UCLA, Los Angeles, CA

Abstract Body:

Understanding the molecular mechanisms of complex diseases needs extensive characterization of cell-types across heterogenous tissues. Adipocytes have been recognized as a vital player in metabolic regulation. Furthermore, dysfunctional adipocytes confer complex cardiovascular diseases (CVDs). Although adipose tissue is the predominant site of adipocytes, they are also residents of other tissues, including the myocardial tissue of each heart chamber i.e., left atrium (LA), left ventricle (LV), right atrium (RA), and right ventricle (RV). However, it is not known whether gene expression profiles of adipocytes differ depending on whether they reside in the adipose tissue or heart. To study the tissue-specific profiles of adipocytes and their associations with cardiovascular disease, we investigated single-nucleus RNA sequencing data from a human myocardial tissue cohort (n=7) (Tucker et al., 2020) and subcutaneous adipose tissue (n=15). We clustered the adipose tissue droplets using Seurat and assigned them into 11 main adipose cell-types, including adipocytes, using SingleR. For myocardial tissue, we clustered droplets of each chamber separately, and then annotated the clusters of each chamber into 10 main heart cell-types, including adipocytes. Identification of adipocyte marker genes (AMGs) and further comparison between adipose and each of the heart chambers resulted in 655 tissue-specific AMGs (162 in LA, 170 in LV, 139 in RA, 63 in RV, and 121 in adipose tissue, respectively), and in 291 shared AMGs. Furthermore, KEGG pathway analysis showed that the heart-specific AMGs of all four chambers are significantly enriched for the propanoate metabolism pathway (FDR<0.05) that is not enriched among the adipose tissue -specific AMGs. Three genes (ACSS2, ECHDC1, and PCCA) of this pathway are shared across all chambers, among which variants in PCCA and ECHDC1 predispose to dilated cardiomyopathy. Adipose tissue-specific AMGs are in turn enriched for metabolic pathways, such as the PPAR signaling pathway, and regulation of lipolysis in adipocytes. Using the GTEx data, we identified cis-expression quantitative trait loci (eQTL) variants, associated with CVD traits, regulating the shared and tissue-specific AMGs across both tissues. Noteworthy, the RA-specific AMGs are also enriched for coronary artery disease and heart failure GWAS SNPs, and the LA-specific AMGs for heart failure GWAS SNPs using Magenta (FDR<0.05). Overall, our results provide insights into the distinct, tissue-specific expression profiles of heart and adipose tissue resident adipocytes, pathways involved in their tissue-specificity, and their genetic links to CVDs.

PB1318. Curation burden mitigation: strategies for empowering high throughput gene panel analysis using whole genome sequencing

Authors:

S. Strom¹, L. M. Amendola¹, A. Coffey², C. Brown³, J. Lowry⁴, A. Kesari¹, J. AVECILLA¹, S. Ajay¹, R. J. Taft⁵, D. Perry³; ¹Illumina Inc., San Diego, CA, ²Illumina Inc, Great Thurlow, United Kingdom, ³Illumina, San Diego, CA, ⁴Illumina Inc., Salt Lake City, UT, ⁵Illumina Inc, San Diego, CA

Abstract Body:

Background: Whole genome sequencing (WGS) is an ideal platform for high throughput screening of gene panels due to the simplicity of the wet laboratory preparation, uniformity of data, access to multiple variant types, and unbiased genome-wide coverage of genetic loci. Without adequate preparation, however, each test can result in a high curation burden with many rare variants present per test subject. As only pathogenic/likely pathogenic variants are typically reported in screening settings, pre-curation and variant filtering strategies are critical for efficiency. We have developed a scalable clinical WGS test for patients with CVD that includes a CVD gene panel. Here we discuss our bioinformatics approach to reducing this workload while maintaining high accuracy. **Methods:** We first reviewed a set of genes potentially associated with CVD for evidence supporting a Definitive or Strong -gene-disease relationship (GDR). For 182 genes with at least one Strong or Definitive GDR CVD-associated condition, we performed a literature review to estimate the prevalence and penetrance of that condition. We then calculated population minor allele frequency (MAF) cutoffs for auto-classification of benign (B), likely benign (LB) and VUS variants. Variants in these genes present in the gnomAD database with overall MAF <5% were then subjected to auto-scoring and used to populate a variant database. Heuristic filters were developed to exclude variants with MAF >5% and variants unlikely to impact the protein sequence. These filters were tested on a 20 negative and 1 positive WGS datasets. **Results:** A total of >7.4 million variants from 182 CVD-associated disease genes with MAF <5% were scored (~4.4M B/LB and ~3M VUS). Across the 21 WGS case datasets, the average number of variants requiring review per case was 3.2 (range 0-11 LB/VUS), with 6 cases (28.5%) having zero variants requiring review. The expected variant in the known positive case was correctly identified. **Conclusions:** Pre-evaluation of GDRs and automated exclusion of B/LB/VUS variants supports scalable reporting of WGS-based gene panels. If done on an *ad hoc* basis, the required curation could extend turnaround time and overall interpretation cost. Screening of a large cohort is planned as a to verify these finding and to support deployment of this test.

Complex Traits Posters - Thursday

PB1319*. Cytokine treatment increases *APOEε4* expression in reactive astrocytes in European local ancestry but not in African local ancestry

Authors:

O. Oron¹, M. Vasquez¹, A. J. Griswold¹, B. DeRosa¹, F. RAJABLI¹, K. Celis¹, B. Feliciano-Astacio², G. W. Beecham¹, L. D. Adams¹, C. Silva², S. J. Tejada¹, P. Mena¹, P. Whitehead¹, K. Hamilton-Nelson¹, T. Starks³, G. S. Byrd³, M. L. Cuccaro¹, j. young¹, M. Pericak-Vance¹, J. Vance¹, D. Dykxhoorn¹; ¹John P. Hussmann Inst. for Human Genomics, Univ. of Miami Miller Sch. of Med., Miami, FL, ²Dept. of Internal Med., Univ. Central Del Caribe, Bayamón, Puerto Rico, ³Maya Angelou Ctr. for Hlth.Equity, Wake Forest Sch. of Med., Winston-Salem, NC

Abstract Body:

Background: Local genomic ancestry (LA) determines the difference in Late-Onset Alzheimer's Disease (LOAD) risk between European (EU) and African (AF) carriers of *APOEε4/4*. Single-Nuclei RNA sequencing (snRNA-seq) from frontal cortex suggest that this risk difference is at least partially explained by increased *APOEε4* expression in *APOEε4/4* homozygotes with EU LA compared to *APOEε4/4* homozygotes with AF LA. In some of the EU LA patients, an astrocyte cluster with the highest *APOEε4* expression also expressed a signature of genes consistent with A1 Reactive Astrocytes (A1RA).

Understanding if astrocyte reactivity is a precursor for an increase in *APOEε4* expression in specific astrocyte subtypes and contributes to LOAD risk is crucial for identifying new therapeutic targets in AD.

Methods: To determine if cytokine treatment affects *APOEε4* expression in astrocytes or astrocyte subtypes, iPSC lines were derived from *APOEε4/4* patients with either EU LA (n=1) or AF LA (n=1) and differentiated into iPSC-derived astrocytes (iAstrocytes). Mature (days in-vitro 49) iAstrocytes were treated for 24 hours with a cytokine cocktail (IL-1a, hTNFα and C1q) to induce A1RA and then subjected to Single-Cell RNA sequencing (scRNA-seq) along with control iAstrocytes. scRNA-seq was performed with the 10X Chromium Next GEM Single Cell 3' v3.1 kit and sequencing on the Illumina NovaSeq 6000. Following raw data processing via CellRanger v6.0 the data was analyzed using the Seurat v4.0 pipeline to identify differences in expression between treated and untreated iAstrocytes carrying either EU or AF LA.

Results: Overall, 29,836 cells were sequenced at a median depth of ~135,000 reads per cell detecting on average ~5900 genes per cell. Integration of all four samples at a resolution of 0.4 in the Seurat FindClusters command resulted in 9 distinct clusters. The EU LA *APOEε4/4* carrier had a significant increase in *APOEε4* expression in 7 out of the 9 clusters upon cytokines treatment compared to control. Moreover, in these 7 clusters, multiple A1RA biomarkers (*C3*, *IFITM3*, *IL6*, *GBP2*, *IL1R1* and *ICAMI*) also increased in expression. Conversely, in the AF LA *APOEε4/4* carrier, no clusters showed increased *APOEε4* expression but did show increased expression of the A1RA biomarkers *C3*, *IL6* and *ICAMI*.

Conclusions: In this preliminary study, we suggest a relationship between cytokine induced increase in *APOEε4* and A1RA gene expression in EU LA *APOEε4/4* carriers but not in AF LA *APOEε4/4* carriers. This suggests a difference in molecular response to inflammatory cues depending on *APOEε4/4* local ancestry which may modulate the differences in AD risk.

Complex Traits Posters - Wednesday

PB1320. Data-driven Clustering of Human Cardiovascular Disease (CVD) Related Variables

Authors:

M. Mandal¹, J. Levy², C. Ives³, S. Hwang⁴, Y. Zhou⁵, A. Motsinger-Reif⁶, H. Pan⁷, W. Huggins⁸, C. Hamilton⁷, F. Wright⁹, S. Edwards¹; ¹RTI Intl., RTP, NC, ²Levy Informatics, RTP, NC, ³RTI Intl., Apex, NC, ⁵North Carolina State Univ., Raleigh, NC, ⁶Natl. Inst. of Environmental Hlth.Sci., Durham, NC, ⁷RTI Intl., Durham, NC, ⁸RTI Intl., Research Triangle Park, NC, ⁹North Carolina State Univ, Raleigh, NC

Abstract Body:

While large nationwide studies such as All of Us represent a new paradigm for understanding human health and disease, there is a wealth of existing data that can provide valuable insights potentially missed in the larger cohorts. This study aims to programmatically identify related variables within each study, thus streamlining the integration of data from existing human cohorts.

The Atherosclerosis Risk in Communities (ARIC) study was used to evaluate automated methods for identifying biologically relevant groups of variables. First, correlations between ARIC variables were calculated and used to assemble the variables into clusters. Cluster quality was evaluated via a manual review of the 391 clusters generated from 3,285 variables. Based on the results of the manual review process, 95% of the clusters containing more than one variable were determined to be related to some degree. To assess the possibility of confirmation bias among the manual reviewers, natural language processing (NLP) was used to generate a semantic similarity score for each cluster. There was a good correspondence between the reviewer evaluation and the semantic similarity score with most exceptions explained by the limitations of the NLP. Second, a network of variable clusters was created based on the average inter-cluster correlations. Community-finding algorithms were used to group the variable clusters into higher order communities. These communities were evaluated for biological coherence and used to identify the major themes addressed by the study.

We have developed a fully automated workflow that hierarchically groups variables from the ARIC study. Manual evaluation of this automated grouping confirmed the biological relevance of individual clusters and showed that the hierarchy corresponds well with the themes expected from the original study design. This workflow is intended as an aid to human annotators when performing data harmonization and curation on existing studies. Since the variables and clusters from the data driven approach captured the major themes of the study, this should also reduce the overall number of variables considered by curators. Streamlining this labor-intensive step should unlock a wealth of existing data for new analyses to complement ongoing efforts in new data collection.

Complex Traits Posters - Thursday

PB1321. Data-driven genome-wide association study of longitudinal pain and mobility trajectories among cases of Parkinson's disease from the Fox Insight Data Exploration Network

Authors:

S. Liu¹, D. D. Gunzler^{2,1}, S. A. Gunzler³, D. C. Crawford^{1,4,5}, F. Briggs¹; ¹Dept. of Population and Quantitative Hlth.Sci., Case Western Reserve Univ. Sch. of Med., Cleveland, OH, ²Ctr. for Hlth.Care Res. and Policy, Sch. of Med., Case Western Reserve Univ., Cleveland, OH, ³Neurological Inst., Univ. Hosp. Cleveland Med. Ctr. and Case Western Reserve Univ. Sch. of Med., Cleveland, OH, ⁴Cleveland Inst. for Computational Biology, Cleveland, OH, ⁵Genetics and Genome Sci., Case Western Reserve Univ., Cleveland, OH

Abstract Body:

Parkinson's disease (PD) is the second most common progressive neurodegenerative disease. It affects moment control and leads to both motor and non-motor symptoms. There is no cure or neuroprotective medication to slow PD progression, which is heterogeneous and unpredictable. Genome-wide association studies (GWAS) have identified ~90 risk variants, but these loci are not associated with pain, a PD non-motor symptom that broadly impacts daily functioning, or mobility deficits, a common PD motor symptom that causes disability. To identify genetic variants specific to pain or mobility deficit trajectories, we accessed longitudinal patient-reported measures from the Fox Insight Data Exploration Network (Fox DEN) linked to 23andMe genome-wide data. FoxDen PD participants (n=37,769) are on average 66 years of age, European descent (96%), and male (~65%). Self-reported pain and mobility deficits from routine longitudinal assessments using the questionnaire items were available for 8,612 persons with PD (PWP) early in their disease course (<3 years). Five clusters were obtained with the latent class growth analysis leveraging the longitudinal patient-reported outcome of pain for the 8,612 PWP. For mobility deficits, we identified four clusters. Among those with genotypes, we stratified the data by genotyping platform (v4, a fully customized Illumina array, n = 443; v5, a customized Illumina Infinium Global Screening Array, n=3,696) for quality control and imputation using the TOPMed reference panel. We performed tests of association using logistic regression comparing the cluster of PWP of very low pain (n=977, 22.1%) with the cluster experiencing severe pain (n=105, 2.4%), and the cluster of PWP of low mobility deficits (n=1,743, 39.5%) with that of severe mobility deficits (n=137, 3.15%), adjusting for age at recruitment, sex, and 20 principal components. We did not identify associations at genome-wide significance. The most significant association identified for pain was rs72794357 (OR=5.1; 95% CI=2.8, 9.6; p=3.0x10⁻⁷), an intronic variant of *MAPK8* (this gene has been associated with opioid dependence), and rs11047777 (OR=3.5; 95% CI=2.2, 5.6; p=5.2x10⁻⁸) for mobility deficits, an intronic variant of *IRAG2*. A multinomial GWAS comparing all the clusters constructed is ongoing, as are gene-based and pathway enrichment analyses. The successful identification of genetic variants associated with subgroups from their longitudinal trajectories has the potential to lead to a better understanding of the mechanisms underlying PD progression, providing potential novel targets for therapeutics.

Complex Traits Posters - Wednesday

PB1322. *De novo* CNVs impacting constraint overlapping genes in neurodevelopmental disorders and congenital anomalies.

Authors:

S. Safizadeh Shabestari¹, N. Nassir¹, S. Sopariwala², I. Karimov³, R. Tambi¹, B. Zehra¹, N. Kosaji¹, H. Akter⁴, B. K. Berdiev¹, M. Uddin^{1,5}; ¹Mohammed Bin Rashid Univ. of Med. and Hlth.Sci., Dubai, United Arab Emirates, ²Univ. of Guelph, Guelph, ON, Canada, ³Univ. of Bremen, Bremen, Germany, ⁴NeuroGen Hlth.care Ltd., Dhaka, Bangladesh, ⁵GenomeArc Inc, Toronto, ON, Canada

Abstract Body:

Background: Neurodevelopmental disorders (NDDs) and congenital anomalies (CAs) are a collection of rare disorders with complex etiology. While both conditions have strong genetic component and phenotypes often co-manifest in patients, their underlying genomic overlap is less explored. In this study, we investigated the genomic overlap of copy number variants (CNVs) in two large cohorts of NDD and CA patients to identify *de novo* CNVs and candidate genes that are strongly associated to both NDD and CA phenotypes. **Methods:** We analyzed clinical microarray CNV data from 10,620 NDD and 3,176 CA cohorts, recruited from Sickkids Hospital, Toronto and Credit Valley Hospital, Mississauga, Canada. We annotated CNVs using GenomeArc Analytics, a platform to annotate and delineate CNVs, and then used rigorous downstream analysis to evaluate overlapping genes from NDD and CA CNVs. The gene enrichment analysis, human developmental transcriptomic landscape and descriptive statistics were carried out for the overlapped candidate gene set to infer biological pathways and brain developmental trajectory. **Results:** Out of 154 patients (NDD and CA cases), we extracted overlapping genes from 217 *de novo* CNVs (47.3% (80/169) of NDD and 64.6% (31/48) CA cases) and performed constraint gene analysis. 79 genes were found to have significantly enriched genomic overlap between NDD and CA patients within rare *de novo* pathogenic deletions (P-value = 0.01, OR = 1.58) and 45 genes identified within *de novo* pathogenic duplications (P-value = 0.01, OR = 1.97). The *de novo* CNVs encompass 138 overlapping genes impacted in both disorders, of which at least one exon is impacted by pathogenic deletions, and this shows significant (P-value = 2.87×10^{-90} , OR = 14.69) functional disruptions. Analysis of spatiotemporal transcriptome demonstrated both pathogenic deletion and duplication genes to be highly expressed during prenatal stage in human developmental brain (P-value = 4.95×10^{-6}). Analysis from the total cohort including pathogenic and variant of uncertain significance (VUS) identified 1086 overlapping constraint genes from CNVs and 90 genes (8%) had no Online Mendelian Inheritance in Man (OMIM) entries. From the list of overlapping genes, *EHMT1*, an interesting known NDD gene encompassed *de novo* pathogenic CNVs from both NDD and CA patients, whereas *FAM189A1*, and *FSTL5* are new candidate genes from non-OMIM entries which may have common etiology in NDD and CA. **Conclusion:** In this study of two large cohorts, we have identified overlapping CNVs and genes in NDD and CA patients. We propose a list of constraint genes that have the potential to play important role into the common etiology of NDD and CA.

Complex Traits Posters - Thursday

PB1323. *De novo* germline and somatic variants as modifiers of cleft lip/palate severity in mice

Authors:

S. Rao¹, E. Farrow², T. Cox¹; ¹Univ. of Missouri-Kansas City, Kansas City, MO, ²Children's Mercy Hosp, Kansas City, MO

Abstract Body:

Cleft lip/palate (CL/P) is one of the most common human birth defects affecting 1 in 700 live births around the world each year. Non-syndromic CL/P accounts for about two-thirds of all cases and is typically characterized by low penetrance and highly variable presentation. Population-level genetic and epidemiological data as well as teratogenic studies support a threshold model of susceptibility, with genetic and environmental (or epigenetic) contributions. Common variants at over 40 loci contribute ~30% of the genetic risk of non-syndromic CL/P in different ethnic populations. In contrast, rare, high-impact, inherited and *de novo* germline pathogenic variants underlie as many as 40% of familial and ~5% of isolated cases. Notably, marked inter-individual phenotypic variability is also seen in inbred mouse CL/P models that have long been presumed to be genetically identical. While there is growing evidence to support the role of epigenetics and maternal nutrition in cleft risk, we hypothesize that *de novo* germline variants (ie. individual-specific genetic variation) and/or postzygotic (ie. somatic) mutations arising during embryogenesis may also contribute to penetrance and variability in presentation of CL/P, that is, they may function as phenotypic modifiers of cleft risk and severity even in the presence of an inherited risk allele. To begin to investigate this, we have used the *Wnt9b* KO mouse CL/P model, which exhibits the full variability of cleft presentations as seen in humans, including incomplete penetrance. Using both whole genome sequencing and total RNA-sequencing approaches on the same embryonic facial tissue, we have identified a high incidence of both *de novo* germline and tissue-specific mutations, indicating that significant numbers of somatic variants are present in all embryonic tissues. Using standard filters for coding region pathogenicity and predicted regulatory region function, we find dozens of variants that could potentially impact the expression or function of genes or pathways crucial for facial development. While the true impact of such variants is still to be functionally tested, if proven, the data will have significant implications for all birth defects, including relative risk calculations, counselling of families, and personalized medicine interventions.

Complex Traits Posters - Wednesday

PB1324. *De novo* variant analysis of childhood-onset obsessive-compulsive disorder in the French-Canadian population.

Authors:

K. Bornais^{1,2}, J. P. Ross^{1,2}, Z. Schmilovich^{1,2}, M. Medeiros^{1,2}, D. Spiegelman^{1,2}, P. A. Dion^{1,2}, G. A. Rouleau^{1,2}; ¹McGill Univ., Montreal, QC, Canada, ²Montreal Neurological Inst. and Hosp., Montreal, QC, Canada

Abstract Body:

Obsessive-compulsive disorder (OCD) is a neuropsychiatric disorder with a global prevalence of 1-2%. Affected individuals experience cycles of intrusive thoughts or sensations (obsessions) and repetitive behaviours (compulsions). There is a genetic component to early-onset OCD, with estimates of heritability being 45-65%, but most of this heritability cannot currently be explained by known genetic factors. *De novo* variants (DNVs) arise post-zygotically in an individual but are not present in either biological parent and may contribute significantly to OCD risk. However, the number of identified DNVs in OCD remains limited and the level of genetic contribution to OCD suggests that more are likely to exist. Here, we aimed to identify DNVs in the probands of French-Canadian (FC) childhood-onset OCD trios. Given that leveraging the genetically homogenous FC population increases the power for genetic discovery, we hypothesized that DNVs observed in the FC childhood-onset OCD probands would identify OCD genetic risk factors.

Whole-exome sequencing (WES) was performed on 53 FC OCD trios ($n = 159$). Initial inclusion criteria selected only trios where all three trio participants self-reported as FC. DNVs were called by filtering for variants that are heterozygous in the probands and not carried by either parent. Candidate DNVs were selected based on their estimated impact on gene function, a minor allele frequency of less than 0.1% in the general population, and biological relevance to OCD. DNVs were collapsed into genes to identify candidate childhood-onset OCD risk genes. This candidate gene list was then used to identify enriched molecular and biological pathways underlying childhood-onset OCD.

1,441 candidate DNVs across 504 genes were observed in the probands of the trios. 44 of these genes were previously identified in large-scale DNV analyses of OCD (Halvorsen et al., 2021; Cappi et al., 2020). Additionally, our analysis identified 260 previously unobserved genes in OCD carrying DNVs that rank in the top 0.1-1% of deleterious variants in the human genome (average CADD score = 26.3). The top enriched Gene Ontology (GO) terms of interest include “regulation of neuron projection” ($p = 0.003$), “histone acetylation” ($p = 0.0009$), “calcium channel activity” ($p = 0.0006$), and “cadherin binding” ($p = 0.0004$). Findings from this study will shed light on the genetic and biological factors underlying childhood-onset OCD risk, further highlighting the ability to leverage the FC population to elucidate the genetics of complex neuropsychiatric disorders.

Complex Traits Posters - Thursday

PB1325. Deciphering the causal relationship between blood pressure and white matter integrity: a Mendelian Randomization study in the UK Biobank

Authors:

Z. Ye¹, C. Mo², S. Liu³, S. Gao¹, B. Zhao⁴, T. Canida⁴, Y-C. Wu⁴, K. Hatch¹, Y. Ma¹, B. Mitchell¹, E. HONG¹, P. Kochunov¹, C. Chen¹, B. Zhao⁵, S. Chen¹, T. Ma⁴; ¹Univ. of Maryland, Baltimore, Baltimore, MD, ²Harvard Med. Sch., Boston, MA, ³Qilu Univ. of Technology (Shandong Academy of Sci.), Jinan, China, ⁴Univ. of Maryland, College Park, MD, ⁵Purdue Univ., West Lafayette, IN

Abstract Body:

Background: Elevated arterial blood pressure (BP) is one of the most common risk factors for cerebrovascular and cardiovascular diseases. It has been associated with the atrophy of cerebral white matter (WM) in the brain, but no causal relationship has been established.

Methods: In this study, we performed a two-sample Mendelian Randomization (MR) analysis to evaluate the causal effects of BP on WM integrity within different brain regions, which were measured by fractional anisotropy (FA) of diffusion tensor imaging. We followed the MR assumptions to select genetic variants as valid instrumental variables and used two non-overlapping sets of epidemiological samples collected by the UK Biobank to estimate gene-exposure association (N = 203,111; mean age = 56.71 years) and gene-outcome association (N=16,156; mean age = 54.61 years). The causal effect of BP on regional FA was then estimated by combining the two association estimates using an inverse-variance weighted approach. We also performed two additional MR analyses to exclude the possibility of reverse causality.

Results: We found significantly negative causal effects (adjusted $p < 0.05$) of two BP measures (systolic blood pressure (SBP) and diastolic blood pressure (DBP)) on FA in eight brain regions: bilateral posterior thalamic radiation (PTR-R/PTR-L), fornix (cres)/stria terminalis left (FX/ST-L), superior fronto-occipital fasciculus right (SFO-R), bilateral sagittal stratum (SS-R/SS-L), Body of corpus callosum (BCC) and retrolenticular part of internal capsule (RLIC-L), which are related to memory and cognitive functions.

Conclusion: Our study extended the previous findings of associations between BP and WM integrity to the causation and provide more insights into the pathological processes of elevated BP that might chronically alter the brain microstructure within specific brain regions.

Complex Traits Posters - Wednesday

PB1326. Deep embedded clustering by phenotype and genome-wide association study in autism from SPARK individuals

Authors:

F. Ueno¹, T. Onuma¹, I. Takahashi¹, H. Ohseto¹, A. Narita¹, T. Obara¹, M. Ishikuro¹, K. Murakami¹, A. Noda¹, F. Matsuzaki¹, H. Metoki^{1,2}, G. Tamiya^{1,3}, S. Kure^{1,4}, S. Kuriyama¹; ¹Tohoku Univ., Sendai, Japan, ²Tohoku Med. and Pharmaceutical Univ., Sendai, Japan, ³RIKEN Ctr. for Advanced Intelligence Project, Tokyo, Japan, ⁴Miyagi Children's Hosp., Sendai, Japan

Abstract Body:

Autism spectrum disorder (ASD) has heterogeneous phenotypic and genetic characteristics, with associated variants in ~1,000 genes. Stratifying ASD patients may help identify more genetically homogeneous subgroups. Using a deep embedded clustering algorithm, we conducted cluster analyses of Simons Foundation Powering Autism Research for Knowledge (SPARK) datasets and performed genome-wide association studies (GWAS) of the clusters. We observed no significant associations in the conventional GWAS comparing all patients to all controls, whereas in cluster-based GWAS (cGWAS), we identified 90 chromosomal loci that satisfied the $P < 5.0 \times 10^{-8}$. Many of these loci were located within or near previously reported candidate genes for ASD. Many other revealed genes were previously suggested to be associated with other brain disorders. These findings suggest that clustering may successfully identify subgroups with relatively homogeneous disease etiologies.

Complex Traits Posters - Thursday

PB1327. Deep learning models of gene regulation in Alzheimer's disease improve functional fine-mapping and thereby cross-ancestry PRS portability

Authors:

T. Lin¹, C. M. Lakhani¹, T. Raj², D. Knowles¹; ¹New York Genome Ctr., New York, NY, ²Icahn Sch. of Med. at Mount Sinai, New York, NY

Abstract Body:

Alzheimer's Disease (AD) is the most prevalent type of dementia and has been shown to have a substantial genetic component. Previous genome-wide association studies (GWAS) found many, predominantly non-coding, loci that are associated with AD and which can be used to predict AD via polygenic risk score (PRS). However, due to European-centric studies and the different linkage disequilibrium (LD) patterns and allele frequencies across various ethnic backgrounds, these results are not necessarily applicable to non-European populations. We hypothesized that using functional fine-mapping to detect the causal variants underlying GWAS loci could improve PRS cross-ancestry portability for AD. Hence we used deep learning models of gene regulation in AD-relevant cell types to empower functional fine-mapping and improve cross-ancestry AD prediction. We used three different published GWAS for downstream analysis. We combined 48 functional annotations selected by stratified LD score regression from Roadmap and DeepSEA with brain ATAC-seq from cell types that are reported to be associated with AD progression. We also included 187 "baseline" LD-related annotations to perform our study. Tests were built using functional fine-mapping (PolyFun) and PRS, compared with (1) statistical Fine-mapping (SuSiE), (2) baseline using clumping and P-value thresholding (PLINK), and (3) other published methods (SBayesR and PRSice). Using whole-genome sequencing data from the AD Sequencing Project, 5,122 cases and 6,599 controls were included after filtering out samples under the age of 65. European (EUR), African American (AFR), and Hispanic (AMR) groups account for 57.2%, 22.6%, and 18.9% of the total samples, respectively. Since our target data has a relatively diverse ancestral composition, we tested the performance of each ethnic group independently. We achieved our best performance using GWAS from Kunkle (2019); after removing the two most significant APOE-ε4 loci rs429358 and rs7412, the AUC and R-squared reached 0.58 and 3.9% in the EUR cohort, which is consistent with previous studies. We found functionally-informed fine-mapping with deep learning annotations did increase trans-ethnic portability of PRS in AFR and AMR cohorts. Using a PRS trained on the Bellenguez (2021) GWAS, we found AUC increased from 0.528 to 0.55 in the AMR population and from 0.515 to 0.516 in the AFR population. While the model trained on summary statistics from Kunkle (2019) increased PRS AUC from 0.512 to 0.517 in the AFR cohort but decreased from 0.53 to 0.524 in the AMR cohort. To sum up, our work provides new insight into the applicability of functional annotations in cross-ethnic AD prediction.

Complex Traits Posters - Wednesday

PB1328. Deep venous thrombosis: genotyping and whole-exome sequencing data to improve genetic risk prediction

Authors:

V. Lo Faro, T. Johansson, J. Höglund, F. Hadizadeh, Å. Johansson; Uppsala Univ., Uppsala, Sweden

Abstract Body:

Background: Deep venous thrombosis (DVT) is the formation of blood clots in the deep veins. Blood clots traveling to the lung can cause organ damage or sudden death. More than 60% of DVT risk is influenced by genetic factors, such as the Leiden mutation in *F5* (FVL). Characterizing the genetic contribution and stratifying individuals based on their genetic makeup can favorably impact risk prediction. **Methods:** We performed a genome-wide association study and constructed a polygenic risk score (PRS) in the 60% (N=284,591) of the UK Biobank cohort. The remaining 40% (N=198,362) was employed to evaluate the PRS and to perform a gene-based test on exome-sequencing data to investigate the effects of rare variants. **Results:** We identified and replicated a new variant (rs11604583) near the *TRIM51* gene, and a rare variant (rs187725533), associated with a 2.2-fold higher risk of DVT, in the *CREB3L1* gene. The top PRS decile was associated with a 3.4-fold risk of DVT, an effect that was still 2.3-fold when excluding FVL carriers. The cumulative risk of DVT at the age of 70 years for FVL carriers in the top PRS decile is 10%, contraposed to 5% for non-carriers. **Conclusion:** We showed that common and rare variants influence DVT risk and that the PRS improves risk prediction on top of FVL. This suggests that individuals classified with high PRS scores could benefit from early genetic screening.

Complex Traits Posters - Thursday

PB1329. Differential gene expression analysis of alcohol use disorder across postmortem human brain tissues.

Authors:

C. Willis¹, J. White¹, B. Quach¹, S. Han², R. Tao², J. Shin², A. Deep-Soboslay², R. Mayfield³, B. Webb¹, E. Johnson¹, J. Kleinman², L. Bierut⁴, D. Hancock¹; ¹RTI Intl., Research Triangle Park, NC, ²Lieber Inst. for Brain Dev., Baltimore, MD, ³University of Texas at Austin, Austin, TX, ⁴Washington Univ Sch Med, St Louis, MO

Abstract Body:

Alcohol use disorder (AUD) is a common psychiatric disorder that increases risk of many diseases, including liver disease and many cancers. AUD is 50–60% heritable, but specific genes contributing to AUD risk and gene regulation in response to alcohol exposure are not fully understood. Here, we conducted a differential gene expression analysis in two different human brain tissues, nucleus accumbens (NAc) and dorsolateral prefrontal cortex (DLPFC), to better understand AUD. Bulk RNA sequencing was performed on both NAc and DLPFC tissues from 122 deceased individuals with next-of-kin reporting to define cases (2+ AUD symptoms) and controls (no symptoms). Following quality control, 100 NAc samples (53 AUD cases, 47 controls) and 97 DLPFC samples (51 AUD cases, 46 controls), all of European ancestry, remained for analysis. 20,324 and 20,666 genes for NAc and DLPFC, respectively, were tested for differential expression by AUD status using negative binomial regression models that accounted for major depressive disorder status, smoking status, and surrogate variables, which serve as proxies for known covariates as well as unmeasured technical and biological confounders. We used false discovery rate (FDR) <0.05 to declare genome-wide statistical significance and removed potential false positives based on Cook's distance. We identified 105 and 637 genes as differentially expressed for NAc and DLPFC, respectively. Of these, 28 genes were differentially expressed in both NAc and DLPFC. We used our results to assess evidence for replication of genes previously reported in a similarly powered differential gene expression study of AUD in pre-frontal cortex (65 cases and 73 controls of European ancestry, Kapoor et al. *Transl Psychiatry* 2019). Of the 129 genes reported for differential expression, we replicated 24 genes in our DLPFC results at $P < 3.9 \times 10^{-4}$, based on Bonferroni correction for 129 genes tested. Six of the 24 were also implicated in NAc: *HMG2*, *MGEA5*, *ARRDC3*, *HMGB2*, *MDK*, and *ODCI*. In addition, 24 and 5 of the genes with differential expression in DLPFC and NAc, respectively, were identified as significant for gene-based association with alcohol consumption or use disorder, as derived from genome-wide association studies (GWAS) (Sey et al. *Mol. Psychiatry* 2022), suggesting that a subset of our findings represent genetically-driven differential expression that influences risk for AUD while other identified genes may result from alcohol exposure. The replication of differentially expressed genes in DLPFC, converging evidence with GWAS, and other differentially expressed genes identified in NAc helps expand understanding of the neurobiology of AUD.

Complex Traits Posters - Wednesday

PB1330. Differential splicing occurs in individuals with disseminated coccidioidomycosis infections.

Authors:

S. Jensen¹, S. J. Spendlove¹, A. V. Stephens¹, R. H. Johnson^{1,2}, A. Heidari^{1,2}, R. Kuran^{1,2}, H. Pimentel¹, M. J. Butte¹, V. A. Arboleda¹; ¹UCLA, Los Angeles, CA, ²Valley Fever Inst., Bakersfield, CA

Abstract Body:

Coccidioidomycosis is a disease caused by inhalation of the fungal spores from the fungi *Coccidioides immitis* and *posadasii*. The fungi infect approximately 150,000 people in the United States yearly, the vast majority of whom remain asymptomatic or develop mild respiratory symptoms and are considered to have uncomplicated Valley Fever (UVF). In an estimated 1-2% of infections, the fungi spread to other parts of the body, a potentially fatal form of the disease known as disseminated coccidioidomycosis (DCM). Recent work in patients with DCM has identified ultra-rare risk variants associated with the immune system and prompted the use of immunomodulatory drugs to successfully treat DCM. We hypothesized that analysis of whole blood transcriptomes could improve our identification of genes and pathways associated with susceptibility to DCM. In order to identify other patients with similar genetic susceptibilities, our study has recruited individuals with coccidioidomycosis from UC Davis and the Valley Fever Institute. Whole genome and RNA sequencing were performed for a cohort of 39 individuals who had (n=23) or did not have (n=16) a history of dissemination. Differential gene expression analysis was carried out with DESeq2 and differential splicing analysis with LeafCutter. Gene ontology enrichment and pathway analyses were carried out for significant results. We detected no significant differences in global gene expression profiles between individuals with history of DCM and those with more mild forms of coccidioidomycosis. Assessment of the proportion of splice isoforms between the severity groups revealed significant (FDR<0.05) differential splicing for six genes: *ARHGAP12*, *ATP6V1H*, *ERCC6*, *GSDMB*, *MRPL52*, and *PCGF5*. These transcripts are highly expressed in immune cells. Transcriptional analyses are an important first step to understanding the role splicing plays in determining risk factors for coccidioidomycosis dissemination. Future work will explore splicing QTLs and other genetic regulators of transcript abundance.

Complex Traits Posters - Thursday

PB1331. Differentiating Mesenchymal Stem Cells from iPSCs for Analysis of Type 2 Diabetes and Related Trait GWAS Loci

Authors:

C. Ventresca¹, A. Varshney¹, P. Orchard¹, A. Monteiro da Rocha¹, M. Laakso^{2,3}, J. Tuomilehto⁴, T. Lakka², K. Mohlke⁵, M. Boehnke¹, L. Scott¹, H. Koistinen⁴, F. Collins⁶, T. Herron¹, S. Parker¹; ¹Univ. of Michigan, Ann Arbor, MI, ²Univ. of Eastern Finland, Kuopio, Finland, ³Kuopio Univ. Hosp., Kuopio, Finland, ⁴Finnish Inst. for Hlth.and Welfare, Helsinki, Finland, ⁵Univ. of North Carolina, Chapel Hill, NC, ⁶NIH, Bethesda, MD

Abstract Body:

Background Some type 2 diabetes (T2D) and related trait genome wide association study (GWAS) signals likely impact T2D risk via skeletal muscle, a primary insulin responsive tissue. We previously generated in vivo mesenchymal stem cell (MSC) data through single nucleus (sn-)multi-omics (RNA+ATAC) profiling of 286 skeletal muscle biopsies and found that a subset of GWAS signals colocalize with cell-type specific e/caQTL active in skeletal muscle MSCs. One method to investigate these signals is to differentiate MSCs from induced pluripotent stem cell (iPSC) lines, allowing us greater flexibility to explore these pathways. From the same individuals with muscle sn-multi-omics, we derived 50 iPSC lines from fibroblasts. To develop a greater understanding of T2D and related trait mechanisms, we can use techniques on the iPSCs differentiated to MSCs to nominate target genes and regulatory elements at each GWAS signal. These approaches include sn-multi-omics and CUT&Tag, a sensitive method to analyze genome-wide histone marks. We have already optimized both techniques on multiple cell types. **Hypothesis** We hypothesize that MSCs can be differentiated from iPSC lines for the purpose of investigating the impact of MSC-specific molecular mechanisms on T2D risk and T2D-related traits. **Results** Here, we demonstrate that MSCs can be derived from iPSC lines for deep molecular phenotyping. These iPSC-derived MSCs display MSC morphology, expression of MSC marker genes, and loss of expression of pluripotency and hematopoietic markers. Over the course of the differentiation, *Oct3/4*, a pluripotency marker, drops from 73.4% of cells expressing this down to 0.42%. Meanwhile, *CD73*, a MSC marker, increases from 7.25% of cells expressing up to 60.2%, based on flow cytometry analysis. We are currently performing a time course analysis with this experimental system with ten independent iPSC lines all multiplexed to explore the trajectory from iPSC progenitors to fully-differentiated MSCs, and compare in vitro sn-multi-ome signatures to those observed in matched in vivo MSCs. **Future Directions** We will use a cohort of 50 iPSC-derived MSC samples to investigate stimulatory state specific genetic regulatory effects (e/caQTL) within T2D pathways and will validate our results by performing CRISPRi knockdown and CRISPRa activation on a subset of nominated loci.

Complex Traits Posters - Wednesday

PB1332. Direct participation of individuals scales the development of cardiometabolic polygenic risk score models.

Authors:

A. Lopez Pineda^{1,2}, M. Vernekar^{3,4}, S. Moreno Grau¹, B. Moatamed¹, M. Lee¹, M. Nava-Aguilar^{1,2}, G. Gonzalez-Arroyo^{1,2}, K. Numakura^{3,4}, Y. Matsuda^{3,4}, A. Ioannidis^{5,1}, N. Katsanis¹, T. Takano^{3,4}, C. Bustamante^{5,1}; ¹Galatea Bio, Inc., Hialeah, FL, ²Amphora Hlth., Morelia, Mexico, ³Genomelink, Inc., Berkeley, CA, ⁴Awakens Japan K.K., Tokyo, Japan, ⁵Stanford Univ., Palo Alto, CA

Abstract Body:

More than 30 million people have been genotyped by direct-to-consumer (DTC) companies, providing a potential mechanism for enabling biomedical research at a global scale. However, phenotypic information is sequestered in the initial provider networks. The scientific community has limited ability to integrate clinico-genomic datasets to fulfill the promise of precision health, catalyzing improvements in patient outcomes.

Here, we present a novel geno-pheno platform that integrates data from more than 300,000 participants who uploaded their genotype data files, and were invited to answer general health questionnaires regarding two common chronic disease conditions: Type 2 diabetes (T2D) and hypertension. Quality control, imputation, and genome-wide association studies were performed, also polygenic risk scores (PRS) were calculated using the BASIL algorithm.

Over a period of 6 months, we collected data on 4,550 participants who reported being affected for T2D and 4,528 participants for hypertension. We identified 164 (60%) variants in T2D, and 230 (63%) in hypertension showing identical effect direction to previously reported genome-significant findings in Europeans. Moreover, the performance of our PRS models (AUC of 0.68 in T2D, and 0.69 in hypertension) is comparable to previously published models trained with larger academic datasets.

The direct participation of individuals has shown the potential to generate rich datasets enabling the creation of PRS cardiometabolic models. The generation of clinico-genomic datasets, which leverages the direct participation of individuals, accelerates data acquisition for biomedical research. However, it is important to use proven quality control (QC) mechanisms to successfully enable traditional GWAS and PRS analyses.

Our study shows that predictive tools for both T2D and hypertension can be successfully trained with heterogeneous genotypic and phenotypic data generated outside of clinical environments. Our methods can recapture prior findings with fidelity, which are also highly comparable to those results obtained from controlled (and academic) datasets. DTC data provides a mechanism for scaling precision health care delivery beyond the small number of countries who can afford to finance these efforts directly.

Complex Traits Posters - Thursday

PB1333. Discovering disease context eQTLs in a patient cohort with active psoriatic arthritis

Authors:

M. Guan, A. Hart, W. Chen, K. Sweet, D. Waterworth; Janssen R&D, Spring House, PA

Abstract Body:

Psoriatic arthritis (PsA) is a heterogeneous, heritable, chronic inflammatory disease that occurs in ~20-30% of psoriasis patients. It variably affects synovial joints, tendons, entheses and axial sites in addition to skin, resulting in signs and symptoms including peripheral joint inflammation, enthesitis, and dactylitis. Genetic factors play an essential role in the dysregulation of key pathways in PsA, but information on genetic variants and their functional relevance associated with PsA susceptibility and pathology is limited. Expression Quantitative Trait Loci (eQTL) mapping is a tool to identify allelic variants associated with gene expression. Disease context eQTL mapping provides a deeper understanding of candidate susceptibility genes at risk loci and PsA etiology. We performed eQTL mapping using RNA sequence data from whole blood (WB) and imputed genetic data from 644 patients with active PsA to identify disease context eQTLs. A linear model, adjusting for age, sex, top 10 genetic principal components, and 3 surrogate variables capturing unknown sources of variability from expression data, was used for cis-eQTL analysis. Among 10,984 genes identified as eGenes (genes with significant cis-eQTLs), 8,046 (~73%) were overlapping with eGenes from a non-disease Genotype-Tissue Expression (GTEx) project v8 WB dataset (n=670 samples); 2,938 (~27%) eGenes were significantly associated with up-/downregulated genes in the PsA cohort (FDR $p < 0.05$). Pathway analysis of eGenes significant in PsA indicated their involvement in metabolism, signal transduction, and cytokine signaling in the immune system. Notable SNP-eGene pairs included rs10889664-IL23R, rs2837-ILDR2, rs4577297-IL1RL1, rs5744249-IL18, and rs78031781-S100A3. The identification of the eQTL rs10889664 further supports IL23R as a robust genetic susceptibility locus for PsA. In addition, 25 of 824 SNP-eGene pairs that were significant in both GTEx and PsA cohorts showed effect size differences ($< 25\%$ interquartile - 1.5 IQR or $> 75\%$ interquartile + 1.5 IQR). These include rs114351845-IL17RE, rs146047341-TGFB3 and rs77366070-SMURF2, which are involved in inflammatory conditions. IL-17RE encodes the IL-17C receptor implicated in skin inflammation and relevant to PsA. In summary, we identified eQTLs associated with PsA, enabling a better understanding of the association between genetic risk loci and PsA disease susceptibility. These data may facilitate the discovery of genetic factors to enable disease stratification and fine-mapping of PsA genetic associations for target identification.

Complex Traits Posters - Wednesday

PB1334*. Discovering the early molecular markers of lipid dysregulation using deep phenotyping and adipose tissue gene expression.

Authors:

M. Tomlinson, J. El-Sayed Moustafa, A. Hodgkinson, K. Small; King's Coll. London, London, United Kingdom

Abstract Body:

Cardiovascular disease is characterised by the accumulation of fatty deposits in the arteries and pro-atherogenic effects of adipose tissue signalling. Accordingly, dysregulation of lipid metabolism is a major contributor to the development of cardiovascular disease. To reduce the burden of cardiovascular disease, we need to improve prognostic approaches that identify individuals at risk of lipid dysregulation so they can modify their environmental exposures or start taking medication before it accelerates the onset of cardiovascular disease. Here we explore associations between the future use of lipid-regulating drugs and 287 intermediate quantitative phenotypes relevant for cardiovascular disease risk including biochemical measures, clinical diagnoses, and DXA scans of body composition at baseline (2001-2010) and follow-up (2014-2019) in a cohort of British twins. We find 27 phenotypes at baseline (2001-2010) and trajectories of 18 phenotypes are linked with future lipid-regulating drug use including measures of lipid metabolism and cardiovascular health (FDR 5%). Utilising transcriptional profiles from a subset of twins ($n = 766$), we find adipose tissue gene expression at baseline (2007-2009) is associated cross-sectionally with 16 of the phenotypes linked with future drug usage (FDR 5%). The genes with expression levels that are associated with 10 of these phenotypes also produce greater absolute log-fold changes in participants that go on to require lipid-regulating drugs ($p < 0.05/16$), and overall, these genes are enriched for processes related to atherosclerosis, inflammation, and lipid metabolism. Finally, we show 13 unique genes are differentially expressed at baseline in participants that go on to require lipid-regulating drugs by follow-up (2014-2019) compared to matched controls (FDR 5%), including top hit *ESM1* ($p < 1.82 \times 10^{-16}$), which has been implicated in angiogenesis and inflammation. Taken together, our findings highlight early phenotypic and molecular markers of lipid dysregulation that could help identify individuals at higher risk of lipid dysregulation and future cases of cardiovascular disease.

Complex Traits Posters - Wednesday

PB1335. Discovery of rare variants in 219 genes associated with adult human height via burden analysis in exomes of 785,210 individuals

Authors:

A. Locke¹, J. Kosmicki¹, D. Sharma¹, X. Bai¹, A. Marcketta¹, K. Watanabe¹, H. Kang¹, S. Balasubramanian¹, J. Torres², P. Kuri Morales³, R. Tapia-Conyer³, J. Alegre³, J. Berumen³, J. Emberson², R. COLLINS², J. Backman¹, J. Reid¹, Regeneron Genetics Center, RGC Research Partners, A. Baras¹, J. Marchini¹, G. Abecasis¹, M. Ferreira¹; ¹Regeneron Genetics Ctr., Tarrytown, NY, ²Univ. of Oxford, Oxford, Oxon, United Kingdom, ³Univ. Natl. Autónoma de México, Mexico City, Mexico

Abstract Body:

Human height is a highly heritable polygenic quantitative trait frequently used as a model to study the genetic contribution to individual variation. Through GWAS meta-analysis, the global GIANT Consortium has arguably explained all the additive variance in adult human height attributable to common genetic variation, implicating ~20% of the genome (Yengo et al. 2021). Yet the independent role of rare genetic variation (MAF<1%) in height remains largely unexplored. To this end, we performed a multi-cohort, multi-ancestry, joint association analysis of rare coding variation on adult human height in 785,210 individuals, including 209,676 individuals of non-European ancestry, from a joint call set of >1.1 million exomes. We tested rare predicted loss-of-function (pLoF) and deleterious missense variants, for association with height using burden and SKAT tests. After correcting for multiple testing ($p < 5 \times 10^{-8}$), we identified 219 unique genes associated with height, most of which remained significant after conditioning on common variant association signals. The effects of these genes ranged from -2.3 standard deviations (SD; *ACAN*) to 1.5 SD (*FBNI*), or ~24.7 cm shorter to 15.7 cm taller. The mean effect of these associated genes was -0.1 SD (-1.07 cm). As anticipated, effect sizes increased with greater predicted protein impact and/or decreasing allele frequency. For example, burden tests including only pLoF variants had mean effect 3x larger (-0.34 SD) than the average gene test, and the average effect size tripled again, to -0.99 SD (10.7 cm), when testing only pLoF variants that are singletons in our data. In an independent dataset of ~29,000 adults of European ancestry, putatively functional rare variants in these 219 genes explained ~1.4% of the variation in adult height. Thirty-six of 219 associations were with genes previously identified with extreme height phenotypes or skeletal growth disorders in the Online Mendelian Inheritance in Man database, and 77% (167 of 219) represent new gene-based associations compared to GIANT Consortium results from the exome chip (Marouli et al. 2017). While 169 of 219 height-associated genes found here are also near common variant GWAS signals, our analyses provide direct independent evidence for specific genes influencing mechanisms related to growth. Our results from coding variation in nearly 800,000 individuals provide strong evidence that rare variant associations are strongly complementary to, but dramatically more specific than, common variant GWAS association, and while individually rare, can, due to large effect sizes, account for a considerable proportion of population variation.

Complex Traits Posters - Thursday

PB1336. Discovery of Type 2 Diabetes genes using an accessible tissue.

Authors:

D. Davtian¹, J. Schwenk², M. McCarthy³, A. Mahajan⁴, M-G. Hong⁵, E. Dermitzakis⁶, H. Im⁷, E. Pearson¹, A. Viñuela⁸, A. Brown¹; ¹Univ. of Dundee, Dundee, United Kingdom, ²SciLifeLab, Stockholm, Sweden, ³University of Oxford, Oxford, United Kingdom, ⁴Genentech, South San Francisco, CA, ⁵Karolinska Inst, Stockholm, Sweden, ⁶GSK, Geneva, Switzerland, ⁷Univ. of Chicago, Chicago, IL, ⁸Univ. of Newcastle, Newcastle, United Kingdom

Abstract Body:

Transcriptome Wide Association Study (TWAS) methods use reference expression datasets to link genes to disease. Often these use samples from a disease relevant tissue, but these may be difficult to collect, limiting sample size. We evaluate the power to discover Type 2 Diabetes (T2D) causal genes using a well powered whole blood expression reference against smaller reference datasets from disease relevant tissues.

Predictive models were built using whole blood expression and proteomic data (DIRECT consortium, n = 3029), pancreatic islets eQTL data (INSPIRE consortium, n = 420) and eQTL data from 49 tissues (GTEx consortium). These models were combined with GWAS summary statistics (DIAGRAM consortium, n = 898,130) to calculate gene-T2D association scores using S-PrediXcan.

We indeed find that larger reference panels discover more genes (97 significant associations when using DIRECT, 43 with the pancreatic islets model and from 2 to 84 for GTEx results, Spearman correlation = 0.9 between sample size and number of significant associations) and relevance of the tissue did not appear as a significant factor. However, we do find that genes implicated by relevant tissues are more likely to be near genome wide significant GWAS associations such as *TCF7L2* and *IGF2BP2*, suggesting that these variants are tissue specific eQTLs. In contrast, genes implicated using a well powered reference dataset are more likely to have multiple lines of genetic evidence, with multiple eQTLs which also show moderate disease association. Finally, we find that controlling for BMI when looking at T2D associations reduces our power by around one-third, suggesting many of the implicated genes are involved in insulin resistance with BMI as a mediating factor.

Our findings indicate that large studies in non-relevant tissues identify disease causal genes but can miss relevant tissue specific signals. In addition, correcting for environmental factors such as BMI could help to investigate the underlying biology of these associations.

Complex Traits Posters - Wednesday

PB1337. Discrepancy between genetically-predicted and actual body mass index is a significant predictor of incident cardiovascular disease

Authors:

T-M. Rhee¹, J-B. Park¹, S-H. Kwak¹, H. Lee¹, J. Choi¹, N. Kim², S. Lee², S-P. Lee¹; ¹Seoul Natl. Univ. Hosp., Seoul, Korea, Republic of, ²Seoul Natl. Univ., Seoul, Korea, Republic of

Abstract Body:

Background: Body mass index (BMI) is a key predictor of cardiovascular diseases (CVD) and related mortality. Polygenic risk scores (PRS) derived from genome-wide association studies (GWAS) can accurately predict BMI and genetically-predicted BMI (BMI-pred) could serve as a threshold for personal fat storage. We hypothesized that difference between BMI-pred and actual BMI (BMI-diff) could reflect severity of environmental factors affecting BMI and may predict incident CVD morbidity and mortality in general population. **Methods:** From the UK Biobank prospective cohort, we selected participants of white British descent without a history of the major CVD; myocardial infarction (MI), stroke, or heart failure (HF). The global extended PRS for BMI was calculated using polygenic prediction via Bayesian regression and continuous shrinkage priors (PRS-CS) with summary statistics from the Genetic Investigation of ANthropometric Traits consortium GWAS. According to the calculated BMI-diff, the 10-year risk of all-cause death and major adverse cardiovascular events (MACE, composite of cardiovascular death, MI, stroke, and HF) was compared using Cox proportional-hazards model. Optimal range of the BMI-diff was determined by restricted cubic spline curves for each outcome. **Results:** A total of 385,270 participants (mean age 56.7±8.0, male 45.0%) were randomly divided into train set (n=269,394) and test set (n=115,876) to establish the most accurate BMI-pred using PRS-CS. The BMI-pred could explain 7.3% of the variance of BMI in the test set. All-cause death and incident MACE occurred in 7,916 (6.8%) and 8,535 (7.4%) cases during 10-year follow-up, respectively. In the adjusted hazard ratio curves, the lowest risk of both all-cause death and MACE was observed in participants who were mildly underweight than genetically-predicted, providing the optimal BMI-diff range between 0 to 1.9 kg/m² for all-cause death, and 0 to 6.6 kg/m² for MACE, respectively. In the obese group with genotype-phenotype mismatch (BMI-diff <-5 kg/m²), the risk of both all-cause death and MACE was significantly higher than obese group with matched genotype-phenotype. However, the underweight group with mismatch (BMI-diff >5 kg/m²) was only associated with increased risk of all-cause death, not MACE. **Conclusion:** Deviation of actual BMI from BMI-pred which reflects severity of environmental factors is a significant predictor of incident CVD morbidity and mortality. As a step towards precision medicine, we suggest the optimal target range of body weight reduction for individuals determined by their own BMI-pred to prevent future risk of CVD.

Complex Traits Posters - Thursday

PB1338. Dissecting autism heterogeneity by genotype phenotype analysis among autism risk gene carriers in SPARK

Authors:

C. Shu^{1,2}, P. Feliciano³, L. Snyder³, N. Volfovsky³, Y. Shen², W. K. Chung¹, SPARK Consortium; ¹Dept. of Pediatrics, Columbia Univ. Irving Med. Ctr., New York, NY, ²Dept. of Systems Biology, Columbia Univ. Irving Med. Ctr., New York, NY, ³Simons Fndn., New York, NY

Abstract Body:

There is significant heterogeneity on the severity of autism spectrum disorder (ASD) core symptoms and comorbid symptoms that complicate the behavioral manifestations of ASD. We comprehensively assessed the gene-specific contributions to ASD core symptoms and comorbidities based on ASD cases carrying *de novo* or inherited coding variants among known and newly identified ASD risk genes using the Simons Foundation Powering Autism Research for Knowledge (SPARK) cohort. To dissect the ASD phenotypic spectrum, we performed principal component analysis (PCA) among ~15,000 ASD cases on ~200 ASD phenotypic measures on medical and psychiatric history, developmental milestones and standardized surveys measuring levels of social communications, repetitive behaviors and motor skills. We represented ASD phenotypic spectrum by the top two principal components (PCs) and visualized the ASD risk gene carriers in phenotypic spectrum. We found that carriers with *de novo* heterozygous mutations in genes like *ADNP*, *SHANK3*, *CHD8*, *FOXP1* and *SCN2A* have greater severity of social communication impairment, delayed developmental milestones, more need for specialized ASD services. Gene carriers with mutations on *ARID1B*, *GIGYF1* and *NAV3* have less developmental issues but more severe repetitive behaviors. These results support that gene-level genotype-phenotype analyses are necessary rather than overall *de novo* burden analysis to dissect the ASD phenotypic heterogeneity.

Complex Traits Posters - Wednesday

PB1339. Dissecting single cell splicing isoforms in human hearts using single cell nanopore sequencing

Authors:

L. Lu¹, C-K. Shiau¹, R. Kieser², K. Youker³, R. Gao¹; ¹Northwestern Univ., Chicago, IL, ²Houston Methodist Res. Inst., Houston, TX, ³Houston Methodist Res. Inst., Houston, IL

Abstract Body:

Heart disease remains one of the leading causes of death in the world. Dysregulation of alternatively spliced isoforms plays critical roles in molecular etiologies of heart diseases. High throughput single cell nanopore sequencing (HT-scNanoSeq) of full-length mRNAs provides an ideal approach to investigate single cell splicing isoform profiles. However, detection of cell population specific isoforms has been challenged due to the high drop off rates in individual cells. To address this challenge, we developed a new computational toolkit, scNanoPSI (single cell Nanopore sequencing for Population Specific Isoform) to detect both differentially spliced and differentially expression isoforms in distinct cell types and cell states. In this study, we dissected the atlas of single cell splicing isoforms of major cell types in adult human hearts including cardiomyocytes, pericytes, fibroblasts, endothelial cells, lymphocytes, macrophages as well as neuronal cells. Moreover, we detected a list of aberrant isoforms in sub-cell types in failed human hearts. In summary, scNanoPSI enables robust detection of splicing isoforms traceable to cell types and cell states, and our findings in human hearts provide important evidence for developing new therapeutics by targeting abnormal isoforms to treat heart diseases.

Complex Traits Posters - Thursday

PB1340. Dissecting the relationship between recurrent pregnancy loss and type 1 and type 2 diabetes in Western Ukrainian population

Authors:

Y. Sharhorodska^{1,2,3}, V. Pascat⁴, Z. Balkhiarova^{2,3,5}, A. Ulrich^{3,5}, L. Chorna¹, I. Shymanska¹, D. Zastavna¹, O-R. Gnateyko¹, M. Kaakinen^{3,2,5}, H. Makukh¹, I. Prokopenko^{3,2,5}; ¹Inst. of Hereditary Pathology of Natl. Academy of Med. Sci. of Ukraine, Lviv, Ukraine, ²People-Ctr.d AI Inst., Univ. of Surrey, Guildford, United Kingdom, ³Dept. of Clinical and Experimental Med., Univ. of Surrey, Guildford, United Kingdom, ⁴Université de Lille, Lille, France, ⁵Dept. of Metabolism, Imperial Coll. London, London, United Kingdom

Abstract Body:

Aims/hypothesis: The loss of two or more sequential pregnancies before 24 weeks of gestation is defined as recurrent pregnancy loss (RPL). It is a frequently occurring human infertility-related condition affecting ~0.8% to 1.4% of women in the general population. The causal factor for RPL leading to treatment is usually identified in ~50% of patients only. Given the lack of GWAS studies and the possibility of various, currently unknown RPL risk factors, we tested a hypothesis about metabolic pathways contributing to RPL susceptibility. We investigated whether RPL shares biological pathways with type 2 and type 1 diabetes (T2D & T1D).

Methods: We investigated the predictive ability of T2D/T1D polygenic risk scores (PRS) for RPL risk using the LUCAR study (Lviv Ukrainian Cohort for Advancing Reproductive Health) from the Western Ukraine. LUCAR includes 273 idiopathic RPL cases and 535 controls with at least one healthy child, all having their genome-wide data imputed to TopMED panel. For PRS, we used 552 SNPs previously validated for T2D (PMID: 32541925) and 61 SNPs established for T1D (PMID: 32770166) in genome-wide association studies and assessed their associations with RPL via logistic regression.

Results: We showed that neither of the PRSs for T1D or T2D was associated with the risk of RPL (T1D: odds ratio 1.02, 95%CI[0.88-1.18]), (T2D: odds ratio 0.97, 95%CI[0.84-1.12]), although we did identify six individuals with a high polygenic susceptibility to T1D, of which one individual was also at high risk of developing T2D. The receiver operator characteristic (ROC) analysis demonstrated no predictive ability of T1D PRS with the area under the curve (AUC) of 0.49, 95%CI(0.45-0.53), and for T2D AUC=0.50, 95%CI(0.45-0.54).

Conclusions: Despite previous epidemiological studies suggesting associations between RPL and diabetes types, we did not detect such a relationship in the LUCAR study from Western Ukraine.

PB1341. Dissecting the role of pleiotropy in the genetic adaptation of Tibetans to high altitudes.

Authors:

A. Thornburg, I. Aneas, S-Y. Park, D. Sobreira, O. Gray, A. Di Rienzo, M. Nobrega; Univ. of Chicago, Chicago, IL

Abstract Body:

Several loci in the human genome have undergone positive selection, allowing local adaptation of a population to a specific selective pressure. Typically, positive selection in human populations is not necessarily driven by selective sweeps where variants at one locus are selected for and reach a high frequency in a given population. However, the Tibetan population has undergone strong positive selection in response to hypoxic stress at high altitudes in the *EPAS1* gene locus, which encodes a transcription factor subunit of the HIF pathway. Understanding why this locus is under strong positive selection will help understand the forces shaping genetic adaptation in humans. We identified an enhancer of *EPAS1* within the positively selected genomic region and harboring variants strongly associated with high altitude in Tibetans. We showed that this enhancer, ENH5, is active in several human cell types important for hypoxic response, such as heart, kidney, and endothelial cells, as well as having higher activity in response to hypoxia but with the Tibetan allele having a blunted response compared to the Han Chinese (lowlanders) allele. Generating a mouse ENH5 knockout line to model the effects of ENH5 *in vivo* also showed differences in gene expression in several tissue types. This suggests that adaptive pleiotropy could be the driver behind the strong selection signals in the *EPAS1* gene locus, meaning that differences in gene expression between tissues due to ENH5 can be conferring different, yet adaptive phenotypes. Thus, ENH5 could have been positively selected for due to its pleiotropic activity that results in multiple adaptive phenotypes to hypoxia. Interestingly, ENH5 was also shown to be active in adipose tissue, suggesting a yet to be characterized physiological role. To dissect the role of ENH5 in adipocytes, we place wildtype and ENH5 knockout mice on a high fat diet to induce adiposity. Prior to being placed on the high fat diet, wildtype and ENH5 knockout mice were subjected to an intraperitoneal glucose tolerance test (IPGTT). Male ENH5 knockout mice were found to be more glucose intolerant than wildtype mice, suggesting that ENH5 has a role in metabolism in adipose tissue. This finding as well as additional insight that will be gained from histological analysis and RNA-seq from these mice after being placed on a high fat diet will provide yet another phenotype this enhancer effects and a better understanding of the role of pleiotropy in genetic adaptation of Tibetans.

Complex Traits Posters - Thursday

PB1342. Dose-responsive mRNA biomarkers of alcohol consumption and placebo response: A transcriptome-wide gene expression analysis.

Authors:

A. Shetty¹, J. Cornell², X-Q. Wang³, L. Sadzewicz¹, L. Tallon¹, C. Seneviratne^{1,2}; ¹Inst. for Genome Sci. (Univ. of Maryland), Baltimore, MD, ²Dept. of Psychiatry (Univ. of Maryland), Baltimore, MD, ³Dept.s of Publ. Hlth.Sci. (Univ. of Virginia), Charlottesville, VA

Abstract Body:

Purpose: Gene expression is complex, and highly sensitive to environmental factors that temporospatially interact with an individual's biology. Gene expression studies delineating alcohol's pharmacologic effects from placebo and other factors in living individuals are scarce. This study aimed to screen for mRNA biomarkers of varying drinking patterns utilizing a longitudinal study conducted in a highly controlled environment minimizing environmental effects. **Methods:** Total RNA from peripheral white blood cells (WBC) were extracted from whole blood collected from 8 healthy binge drinkers who were enrolled in a 12-day randomized, placebo-controlled, double-blind human laboratory trial conducted for testing a series of biomarkers of alcohol consumption (NCT04363424). Three alcohol doses - placebo, moderate, and high were administered in 3 separate 4-day long experiments each with 3 drinking sessions and 7-day washout period. The high dose corresponded to binge level drinking. Bulk RNAseq was performed using Illumina HiSeq4000 platform. Gene expression was normalized for library size and baseline expression at each dosing experiment. We assessed dose-responsive alcohol effects on gene expression in WBC using a generalized linear mixed-effects model. The model included individuals as a random effect and was adjusted for dose administration visit, alcohol dose and their interaction. Significantly differentially expressed genes between conditions (i.e., alcohol doses) were determined using a false discovery rate (FDR) of 10% and a minimum $\log_2(\text{fold-change})$ of 0.25. **Results:** 18 genes (e.g., CD74) were associated with response to placebo although EtG and BrAC measures did not change from baseline throughout placebo administered days. Compared to placebo-alcohol, the high-dose was associated with 36 genes (e.g., RRM2; CRHBP; SYNPO) that were enriched in 34 pathways, including pathways for cellular transporter activities. The middle-dose dose was associated with 64 genes (e.g., ACACA; BAX; CCNB1) that were almost exclusively enriched in pathways governing cellular component organization. Validation of findings with *NanoString* assays and associated DNA variation are on-going. **Conclusion:** By testing gene expression patterns in response to placebo, moderate and binge-level drinking within an environment that minimized confounding effects, we identified potential mRNA biomarkers representing pathophysiology underlying binge drinking that warrants further validation for clinical application. Furthermore, to our knowledge, comprehensive statistical modeling that we have tested here has not been applied at transcriptome-wide level.

Complex Traits Posters - Wednesday

PB1343. Drug repurposing for osteoporosis in men by integrating multi-omics and pharmacogenomics

Authors:

J. Greenbaum, C. Qiu, K-J. Su, D-Y. Liu, Q. Tian, H. Shen, H-W. Deng; Tulane Ctr. of BioMed. Informatics and Genomics, New Orleans, LA

Abstract Body:

Current pharmacological interventions for osteoporosis are categorized as either antiresorptive (e.g., bisphosphonates), which decrease the rate of bone resorption by osteoclasts, or anabolic (e.g., parathyroid hormone analogues), which stimulate bone formation by osteoblasts. Despite the remarkable advancements in our understanding of the disease pathogenesis, the current osteoporosis medications are not satisfactory and can have major side effects. We integrated the paired transcriptome and methylome profiles in peripheral blood monocytes (PBMs) from a multi-ethnic sample of Caucasian (n=558) and African American (n=359) men sampled from the Louisiana Osteoporosis Study (LOS) with interactome and pharmacogenomics information to identify novel drug candidates for osteoporosis treatment. Beginning from initial seed genes that are differentially expressed/methylated between low/normal BMD groups, we used nonparametric bootstrapping-based simulated annealing to derive driver signaling networks by growing subnetworks until a predefined network score was optimized. Next, we used drug similarity information from STITCH to reconstruct the drug-drug functional similarity network for >1,000 compounds that have drug induced gene expression profiles for skeletal muscle, which is the best available disease relevant tissue, in the LINCS L1000 dataset. The known targets of drugs were collected from various databases, and a recommendation algorithm was applied to predict the off-targets. Drugs were then ranked by evaluating the strength of their targeting effects on the driver signaling networks identified using the multi-omics profiles. The findings revealed several plausible repurposing candidates including lovastatin (statin), thalidomide (immunomodulator), carvedilol (beta blocker), flavopiridol (CDK inhibitor), and several polyphenol compounds such as quercetin and apigenin. Although still requiring functional validation experiments, the findings from this study could potentially reduce the cost and increase the speed for the development of novel therapies to treat osteoporosis and prevent fragility fractures.

Complex Traits Posters - Thursday

PB1344. Effect of artificial light on metabolic disorders and circadian gene expression

Authors:

N. Fatima; King George's Med. Univ., Lucknow, India

Abstract Body:

The large no. of world population daily exposed to the blue light, from few minutes to several hours. Blue light/ screen light provide negative effect on circadian rhythm which causes sleep deprivation and develops many diseases. Total 12 Wistar rats were enrolled and divided into two groups. Control group and Blue Light (BL) treated group which consist of six rats in each group. BL model was developed by placing the rats in 12hr blue light and 12 hr in dark till three months. Half of the rats were sacrificed and remaining rats were shifted to Normal Light (NL) for three months to see the legacy effect. These rats were sacrificed and blood samples were collected. Body weight was measured monthly, with blood glucose, Insulin, melatonin, lipid profile were estimated and mRNA were expressed by RTPCR. The percentage gain of body weight of BL treated group was **27.9%** as compared of control group (**20.2%**). Blood glucose levels were increased and circulatory level of insulin, melatonin, total cholesterol, TG, HDL and LDL were decreased in blue light treated rats. BL treated group were shifted on NL they showed increase in **2.3%** body weight, melatonin and total cholesterol and HDL were significantly increased (**p= 0.0258**) and (**p= 0.037**) respectively. Level of glucose were significantly decreased (**p>0.05**) and no change in insulin level. Per1 and Bmal1 gene were up regulated in BL group and the expression of these gene shows the significantly down regulated in NL group **p= 0.0394** and **p= 0.0403** respectively. We found that the exposure of artificial light increases the prevalence of obesity and metabolic disorders.

Complex Traits Posters - Wednesday

PB1345*. Effect of cortisol on cortical organoids: Building a "stress in a dish" model system.

Authors:

C. Purmann, K. Farrise, Y. Huang, R. Pattni, M. Ho, V. G. Carrion, A. E. Urban; Stanford Univ., Palo Alto, CA

Abstract Body:

Research shows that exposure to chronic stress and traumatic experience can impact brain health and development. For some individuals, it may lead to Post Traumatic Stress Disorder (PTSD) and other forms of psychopathology. However, less is known about the factors that make an individual more or less susceptible to developing severe psychopathology after stress exposure. Especially understanding of cellular and genomic mechanisms is lacking. Here, we present a model system to study chronic and acute stress in an *in vitro* brain organoid system that is accessible to genomic analyses. We differentiated cortical organoids from human iPSCs and confirmed the expression of the glucocorticoid receptor gene *NR3C1* and the response of the receptor to cortisol. Mature organoids were exposed to physiological stress levels using 1 μ M and 500 nM cortisol. The reaction to cortisol was analyzed using single-cell RNA-seq. We found differentially expressed genes that are known to respond to cortisol in particular and stress in general. We identified several genes that are linked to PTSD. We also discovered new differentially expressed genes that have not been linked to stress and PTSD previously. In summary, we have built a model system to study stress in a dish.

Complex Traits Posters - Thursday

PB1346. Effects of epigenetic age acceleration on kidney function: a mendelian randomization study.

Authors:

Y. Pan¹, X. Sun¹, Z. Huang¹, R. Zhang¹, C. Li², A. Anderson¹, L. James³, T. Kelly¹; ¹Tulane Univ., New Orleans, LA, ²Tulane Univ. Sch. of Publ. Hlth.and Tropical Med., New Orleans, LA, ³Univ. of Illinois Chicago, Chicago, IL

Abstract Body:

Previous studies have reported cross-sectional associations between measures of epigenetic age acceleration (EAA) and kidney function phenotypes. However, the temporal and potentially causal relationships between these variables remain unclear. We conducted a bidirectional two-sample Mendelian randomization (MR) study of EAA and kidney function. Genetic instruments for EAA and estimate glomerular filtration rate (eGFR) were identified from previous genome-wide association study (GWAS) meta-analyses. Causal effects of EAA on kidney function and kidney function on EAA were assessed through summary-based MR analyses utilizing data from the CKDGen GWAS meta-analysis of log-transformed estimated glomerular filtration rate (log-eGFR; n=567,460) and GWAS meta-analyses of EAA (n=34,710). A powerful, allele score-based MR leveraging individual-level data from UK Biobank participants (n=433,462) further examined the effects of EAA on kidney function. Using summary-based MR, we found that each 5-year increase in intrinsic EAA (IEAA) and Grim age acceleration (GrimAA) was associated with -0.01 and -0.02 unit decreases in log-eGFR, respectively (P=0.02 and P=0.09, respectively), findings which were strongly supported by allele-based MR study (both P<0.001). Summary-based MR identified 24% increased odds of CKD with each 5-unit increase in IEAA (P=0.05), with consistent findings observed in allele-score based MR (P=0.07). Reverse-direction MR identified potentially causal effects of decreased kidney function on Hannum Age acceleration (HannumAA), GrimAA, and PhenoAge acceleration (PhenoAA), conferring 3.14, 1.99, and 2.88 year decreases in HanumAA, GrimAA, and PhenoAA, respectively (P=0.003, 0.05, and 0.002, respectively) with each 1-unit increase in log-eGFR. This study supports bidirectional causal relationships between EAA and kidney function.

Complex Traits Posters - Wednesday

PB1347. Effects of the Tau Haplotype on Cognition in Childhood

Authors:

D. Dokuru¹, C. Reynolds², M. Stallings³; ¹Univ. of Colorado, Boulder, Boulder, CO, ²Univ. of California - Riverside, Riverside, CA, ³Univ Colorado, Boulder, CO

Abstract Body:

Progressive supranuclear palsy (PSP) and corticobasal degeneration (CBD) are rare neurodegenerative diseases characterized by aggregates of tau. Compared to diseases with mixed pathology like Alzheimer's, these disorders do not show presence of other protein aggregates. To date, the largest genetic risk factor identified in both diseases is the tau haplotype, an inversion of a ~900kb block on the long arm of chromosome 17 and includes MAPT, the gene encoding the tau protein. While the alternative haplotype with the inversion confers protection against the development of tauopathies, the impact of the haplotype on cognition is largely unknown. In this study, we are assessing the effects of the tau haplotype on cognitive outcomes in children ages 7-9 (prior to the development of sufficient tau aggregates). For the initial exploratory analysis we used data from 9,457 9-year old individuals in the Adolescent Brain Cognitive Development (ABCD) study. We used PLINK to extract the haplotype tagging variant rs8070723 (G) to determine H2 haplotype dosage. The phenotypes we tested in the study included composite scores from the NIH Toolbox® Cognition Battery (<http://www.nihtoolbox.org>) (fluid, crystallized, and total), the WISC matrix reasoning task (estimate for IQ), and total whole brain cortical area (mm²). We generated general linear models for each phenotype. We created the models using the H2 haplotype tagging variant as a dosage with values of 0,1,2. We also controlled for the covariates age, sex, and race/ethnicity (PCs). All statistical models were constructed in the R software package (<http://www.r-project.org/>). We used a stringent Bonferonni corrected threshold of 0.01 to determine significance. Aside from crystallized composite score, all other measure showed significant decrement in cognitive outcomes associated with the H2 haplotype (IQ was marginally significant). This study shows that while the H2 haplotype is protective for developing tauopathies in the aging population (post-reproductive age), it is associated with more negative cognitive outcomes in early age (pre-reproductive age). To confirm our findings we replicated them in the Colorado Adoption/Twin Study of Lifespan behavioral development (CATSLife) dataset (N=953) using the cognitive measures available when the participants were aged 7: performance WISC, verbal WISC, and full scale WISC. While tests of mean differences did not reach significance for any of the measures in this small replication, the direction of effects was consistent with the initial findings.

Complex Traits Posters - Thursday

PB1348. Elevated levels of CXCL16 in severe COVID-19 patients: Effects on mortality.

Authors:

C. Johnson, J. Brzezynski, A. Kaden, S. Smieszek, V. Polymeropoulos, B. Przychodzen, C. Polymeropoulos, G. Birznieks, M. Polymeropoulos; Vanda Pharmaceuticals Inc., Washington, DC

Abstract Body:

Genome-wide association studies (GWAS) have recently identified chromosome 3p21.31, with a lead variant pointing to the *CXCR6* gene, as the strongest reported susceptibility locus for severe COVID-19 thus far. CXCL16 is synthesized as a transmembrane molecule that is expressed as a cell surface-bound molecule and as a soluble chemokine. The CXCR6/CXCL16 axis mediates homing of T cells to the lungs in a diseased state, and hyper-expression is associated with localized cellular injury. The aim of this GWAS was to characterize the CXCR6/CXCL16 axis in the pathogenesis of severe COVID-19. Plasma concentrations of CXCL16 collected at baseline from 115 hospitalized COVID-19 patients participating in the ODYSSEY clinical study were assessed together with a set of controls. Another cohort of samples (n = 79) from COVID-19 patients participating in the CALYPSO clinical study were evaluated to see if the effect could be replicated. CXCL16 levels in plasma were determined using enzyme-linked immunosorbent assay (ELISA). Furthermore, whole genome sequencing was conducted on all samples.

We report elevated levels of CXCL16 in this cohort of COVID-19 hospitalized patients, specifically in severe hospitalized COVID-19 patients (p -value < 0.02). Importantly, we report a significant effect of elevated CXCL16 on the mortality of this cohort (p -value < 0.03) and show that the effect is replicated in our second cohort (p -value < 0.0004). Clinically, at 700 pg/mL, the odds ratio is 20.6 (p -value = 0.04), suggesting that a COVID-19 patient has approximately a 25% mortality rate when CXCL16 levels are above 700 pg/mL. We further characterize the role of the *CXCR6* expression on CD8 T cells.

These latest findings further support the significant role of the CXCR6/CXCL16 axis in the immunopathogenesis of severe COVID-19 and warrant additional studies to understand which patients would benefit most from targeted treatments.

Complex Traits Posters - Thursday

PB1349*. Enriching genetic hypotheses of schizophrenia through neuroimaging transcriptomics.

Authors:

X. Bledsoe¹, E. Gamazon²; ¹Vanderbilt Univ., Nashville, TN, ²VUMC Clare Hall, Univ. of Cambridge, Nashville, TN

Abstract Body:

The pathophysiology of schizophrenia is highly complex, involving associations with hundreds of SNPs and genes. The effort to synthesize these disparate genetic elements into pathophysiological risk pathways is far from complete. Biochemical studies are complemented by neuroimaging data which highlight altered brain regions in schizophrenic patients. Hippocampal variation has emerged as a highly replicable neurologic markers of schizophrenia risk and severity.

We use novel methods to prioritize a high-confidence set of genes and cellular functions as candidate pathophysiological intermediates in schizophrenia. Integrating data from the United Kingdom Biobank neuroimaging study and 17 neuro-relevant in silico gene expression models from the Genome Tissue-Expression consortium, we conduct transcriptome-wide association studies for 18 quantitative measures of the hippocampus in healthy patients. We then query pre-existing data to identify the subset of these hippocampus-associated genes that colocalize to topologically associated domains (TADs) that are disrupted in neurologic iPSCs derived from schizophrenic patients.

We show that 123 of the genes impacted by TAD disruptions in cells from schizophrenic patients are significantly associated with morphological change in the hippocampus according to a study-wide Bonferroni corrected p-value threshold. We identify 115 genes that both localize to genomic regions disrupted in schizophrenogenic neuronal iPSCs and demonstrate significant associations with hippocampal morphology via genetically regulated expression. We identify 47 hippocampus-associated genes in disrupted TADs from schizophrenic glial iPSCs and 108 hippocampus genes in disrupted TADs from schizophrenic neural progenitor cell iPSCs. Through gene set enrichment analyses and systematic chart reviews of the pathways and cell functions impacted by these genes, we identify themes of neuronal morphogenesis, axonal development, cell adhesion, neurotransmitter release, and prior association with neurodegenerative disorders.

Through the integration of SNP data, gene expression, 3D genomic organization, neuroanatomical variation and clinical phenotyping, this work traces the impact of schizophrenia-associated variation through multiple levels of biological organization. We highlight a key set of candidate genetic contributors to schizophrenic risk along with putative cellular mechanisms of action. Through this novel integration of neuroimaging transcriptomic data with 3D genomic studies we demonstrate the utility of this study design to inform mechanisms of complex disease.

Complex Traits Posters - Wednesday

PB1350. Enrichment of Patients with Ehlers Danlos Syndrome in Idiopathic Gastroparesis - A Gene Set Enrichment Analysis.

Authors:

J. Carlin, S. Smieszek, M. Fisher, D. Madonick, C. Kupersmith, P. Moszczynski, C. Xiao, G. Birznieks, M. H. Polymeropoulos; Vanda Pharmaceuticals Inc., Washington, DC

Abstract Body:

Ehlers Danlos Syndrome (EDS) is a heritable disorder of the connective tissue. It is usually inherited as an autosomal dominant trait. EDS comprises a genetically heterogeneous group of connective tissue disorders of which the main clinical features are joint hypermobility, skin hyperextensibility, delayed wound healing with atrophic scarring, and generalized connective tissue fragility. The genetic etiology is not well explained. In the current gastroparesis study, we report 16 cases of EDS (confirmed by electronic medical records), specifically enriched in the cohort of idiopathic gastroparesis. Assuming incidence rate of 1 in 5000 the enrichment is 160-fold ($p=8.18743E-26$). In order to explore the genetic surrogates of EDS we have done gene set enrichment analysis on core EDS genes: COL1A1, COL1A2, COL3A1, COL5A1, and COL5A2 and ADAMTS2, FKBP14, PLOD1, and TNXB, as reported in LOVD. All EDS cases are of Caucasian ancestry, females with idiopathic gastroparesis. We report all coding/splicing variants in the core genes with a minor allele frequency (MAF) <0.05 . Most of our EDS cases with exception of 1, have at least one such nonsynonymous variant/or splicing variant within the core gene set. We report 2 duplicate variants across this set. The first variant is COL5A1:NM_000093:exon13:c.G1588A:p.G530S (rs61735045). It has a global MAF in gnomAD of 0.03 (ranging from 0.04 NFE to 0.0009 amongst East Asian). The variant is reported in ClinVar as pathogenic and associated with EDS, classic type and has a high CADD score of 24.9. The past findings suggest that heterozygosity for the Gly530Ser substitution is associated with mild ultrastructural abnormalities, while homozygosity for this mutation is associated with classical EDS. Furthermore, the variant is significant in association analysis of idiopathic versus diabetic gastroparesis patients. We report 5/128 diabetic versus 27/238 idiopathic, $p\text{-value}<0.007$ (EDS gene set). The other variant duplicated in our cohort is the TNXB:NM_019105:exon26:c.A9044G:p.K3015R, with a high CADD score of 23.3. Additionally, a gene enrichment analysis was performed on core genes, $MAF<5$, idiopathic versus diabetic gastroparesis, and led to a significant result, specifically enrichment of variants in COL5A1 and TNXB. These results suggest a statistically significant (corrected $p\text{-value}<0.001$) enrichment of EDS patients in this gastroparesis study, with confirmed known and novel variants in the EDS gene set. Furthermore, these results suggest an enrichment of such gene variants in the entire idiopathic cohort of patients with idiopathic gastroparesis.

Complex Traits Posters - Thursday

PB1351. Epstein-Barr virus- and genotype- dependent transcriptional regulation in B cells from patients with multiple sclerosis

Authors:

M. Granitto¹, S. Parameswaran¹, C. Forney¹, O. Donmez¹, K. Dunn¹, A. Diouf¹, C. Yin¹, A. Zabeti², L. Kottyan¹, M. Weirauch¹; ¹Cincinnati Children's Hosp. Med. Ctr., Cincinnati, OH, ²Univ. of Cincinnati Med. Ctr., Cincinnati, OH

Abstract Body:

Multiple sclerosis (MS) is caused by genetic and environmental risk factors. To date, over 200 robust genetic associations have been identified through GWAS. Epstein-Barr virus (EBV) is the most consistently replicated environmental factor. We aim to globally identify the contribution of EBV and genotype-dependent transcriptional regulation in B cells. We discovered that 44 of the 109 MS-associated genetic loci contain an MS-associated variant directly located within a human genomic region occupied by the EBNA2 protein, with our latest unpublished data implicating EBV-encoded EBNA2, EBNA3C, and EBNA-LP proteins at 93 of the now 201 MS risk loci. A subsequent functional genomics study by our group revealed more than 400 EBNA2-dependent human genes, over 2,000 regions in the human genome with EBNA2-dependent chromatin accessibility, and more than 1,700 regions where EBNA2 alters chromatin looping interactions. We isolated peripheral blood B cells from patients with MS and controls. We created EBV-transformed B cell lines (LCLs) from each subject. We measured gene expression (RNA-seq), chromatin accessibility (ATAC-seq), and binding of EBNA2 co-factors RBPJ and PU.1 from primary B cells and LCLs using ChIP-seq. Genome-wide EBNA2 binding was also measured in LCLs. Strikingly, no genes were differentially expressed in primary B cells from patients with MS vs controls. In contrast, several hundred genes were differentially expressed in EBV B cell lines derived from MS patient primary B cells compared to EBV B cell lines derived from primary B cells of control subjects. These differences were not due to differences in the expression of EBV-encoded genes. We observed extensive genotype-dependent binding of EBNA2, RBPJ, and PU.1 at MS risk loci. Ongoing analyses focus on identifying MS-dependent binding of EBNA2, RBPJ, and PU.1 and integrating these data with differential gene expression data to comprehensively catalog EBV and MS-dependent gene regulation at MS risk loci in B cells.

Complex Traits Posters - Wednesday

PB1352. ERAP1, ERAP2, and two copies of HLA-Aw19 alleles increase the risk for Birdshot Chorioretinopathy in HLA-A29 carriers

Authors:

S. Gelfman¹, D. Monnet², A. Ligocki³, T. TABARY⁴, A. Moscati³, X. Bai¹, J. Freudenberg¹, B. Cooper³, J. Kosmicki¹, S. Wolf¹, Regeneron Genetics Center, GHS-RGC DiscovEHR Collaboration, M. Ferreira¹, J. Overton¹, J. Weyne³, E. Stahl¹, A. Baras¹, C. Romano³, J. Cohen⁴, G. Coppola¹, A. Brézin²; ¹Regeneron Genetics Ctr., Tarrytown, NY, ²Université de Paris, Hôpital Cochin, service d'ophtalmologie, Paris, France, ³Regeneron Pharmaceuticals, Tarrytown, NY, ⁴Univ. of Reims Champagne Ardennes, LRN EA4682, Reims, France

Abstract Body:

Purpose Birdshot Chorioretinopathy (BSCR) is strongly associated with HLA-A29. This study was designed to elucidate the genetic modifiers of BSCR in HLA-A29 carriers. **Methods** We sequenced the largest BSCR cohort to date, including 286 cases and 108 HLA-A29 positive controls to perform genome wide common and rare variant associations. We further typed the HLA alleles of cases and 45,386 HLA-A29 controls of European ancestry to identify HLA alleles that associate with BSCR risk. **Results** Carrying a second allele that belongs to the HLA-Aw19 broad antigen family (including HLA-A29, A30, A31, and A33) increases the risk for BSCR (OR=4.44, p=2.2e-03). This result was validated by comparing allele frequencies to large HLA-A29-controlled cohorts (n=45,386, OR>2.5, p<1.3e-06). We also confirm that ERAP1 and ERAP2 haplotypes modulate the risk for disease within our HLA-A29 controlled cohort. A meta-analysis with an independent dataset confirmed that ERAP1 and ERAP2 haplotypes modulate the risk for disease at a genome-wide significant level: ERAP1-rs27432 (OR 2.46; 95% CI 1.85-3.26; p=4.07e-10), an eQTL decreasing ERAP1 expression, and ERAP2-rs10044354 (OR 1.95; 95% CI 1.55-2.44; p=6.2e-09), an eQTL increasing ERAP2 expression. Furthermore, ERAP2-rs2248374 that disrupts ERAP2 expression is protective (OR 0.56; 95% CI [0.45-0.70]; p=2.39e-07). BSCR risk is additively increased when combining ERAP1/ERAP2 risk genotypes with two copies of HLA-Aw19 alleles (OR 13.53; 95% CI 3.79-54.77, p=1.17e-05). **Conclusions** The genetic factors increasing BSCR risk on the background of HLA-Aw19 alleles include gene variants associated with increased processing and presentation of ERAP2 specific peptides. This finding suggests that exceeding a peptide presentation threshold may predispose to BSCR by evoking an aberrant immune response in choroids of A29 carriers

Complex Traits Posters - Thursday

PB1353. Essential hypertension genomic regions from linkage analysis studies

Authors:

V. Magalhaes Borges¹, A. V. R. Horimoto², R. C. Mingroni-Netto³, A. Nato¹; ¹Dept. of BioMed. Sci., Joan C. Edwards Sch. of Med., Marshall Univ., Huntington, WV, ²Univ. of Washington, Seattle, WA, ³Univ de Sao Paulo, Sao Paulo, Brazil

Abstract Body:

Essential hypertension (EH) is a major risk factor for cardiovascular diseases, and it causes ~9.4 million deaths per year worldwide. Hypertension is a complex disease characterized by high systolic blood pressure (SBP) and/or high diastolic blood pressure (DBP). Reference values used by the International Society of Hypertension (2020 Hypertension Practice Guidelines) are SBP \geq 140 and/or DBP \geq 90 mmHg. The 2015 World Health Organization global data indicated that 22.1% of the worldwide population has hypertension (the prevalence was 24.6% in 2000). Family/twin studies revealed an estimated global population heritability of 15-60%. In the last few decades, a vast scientific production revealed several genome-wide genomic regions for the EH phenotype, many of which were later corroborated by other approaches. Our goal is to identify, cross examine, and compare these genomic regions implicated by independent linkage analysis studies for EH, then rank them based on LOD score and the impact of genetic factors (genes and variants). Identification of genomic regions implicated in EH from various studies allows researchers to focus on a smaller sample space instead of the entire genome. We evaluate 25 linkage analysis studies from 1999 until 2021, all of them using LOD score as the metric for linkage studies. The genomic regions were standardized for the GRCh37/hg19 genome build. Using R scripts, marker names and genetic locations from these linkage studies, and from Rutgers Combined Linkage-Physical Map (NCBI34/hg16, NCBI35/hg17 and NCBI36/hg18) were used to define the boundaries of each ROI and 26 ROIs were identified. The genomic regions found with the highest LOD score are: 2p25-p24 (LOD score 7.57) and 17q12 (LOD score 4.7). The genomic regions containing the most relevant genetic factors known to EH, are: 1q42-43 (AGT gene), 2p25.1-p22.3 (HYT3 locus), 7q36-q22 (CYP3A5 and NOS3 genes), 12p12.2-p13 (HYT4 locus and GNB3 gene), 12q21-q23 (ATP2B1 gene) and 17q21-q25 (HYT1 locus). Narrowing down these regions by investigating variants has the potential to elucidate EH etiology.

Complex Traits Posters - Wednesday

PB1354*. Estimating the causal influence of body mass index on gut microbiome variation

Authors:

N. Timpson¹, C. Hatcher¹, L. Corbin¹, K. Wade², J. Raes¹, **D. Hughes¹**; ¹Bristol Univ., Bristol, United Kingdom, ²Univ. of Bristol, Bristol, United Kingdom

Abstract Body:

Variation in the accumulation of body fat, body composition and obesity can all be proxied by body mass index (BMI) which itself is a recognized risk factor for numerous health outcomes including life expectancy, various cancers and cardiometabolic diseases. What remains unclear is the complete picture of factors influencing BMI. One possible factor is gut microbiome variation, which previous research has demonstrated to be strongly correlated with BMI. Critically, whilst it may be the case that human gut flora variation influences BMI, it remains at least equally - if not more - likely that the opposite effect is true. Here, we use a combination of genetic contributions to both BMI and faecal 16S rRNA sequencing data from the Flemish Gut Flora Project (n=2257) to estimate causal associations between BMI and gut flora - microbiome profiles being a likely downstream effect of BMI and the factors related to variation in this risk factor at a population level. Mendelian randomization (MR) analysis, using a polygenic score reliably associated with BMI, yielded evidence from total and sex-specific sub-analysis suggesting the presence of causal effects of BMI on gut flora. In total, 215 microbiome traits (MTs), including three alpha-diversity, one beta-diversity, 115 presence (vs. absence), 40 zero-truncated abundance, and 51 abundance traits, were included in all analyses. After correcting for multiple testing, 67 MTs were associated with standard deviation change in BMI ($\sim 4.5\text{kg/m}^2$) in (generalized) linear modelling. MR-derived effect estimates were strongly correlated with estimates from (generalized) linear models. After correcting for multiple testing, 14 MTs retained evidence for a strong causal association with BMI in the total population. These include genera *Sporobacter* and *Barnesiella*, family Porphyromonadaceae, beta-diversity MDS1, two alpha diversity metrics and enterotype Bact2. Sex-specific MR analyses showed that 10 MTs were persistently associated with BMI in females, but 0 MTs were associated with BMI in males specifically. All but one of these associations overlapped with those seen in the total population, the phytoestrogen metabolizing genera *Adlercreutzia*, which appeared for females only. Overall, results support a conclusion that gut microbiome variation can be causally influenced by variation in BMI and that observational studies of the microbiome as a risk factor need to account for likely reverse causality as one source of association when analysing BMI.

Complex Traits Posters - Thursday

PB1355. Ethnicity- and sex-specific genome-wide association study on Parkinson's disease

Authors:

S. Chung¹, K. Park¹, H-S. Ryu², S. Jeon¹, S. Kim¹, J. Kim¹; ¹Asan Med. Ctr., Seoul, Korea, Republic of, ²Kyungpook Natl. Univ. Hosp., Daegu, Korea, Republic of

Abstract Body:

Background: Most previous genome-wide association studies (GWASs) on Parkinson's disease (PD) focus on the European population. In addition to ethnicity, there are several sex-specific clinical differences in PD, but little is known about its genetic background. **Objectives:** We aimed to investigate ethnicity-specific, and sex-specific GWAS on PD in the Korean population. **Methods:** A total of 1,050 Korean PD patients and 5,000 controls were included. For primary analysis between, we performed a GWAS using a logistic additive model adjusted for the age and sex using a Korean Chip. Same statistical models were also applied to sex-specific analyses, between 554 female PD patients and 2,610 female controls and 496 male PD patients and 2,390 male controls. **Results:** Eight single nucleotide polymorphisms (SNPs) including four in the *SNCA* locus and three from the *PARK16* locus were associated with PD in Koreans. The rs34778348 in the *LRRK2* locus showed a strong association but failed to pass cluster quality control. There were no notable genome-wide significant markers near the *MAPT* or *GBA* loci. In the female-only analysis, rs34778348 in *LRRK2* and the four other SNPs in the *SNCA* showed strong association with PD. In the male-only analysis, no SNP surpassed the genome-wide significance threshold under Bonferroni correction; however, the most significant signal was rs708726 in the *PARK16* locus. **Conclusion:** This ethnicity- and sex-specific GWAS on PD implicates the pan-ethnic effect of *SNCA*, the East Asian-specific role of the *PARK16* and *LRRK2* G2385R variants, and the possible disproportionate effect of *SNCA* and *PARK16* between sexes for PD susceptibility. These findings suggest the different genetic contributions to sporadic PD in terms of ethnicity and sex.

Complex Traits Posters - Wednesday

PB1356. Evaluating the causal effect of tobacco smoking on whitematter brain aging: a Mendelian randomization analysis in UK Biobank

Authors:

C. Mo¹, J. Wang², Z. Ye³, H. Ke⁴, S. Liu⁵, K. Hatch⁶, S. Gao⁶, J. Magidson⁷, C. Chen⁶, B. Mitchell⁸, P. Kochunov⁶, L. Hong⁶, T. Ma⁷, C. Shuo⁶; ¹Harvard Med. Sch., Boston, MA, ²Qilu Hosp. of Shandong Univ., Jinan, China, ³Univ. of Maryland, Rockville, MD, ⁴Univ. of Maryland, Coll. Park, College Park, MD, ⁵Qilu Univ. of Technology (Shandong Academy of Sci.), Jinan, China, ⁶Univ. of Maryland Sch. of Med., Baltimore, MD, ⁷Univ. of Maryland, College Park, MD, ⁸Univ Maryland, Baltimore, Baltimore, MD

Abstract Body:

Background and aims: Tobacco smoking is a known risk factor associated with the accelerated decline of brain structures and functions during aging. However, the causal effect of smoking on brain aging remains unclear. To close this knowledge gap, we performed Mendelian randomization (MR) analysis to estimate the causal effect of smoking on white matter brain aging using genetic and neuroimaging data. **Design:** We used the generalized weighted regression model, extended from the inverse-variance weighted model, for causal effect estimation based on multiple correlated genetic instrumental variables (IVs) in an MR analysis. **Measurements:** The primary exposures were smoking status (SS) and cigarette per day (CPD), and the IVs were the genetic variants that met the MR analysis assumptions. The outcome variable was the “Brain Age Gap” (BAG), a neuroimaging-based metric that characterizes the progression level of age-related neural decline. We constructed the optimal model for BAG estimation based on a training set independent of a testing set used in the MR analysis. **Setting and participants:** The study included N = 23,624 subjects who have genotype, neuroimaging, and smoking data available from the UK Biobank. Among them, 10,717 non-smokers were used to train the BAG predictive model. The remaining 10,746 non-smokers and 2,161 smokers constituted the testing set for genetic-outcome association tests in MR analysis. **Findings and conclusions:** We found adverse causal effects of smoking behaviors on the brain aging process. The brain age of smokers was 0.37 years (causal effect = 0.37, 95% confidence interval (CI) = 0.10, 0.64; p-value = 6.4×10^{-3}) older than comparable non-smokers. Also, an extra cigarette per day increased brain age by 0.16 years (causal effect = 0.16, 95% CI = 0.07, 0.25; p-value = 5×10^{-4}). These suggested that smoking caused accelerated brain aging and supported previous findings of smoking-related cognitive decline.

Complex Traits Posters - Thursday

PB1357. Evaluating the frequency and impact of structural variation in amyotrophic lateral sclerosis.

Authors:

A. Dillio^{1,2}, S. Griese², G. A. Rouleau^{1,2}, The International Consortium on Amyotrophic Lateral Sclerosis Genetics (ALSGEN), The FALS Sequencing Consortium, S. M. K. Farhan^{1,2}; ¹Montreal Neurological Inst.-Hosp., Montreal, QC, Canada, ²McGill Univ., Montreal, QC, Canada

Abstract Body:

Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disease. In our recent study of 3,864 ALS cases and 7,839 ancestry matched controls, we observed a significant excess of rare protein-truncating variants among ALS cases, which was concentrated in constrained genes (Farhan et al., 2019). We also observed multiple distinct protein-truncating variants in a highly constrained gene, *DNAJC7*. While the study advanced our understanding of the genetic architecture of ALS, one major limitation was it did not consider larger variation, including structural or copy number variants (CNVs). Structural variants within the genome are known to be important risk factors in neurodegenerative disease risk, such as the hexanucleotide repeat expansion in *C9orf72* (DeJesus-Hernandez et al., 2011; Renton et al., 2011) implicated in ALS; however, there is little information on other structural variation, particularly CNVs, underlying ALS as they have been under studied given their complexity, and consequently, detection difficulties using conventional variant calling approaches. Here, we are applying an optimized dosage sensitive genomic framework on a sequencing dataset of 4,828 ALS cases and 14,091 controls to identify structural variant signatures unique to ALS cases. Following the generation of a joint called sequencing dataset, we used an optimized workflow, GATK-gCNV, and appropriate quality control to generate a CNV callset outlining genomic gains and losses. We are now applying logistic regression models incorporating covariates such as sample sex and population structure to detect signals of enrichment of genomic gains (duplications) and/or losses (deletions) in the ALS cases. Preliminarily, gene-set enrichment analyses suggest there is a significant enrichment of CNVs in ALS associated genes in the ALS cases versus controls, primarily resulting from deletions. Further, in addition to several potential significant associations between CNVs in novel genes and ALS, we have identified an association between the known genomic disorder associated CNV, 16p11.2 duplication, and ALS case status. As we continue to explore our preliminary findings, our analyses are undergoing replication by our collaborators at King's College London (Project MinE ALS) using the same optimized approach on 4,322 ALS cases and 1,832 age-matched controls, with the goal of harmonizing our data and performing a meta-analysis from the two independent datasets. Our study is among the first to advance our knowledge of the frequency and impact of structural variation in neurodegeneration — specifically ALS — using a large, powerful sample size.

Complex Traits Posters - Wednesday

PB1358. Evaluation of genetic support for targeting the IL-23 pathway: current and future therapeutic opportunities

Authors:

A. Hart¹, K. Sieber¹, J. Molineros¹, FinnGen, A. Fourie², D. Cua¹, D. Waterworth¹; ¹Janssen R&D, Spring House, PA, ²Janssen R&D, La Jolla, CA

Abstract Body:

Interleukin 23 (IL-23) is a key pro-inflammatory cytokine implicated in the pathogenesis of immune-mediated disease. To date, therapies targeting IL-23 through the *IL23A*-encoded p19 subunit, or the *IL12B*-encoded p40 subunit common to IL-12 and -23, have been approved for the treatment of psoriasis (PsO), inflammatory bowel disease (IBD), and psoriatic arthritis (PsA); however, there may be opportunities for expansion into new indications. Given that genetic evidence provides links to causal human biology, genetics can be used to evaluate target-indication pairs and provide rationale for new indications. Here, using a combination of fine-mapping and colocalization analyses, we comprehensively evaluated genetic evidence for ten key genes within the IL-23 pathway with the goal of identifying additional indications that may be targeted by IL-23 blockade.

We conducted meta-analyses of 24 immune-mediated diseases utilizing summary statistics from published GWAS, FinnGen, and UK Biobank and performed statistical fine-mapping and colocalization (coloc) with eQTLs from GTEx and the EBI eQTL Catalogue to nominate potential causal genes at disease-associated loci. We evaluated variant-to-gene mapping evidence (V2G) for loci at *IL23A*, *IL23R*, *IL12A*, *IL12B*, *IL12RB1*, *STAT3*, *JAK2*, *TYK2*, *IL17A*, and *IL17F*. Overall, we found genetic support consistent with the indications approved for therapies targeting *IL23A* and *IL12B*. For example, we found coding evidence for *IL23R* (R381Q) and coloc evidence for *IL12B* for IBD, PsO, and PsA. We observed very different patterns of V2G evidence for *IL12A* (IL-12 p35 subunit which forms heterodimer with p40 to make IL-12), where significant associations were identified with multiple sclerosis (MS), SLE, Sjogren's, Celiac disease, rheumatoid arthritis, and primary biliary cholangitis; colocalization demonstrated that risk was associated with decreased *IL12A* expression in these diseases. Interestingly, blockade of IL-12 and -23 (through the shared p40 subunit) failed to show efficacy in several of these indications (MS, SLE, RA).

In this study, we used data from well-powered meta-analyses to nominate target genes for immune-mediated diseases, and subsequently evaluated the genetic evidence for IL-23 pathway genes to guide indication expansion efforts. We largely identified associations with known indications such as IBD, PsO, and PsA, but also generated evidence for where p40 inhibition has not been or is not likely to be successful. Overall, our results demonstrate the utility of genetic data to support target and indication selection with the aim of bringing new medicines to patients.

Complex Traits Posters - Thursday

PB1359. Evaluation of mitochondrial DNA variation in autism and neurodevelopmental disorders

Authors:

Y. Wang¹, X. Guo¹, X. Hong², G. Wang², A. G. Clark^{3,4}, K. O. O'Brien¹, X. Wang^{2,5}, Z. Gu¹; ¹Div. of Nutritional Sci., Cornell Univ., Ithaca, NY, ²Ctr. on Early Life Origins of Disease, Dept. of Population, Family and Reproductive Hlth., Johns Hopkins Univ. Bloomberg Sch. of Publ. Hlth., Baltimore, MD, ³Dept. of Molecular Biology and Genetics, Cornell Univ., Ithaca, NY, ⁴Dept. of Computational Biology, Cornell Univ., Ithaca, NY, ⁵Dept. of Pediatrics, Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract Body:

Mitochondrial oxidative phosphorylation is essential for brain development. Its function is partially encoded by the mitochondrial genome (mtDNA). Defects in the quality and quantity of mtDNA have been previously suggested to be associated with neurological and developmental deficits in children. Here, we investigated the associations of mtDNA heteroplasmies (co-existence of mutated and unmutated mtDNA) and content, markers for mtDNA quality and quantity, with neurodevelopmental disorders in two independent samples: a family-based study (using peripheral blood samples from 1,938 families with parents, probands with autism and sibling controls in the Simons Simplex Collection [SSC]) and a prospective birth cohort (using peripheral/cord blood samples from 997 mother-child pairs, including 621 children with a future diagnosis of neurodevelopmental disorder and 376 children with neurotypical development in the Boston Birth Cohort [BBC]). We evaluated mtDNA heteroplasmies and content using data from whole-genome sequencing in the SSC and mtDNA-targeted sequencing (STAMP) in the BBC. In both samples, we obtained an average coverage of ~4,000-fold depth of unique reads on mtDNA. We found that predicted pathogenic (PP) heteroplasmies in children were associated with an increased risk of autism (Meta-OR=1.56, $P=0.00068$; $P<0.05$ in both samples), which contributed to ~3% (population attributable risk) of autism cases in the current study. In children diagnosed with autism, those carrying PP heteroplasmies had worse cognition (verbal and non-verbal IQ), adaption (VABS composite score), and motor functions (VABS motor skills). Furthermore, we detected decreased mtDNA content in children with autism and/or other neurodevelopmental disorders in both SSC and BBC. Interestingly, among children with autism and PP heteroplasmies in the SSC, increased mtDNA content showed benefits for cognition, communication, and behaviors, suggesting that increased mtDNA quantity may complement defective mtDNA quality in autism.

Collectively, our results from two independent and complementary study cohorts found a decline in the quality and quantity of mtDNA in children with autism and potentially other neurodevelopmental disorders. These alterations may be detectable years before the diagnosis of diseases. Comprehensive evaluation of mtDNA variation using sequencing approaches may offer predictive value for neurodevelopmental diseases in childhood.

Complex Traits Posters - Wednesday

PB1360. Evaluation of polygenic risk scores to differentiate between type 1 and type 2 diabetes.

Authors:

M. Shoaib¹, Q. Ye¹, M. Boehnke², C. Burant², S. Soleimanpour², S. Gagliano Taliun¹; ¹Montreal Heart Inst., Univ. of Montreal, Montreal, QC, Canada, ²Univ. of Michigan, Ann Arbor, MI

Abstract Body:

Polygenic risk scores (PRS) quantify the genetic liability to disease and are calculated using an individual's genotype profile and disease-specific genome-wide association summary statistics. Type 1 (T1D) and type 2 (T2D) diabetes both are determined in part by genetic loci across the genome. Correctly differentiating diabetes subtypes is crucial for accurate diagnosis and treatment. PRS have the potential to address possible misclassification of T1D and T2D for eventual use in clinical practice through genetic testing. Here we evaluated PRS models for T1D and T2D in UK Biobank (UKB) participants. Specifically, we investigated the utility of both T1D and T2D PRS models to discriminate between diabetes subtypes (T1D and T2D) and controls in unrelated UKB individuals of European ancestry; T1D (n=2383, n=494 with age diabetes diagnosed ≤ 25 years), T2D (n = 15,284, n=7669 with age of diabetes diagnosed ≥ 45 years), and non-diabetic controls (n = 297,700). We split the data into a training and test sets for model training (via the clumping and thresholding approach) and subsequent testing of predictive accuracy. We derived PRS models from disease risk SNPs from external non-UKB genome-wide association studies (GWAS). The T1D PRS model with the best discrimination between T1D cases and controls (AUC=0.805) also yielded the best discrimination of T1D from T2D cases of European ancestry in the UKB (AUC=0.792) and provided modest separation in an independent validation cohort (AUC=0.686). The same model did not perform well when we applied it to individuals of another UKB ancestry group, Indian British (AUC=0.574). In contrast to the T1D model, the best T2D model did not discriminate between the two diabetes subtypes (AUC=0.527). Our analysis suggests that a T1D PRS model based on independent SNPs may help differentiate between T1D, T2D, and controls in European ancestry individuals.

Complex Traits Posters - Thursday

PB1361. Evidence of allelic series with fine-mapped protein quantitative trait loci across 1,470 protein abundance measurements and 30 biochemistry measurements in UK Biobank participants.

Authors:

A. Cortes¹, N. Bowker¹, Q. Wang¹, E. Arciero¹, C. Robins², P. Surendran¹, J. Sandhuria¹, J. Davitte³, E. Ingelsson⁴, M. Dermitzakis¹, T. Johnson⁵, R. Scott¹; ¹GSK, Stevenage, United Kingdom, ²GSK, Atlanta, GA, ³GlaxoSmithKline, Exton, PA, ⁴GlaxoSmithKline Pharmaceuticals, South San Francisco, CA, ⁵GlaxoSmithKline, Stevenage, United Kingdom

Abstract Body:

The UK Biobank Pharma Proteomics Project (UKB-PPP Consortium) has quantified 1,470 proteins in plasma samples from over 53,000 UK Biobank participants, greatly enabling identification of pQTLs and subsequent causal inference on the relationship between proteins and disease. Here we present fine-mapping results from genome-wide analysis of protein quantitative trait loci in individuals of European ancestry. We quantify the number of conditional independent associations for each protein in the cis region of the corresponding gene and perform colocalization analysis with fine-mapped GWAS statistics for 30 biochemistry traits from the UK Biobank. We investigate and identify evidence of allelic series where multiple independent signals observed for a protein colocalise with multiple independent signals in a biochemistry trait. For PCSK9 abundance, we found evidence of allelic series with LDL and total cholesterol, where multiple conditionally independent signals (each with p -value $< 5 \times 10^{-6}$ in a multivariate analysis) showed evidence of shared causal variant ($PP_{\text{coloc}} > 0.90$) with a conditionally distinct cholesterol association. With this example we illustrate how perturbation of PCSK9 can be instrumented by more than one genetic variant and how we can investigate a dose dependent effect of PCSK9 modulation on LDL levels. This example corroborates genetic and observational studies on the causal role of PCSK9 function and lipid levels and the therapeutic benefit to treat cardiovascular disease.

Complex Traits Posters - Wednesday

PB1362. Examination of PTSD symptoms in older veterans as a function of AD risk genes and combat implicates *CLU* as a stress-response gene

Authors:

M. Logue^{1,2}, E. J. Wolf¹, M. W. Miller¹, R. Zang¹, R. Sherva², K. M. Harrington^{3,2}, F. R. Jennifer^{4,2,5}, Z. Neale^{1,2}, the Million Veteran Program; ¹Natl. Ctr. for PTSD at VA Boston, Boston, MA, ²Boston Univ. Sch. of Med., Boston, MA, ³MAVERIC, VA Boston Hlth.care System, Boston, MA, ⁴TRACTS, VA Boston Hlth.care, Boston, MA, ⁵Harvard Med. Sch., Boston, MA

Abstract Body:

Studies have suggested that late onset Alzheimer's disease (AD) risk genes, and in particular the high-risk *APOE* $\epsilon 4$ variant, may interact with combat exposure to increase posttraumatic stress symptoms (PTS) particularly in older veterans. However, results have been inconsistent, and large-scale posttraumatic stress disorder (PTSD) genome-wide association studies (GWASs), which include younger participants and non-veterans, have not identified PTSD risk variants in the *APOE* region. This study examined associations between survey-based current PTS (PTSD Checklist - Civilian version (PCL-C), G x E effects involving AD risk variants, and self-report combat exposure (Deployment Risk and Resilience Inventory) using cohorts of combat-deployed European ancestry (EA) and African ancestry (AA) veterans from the Million Veteran Program (MVP). As we were interested in PTS as a function of aging, and based on differential risk of AD, we included veterans age 45 and older split into a middle age group (ages 45 to 64; n=23,167 and 4,912 in EA and AA cohorts respectively) and an older age group (65+; n=68,707 and 5,353 in the EA and AA cohorts). Regression models assessed the association of PTS with interactions between combat and $\epsilon 4$ in the EUR and AA cohorts. In the EUR cohort, we also examined an AD polygenic risk score (PRS) excluding *APOE* and candidate risk loci from a recent EUR AD GWAS (Bellenguez et al. 2022). Our results did not reveal either $\epsilon 4$ or AD PRS x combat interactions. However, in the middle age EA group, we observed a combat x SNP interaction with rs11787077 in the gene *CLU*, such that the AD risk allele was associated with an increased impact of combat on PTS (beta=0.75, p=0.00016, p_{FDR}=0.014). An examination of results from our prior study of PTSD and gene expression (Logue et al. 2021) found higher *CLU* expression in the dorsolateral prefrontal cortex of decedents with PTSD (p=0.017) and that rs11787077 was an expression quantitative trait locus. In conclusion, in the largest sample employed to date to address this question, we did not replicate previously reported interactions between *APOE* $\epsilon 4$ (or AD PRS) and combat in predicting PTS among aging veterans. However, we did find that an AD risk locus in the gene *CLU*, also known as *APOJ*, interacted with combat in its association with PTSD severity, which was supported by an examination of *CLU* expression in the PFC. *CLU* variants have been associated with reduced hippocampal volume and default mode network connectivity, both of which are associated with PTSD. This veteran-relevant *CLU* interaction may represent a target for PTSD treatment and a possible genetic link underlying the increased risk for dementia in veterans with PTSD.

Complex Traits Posters - Thursday

PB1363. Exome analysis reveals plausible glaucoma causing mutations in novel genes in dominant JOAG families of Pakistani origin.

Authors:

H. Ayub¹, F. Akhtar², M. Azam³, S. Ali³, H. Khan¹, R. Qamar³; ¹Pak Austria Fachhochschule: Inst. of Applied Sci. and Technology, Haripur, Pakistan, ²Pakistan Inst. of Ophthalmology, Al-Shifa Trust Eye Hosp., Rawalpindi, Pakistan, ³COMSATS Univ. Islamabad, Islamabad, Pakistan

Abstract Body:

Glaucoma is a complex disease with varying mode of inheritance, age of onset & intricate genetic heterogeneity. The current study was aimed to identify the genetic basis of 32 conscripted glaucoma families of Pakistani origin. The families were recruited based on raised intra ocular pressure, visual field damage & gonioscopic findings. Candidate genes exclusion mapping was done by direct sequencing of the probands of each family. Sequence analysis revealed no pathogenic mutation in myocilin and optineurin. Further exome sequencing was done for 2 families with juvenile glaucoma onset & dominant inheritance of the disease that assisted in identification of a novel variant in *PHKG1* (c.125 C>T; p.Thr42Met) to be segregating with the disease in one family. A unique pattern of trigenic inheritance was observed in the second family where three variants segregated with the phenotype (*MYO18A* c.2071G>A; p.Arg691Cys, *COL9A2* c.1061C>T; p.Pro354Leu, *ENOX1* c.171C>T; p.Met57Ile). We postulate the third variant in *COL9A2* to be disease causative variant in combination with other two variants in a family thus has a modifier effect. The study contributes to the current genetic etiology of glaucoma & adds to the understanding of the molecular mechanisms.

Complex Traits Posters - Wednesday

PB1364. Exome sequencing of six singlet Qatar families identified nine neurodevelopmental candidate genes

Authors:

V. Gupta, A. Ben-Mahmoud, A. Kubbar, F. Alshaban, L. W. Stanton, H. G. Kim; Qatar BioMed. Res. Inst., Doha, Qatar

Abstract Body:

Phenotypically and genetically heterogeneous, the genetic etiology of 20-60% of autistic individuals remains unknown. Exome sequencing on six syndromic autism trios from Qatar resulted in the identification of seven novel candidate genes (*SLC25A6*, *MFSD6*, *GRK6*, *KLRC3*, *SCFD2*, *PTGRI*, *LRRCL18*), pathogenicity of which has been substantiated by the CADD scores, frequency in gnomAD, and reported sporadic variants. In three consanguineous and two non-consanguineous families, we identified five candidate homozygous, one *de novo*, and one X-linked recessive variants including one splicing and six missense variants. Additionally, two variants (one novel and one known) were found in known autism genes, *KMT2C* and *ZBTB11*. Common phenotypes found in all probands were autism, developmental disorder, and language/speech delay. One out of six individuals had vision problem, and two out of six individuals had loss of acquired language as additional phenotypes along with autistic features. Extensive data sharing through GeneMatcher and international collaboration will be pivotal to recruit additional deleterious variants, which will result in the disease gene identification and delineation of genotype/phenotype relationship.

Complex Traits Posters - Thursday

PB1365. Exome-wide association study of DSM-5 antisocial personality disorder in a nationally representative sample

Authors:

H. Zhang; NIH/NIAAA, Bethesda, MD

Abstract Body:

Antisocial personality disorder (ASPD) is a prevalent, severe mental health condition with prevalence of 4.3% in the general population. Twin and adoption studies show that genetic factors account for half of the risk for antisocial behavior. Previous association studies typically focus on common variants. To test the effects of rare and low-frequency coding variants on ASPD, we performed an exome-wide association study on an Affymetrix exome and custom SNP array (n=363,496 SNPs), which included 603 ASPD cases and 3,983 super controls who had neither a SUD nor a psychiatric disorder in the European ancestry (EA) and 258 ASPD cases and 1,899 super controls in the African American (AA). All samples were collected from the National Epidemiologic Survey on Alcohol and Related Conditions-III (NESARC-III) and diagnosed by DSM-5 following a direct, structured psychiatric interview. Case-control analysis unraveled 4 SNPs ($P < 5 \times 10^{-5}$) and 5 gene-level loci ($P < 5 \times 10^{-5}$) with rare and low-frequency coding variants in EA. Among these loci, 2 gene-level signals (*ZADH2*, *AKAP5*) were replicated in African Americans within NESARC-III. For SNPs that yielded $P < 10^{-3}$ in the EA discovery cohort, three common variants (*FAM111A*, *RP13-348B13.2*, *LRRC63*) passed a significant threshold ($P < 0.05$) in the AA replication cohort and generated significant outcomes in a meta-analysis ($P < 10^{-3}$). Our analysis indicated both common and uncommon variants within susceptibility genes are involved in the pathogenesis of ASPD. Our results also suggest that gene-based analysis on uncommon variants may be powerful in identifying and prioritizing candidate loci for association studies.

Complex Traits Posters - Wednesday

PB1366. Exploring disease-course trajectories using genomic scores in the Finnish SUPER study - a cohort of 10,407 psychotic individuals.

Authors:

A. Kämpe¹, A. Ahola-Olli¹, O. Pietilainen², L. Urpa¹, T. Singh³, J. Suvisaari⁴, M. Lahteenvuo¹, S-F. Researchers¹, M. Daly¹, A. Palotie¹; ¹Inst. for Molecular Med. Finland, Helsinki University, Helsinki, Finland, ²Dept. of Publ. Hlth., Helsinki Univ., Helsinki, Finland, ³Massachusetts Gen. Hosp., Boston, MA, ⁴Natl. Inst. for Hlth. and Welfare, Helsinki, Finland

Abstract Body:

Psychotic disorders are phenotypically heterogeneous, and specific diagnoses often change during an individual's lifetime. In registry-based research, hierarchical models for lifetime psychotic diagnoses have been proposed to address the interchangeability of diagnoses over time. Here, we provide clinical and genetic support for the hierarchical model previously published within the SUPER study, ranking the four major psychotic disorders based on clinical perception of severity as: 1) Schizophrenia; 2) Schizoaffective disorder; 3) Bipolar disorder and 4) Major depressive disorder with psychotic features.

The Finnish SUPER study comprises 10,407 individuals with a psychotic disorder. The SUPER study's inclusive recruitment of all psychotic disorders and its extensive retrospective follow-up time from Finnish healthcare records (median 48 yrs, IQR 36-49 yrs) provides a unique opportunity to study the interchangeability between, and disease severity within, psychotic disorders. We show that the order of severity, measured as hospitalisation burden over time, well reflect the hierarchical ranking of the four major psychotic groups. High polygenic score for schizophrenia was associated with increased hospitalisation burden ($p=6.51e-05$) and the transitioning from an initial lower ranked psychotic diagnosis to a more severely ranked psychotic diagnosis. The strongest genetic support for the hierarchical model was seen for individuals with bipolar disorder ($n=2438$) where the schizophrenia score was highly associated with the later conversion to schizophrenia or schizoaffective disorder (HR: 1.20, $p=6.29e-05$). Major depressive disorder with psychotic features ($n=1554$) had the widest range of onset age and the shortest survival until conversion to a more severely ranked disorder, suggesting the diagnosis to be more transitory.

Next, we investigated the association of genomic scores commonly used to measure psychotic susceptibility with diagnosis specific disease severity. We show that apart for the schizophrenia score, the educational attainment score had the largest discriminatory power on disease severity. For individuals with schizophrenia the educational attainment score was positively associated to a broad range of functional outcomes such as hospitalisation burden ($p=0.00026$), cognitive measures (PAL adjusted total errors, $p=9.9e-04$), and job-status (OR=1.19, $p=0.0011$). We provide support that the effect of the genomic score for educational attainment on hospitalisation burden is at least partly mediated by its large effect on risk of drug abuse (HR=0.66, $p=1.80e-24$), which is a major risk factor for needing hospital care.

PB1367. Exploring genome-wide association results for neuroticism as a proxy for mental health disorders in individuals of African ancestry

Authors:

M. Kaka, P. Jain, A. Topaloudi, P. Paschou; Purdue Univ., West Lafayette, IN

Abstract Body:

To date, most of the genome-wide association studies (GWAS) are performed in populations of European descent. Given the differences in population genetic structure between Europeans and African populations, it is of urgent need to investigate whether non-European populations can already start benefiting from the results uncovered in large-scale European studies. Neuroticism is a relatively stable personality trait characterized by negative emotionality and is assessed using the 12 items of the neuroticism scale from the Eysenck Personality Questionnaire-Revised Short Form (EPQ-R-S). It has been found to be genetically correlated with some neuropsychiatric disorders such as Schizophrenia, Major Depressive Disorder and Bipolar Disorder. In exploring the transferability studies, GWAS in individuals of African ancestry from UKBB dataset is performed, using quantitative and qualitative phenotypes. Imputation of the variants was performed using an African reference panel and standard quality control measures were used in filtering the dataset. Principal component analysis as well as admixture mapping was also carried out to identify and confirm individuals of African ancestry in the dataset. Afterwards, we performed association testing for each of the 12 Neuroticism items- as qualitative phenotypes, as well as Neuroticism- as a quantitative phenotype. Significant SNPs were identified, and these were then subsequently explored in relevant downstream analyses. In addition, we explored the genetic relationship between Africans and Europeans to confirm the transferability of the GWAS results for Neuroticism, using Popcorn. Hence, as a preliminary study, this study bears the potential to establish Neuroticism as a proxy for mental health disorders in populations of African ancestry as published in Europeans.

PB1368. Exploring the complexity of scleroderma etiology by trio whole genome sequencing

Authors:

S. Ketkar¹, H. Dai², T. Tan¹, E. Atkinson¹, L. Burrage³, B. Dawson¹, K. Worley³, M. Lyons⁴, S. Assassi⁴, M. Mayes⁴, B. Lee¹; ¹Baylor Coll. of Med., Houston, TX, ²Baylor Coll. of Med. / Baylor Genetics, Houston, TX, ³Baylor Coll. Med., Houston, TX, ⁴Univ. of Texas Hlth.Sci. Ctr., Houston, TX

Abstract Body:

Scleroderma is a heterogeneous rare autoimmune fibrosing disorder affecting connective tissue, which can be grouped into localized scleroderma (LSc) and systemic scleroderma (SSc) depending on if skin is the only affected organ or not. It has been estimated that around 20 cases in every 100,000 individuals worldwide and one in every 4,000 adults in United States. Etiology of scleroderma is still largely unknown, while many genes have been suggested as candidates. Multiple factors, including those environmental, can contribute to the pathological process of the disease, which make it more difficult to identify possible disease-causing genetic alterations. In this study, we have applied whole genome sequencing (WGS) in 101 indexed family trio, supplemented with transcriptome sequencing on six cultured fibroblast cells of patients and five family controls where available. Small nucleotides variations (SNV) and copy number variations (CNV) have been examined, emphasizing on *de novo* calls. We also tested enrichments of rare variants from candidate genes previously proposed in literature by comparing with GnomAD dataset and also conducting simulation test. We identified 42 exonic and 34 ncRNA *de novo* SNV changes in the 101 trios, from total of over 6000 *de novo* calls genome wide. While the clinical significances of those *de novo* calls are still unknown, higher than expected *de novo* calls along with increased expression level of *NEK7* gene in patients could suggest further investigation on possible roles in the pathogenesis of this gene. We also observed significant enrichment of rare variants in candidate genes in the patient cohort, further supporting the complexity/multi-factorial etiology of scleroderma. We didn't find clinically diagnostic genetic alterations in the 101 trios through whole genome sequencing while further investigations should be continued to dissect more on our current findings. For those proposed candidate genes, we have observed enrichment only for rare variants but not any disease-causing *de novo* calls, which suggest more efforts should be warranted to further clarify the candidate genes and possible pathogenetic mechanism.

Complex Traits Posters - Thursday

PB1369. Expression of adipokine genes associated with gestational diabetes mellitus

Authors:

R. Issa; Inst. of Genetic Engineering, Cairo, Egypt

Abstract Body:

Diabetes mellitus is a group of metabolic diseases in which there are higher sugar levels over a prolonged period .Diabetes is due to either the pancreas not producing enough insulin or the cells of the body not responding properly to insulin produced .Aim of this study to assess the expression profile of genes with potential role in the development of insulin resistance .(Adipokines).Adipokines have over 50 different proteins.They are very different from each other in their structure and function which gives them a unique ability to regular process such as lipid metabolism,vascular function,insulin resistance and glucose intolerance..RT -PCR was used for expression analysis of the studied genes which are leptin,adiponectin receptor 1and 2and resistin.Materials and methods:This case control study was performed on 50 pregnant women (35 gestational diabetes GDM patients and 15 control subjects without GDM)All women aged between 26-+5 years,are screened for family history for GDM.Excluded criteria ;patients who have other disorders in their liver and renal function analysis or have high blood pressure Diagnosis;Fasting blood sugar and 2hr after oral glucose 75 gm The results were interpreted according to National Diabetes data group criteria (NDDC)Results Leptin gene expression is higher in patients with GDM ,than in normal pregnant women.Expression of adiponectin genes in pregnant women with GDM decreases in comparison with their matched healthy pregnant group.Adiponectin receptor 1is in the same range in both groups with slight high in GDM compared with controls While adiponectin receptor 2decreases in patients with GDM Expression of Resistin gene is significantly elevated in GDM women compared to matched group

PB1370. Expression profiling of small bowel tissue from Crohn's disease patients reveals alterations of immune functions and dampening of epithelial response.

Authors:

Y. Lee¹, J. Baek¹, Y. Kim¹, S. Park¹, S. Jung¹, D. Park¹, S. Hwang², J. Lee³, S. Park², S-K. Yang², K. Song¹, Y. Yoon³, B. Ye², H-S. Lee¹; ¹Dept. of Biochemistry and Molecular Biology, Univ. of Ulsan Coll. of Med., Seoul, Korea, Republic of, ²Dept. of Gastroenterology, Asan Med. Ctr., Univ. of Ulsan Coll. of Med., Seoul, Korea, Republic of, ³Div. of Colon and Rectal Surgery, Dept. of Surgery, Asan Med. Ctr., Univ. of Ulsan Coll. of Med., Seoul, Korea, Republic of

Abstract Body:

Crohn's disease (CD) is a chronic inflammatory disease associated with dysregulated immune responses in the gut. Previous studies on inflamed bowel tissues from CD patients showed significant transcriptional changes. We examined the gene expression profiles of uninflamed samples of small bowel to identify alterations in intestinal cells associated with the chronic and progressive course of CD. Macroscopically uninflamed small bowel tissues were obtained from 70 patients with CD and 9 patients with colon cancer during bowel resection, and the latter were used as non-inflammatory bowel disease (IBD) controls. Paired-end RNA sequencing was performed using Illumina HiSeq4000. We performed differential gene expression analysis using DESeq2 and pathway analysis using Gene Set Enrichment Analysis (GSEA). Correlation networks analysis (WGCNA) and cell deconvolution methods (CIBERSORTx) were applied to identify modules and functionally enriched transcriptional signatures of CD. The identified genes were verified using the publically available single-cell RNA sequencing data set (GSE134809). A comparison of CD patients (63% male, median age: 34 years) and non-IBD patients (44% male, median age: 67 years) showed 372 differentially expressed genes (false discovery rate $P < 0.01$, $|\log_2$ fold change > 1.2) comprising 305 protein-coding genes and 67 lncRNAs. Among the 372 genes, 49 protein-coding genes and 5 lncRNAs overlapped with IBD susceptibility loci. Pathways related to immune and inflammatory reactions including TNF- α signaling via NF- κ B ($P = 1.76 \times 10^{-3}$) and IFN- γ response ($P = 1.80 \times 10^{-3}$) were up-regulated in CD, while metabolic pathways including oxidative phosphorylation ($P = 2.24 \times 10^{-3}$) were down-regulated. Compared with non-IBD controls, CD patients had significantly higher proportions of immune cells including plasma cells ($P = 1.26 \times 10^{-10}$) and T-cells ($P = 1.49 \times 10^{-7}$), but a lower proportion of epithelial cells ($P = 1.57 \times 10^{-6}$). We also identified co-upregulated genes (CD module) and co-downregulated genes (anti-CD module) in CD; the hub genes in the CD module were mainly expressed in plasma cells and T-cells, whereas the hub genes in the anti-CD module were enriched in epithelial cells (GSE134809). In conclusion, significant differences in gene expression and cellular composition between CD patients and non-IBD controls implicate molecular alterations associated with immune functions in the uninflamed margins of bowel tissues in CD patients.

PB1371. Extensive Transcriptional Complexity of Autism Associated *SHANK* Family Genes by Capture Based and Long Read sequencing Method

Authors:

X. Lu¹, P. Meade², Y. Ma³, G. Peng⁴, A. J. Forte⁵, H. Zhao⁴, Y. Wang⁶, G. Wang⁷, A. Quiñones-Hinojosa², Y-H. Jiang¹; ¹Dept. of Genetics, Yale Sch. of Med., New Haven, CT, ²Dept. of Neurosurgery, Mayo Clinic, Jacksonville, FL, ³3. Dept. of Neurology, Children's Hosp. of Fudan Univ., Shanghai, China, ⁴Dept. of Biostatistics, Yale Sch. of Publ. Hlth., New Haven, CT, ⁵Div. of Plastic Surgery, Mayo Clinic, Jacksonville, FL, ⁶Dept. of Neurology, Children's Hosp. of Fudan Univ., Shanghai, China, ⁷Yale Ctr. for Genome Analysis, Yale Sch. of Med., New Haven, CT

Abstract Body:

Transcriptional regulations of alternative promoter and splicing contribute to the neural protein diversity and are critical for the development and functions of brain. Transcriptome-wide isoform-level dysregulation has been implicated in neuropsychiatric disorders including autism. However, the transcript structures of most neuronal genes remain to be fully characterized. Assembled RNA-seq could uncover transcriptome regulation but are suboptimal for identifying low abundant and long mRNA isoforms and new exons. *SHANK* family genes (*SHANK1-3*) are strong ASD causing genes and isoform diverse. Isoform specific functions are supported by isoform specific mutant mice. However, the full structures of *SHANK1-3* isoforms remain uncharacterized because of their longer than 10kb-sized mRNAs. We applied single molecule long-reading RNA sequence (standard Iso-Seq), with target enrichment (captured Iso-Seq) using specific designed probe panel, assessed isoform diversity of *SHANK1-3* without transcript assembly error. We applied standard and captured Iso-Seq to normal children and adult human cortex, and striatum and cortex from wild-type, *Shank3*^{Δe4-22}, *Shank3*^{Δe4-9} and *Shank3*^{Δe21} mutant mice. We uncovered 345 and 545 *Shank3* isoforms in mouse cerebral cortex and striatum respectively. Initial analysis has shown that mouse *Shank1* and *Shank2* have ~350 isoforms in cerebral cortex and ~200 isoforms in striatum. In normal human, *SHANK1-3* genes presented ~500 isoforms. In silico analysis revealed that 76% of transcripts have coding capability. The combination of SAM, PRO and SH3 domains of all *SHANK* family proteins exist in cortex, but not in striatum of mouse. The combination of SAM, PRO, ANK and ubiquitin-like domains exist in striatum, but not in cortex. The alliance of SAM, SH3 and ANK domains is only observed in *SHANK1* in cortex but not for *SHANK2* and *SHANK3*. We observed novel exons, extensive fusion transcripts between *SHANK* family and adjacent genes in both human and mouse. Analyses of exonic deletions in *Shank3* mutant mice validated the methods and revealed an unusual pattern of residual isoforms that is specific to targeted mutation of *Shank3*. We also observed extensive new and alternative promoters with tissue specific usage. Further, quantified by single cell RNA-seq, above isoform diversity presented cell type specificity. Our novel technical platform using capture based and long reading sequence has revealed an extreme complexity of transcriptional regulation of *SHANK* family genes. This new knowledge will guide the future functional studies of dissecting the pathophysiology of *SHANK* family causing autism and neuropsychiatric disorders.

Complex Traits Posters - Wednesday

PB1372. Findings at both known and novel loci in genome wide linkage and association study of a depression endophenotype, major depressive disorder with chronic pain.

Authors:

D. Nolan^{1,2}, W. Valentine-Cooper¹, J. Burian¹, V. Vieland³; ¹Nationwide Children's Hosp., Columbus, OH, ²The Ohio State Univ., Columbus, OH, ³The Res. Inst. at Nationwide Children's Hosp., Columbus, OH

Abstract Body:

Although multiple lines of evidence suggest a strong genetic component to major depressive disorder, the susceptibility loci identified thus far account for an extremely small proportion of the genetic variance. We have performed a genome wide linkage and association scan using a biologically relevant endophenotype, major depressive disorder with chronic pain, to identify susceptibility loci within this patient subset. We used a family-based sample from the National Institute of Mental Health Repository and Genomic Resource (NRGR). The samples were originally collected in the GenRed study of early onset recurrent depression and individuals were assessed by DSM IV criteria in addition to completing the diagnostic interview for genetic studies (DIGS), a structured interview of over 2,000 items. Using these data, we were able to define an affection status that incorporated the DSM IV diagnosis of major depressive disorder along with a classification of chronic pain, defined by medical history and medication usage. These data were analyzed under the posterior probability of linkage (PPL) and/or trait-marker linkage disequilibrium (PPLD) framework, as implemented in the software package KELVIN, which measures the evidence of linkage or association on the probability (0,..1) scale. Linkage analysis yielded PPL = 0.35 at chromosome 8p23 and 0.51 at chromosome 16q12. The linked region on 8p23 contains a single gene, *CSMD1*, that has been associated with depression and bipolar disorder as well as quantitative traits such as intelligence in multiple studies. The linkage peak on 16q12 appears to be a novel finding, containing approximately 15 genes, none of which have been associated with similar traits thus far. Our genome wide association results identified some SNP associations within our linked regions. However, our strongest PPL association value was with a SNP on chromosome 5p12 with PPLD= 0.36 in an intronic region of the gene *HCNI*. Multiple studies, including a mouse knockdown model of *HCNI*, have implicated this gene in the therapeutic response to ketamine as well as depression and this gene is being explored as a therapeutic target for depression. Applying the PPL method to this endophenotype of depression, we have identified two genomic regions with well-established roles in the pathogenesis of depression, supporting the utility of the method as well as selection of this endophenotype. Furthermore, we have identified a novel region linked to major depressive disorder with chronic pain. This region warrants further study, as it may contain one or more genes associated with major depression and chronic pain.

Complex Traits Posters - Thursday

PB1373. Fine-mapping 110 migraine risk loci using 98,375 migraine cases

Authors:

H. Hautakangas¹, FinnGen, A. Palotie^{1,2,3}, M. Pirinen^{1,4,5}; ¹Inst. for Molecular Med. Finland FIMM, Helsinki Inst. of Life Sci. (HiLIFE), Helsinki, Finland, ²Analytic and Translational Genetics Unit, Dept. of Med., Dept. of Neurology and Dept. of Psychiatry, Massachusetts Gen. Hosp., Boston, MA, ³The Stanley Ctr. for Psychiatric Res. and Program in Med. and Population Genetics, The Broad Inst. of MIT and Harvard, Cambridge, MA, ⁴Dept. of Publ. Hlth., Univ. of Helsinki, Helsinki, Finland, ⁵Dept. of Mathematics and Statistics, Univ. of Helsinki, Helsinki, Finland

Abstract Body:

Migraine is a common and heterogeneous brain disorder with a strong genetic component. Genome-wide association studies (GWAS) have identified over hundred migraine risk loci but causal variants and genes remain largely unresolved. Here, we aimed to narrow down potential causal variants via fine-mapping the autosomal risk loci identified in the largest migraine GWAS to date using FINEMAP software.

Accurate linkage disequilibrium (LD) information is crucial for reliable fine-mapping as mismatches between GWAS population and LD reference can lead to spurious results. Further, common fine-mapping methods assume that same samples have been used for all variants, but this is rarely true in large meta-analyses. An ability to quantify how these issues affect a fine-mapping study is an important, although often neglected, topic.

Our meta-analysis combined GWAS from 23andMe, Inc., UK Biobank and FinnGen for a total sample size of 98,375 migraine cases and 869,160 controls. To avoid methodological problems due to varying sample sizes across variants, we included only variants that were available in all three cohorts. For all loci, we had access to LD from UK Biobank+FinnGen (UKB+FG). Additionally, for 28/110 loci, we had access to complete in-sample LD including 23andMe. Across these 28 loci, we observed that fine-mapping was accurate in 89% of the loci when UKB+FG was the LD reference and in 68% when only UKB was used as LD reference. Here fine-mapping is called accurate if for all variants posterior inclusion probability (PIP) was within 0.10 of its in-sample result. We conclude that UKB+FG reference leads to reliable results in a large majority of loci, clearly improving over the common method of using only UKB.

For a majority of the migraine risk loci, FINEMAP suggested only one (53%) or two (36%) causal variants. Sizes of 95% credible sets ranged from 1 to 5,362 variants, and ten variants had very high PIP (>0.9). We searched the VEP database for the credible set variants that affected protein function. In total, 310 unique missense variants were found of which four had high PIP: rs1133400 (PIP=0.93) in *INPP5A*, rs28929474 (PIP=0.64) in *SERPINA1*, rs6330 (PIP=0.61) in *NGF*, and rs6339 (PIP=0.56) in *NTRK1*. Further, 20 high impact variants (stop gained, splice acceptor, or splice donor) were among the credible sets with modest PIPs ranging from 4.3×10^{-5} to 0.06.

To conclude, prioritizing putative causal variants in migraine risk loci is essential for future translational research on migraine. Here, we presented fine-mapping of 110 migraine risk loci. The high concordance with the results from in-sample LD suggests that our results are reliable in a large majority of the loci.

Complex Traits Posters - Wednesday

PB1374. Fine-mapping 56 lipidomics loci identified by univariate and multivariate genome-wide association analyses

Authors:

L. Ottensmann¹, R. Tabassum¹, S. Ruotsalainen¹, M. Gerl², E. Widen¹, K. Simons^{2,3}, S. Ripatti^{1,4,5}, M. Pirinen^{1,5,6}; ¹Inst. for Molecular Med. Finland (FIMM), Helsinki, Finland, ²Lipotype GmbH, Dresden, Germany, ³Max Planck Inst. of Molecular Cell Biology and Genetics, Dresden, Germany, ⁴The Broad Inst. of MIT and Harvard, Cambridge, MA, ⁵Dept. of Publ. Hlth., Clinicum, Faculty of Med., Univ. of Helsinki, Helsinki, Finland, ⁶Dept. of Mathematics and Statistics, Univ. of Helsinki, Helsinki, Finland

Abstract Body:

Aims: The human plasma lipidome captures information beyond traditional lipids and is strongly associated with the risk of cardiovascular diseases (CVD) and beyond. Genome-wide association studies (GWAS) of individual lipid species (univariate analysis) have identified many lipid-associated loci, however the influence of genetic variants on lipid metabolism and CVD risk is still mostly not understood. Multivariate analysis of correlated lipid species improves statistical power and therefore has potential to identify additional lipid-associated loci and identify the causal variants underlying the associations.

Methods: We performed univariate GWAS of 179 lipid species for 7177 participants from the Finnish GeneRISK cohort and multivariate analyses for 11 clusters of correlated lipid species using metaCCA software. The associations were fine-mapped with FINEMAP software to identify the likely causal variant sets and for gene prioritization. We also compared the fine-mapping results to those for the traditional lipids HDL-C, LDL-C, TC and TG in the UKBB.

Results: Univariate and multivariate analysis identified 495 trait-region pairs reaching the Bonferroni-corrected P-value threshold and distributed across 56 loci. Fine-mapping analysis detected 98 independent credible set signals. We identified 11 new loci, where the lead variant was in or near genes *DTL*, *STK39*, *CDS1*, *AGPAT2*, *SGPL1*, *SOAT2*, *KCNJ12*, *YPEL2*, *SPHK2*, *NINL* and *AGPAT3* in multivariate analysis, of which only *AGPAT2*, *SGPL1* and *SOAT2* reached the threshold in univariate analysis. For 26 loci, fine-mapping identified variants with high probability of being causal (>0.9) including 11 deleterious missense variants in 7 known and 2 new loci. Comparison with fine-mapping of traditional lipids in UKBB showed that 5 of the 11 variants did not reach a probability > 0.001 in UKBB results. We prioritized 20 genes, for which fine-mapping analysis identified functional variants with probability > 0.5. These genes are most enriched for the lipid metabolic process gene set of Gene Ontology (adjusted P=3e-17). The prioritized genes were taken to screening in cell lines.

Conclusions: We identified 11 novel loci by multivariate analysis of which only 3 were identified by univariate analysis. Fine-mapping identified 11 deleterious missense variants with high probability of being causal and comparison with results in the UKBB showed that 5 of these variants reached high probability only in our GWAS.

Complex Traits Posters - Thursday

PB1375. Fine-mapping and genomic analyses identify causal variants and genes for hypertension

Authors:

C. Bell¹, S. Van Duijvenboden¹, J. Ramírez¹, A. P. Morris², P. B. Munroe³; ¹Queen Mary Univ. of London, London, United Kingdom, ²Ctr. for Genetics and Genomics Versus Arthritis, The Univ. of Manchester, Manchester, United Kingdom, ³Queen Mary Univ. of London, London, United Kingdom

Abstract Body:

Genome-wide association studies (GWAS) of blood pressure (BP) have successfully identified >1000 loci. However, the genes and biological pathways through which these impact are mostly unknown. We applied a fine-mapping pipeline to identify causal variants at systolic BP (SBP), diastolic BP (DBP) and pulse pressure (PP) loci through integration of published European ancestry GWAS (PMID:30429575), tissue-specific epigenomic annotations (Roadmap/Epilogos), colocalization with transcriptomics (GTEx), and Promoter Capture Hi-C (PMID:31501517). We partitioned BP associations at 606 loci into 1,850 distinct association signals for ≥ 1 BP trait at genome-wide significance ($P < 5 \times 10^{-8}$) using conditional analyses. Of these signals, 532 were associated with at least two BP traits (333 SBP & DBP, 267 SBP & PP, 100 DBP & PP), and 84 with all three. All shared signals were directionally concordant, except for 17 discordant DBP & PP shared signals (*i.e.*, DBP increasing allele was decreasing PP). For 208 (24%), 224 (24.8%) and 159 (22.9%) of SBP, DBP and PP signals, respectively, a single SNV accounted for >75% of the posterior probability of driving the BP association under an annotation-informed prior, and, therefore, was “high-confidence” for causality. We identified 65 high-confidence missense variants, including 20 across two BP traits, and *RGL3* (p.Pro162His) for all three. Three distinct signals reside in the hereditary hemochromatosis *HFE* gene (p.His63Asp, p.Ser65Cys & p.Cys282Tyr) with portal hypertension a recognised phenotype of this condition. Several include genes implicated in kidney-related disorders: *NCOA7*, *LAMB2*, *NPHS2* & *PLXNB2*. Fifteen missense variants had a posterior probability of >99.9%, including at known BP genes, *e.g.*, *SLC39A8*, *ADRB2* & *DBH*, as well as candidates *NR1P1* (regulator of the mineralocorticoid receptor, *MMP14*) and *PLCB3* (intracellular signal transduction enzyme increased in mouse hypertension/trophy models). We integrated our fine-mapped results with *cis*-eQTL in disease relevant tissues from GTEx and observed pairwise colocalization for 96 (SBP), 107 (DBP) and 84 (PP) distinct signals. We also overlapped our signals with the *cis*-regulatory elements identified to target protein-coding gene promoters (capture Hi-C) and for 34 signals the indicated gene was the same as the eQTL analyses, and for 23/34 the same tissue (*RERE*, *ASAP2*, *FGD5*, *MAP1B*, *MXD3*, *RNF130*, *GOPC*, *TNS3*, *IRF5*, *AKR1B1*, *CLN8*, *SLC20A2*, *COL27A1*, *RAD52*, *DPF3*, *PRKCA*, *USP36*, *TGFBI*, *OSER1*, *RGS19*, *MRPS6*, *SLC5A3*, *TRIOBP*). Our analyses provide supporting data for 100s of potential candidate genes at BP loci providing new mechanistic hypotheses for functional validation.

Complex Traits Posters - Wednesday

PB1376. Fine-mapping and signal co-localization of asthma and white blood cell traits within the chr17q12-21 locus across diverse ancestries.

Authors:

C. Ben-Eghan^{1,2}, M. Munter², C. TERAQ³, G. Lathrop^{1,2}, A. Grant^{1,4}; ¹Dept. of Human Genetics, McGill Univ., Montreal, QC, Canada, ²McGill Univ. and Genome Quebec Innovation Ctr., Montreal, QC, Canada, ³RIKEN IMS, Tokyo, Japan, ⁴Faculty of Dental Med. and Oral Hlth.Sci., Dept. of Anesthesia, Faculty of Med., Alan Edwards Ctr. for Res. on Pain, McGill Univ., Montreal, QC, Canada

Abstract Body:

Asthma is a heterogeneous disease, with certain forms related to age-of-onset (AO), characterized by the activation and expansion of white blood cell (WBC) subsets, including eosinophils and neutrophils, in the lower airways. Across genome-wide association studies of complex diseases in large study populations, chr17q12-21 stands out as one of the highest peaks, first identified for childhood asthma in a European-descent population. While specific biological mechanisms explaining the top signal have been explored, the role of WBC subset distributions have not been investigated in a comprehensive evaluation across all independent asthma signals within the locus.

We analysed chr17q12-21 (37.2-38.8Mb, hg19) across 5 populations: European (EUR); African (AFR); East-Asian (EAS); South-Asian (SAS) from the UK Biobank and East-Asian from the Biobank Japan (BBJ). We ran 2 association scans for asthma: (1) A population-based & meta-analysis scan.(2) AO-stratified analysis in EUR: onset <18years (13,419); 18-40 years (12,526); <40years (25,945) and >40years (18,052) using 361,244 controls. We also ran association testing for basophil (BASO); eosinophil (EOS); lymphocyte (LYM); monocyte (MON); neutrophil (NEU) and total WBC counts (WBC#). We identified independent signals using GCTA-COJO and tested for co-localization in all asthma & WBC trait combinations via COLOC. Finally, we ran statistical fine-mapping (SuSiE & FINEMAP) and screened for evidence of mediation through WBC traits (Regmedint).

A union of 8 independent signals (*S1-S8*)($R^2 \geq 0.5$) were identified through conditional association analysis across AO-related strata among EUR. The top signal (*S4*) was also identified in a meta-analysis of non-EUR study populations. Three signals including *S4* were found to co-localize with a EUR asthma phenotype and EOS, LYM, MON, NEU, or WBC# (posterior probability ≥ 0.6). For 2 of these signals, *S4* & *S8*, multi-causal variant co-localization with LYM was identified. Moreover, signal *S4* was found to co-localize with LYM for asthma phenotype AO-<18years and among SAS and BBJ. Evidence of mediation through EOS with AO-<40years was found for 30% of the total effect of *S8* on asthma.

Our results of co-localization and mediation with evidence from diverse ethnicities demonstrate that despite the distance of WBC trait measures from the site (lung) or from the time of an asthma exacerbation, resting WBC levels may be causally related to certain asthma association signals. A causal pathway with a specific impact on a specific WBC trait as a potential mediator is likely to point to a relevant candidate molecular pathway for pharmacological intervention.

Complex Traits Posters - Thursday

PB1377*. Fine-mapping the association of *CYP2A6* with nicotine metabolism in African ancestry smokers.

Authors:

J. Pouget¹, A. El-Boraie¹, A. Langlois¹, C. Lerman², J. Knight³, L. S. Cox⁴, N. Nollen⁴, J. Ahluwalia⁵, M. Chenoweth⁶, R. Tyndale¹; ¹CAMH and Univ. of Toronto, Toronto, ON, Canada, ²Univ Pennsylvania Hlth Sys, Philadelphia, PA, ³Univ. of Toronto and Lancaster Univ., Bailrigg, United Kingdom, ⁴Univ. of Kansas, Lawrence, KS, ⁵Brown Univ., Providence, RI, ⁶Univ. of Toronto, Toronto, ON, Canada

Abstract Body:

Background: Tobacco use is the leading preventable cause of death and disease in North America. Nicotine is the primary addictive agent in tobacco, and individual differences in metabolism of nicotine by the liver enzyme *CYP2A6* alter smoking behaviours as well as cessation and health outcomes. The nicotine metabolite ratio (NMR; 3'hydroxycotinine/cotinine) is a stable biomarker for nicotine clearance with demonstrated clinical utility in personalizing cessation treatment. We previously found that genetic variation in the *CYP2A6* region on chromosome 19 was strongly associated with the NMR in African ancestry smokers. In this study, we investigated this regional association in more detail.

Methods: Our sample comprised African ancestry smokers from two clinical trials, Pharmacogenetics of Nicotine Addiction Treatment (PNAT)-2 (n=504) and Kick-it-at-Swope (KIS)-3 (n=450). The NMR was measured at intake, with levels of cotinine and 3'hydroxycotinine determined from blood samples using mass spectrometry. Genome-wide genotyping was conducted using the Illumina OmniExpressExome array, with a custom add-on for 2,688 variants previously associated with nicotine metabolism/smoking for richer coverage of regions of interest (including *CYP2A6*). Known *CYP2A6* structural variants were directly genotyped. Chromosome 19 variants were imputed using the TOPMed Imputation Server, with the cosmopolitan Version R2 reference panel. Association testing was completed using SNPTEST. Stepwise conditional analyses were completed to identify independent associations in regions reaching genome-wide significance. Bayesian fine-mapping was undertaken using FINEMAP to identify putatively causal variants.

Results: Our analyses confirmed genome-wide association of the *CYP2A6* region of chromosome 19 with the NMR among African ancestry smokers. Stepwise conditional analyses identified four independent associations in the *CYP2A6* region (5.5kb upstream of *CYP2A6*, 16kb and 9kb downstream of *CYP2A6*, and further downstream of *CYP2A6* within a long non-coding RNA transcript). Bayesian fine-mapping identified four putatively causal variants, including a SNP in linkage disequilibrium with *CYP2A6**17 (a known functional allele conferring decreased *CYP2A6* activity).

Conclusions: Our study highlights multiple independent genetic associations with the NMR in the *CYP2A6* region in African ancestry smokers. These variants may causally influence nicotine clearance and thus smoking behaviours, and tobacco-related disease risk. Future work includes replication and evaluation of the potential functional impact of robustly associated variants.

PB1378. Fine-mapping to find differences in effect sizes across ancestries for skeletal phenotypes

Authors:

E. Bartell^{1,2,3}, K. M. Tsuo^{1,2,4}, K. Lin⁵, W. Gan⁵, J. B. Cole^{6,1,2,3,7}, S. Vedantam^{3,2}, R. M. Salem⁸, R. G. Walters^{5,9}, J. N. Hirschhorn^{1,2,3}; ¹Dept. of Genetics, Harvard Med. Sch., Boston, MA, ²Program in Med. and Population Genetics, Broad Inst. of Harvard and MIT, Cambridge, MA, ³Div. of Endocrinology and Ctr. for Basic and Translational Obesity Res., Boston Children's Hosp., Boston, MA, ⁴Massachusetts Gen. Hosp. Res. Inst., Boston, MA, ⁵Nuffield Dept. of Population Hlth., Univ. of Oxford, Oxford, United Kingdom, ⁶Program in Metabolism, Broad Inst. of MIT and Harvard, Cambridge, MA, ⁷Diabetes Unit and Ctr. for Genomic Med., Massachusetts Gen. Hosp., Boston, MA, ⁸UC San Diego, La Jolla, CA, ⁹MRC Population Hlth.Res. Unit, Univ. of Oxford, Oxford, United Kingdom

Abstract Body:

Background: Humans share the vast majority of their DNA across ancestral groups; shared heritability suggests genetic effects are mostly shared. However, identifying genetic signals with true differences in effect sizes across ancestries can prove difficult, as differences in linkage disequilibrium and allele frequencies can create differences in association despite no differences in variant effects. Genome-wide association studies (GWAS) and variant level fine-mapping give us tools to identify loci with potential differences in genetic effects between ancestries even in the presence of differing LD.

Goal: Use statistical fine-mapping to detect loci with variants having different genetic effects across ancestries.

Design: We used data from the UK Biobank (UKB) and China Kadoorie Biobank (CKB) to study height and sitting height ratio (SHR) in ~475k individuals from 2 ancestries. We performed GWAS using BOLT-LMM in ~400k European and ~76k East Asian individuals, and performed fine-mapping in UKB using SuSiE. For all SNPs identified in credible sets (CSs) by SuSiE, we evaluated effect size heterogeneity between ancestries using Cochran's Q. To identify heterogeneous association signals, we defined CSs as significantly heterogeneous if all effect alleles in the CS had significantly heterogeneous effect sizes across ancestries. SNPs were checked for allele flips as an artifactual cause of heterogeneity. For heterogeneous CSs, we then tested for enrichment of functional annotations overlapping each CS's highest PIP SNP.

Results: We identify 40 height and 28 SHR associated CSs that are significantly heterogeneous between UKB and CKB (2.8% of height and 2.5% of SHR CSs). All CSs identified had SNPs with opposite directions of effect, likely because this scenario yields greatest power given these stringent criteria. Similarly, these SNPs had smaller minor allele frequencies differences across ancestries than SNPs in non-heterogeneous CSs, and the median number of SNPs in heterogeneous CSs were lower (1 vs 6 for height and 10 for SHR in all CSs), likely also reflecting greater power for detection. Heterogeneous CSs for height and SHR never overlapped. Height heterogeneous CSs were most enriched for H3K9ac peaks (t-test $p=0.0048$ vs CS SNPs), and those for SHR were most enriched for H3K27ac ($p=0.0076$).

Conclusions: Using GWAS of height and SHR and statistical fine-mapping across 2 major ancestries, we identify 68 CSs that significantly differ in effect size between ancestries. Our stringent criteria identify a small subset of signals; these loci with evidence of differential effect sizes across ancestries are enriched for multiple functional annotations.

Complex Traits Posters - Thursday

PB1379*. Functional analysis of rare copy number variations across psychiatric disorders

Authors:

W. Engchuan¹, O. Shanta², M. Klein², J. MacDonald¹, B. Thiruvahindrapuram¹, A. Maihofer², G. HUGUET³, K. Kimberley⁴, I. Sønderby⁵, Z. Wang¹, M. Zarrei¹, G. Pellecchia¹, D. Merico⁶, S. Jacquemont³, S. Scherer¹, J. Sebat², PGC BD, SCZ, PTSD, ADHD, MDD, ASD and CNV Workgroups; ¹The Hosp. for Sick Children, Toronto, ON, Canada, ²Univ. of California, San Diego, CA, ³Univ. of Montreal, Montreal, QC, Canada, ⁴Cardiff Univ., Cardiff, United Kingdom, ⁵Oslo Univ. Hosp., Oslo, Norway, ⁶Deep Genomics, Inc., Toronto, ON, Canada

Abstract Body:

Psychiatric disorders have been long known to be highly heritable, however, their genetic etiology is still under-explained due to their complexity and heterogeneity. Besides the known implicated rare copy number variations (CNVs) loci, many studies have attempted to identify additional associations. However, with the limited sample size, many of the findings failed to replicate. In this study, we combined and harmonized multiple microarray datasets, resulting in one of the largest psychiatric disorders data with a total of 542,274 samples of European ancestry (126,936 cases diagnosed with one or more psychiatric conditions and 415,338 controls). The major psychiatric disorders presented in the dataset are major depressive disorder (MDD, n~38,000), schizophrenia (SCZ, n~31,000), bipolar disorder (BD, n~24,000), autism spectrum disorder (ASD, n~15,000), and posttraumatic stress disorder (PTSD, n~13,000). Using a centralized pipeline, we called rare CNVs (case-control combined frequency <1%, size >10kb and >10 underlying probes) and performed multiple levels of CNV association analysis in order to understand the genetic factors that are common and different between major psychiatric disorders, as well as to additionally identify novel disorder-specific genetic factors. A case-control analysis of unrelated samples was done on each individual disorder of MDD, SCZ, BD, PTSD, as well as the cross-disorder (excluding ASD families), while a family-based analysis was performed for ASD. Meta-analysis was performed to combine the test statistics of the cross-disorder analysis and the ASD analysis as a final cross-disorder test statistics. A gene-set and pathway analysis showed an enrichment of deletions impacting synaptic genes, and genes related to nervous system development and neurotrophin signalling pathway to be common in cases of different psychiatric disorders, especially in SCZ and ASD. We also found an enrichment of deletions in genes related to forebrain development in MDD, while duplications impacting ribosomal RNA processing genes were found to be enriched in BD. Analyzing single-cell RNA-seq data of the human neocortex showed that top associated genes in SCZ, ASD and MDD were expressed significantly higher in excitatory neurons. Finally, genome-wide gene-based analysis identified strong signal in previously known SCZ and ASD loci, e.g. 22q11.2 deletion, 16p11.2 duplication, 15q11.2 duplication, 15q13.3 deletion, 3q29 deletion, and deletion of NRXN1 as common risk of psychiatric disorders. Future plans for the analysis on samples of non-European ancestry and cross-ancestry meta-analysis will be also discussed.

Complex Traits Posters - Wednesday

PB1380. Functional validation of rs7132908 as the causal variant at the childhood obesity locus on chr12q13.

Authors:

S. Littleton^{1,2}, J. Maguire², J. Bradfield^{3,2}, J. A. Pippin², C. Su², A. Chesi¹, A. D. Wells^{2,1}, R. I. Berkowitz^{1,2}, M. C. Pahl², S. F. A. Grant^{2,1}; ¹Univ. of Pennsylvania, Philadelphia, PA, ²Children's Hosp. of Philadelphia, Philadelphia, PA, ³Quantinuum Res. LLC, San Diego, CA

Abstract Body:

The *FAIM2* locus is reproducibly associated with childhood obesity by GWAS but is understudied given the association is less pronounced in adults. This locus is tagged by rs7138803 but based on our previously published variant-to-gene mapping efforts plus related eQTL observations, we hypothesize that rs7132908 is the causal variant at this locus. We also hypothesize that rs7132908 resides within an enhancer that regulates *FAIM2* expression and that the rs7132908 risk allele decreases *FAIM2* expression. Enrichment analyses of childhood obesity GWAS signals nominate central nervous system tissue and neuronal cell types. The arcuate nucleus of the hypothalamus brain region is responsible for regulating appetite. We were therefore motivated to study the effect of genotype at rs7132908 on the function of hypothalamic arcuate nucleus neurons. We generated isogenic human embryonic stem cell (hESC) lines homozygous for either the rs7132908 non-risk or risk allele which were validated with karyotyping, *de novo* CNV analysis and Sanger sequencing at the 10 most likely off-target sites. Each hESC line was then differentiated to a heterogeneous *in vitro* model of the hypothalamic arcuate nucleus. We visually observed a smaller proportion of cells demonstrating neuron morphology with the rs7132908 risk genotype. This observation was confirmed at the transcript level using snRNA-seq and at the protein level with immunofluorescence. Using paired snRNA-seq and snATAC-seq, we observed that chromatin accessibility at rs7132908 is significantly correlated with expression of 21 genes within 1Mb, including *FAIM2* (correlation 0.13, adjusted $P=2.2 \times 10^{-6}$). *FAIM2* had decreased expression in the differentiated cells with the rs7132908 risk genotype (fold change 0.51, $P=1.3 \times 10^{-5}$). We also observed decreased chromatin accessibility at rs7132908 (fold change 0.74, adjusted $P=3.4 \times 10^{-9}$) and the *FAIM2* promoter (fold change 0.73, adjusted $P=1.4 \times 10^{-10}$) in the differentiated cells with the rs7132908 risk genotype. We have separately validated the allele-specific enhancer activity of rs7132908 for *FAIM2* with a luciferase assay in human primary astrocytes. The rs7132908 non-risk allele region increased luciferase reporter expression relative to the *FAIM2* promoter alone by a fold change of 1.87, while the risk allele decreased expression by a fold change of 0.68 (non-risk allele+*FAIM2* promoter vs. risk allele+*FAIM2* promoter adjusted $P<0.0001$). These results warrant further replication efforts and investigation into the mechanism underlying the effects of the rs7132908 risk allele on gene expression and neuron differentiation.

Inst. of Allergy and Infectious Diseases, Bethesda, MD, ¹⁶Univ. of Wisconsin Sch. of Med. and Publ. Hlth., Madison, WI

Abstract Body:

Genome-wide association studies (GWAS) have successfully identified thousands of associations between common variants and hundreds of complex traits. However, rare variants, which comprise the bulk of genetic variation, have been largely ignored because they are not well represented by the variants on commonly used genotyping arrays. Moreover, GWAS have focused primarily on European-ancestry cohorts. Thus, little is known about risk variants in other populations. In this study, we explored the contributions of rare variants (MAF <0.01) to asthma-associated quantitative traits using whole-genome sequences in two primarily African-American (67%; 25% Hispanic) cohorts: the Asthma Phenotypes in the Inner City (APIC) study (n=508 children with asthma) and the URban Environment and Childhood Asthma (URECA) prospective birth cohort (n=173 children with asthma and 225 children without asthma). We performed gene-based association tests with STAAR (variant-set test for association using annotation information) and examined associations with traits reflecting the allergic (total IgE, sensitization to specific allergens), pulmonary (FEV1 % predicted, FEV1/FVC, bronchodilator response), and inflammatory/immune (FeNO, blood eosinophil count, blood neutrophil count) components of asthma. One gene (*USF1*; $p=2.18 \times 10^{-7}$) was associated with blood neutrophil count after multiple test correction. Two other gene-trait associations were notable: *TNFRSF21* with total IgE ($p=6.47 \times 10^{-6}$) and *PIK3R6* and blood eosinophil count ($p=4.10 \times 10^{-5}$). These three associations were supported by studies in phenomeXcan or mouse knockouts (KO): predicted expression of *USF1* and *PIK3R6* were associated with neutrophil ($p=4.66 \times 10^{-4}$) and eosinophil ($p=3.96 \times 10^{-6}$) percentages, respectively, in phenomeXcan. *Tnfrsf21* KO mice had increased IgE levels and *Usf1* KO mice had increased blood neutrophil count. These studies identified three novel gene associations with atopic and inflammatory phenotypes, highlighting the potential importance of rare variants in the development of these traits and of including non-European ancestry populations in genetic studies.

Complex Traits Posters - Thursday

PB1382. Gene-based tests for early and late onset Alzheimer Disease: common and non-overlapping factors

Abstract Body:

Background: Early Onset Alzheimer Disease (EOAD, age at onset [AAO] ≤ 65) is a severe form of AD. Most genetic studies have focused on autosomal dominant forms of EOAD, and there is little understanding of similarities and differences between early and late onset forms of AD (LOAD, [AAO] >65). We present here a genome-wide association study of non-Mendelian EOAD and compare it to LOAD GWAS.

Methods: Single-variant analyses were performed using additive logistic regression for case-control models (full: SNPs, PCs, sex and APOE- $\epsilon 4$ dosage as covariates; reduced: SNPs and PCs); secondary models included PCs+sex and PCs+APOE. Models were applied on data of unrelated individuals derived from the Alzheimer Disease Genetics Consortium (ADGC). Samples varied from 1293-1459 cases and 8894-9366 controls for EOAD, and 8795-9508 cases and 9702-10273 controls for LOAD, depending on the considered model. The SNP heritability (h^2) and genetic correlation (r_g) were estimated using LD score regression. Gene-based and pathway analysis (gene sets from Msigdb-v7.0) were performed using FUMA/MAGMA-v1.6.

Results: We identified two novel loci associated with EOAD: Chromosome 4 (full model: chr4:102027610, $P=2.98 \times 10^{-08}$, near *PPP3CA*) and Chromosome 12 (PCs+sex model: rs117001070, $P=2.11 \times 10^{-08}$, between *LINC02444* and *LINC02882*). Heritability and genetic correlation showed moderate but incomplete genetic correlation between EOAD and LOAD. Other than *APOE* ($p=3.89 \times 10^{-12}$), gene-based tests showed nominal association for full model EOAD: *C8orf44-SGK3* ($p=9.95 \times 10^{-06}$), *SGK3* ($p=2.01 \times 10^{-05}$) and *HIST1H2AC* ($p=3.04 \times 10^{-05}$). For full model LOAD, significant genes were *APOE* ($p=7.11 \times 10^{-15}$), *MS4A6A* ($p=2.27 \times 10^{-06}$), *MS4A2* ($p=2.31 \times 10^{-06}$), *APOC1* ($p=2.53 \times 10^{-06}$), *MS4A4E* ($p=2.77 \times 10^{-06}$), *TOMM40* ($p=3.22 \times 10^{-06}$) and *NCF4* ($p=1.80 \times 10^{-05}$). Plausible pathways such as HDL remodeling ($p=5.50 \times 10^{-05}$) and positive regulation of cholesterol efflux ($p=9.79 \times 10^{-05}$) were observed for full model EOAD and were nominally associated with full model LOAD ($p=0.04$ and $p=4.05 \times 10^{-03}$).

Conclusions: Gene-based tests confirmed that *APOE* is a common factor for EOAD and LOAD. Distinct nominally significant genes were detected for EOAD and LOAD, suggesting that the genetic etiology of EOAD has an incomplete genetic overlap with LOAD.

Complex Traits Posters - Wednesday

PB1383. Gene-by-stress interaction in Alzheimer's disease risks.

Authors:

A. Singh, K. Arbeev, A. Yashkin, I. Akushevich, A. Yashin; Duke Univ., Durham, NC

Abstract Body:

The WHO estimates that currently more than 55 million people live with Alzheimer's disease related-dementia (ADRD) worldwide and that with nearly 10 million new cases every year, this number is estimated to increase to 75 million by 2030 and 132 million by 2050, resulting in a significant rise in ADRD-related deaths. Psychosocial stress is considered a risk factor that may contribute in the development of age-related neuro- and psychopathologies. Therefore, we hypothesized that a part of ADRD-risk could be due to complex interplay of genes and psychosocial stress. We tested this hypothesis using the Health and Retirement Study (HRS) surveys and Medicare-linked data. We created a synthetic measure for psychosocial stress using the algorithm based on stress proxy-indicators, as described in Singh et al., 2015. Guided by correlation with stress, we selected age-at-onset of ADRD as an outcome variable and evaluated race-stratified gene-by-stress interaction (i.e., GxE) GWAS using linear regression that included SNP, SEX, STRESS, and ancestry principle components (PCs) as other predictors in the model. We observed GxE associations at p-value of order 10^{-8} in both Black and White samples. Out of the top 25 most significant GWAS SNPs in both races, almost all SNPs were mapped to non-coding regions, indicating that GxE interactions may mostly influence ADRD through gene-regulatory roles. The genic-region SNPs were mapped to four characterized genes (*BCR*, *MCC*, *KCNQ5*, and *DCP2*) in Whites and three genes (*EMCN*, *DPYD*, and *INSYN2A*) in Blacks, which included known associations with neurodevelopmental disorders including autism, mental retardation, intellectual disability, and also for cancers including colorectal carcinoma, gastric carcinoma, chronic myeloid leukemia, and lymphoma. Our findings suggest that a part of ADRD may result from a complex interplay of genes and daily-life stress and that the interplay may possibly influence through shared genes a mechanistic feature shared by both cancer tumors and Alzheimer's disease, i.e., growth of new blood vessels in the brain.

Complex Traits Posters - Thursday

PB1384. Gene-environment interaction of coffee with body mass index in multiple populations

Authors:

M. Shivakumar¹, D. Kim¹, E. Choe²; ¹Univ. of Pennsylvania, Philadelphia, PA, ²Seoul Natl. Univ. Hosp., Seoul, Korea, Republic of

Abstract Body:

Obesity is a global pandemic disease, and its prevalence has tripled in the last four decades. A flurry of genome-wide association studies (GWAS) has found many variants associated with body mass index (BMI) and subsequently, polygenic risk scores (PRS-BMI) derived from them have shown the genetic basis and risk of obesity. Additionally, interactions between genetic factors and environmental risk factors like lifestyle and diet, such as coffee consumption, also play an important role in obesity. In this study, we sought to investigate interactions between PRS-BMI and coffee consumption in the European population (UK Biobank, N = 218,777) and the Korean population (GENIE, N = 5,501).

GAINT consortium and Biobank Japan GWAS summary statistics were used to calculate BMI PRS for UKBB and GENIE populations, respectively. Subjects who consumed less than or equal to 1 cup of coffee per day were considered as control and greater than 1 cup of consumption as cases. Log-rank test was used to check the significance of the interaction between PRS-BMI and coffee consumption, adjusting for age, sex, IPAQ physical activity score, and principal components. Further, the subjects were stratified into BMI categories - BMI \leq 18.5 (underweight), $18.5 < \text{BMI} \leq 25$ (normal) and BMI > 25 (overweight & obese) the PRS BMI-coffee interaction was tested in the subgroups.

The interaction between coffee and PRS BMI was significant (UKBB P = 2.65×10^{-7} and GENIE P = 0.03) in both populations. The interaction was significant even after adjusting for coffee metabolism score. In the subgroup analysis, the interaction was significant in BMI > 25 (P = 0.003) and BMI > 30 (P = 0.027) groups in UKBB.

The findings in this study suggest that there is a significant interaction between BMI-PRS and coffee in different populations. In the case of the European population, there is a significant interaction in overweight and obese subjects. The results from this study may be applicable for personalized medicine and preventive treatment through risk assessments and interventions.

Complex Traits Posters - Wednesday

PB1385. Gene-level GWAS fine-mapping combined with single cell RNA-seq yields insight into neurodegenerative disease biology

Authors:

B. van de Geijn, J. Blischak, M. McCarthy, T. Bhangale; Genentech, South San Francisco, CA

Abstract Body:

Identifying causal genes from GWAS remains challenging since associations are established at the variant and not gene level. Moreover, most causal variants lie in non-coding regions that don't immediately connect to single genes. Methods such as MAGMA condense GWAS associations onto the gene level using windows around genes, but fail to nominate single causal genes due to gene density and linkage disequilibrium. We combined fine-mapping with various recently developed variant-to-gene (V2G) linking strategies to better pinpoint causal genes across the entire genome. We then used our gene-level scores to interrogate single cell expression patterns in Alzheimer's disease cases and controls (Morabito et al 2021).

To create gene-level GWAS scores for a trait, we first QCed summary statistics to avoid spurious causal signals due to reference LD mismatches and performed functional fine-mapping (Weissbrod et al 2020). We used the causal effect sizes to estimate the heritability contribution for each variant, then calculated gene level heritability scores by linking variants to genes using two V2G strategies (cS2G (Gazal et al 2022) and expression modifier scores (Wang et al 2021)) weighted by connection strength. We compared our approach to popular MAGMA by analyzing 44 traits - selected because they have matched silver-standard associated genesets (Zhang et al. medRxiv). We found that the fine-mapped gene scoring with cS2G gene connections produced stronger associations than MAGMA ($p=0.02$).

We then used our gene scores to investigate causal cell-types for disease. We scored cells based on their expression (single nucleus RNA-seq) profiles and gene scores using data from Morabito et al., a study of 191,890 nuclei from postmortem brain tissue that includes both individuals with Alzheimer's disease (AD) and healthy controls. We did this by taking the inner product of the vector of standardized expression for each cell and the vector of gene scores for AD. We examined score differences across cell-types and sub-cell-type clusters. We found that both microglia and astrocytes showed enrichment for cell scores above other frontal cortex cell types (4.8x and 3.9x enrichment respectively; both $p<1e-15$) as well as one subtype of oligodendrocytes (2.14x enrichment; $p<1e-15$). The role of microglia in AD has been described in the past, but our methods highlight additional cell-populations which could point to distinct mechanisms. We also found differences in scoring distributions between cases and controls in sub-cell-type clusters of astrocytes and microglia. We believe fine-mapping gene and cell scoring will aid the understanding of causal cell-types for many diseases.

Complex Traits Posters - Thursday

PB1386. Genes at asthma-associated GWAS loci are induced in activated CD4 tissue resident memory T cell

Authors:

N. Schoettler; Univ. of Chicago, Chicago, IL

Abstract Body:

Asthma is a complex genetic disease with >200 independent loci identified in genome-wide association studies (GWAS). However, the causal variants and causal genes have not been characterized for the majority of loci, possibly as a result of the paucity of relevant cell models of gene expression. Lung CD4 tissue resident memory T (T_{RM}) cells are the most abundant T cell subset in the lung, where they can generate potent memory responses; these cells are rare in other tissues, including blood. I sought to determine whether human lung CD4 T_{RM} cell stimulation modulates the expression of genes at asthma GWAS loci. Human lung leukocytes from 10 donors were cultured for 20 hours with anti-CD3/anti-CD28 or media followed by FACS sorting of CD4 T_{RM} cell and CD4 effector memory T (T_{EM}) cell subsets and RNA sequencing. For two donors, I also conducted single-cell RNA sequencing (scRNAseq) on sorted CD4 T_{RM} cells that were expanded for 14 days as well as unexpanded CD4 T_{RM} cells treated for 20 hours with anti-CD3/anti-CD28. A total of 329 genes were differentially expressed between CD4 T_{RM} cells and CD4 T_{EM} cells after anti-CD3/CD28 treatment (FDR < 5%), with 77 genes having higher expression and 252 genes having lower expression in CD4 T_{RM} cells compared with T_{EM} cells. Of these, 14 genes localized to an asthma GWAS locus. As examples of GWAS response genes, *IL5*, *IL13*, *IL4* (5q31.1), *IL2* (4q27), and *IL4R* (16p12.1) were more highly expressed in activated CD4 T_{RM} cells. The scRNAseq revealed patterns of co-expression of *IL5* and *IL13* in T_{EM} after activation ($R^2 = 0.37$), but not in CD4 T_{RM} cells. While co-expression of the other cytokine genes (*IL4* and *IL2*) was only rarely observed in resting CD4 T_{RM} cells, increased co-expression of *IL4/IL5* and *IL4/IL13* was observed more frequently in activated CD4 T_{RM} cells. These results associate asthma-risk loci with asthma-relevant genes during lung CD4 T_{RM} cell activation suggesting that studies linking GWAS variants to gene function in blood or resting cells are likely missing important features of the gene regulatory landscape in asthma.

Complex Traits Posters - Wednesday

PB1387. Genes causing significant effects on the dynamics of peroxisomes

Authors:

N. Roy, S. Jangam, J. Andrews, M. Wangler; Baylor Coll. of Med., Houston, TX

Abstract Body:

Peroxisomes are single membrane-bounded eukaryotic ubiquitous subcellular organelles, which vary in size, shape and number depending on the cellular environment. Peroxisomes mediate crucial biological functions including beta-oxidation of fatty acids, biosynthesis of plasmalogen lipids, synthesis of bile acids for fat digestion and detoxification of alcohol. Reactive oxidative species (ROS) produced by peroxisomes is one of the major contributors to several multisystem complex diseases of the brain, liver, bone and kidney. Besides environment, several genes are known to play vital role in the dynamics of peroxisomes, causing its enhanced division and fission. Prolonged and continuous consumption of alcohol (>80gm of alcohol for >10 years) stimulates the catalase pathway of alcohol metabolism, mediated by peroxisomes, causing increased production of ROS, resulting in alcoholic chronic liver disease (ALD). Hepatic encephalopathy or loss of brain function is a typical feature of decompensated ALD patients. A list of significantly associated genes (n=150) (OR>1; p-value=<1E-05) from a GWA study was used as the foundation for our study. The list of genes was subjected to DRSC Integrative Ortholog Prediction Tool (DIOPT) Scoring for shortlisting based on their score. RNAi lines of the respective fly (*Drosophila Melanogaster*) genes (orthologs) were obtained from Bloomington Drosophila Stock Center (BDSC) and crossed with ActinGAL4-UASGFPSKL fly lines. UAS-LacZ-RNAi line was used as control. Evaluation of effect of knocked down genes on the dynamics of peroxisomes were done by confocal microscopy imaging (Leica STED) and analysis of size and number of peroxisomes were done by ImageJ Software. Adult flies of each cross were tallied to observe the extent of lethality of knock-down genes. Out of our original list of 69 genes with high DIOPT Score, 52 genes were shown to have a direct neuro-pathological effect. Out of 10 genes analyzed so far, knock-down of two genes, MTPAP and Rabex-5, showed significant effects on size and number of peroxisomes in the cells of salivary glands and fat body as compared to control. The average area of a peroxisome was higher (1.488 and 1.887 micron² for MTPAP and Rabex-5 respectively) as compared to that of 1.021 micron² of LacZ-RNAi line. The role of peroxisomes in degenerative pathways causing devastating complex diseases has not been extensively explored. Therefore, finding genes effecting dynamics of peroxisomes may significantly contribute to finding biological markers and therapeutic interventions for curing or preventing a disease. MTPAP and Rabex-5 genes seem to be potential candidate genes for this purpose.

Complex Traits Posters - Wednesday

PB1388. Genetic analysis of bruxism and its associations to sleep, psychiatric and behavioural traits.

Authors:

T. Strausz¹, S. Strausz^{1,2}, T. Palotie^{3,4}, J. Ahlberg^{3,4}, FinnGen, H. M. Ollila^{1,5,6,7}; ¹Inst. for Molecular Med., HiLIFE, Univ. of Helsinki, Helsinki, Finland, ²Dept. of Genetics, Stanford Univ. Sch. of Med., Stanford, CA, ³Dept. of Oral and Maxillofacial Diseases, Head and Neck Ctr., Helsinki Univ. Hosp., Helsinki, Finland, ⁴Dept. of Oral and Maxillofacial Diseases, Clinicum, Faculty of Med., Univ. of Helsinki, Helsinki, Finland, ⁵Broad Inst. of MIT and Harvard, Cambridge, MA, ⁶Ctr. for Genomic Med., Massachusetts Gen. Hosp., Boston, MA, ⁷Anesthesia, Critical Care, and Pain Med., Massachusetts Gen. Hosp. and Harvard Med. Sch., Boston, MA

Abstract Body:

Sleep bruxism (SB) is a sleep related complex reflex characterized by a cascade of events: tachycardia, deep breathing, blood pressure rise, forceful tooth grinding and jaw clenching and swallowing. Severe and treatment requiring bruxism occurs in 5-10% of the population, with tooth wear or damage and painful conditions such as headaches burdening not only individuals but also health providers. SB reportedly has several underlying factors: psychological, behavioural, pharmacological and physiological. These factors, with varying degrees of evidence for their role at present, are likely to act on an underlying genetic predisposition that is probably polygenic in nature given the lack of evidence for major genes, not to mention the lack overall of sufficiently powered genetic studies even though half of the variation across populations has been suggested to be genetic in origin.

We conducted the first register-based study with 377,277 individuals including 12,297 SB patients (ICD-10 code G47.8 or F45.8) using data from the FinnGen cohort in combination with data from primary care and hospital registries. First, our epidemiological analysis revealed that age (OR=0.97, $P<2.0\times 10^{-16}$), sex (OR=2.79, $P<2.0\times 10^{-16}$), sleep apnoea (OR=1.89, $P<2.0\times 10^{-16}$), gastroesophageal reflux disease (OR=2.06, $P<2.0\times 10^{-16}$), myalgia (OR=4.42, $P<2.0\times 10^{-16}$) and depression (OR=1.80, $P<2.0\times 10^{-16}$) associated with the risk of bruxism as previously reported and hence this analysis also validates our data. Second, in the genome-wide association analysis (GWAS) for SB, we identified one associated genetic locus ($P<5.0\times 10^{-8}$): rs10193179, an intron variant in *MYO3B*. Third, we calculated genetic correlations between bruxism and its known epidemiological correlates and sleep traits revealing significant correlations: sleep apnoea ($rg=0.32$, $P=9.59\times 10^{-6}$), gastroesophageal reflux disease ($rg=0.63$, $P=1.30\times 10^{-8}$), myalgia ($rg=0.76$, $P=1.52\times 10^{-6}$), depression ($rg=0.50$, $P=3.22\times 10^{-8}$), temporomandibular disorder ($rg=0.73$, $P=7.53\times 10^{-9}$), use of hypnotics and sedatives ($rg=0.46$, $P=4.60\times 10^{-9}$), insomnia ($rg=0.31$, $P=0.031$), sleepiness ($rg=0.14$, $P=0.030$) and sleep efficiency ($rg=-0.17$, $P=0.038$).

This study shows that bruxism can be studied through large biobank-based cohorts opening new possibilities for genetic elucidation. It is particularly interesting that we found strong genetic correlations between bruxism and its comorbidities and bruxism and sleep traits, suggesting that these diseases and traits may share a common genetic background. This connection may also bring new insights into the diagnosis and treatment of bruxism.

Complex Traits Posters - Thursday

PB1389. Genetic analysis using large biobank controls validates known genes and discover novel genes in Hirschsprung disease.

Authors:

M. Fu, S. Chatterjee, M. Erazo, H. Berk-Rauch, A. Chakravarti; New York Univ. Sch. of Med., New York, NY

Abstract Body:

Background

Hirschsprung disease (HSCR) is a congenital neurodevelopmental disorder of the enteric nervous system (ENS) and the most common cause of intestinal obstruction in newborns. Recent (Tilghman et al., 2019) molecular analyses of this multifactorial disorder has identified a total of 33 genes and loci explaining 63% of its population attributable risk. The remainder are likely rare pathogenic segregating and de novo variants at many ENS genes. Here we aimed to discover such genes and variants using the largest collection of HSCR patients of European ancestry as cases and the UK Biobank (UKB) data as controls.

Methods

We ascertained 345 HSCR affected individuals as cases and selected 50 controls per case from ~200K UKB exomes based on the nearest Euclidean distance of common ($\geq 1\%$) variants by principal components. Statistical analyses were performed using GATK4 and DeepVariant for cases and controls, respectively. Extensive quality control analyses at the variant level were performed to confirm the comparability of case and control data. We focused our genetic analyses on rare variants ($MAF \leq 0.1\%$ in gnomAD v3) and performed genome-wide burden enrichment analysis by variant types (i.e., loss-of-function (LoF), insertions/deletions, missense & synonymous). Individual genes were assessed using the odds ratio followed by database annotations and pathway enrichment analysis.

Results

We found HSCR was enriched with LoFs as compared to all other variant types and identified 105 genes associated with HSCR. Among them, 22, inclusive of the HSCR major genes *RET* and *EDNRB*, were enriched for gene expression in the human embryonic gut. These genes were enriched for transmembrane receptor protein tyrosine kinase activity with potential interactions with the SOX10, TFAP2C and NKX2-1 transcription factors, all of which are known to be influential in neural cell development.

Conclusion

We demonstrated how very large external biobank data can be used as effective controls to increase the statistical power of gene discovery, adding an additional 20 new genes to the known set of 33 HSCR genes and loci.

Complex Traits Posters - Wednesday

PB1390. Genetic and environmental regulation of caudate nucleus transcriptome in schizophrenia

Authors:

K. Benjamin^{1,2}, A. S. Feltrin¹, B. R. André¹, A. E. Jaffe¹, J. M. Stolz¹, L. Collado-Torres¹, L. A. Huuki¹, Q. Chen¹, E. E. Burke¹, R. Arora¹, J. Shin¹, W. S. Ulrich¹, A. Deep-Soboslay¹, R. Tao¹, BrainSeq Consortium, T. M. Hyde¹, J. E. Kleinman¹, J. A. Erwin¹, D. R. Weinberger¹, A. C. M. Paquola¹; ¹Lieber Inst. for Brain Dev., Baltimore, MD, ²Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract Body:

Recent studies of gene expression in the human brain have provided biological insights about the genetic origins of psychiatric disorders, such as schizophrenia. Most of these studies, however, have focused exclusively on cortical regions though subcortical nuclei, such as striatum, have figured prominently in the circuitry implicated in schizophrenia and its dense dopaminergic innervation is targeted by current antipsychotic drugs. To gain novel insight into risk mechanisms underlying schizophrenia, we performed a comprehensive analysis of the genetic and transcriptional landscape of schizophrenia in the postmortem caudate nucleus of 443 individuals. Integrating expression quantitative trait loci (eQTLs) analysis, Mendelian Randomization with the latest schizophrenia GWAS, transcriptome wide association study (TWAS), and differential expression analysis, we identified many new genes associated with schizophrenia risk including possibly the dopamine D2 receptor short isoform. We examined the effect of antipsychotics in the caudate and show extensive influence on gene expression. Using a new approach based on deep neural networks, we construct caudate nucleus gene expression networks that highlight interactions involving schizophrenia risk. Altogether, these analyses provide a new resource for the study of schizophrenia that can bring insight into risk mechanisms and potential novel therapeutic targets.

Complex Traits Posters - Thursday

PB1391. Genetic architecture of asthma in African American Patients

Authors:

X. Chang, M. March, F. Mentch, H. Qu, Y. Liu, J. Glessner, H. Hakonarson; Children's Hosp. of Philadelphia, Philadelphia, PA

Abstract Body:

Asthma is a chronic inflammatory disorder with a strong genetic inheritance. Although over one hundred loci were reported through the genome-wide association study of European populations, the genetic underpinning of asthma in African Americans remains largely elusive. In this study, we aimed to identify new genetic loci associated with asthma in African Americans. Three cohorts were genotyped using the Illumina SNP array platform, totaling 6,975 cases and 4,429 controls. Genotype imputation was performed using the TOPMed reference panel including whole genome sequencing data from over 100,000 individuals. Meta-analysis was conducted to identify genetic loci associated with asthma in African Americans. Our study identified 12 loci surpassing the classical genome-wide significant threshold (5×10^{-8}) including 8 Loci which reached stricter significant threshold (3×10^{-8}). Among them, six loci are associated with enhancer activities, two loci are in DNase I hypersensitive regions, and all of them are associated with regulatory motifs. Moreover, locus 9p24.1 (rs10975467, $P = 1.63 \times 10^{-8}$) has been previously associated with asthma in Europeans. Locus 11q13.4 locus (rs7480008) is an eQTL (expression quantitative trait loci) of XRRA1 in lung ($P = 9.4 \times 10^{-10}$), and locus 13q14.3 (rs1543525) is a sQTL (splicing quantitative trait loci) of DHRS12 in lung ($P = 1.1 \times 10^{-13}$). Our findings demonstrate that some genetic risk factors in asthma are shared among populations of African and European descent and provide candidate genetic loci for therapeutic target identification and prioritization.

Complex Traits Posters - Wednesday

PB1392*. Genetic architecture of insulin-stimulated glucose uptake reveals novel regulators of post-prandial glucose metabolism

Authors:

A. Williamson^{1,2}, D. M. Norris², X. Yin³, K. Broadaway⁴, A. H. Moxley⁴, S. Vadlamudi⁴, E. P. Wilson⁴, N. Grarup⁵, M. Boehnke³, N. J. Wareham¹, K. L. Mohlke⁴, E. Wheeler¹, S. O'Rahilly², D. J. Fazakerley², C. Langenberg^{1,6}; ¹MRC Epidemiology Unit, Wellcome-MRC Inst. of Metabolic Sci., Univ. of Cambridge, Cambridge, United Kingdom, ²Wellcome-MRC Inst. of Metabolic Sci. Metabolic Res. Lab., Univ. of Cambridge, Cambridge, United Kingdom, ³Dept. of Biostatistics and Ctr. for Statistical Genetics, Univ. of Michigan Sch. of Publ. Hlth., Ann Arbor, MI, ⁴Dept. of Genetics, Univ. of North Carolina, Chapel Hill, NC, ⁵Novo Nordisk Fndn. Ctr. for Basic Metabolic Res., Faculty of Hlth.and Med. Sci., Univ. of Copenhagen, Copenhagen, Denmark, ⁶Computational Med., Berlin Inst. of Hlth.at Charité–Univ.smedizin, Berlin, Germany

Abstract Body:

Insulin resistance and pancreatic beta cell dysfunction are the two key pathophysiological mechanisms predisposing to type 2 diabetes (T2D). The molecular mechanisms through which insulin controls glucose metabolism in fasting and post-prandial states are distinct, with the former primarily involving the control of expression and phosphorylation of enzymes for gluconeogenesis and glycogenolysis in the liver, while the latter involves the rapid translocation of an intracellular pool of stored glucose transporters to the plasma membrane of muscle cells and adipocytes. Despite this, large-scale genetic studies of insulin resistance have predominantly focused on the fasting state and therefore primarily capture insulin action in the liver.

We conducted a genetic discovery of post-prandial insulin sensitivity using two indices which integrate fasting and glucose-stimulated insulin levels during an oral glucose tolerance test (OGTT): insulin fold change and modified Stumvoll Insulin Sensitivity Index. We meta-analysed 27 genome-wide association studies (GWAS) for each of these traits in up to ~54,000 participants representing European, Hispanic American, and East Asian ancestries.

We identified 12 loci ($p < 5 \times 10^{-8}$), of which 10 were novel, including a signal at *SLC2A4* encoding the canonical insulin sensitive glucose transporter GLUT4, associated with post-challenge insulin resistance and reduced expression of *SLC2A4* in skeletal muscle. All but one of the genetic signals were shared with risk of T2D (posterior probability of colocalisation > 80%). Using an integrative approach, incorporating information on glycaemic trait associations and skeletal muscle gene expression, we prioritised 8 additional loci of interest associated with post-challenge insulin resistance that did not meet the traditional genome wide significance threshold.

Knockdown of 41 candidate genes at these loci in a reporter assay in 3T3-L1 adipocytes identified 10 genes newly implicated in GLUT4 trafficking. Knockdown of these genes resulted in changes in regulation of GLUT4 trafficking (N genes = 8) or GLUT4 expression (N genes = 2).

In summary, through the integration of genetic data and *in vitro* experimental follow-up, we identified loci that affect T2D risk through impaired glucose uptake in peripheral tissues.

Complex Traits Posters - Thursday

PB1393. Genetic associations of rare variants in alcohol and tobacco use in up-to 526,400 individuals

Authors:

S-K. Jang¹, X. Wang², J. Otto¹; ¹Univ. of Minnesota, Minneapolis, MN, ²Penn State Coll. of Med., Hershey, PA

Abstract Body:

The use and misuse of alcohol and tobacco are major risk factors of common diseases and disability around the globe with about 50% of population risk attributed to genetic variation. While recent large-scale GWAS meta-analysis was successful at discovering common variants associated with substance use, our knowledge on causal genes and biological mechanisms of these complex behaviors are limited as common variant hits have overall small effect sizes, unclear individual significance, and are frequently in substantial LD. Research into rare variant associations and its implicated genes may identify variants with high impact on alcohol and tobacco use and provide an increasingly refined complete picture of genetic architecture of substance use. Here, we performed rare variant association test with up to 526,400 samples of predominantly European ancestry with Hispanic (N~5,458), African (N~12,813), and East Asian (N~4,306) subsamples. We meta-analyzed data across UK Biobank exome sequences (N~194K), TOPMed-imputed UK biobank microarray genotypes (N~276K), and deep whole-genome sequences from Trans-omics Precision Medicine (TOPMed) consortium (N~53K). We tested the association between alcohol/tobacco use and ~100 million variants with MAF < 1% and minor allele count greater than five. Using fixed-effects meta-analysis, we identified four rare variants that are significantly associated with smoking and three associated with alcohol use (p -value < 1×10^{-9}) and conditionally independent from common variants. These include an intronic variant of *GABRB2* (rs544298483; MAF < 0.01%, T allele associated with ~1SD increase in smoking risk, p -value= 1.62×10^{-10}) for smoking initiation which has higher allele frequency in East-Asian population. We performed gene-based test where rare protein-altering variants were aggregated based on an adaptive MAF threshold using two different masks, one with using only protein-truncating variants (i.e., stop, start, frameshift, splice acceptor/donor) and another using both protein-truncating and missense variants. We found six significant genes associated with tobacco and alcohol use, including the well-known alcohol metabolism gene *ADH1C* (p -value= 1.12×10^{-27}). We will further compare common and rare variant gene signals and test rare variant burden at the level of biological pathways and cell-types, followed by functional validation experiment.

Complex Traits Posters - Wednesday

PB1394. Genetic characterization of central serous chorioretinopathy and pleiotropic effects with age-related macular degeneration

Authors:

J. Rämö^{1,2,3}, E. Abner⁴, E. H. C. van Dijk⁵, X. Wang³, S. H. Choi³, T. Kiiskinen¹, R. Kajanne¹, J. Mehtonen¹, FinnGen, P. Palta^{6,4}, M. Kurki^{3,1}, L. Sobrin⁷, S. Yzer⁸, S. A. Lubitz^{9,3}, P. Ctr., Leiden, Netherlands, ⁶Inst. for Molecular Med. Finland FIMM, Helsinki, Finland, ⁷Harvard Med Sch, Boston, MA, ⁸Dept. of Ophthalmology, Radboudumc, Nijmegen, Netherlands, ⁹Massachusetts Gen. Hosp., Boston, MA, ¹⁰Radboud Univ Nijmegen MC, Nijmegen, Netherlands, ¹¹AbbVie, Genomic Res. Ctr., Cambridge, MA, ¹²Estonian Genome Ctr., Univ. of Tartu, Tartu, Tartumaa, Estonia, ¹³Folkhälsan Res. Ctr., Helsinki, Finland, ¹⁴Dept. of Ophthalmology, Amsterdam Univ. Med. Ctr.s, Univ. of Amsterdam, Amsterdam, Netherlands, ¹⁵Dept. of Ophthalmology, Leiden Univ. Med. Ctr., Leiden, Netherlands, ¹⁶Harvard Med. Sch., Dept. of Ophthalmology, Boston, MA

Abstract Body:

Central serous chorioretinopathy (CSC) is a leakage maculopathy affecting vision in working-age individuals. Although ophthalmologists manage the disease routinely, the etiology of CSC is not known and a better genetic understanding could represent a breakthrough. The chronic form of CSC shares some overlapping features with age-related macular degeneration (AMD), yet other features are distinct. Previous CSC GWAS have identified three loci, including a known AMD locus near the gene coding for complement factor H (CFH) with discordant effects on AMD and CSC risk.

We performed a GWAS meta-analysis of CSC in the FinnGen study (552 cases; 343,461 controls), Estonian Biobank (104 cases, 181,063 controls) and 521 previously reported Dutch chronic CSC patients. We replicated two previously known CSC association loci (near *CFH* and *GATA5*) and identified four novel genetic loci marked by common variants near *NOTCH4*, *CD34/CD46* and *PREX1* and the rare intronic variant rs538404658 in *MSRA* (OR 24.6, $p = 4.1 \times 10^{-9}$, AF 0.1%). Rs538404658 was associated with CSC in FinnGen and Estonian Biobank with similar odds ratios (24.8 and 22.9).

Among 34 reported AMD loci, 5 of 6 loci near complement pathway genes (*CFH*, *CFI*, *C2/C4A/C4B/CFB*, *VTN* and *C9* loci) had discordant effect directions for AMD and CSC (effect estimate $r = -0.76$ across all 6 loci).

We then constructed a polygenic score (PGS) for AMD in FinnGen using PRS-CS based on previous GWAS of AMD and evaluated its association with CSC risk in FinnGen. The AMD-PGS was negatively associated with diagnosis of CSC (OR 0.76 per +1 SD in AMD-PGS, $p = 7.4 \times 10^{-10}$). This association was attenuated by removing the *CFH* region (OR 0.89, $p = 0.006$) and further by removing all 6 AMD loci near complement genes from the PGS (OR 0.93, $p = 0.09$).

Finally, we constructed a PGS for each of the concentrations of circulating CFH and five CFH-related proteins. CFH-PGS was not associated with AMD or CSC, but a PGS for circulating CHFR4 was predictive of AMD (OR 1.06, $p = 8.4 \times 10^{-7}$) and had a discordant but nonsignificant effect estimate for CSC (OR 0.93, $p = 0.073$).

Here, we double the number of genetic risk loci for CSC. We demonstrate that polygenic AMD risk is negatively correlated with CSC risk, and that this pleiotropic effect is mostly mediated by complement-related loci.

Complex Traits Posters - Thursday

PB1395. Genetic colocalization between Covid-19 and diseases of the immune system.

Authors:

M. Zechner, E. Pairo-Castineira, K. Baillie; Univ. of Edinburgh, Edinburgh, United Kingdom

Abstract Body:

The Covid-19 pandemic has had a devastating global impact over the past three years. Despite rapid scientific progress, Covid-19 remains a devastating force of morbidity and mortality across the globe, with the need for better treatment options to emerge from a more thorough understanding of the disease. Here, we aim to further our understanding of the functional mechanisms behind severe Covid-19 by studying its genetic intersection with diseases that affect the immune system. Pleiotropy - whereby a single gene can affect multiple traits - is widespread throughout the human genome, and can be used to elucidate disease mechanisms by highlighting which diseases are likely to share common molecular architecture and therefore potential drug targets. Furthermore, analysis of combined genetic data from multiple diseases allows us to identify genetic variants that have so far been associated with other disease phenotypes but may impact the outcome of Covid-19 as well.

It has been shown that the inflammatory response to SARS-coronavirus-2 (SARS-CoV-2) infection has a major impact on Covid-19 pathogenesis. Both critical illness caused by Covid-19 and immune system-mediated diseases in general are known to have strong genetic components. We therefore chose to compare our genome-wide association study (GWAS) data of patients with severe Covid-19 with 56 GWAS of infectious and autoimmune diseases. In order to ascertain shared genetic loci we performed a genome-wide multi-trait colocalization analysis using the Bayesian algorithm HyPrColoc (Hypothesis Prioritisation for multi-trait Colocalization), which calculates whether the traits share the same causal variant in a genomic region. To date we have found multiple genetic connections between Covid-19 and diseases affecting the immune system, including idiopathic pulmonary fibrosis, asthma, Crohn's disease, systemic lupus erythematosus and allergic disease. Our next step is to identify affected genes in order to gain insight into the functional mechanisms and pinpoint targets for treatment.

Overall, our results shed light on which functional mechanisms severe Covid-19 shares with other illnesses of the immune system, opening up drug targets for already-approved medicines to be used for the treatment of Covid-19.

Complex Traits Posters - Wednesday

PB1396. Genetic epidemiology of carotid intima-media thickness in Sub-Saharan African populations contributes to atherosclerosis biology

Authors:

P. Boua¹, J-T. Brandenburg², H. Sorgho¹, A. Choudhury³, H. Tinto¹, C. G. Mathew⁴, M. Ramsay⁵, as members of AWI-Gen, and the H3Africa Consortium; ¹Clinical Res. Unit of Nanoro (CRUN), Ouagadougou, Burkina Faso, ²Sydney Brenner Inst. for Molecular BioSci., Faculty of Hlth.Sci., Univ. of the Witwatersrand, Johannesburg,, South Africa, ³Sydney Brenner Inst. for Molecular BioSci., Faculty of Hlth.Sci., Univ. of Witwatersrand, Johannesburg, South Africa, ⁴Dept. of Med. and Molecular Genetics, Faculty of Life Sci. and Med., King's Coll. London, London, United Kingdom, ⁵Sydney Brenner Inst. for Molecular BioSci., Faculty of Hlth.Sci., Univ. of the Witwatersrand, Johannesburg, Gauteng, South Africa

Abstract Body:

Atherosclerosis is a complex, progressive disorder affecting large and medium-sized arteries, preceding the development of cardiovascular diseases (CVDs) such as ischemic heart disease, stroke, heart failure, peripheral arterial disease and rheumatic heart disease. Despite the epidemiological complexity of CVDs in sub-Saharan Africa (SSA), genetic susceptibility remains understudied. The evolutionary roots and genetic diversity of the continent represent an opportunity to shed new light on the genetic architecture of complex traits such as atherosclerosis. We used carotid intima-media thickness (cIMT) to investigate the genetic susceptibility to atherosclerosis in SSA. cIMT was measured by ultrasound and genotyping was performed using the H3Africa genotyping array (2.3M SNPs) followed by imputation using Sanger Imputation Server. GWAS was performed in a resident African population-based cohort of 7894 adults from the AWI-Gen study. The current work outlined how the benefit of using multiple genetic epidemiology approaches lead to discovery in underrepresented populations. Additionally to the previous findings from the AWI-Gen cohort (sex-stratification gwas and gene-smoking interaction in West African men), we present results from stratified GWAS of cIMT according to hypertension and obesity. The GWAS identified two new cIMT-associated African-specific loci in *SIRPA* ($p=4.7E-8$) and *FBXL17* ($2.5E-8$). Sex-stratified analysis revealed two male-specific loci in *SNX29* ($6.3E-9$) and *MAP3K7* ($5.3E-8$), and two female-specific loci in *ARNT2* ($2.4E-9$) and *PROK1* ($1.0E-8$). Gene-based analysis resulted with significant associations for *CALD1* ($P=5.9E-7 < 2.6E-6$) and *FLT4* ($P=4.3E-7 < 2.6E-6$). New variants were identified for the gene-smoking interactions for cIMT within the previously described *RCBTB1* region ($3.1E-8$), a newly identified locus in the *BCHE* ($2.2E-8$) region, and variants in the regulatory and open chromatin regions of *TBC1D8* ($5.9E-9$). We found loci associated with cIMT in non-overweight-obese participants for *COX7C* ($4.1E-8$), and with hypertension for *PRSS38* ($1.5E-8$). Overall, this study successfully identified 13 novel loci linked to atherosclerosis biology. These results highlight the role of sex differences, gene-smoking interactions, obesity and hypertension in the pathophysiology of atherosclerosis. Inclusion of under-represented populations in medical genomics research is essential for advancing an understanding of complex trait genetics.

Complex Traits Posters - Thursday

PB1397. Genetic Exploration of Military Sudden Cardiac Arrest (GEMini): Genome Sequencing Results from the First 24 Participants.

Authors:

L. Hellwig^{1,2}, M. D. Wilkerson¹, J. Villar^{1,2}, X. Zhang¹, A. Mains¹, M. J. De Castro³, C. Dalgard¹, M. Haigney¹; ¹Uniformed Services Univ., Bethesda, MD, ²Henry M. Jackson Fndn. for the Advancement of Military Med., Inc., Bethesda, MD, ³Air Force Med. Genetics Ctr., Keesler AFB, MS

Abstract Body:

Background: Heart disease is the most common cause of death in the United States and cardiac arrest is the most common cause of death among heart disease patients. A significant proportion of sudden cardiac death is attributed to underlying genetic risk factors, particularly in the young and the incidence of sudden cardiac death in military recruits is four-fold higher than civilian athletes. Identification of disease-causing genetic variants in individuals who have sudden cardiac arrest (SCA) is critical to their medical management and informs the care of at-risk family members.

Methods: The GEMini study seeks to explore the genetic causes of SCA in military members and beneficiaries. SCA survivors who experienced SCA <40 years old are recruited, consented, and enrolled. Participants have undergone extensive phenotypic evaluation and undergo genome sequencing (GS). Clinically validated primary and secondary genomic findings (ACMGv3) are returned. Samples can also be used to study the functional effects of genetic variants.

Results: At this time, 24 participants have been enrolled. Genomes of the first 22 participants were analyzed, including 20 SCA survivors and 2 first degree relatives. The 22 total SCA survivors also had clinical genetic testing. Only 6 had clinical genetic testing prior to meeting with the study team and the clinical cardiogenetics service. Prior to enrollment, no definitive disease-causing genetic changes were identified in any of the SCA survivors. Updated clinical testing and/or GS identified clinically actionable findings in 20% (4/20) of SCA survivors. One pathogenic variant in *PKP2* and one pathogenic variant in *KCNQ1* were identified via clinical testing upon study enrollment and were consistent with the participants' phenotypes. One pathogenic variant was identified in *SDHA* and one likely pathogenic variant was identified in *ALPK3* via GS. In the first 22 GEMini participants with GS, there were 143 total variants of uncertain significance (VUS) identified within a panel of 450 cardiovascular disease-related genes.

Discussion: Genomic testing identifies clinically-actionable findings in SCA survivors. The GEMini study also suggests that standard-of-care clinical genetic testing for SCA survivors may not be routine in the MHS. These results demonstrate the complexity of GS analysis such as differentiating secondary versus primary findings. So far, GEMini revealed a large number of VUSes in SCA survivors. Additional functional studies will be conducted on high priority VUSes in order to gain new variant-specific information, potentially improving variant classification and clinical management.

Complex Traits Posters - Wednesday

PB1398. Genetic Interactions Implicate Disruption in Ciliogenesis in the Etiology of Non-syndromic Orofacial Clefts

Authors:

A. Alade¹, N. Mukhopadhyay², E. Zeng¹, M. Withanage¹, W. Awotoye³, A. Oladayo⁴, T. Busch¹, V. Sule⁵, L. Gowans⁶, P. Mossey⁷, M. Eshete⁸, W. Adeyemo⁹, A. Adeyemo¹⁰, J. Murray¹¹, S. Weinberg¹², M. Abstract Body:

Background: Non-syndromic orofacial clefts (NSOFCs) are complex traits caused by multiple genes and environmental factors. To date, over 60 risk loci have been implicated in the etiology of NSOFCs. However, the effect size of each locus is quite small, and their combined effect do not account for the total heritability of NSOFCs. SNP-SNP interaction has been shown to be a stronger mechanism for understanding the risk for NSOFCs and to explain some of the missing heritability. Therefore, we conducted a SNP-SNP interaction analysis using data from the African NSOFCs genome-wide association study (GWAS) and replicated our findings in the Pittsburgh Orofacial Clefts (POFC) multiethnic GWAS data. **Methods:** The African and POFC multiethnic GWAS study consisted of 1898 (1000 cases and 898 controls) and 11644 (2915 cases and 8729 controls) participants, respectively. First, we used the w-test to test for the association between SNPs pairs and NSOFCs allowing for interaction. Subsequently, we conducted a likelihood ratio test on the significantly associated SNP pairs comparing the full model (includes the interaction term) with the reduced model (excludes the interaction term), while adjusting for sex and the top principal components. These analyses were done for SNPs within genes in the folate pathway for both datasets, and genome-wide for the African dataset. **Results:** Among the folate pathway genes, we found significant pairwise interactions between SNPs in *MTHFD1* and *MTHFR*, and NSOFCs in both datasets. Genome-wide, we found significant associations with 16 SNP pairs. However, only one SNP pair (rs41269377 (1q43) and rs11558540 (*SAR1B*)) remained significant based on interaction effects alone. **Discussion:** *MTHFR* is a known cleft candidate gene while *MTHFD1* is a widely studied cleft candidate gene with inconsistent results across populations. The SNP rs41269377 lies within a non-coding region (1q43) and an analysis of the topologically associated domain (TAD) around the SNP identified *SDCCAG8* gene as a potential candidate locus. Mouse knock-out models of this gene showed a cleft palate phenotype. Additionally, *SDCCAG8* gene interacts with RAB effector proteins forming complexes important for primary cilia formation. The cilium is a structure essential for hedgehog signaling which is an established signaling pathway in the pathogenesis of NSOFCs. **Conclusions:** In our search for genetic risk factors for NSOFCs, we found evidence for gene-gene joint effects and interactions between folate pathway genes as well as for genes involved in ciliogenesis. Additional studies will be needed to explore the biological mechanisms mediated by these interactions.

Complex Traits Posters - Thursday

PB1399. Genetic Mechanisms of Supraventricular Tachycardias

Abstract Body:

Background: Supraventricular tachycardias such as atrioventricular nodal reentrant tachycardia (AVNRT), and Wolff-Parkinson-White syndrome / atrioventricular reentrant tachycardia (WPW/AVRT) are common heart rhythm abnormalities associated with substantial morbidity. Supraventricular tachycardias have been reported to be heritable, but the genetic determinants are poorly understood. **Methods:** We performed genome-wide association studies from seven studies and meta-analyzed results for each condition separately. For AVNRT, we included 1,996 AVNRT cases and more than 94,000 controls. For WPW/AVRT we included 2,494 cases and over 1 million controls. Significant variants were those with $p < 5 \times 10^{-8}$, and suggestive variants were those with $p < 1 \times 10^{-6}$. We identified expression quantitative trait loci from GTEx version 8 and performed transcriptome-wide analyses. We examined associations between identified variants and cardiovascular and electrocardiogram traits from prior studies. **Results:** For AVNRT (mean age 49-65 years, 30% female, and 98% white), we identified one genome-wide association locus near *NKX2-5* and three suggestive loci near *TTN*, *RAPGEF5*, *LOC105372518*. For WPW/AVRT (mean age 37-65 years, 58% female, and 80% white), we identified two genome-wide associated loci near *CCDC141* and *SCN5A*, and three suggestive loci near *VIT/STRN*, *NEDD9*, and *MYB*. Variants at *TTN* and *STRN* were associated

ASHG 2022 Annual Meeting Poster Abstracts

with *FKBP7* and *STRN* expression in heart tissues, respectively. Associated variants near *NKX2-5*, *CCDC141*, and *SCN5A* were previously associated with heart rate, resting heart rate, and QRS/QT/PR intervals, respectively. **Conclusions:** Our findings highlight genes associated with cardiac development, ion channels, and myocardium as important potential effectors for the risk of supraventricular tachycardias.

Complex Traits Posters - Wednesday

PB1400. Genetic Overlap among Alzheimer's Disease and Five Psychiatric Disorders: Genetic Convergence and Specificity.

Authors:

N. Enduru, B. S. Fernandes, Y. Dai, Z. Zhao; Univ Texas HSC Houston, Houston, TX

Abstract Body:

Background: Alzheimer's Disease (AD) has been one of the most significant health problems for the older population. Several psychiatric disorders have been associated with AD. Clinical and epidemiological evidence suggests that major depressive disorder (MDD), bipolar disorder (BD), schizophrenia (SZ), attention deficit hyperactive disorder (ADHD), and autism spectrum disorder (ASD) increase the risk of developing AD in the later stage of life. Yet very few studies investigated the genetic relationship between AD and these psychiatric disorders.

Methods: We obtained genome-wide association study (GWAS) summary statistics data on AD, BD, MDD, ADHD, and ASD from the Psychiatric Genomic Consortium (PGC) working group. We implemented two approaches to identify genetic overlap between any two traits. We applied conjunctive false discovery rate (cFDR) analysis through pleioFDR, and the case-case genome-wide association study (CC-GWAS) method. Finally, we tested causality between psychiatric disorders and AD using Mendelian randomization based on the 2SMR method.

Results: Overall there was no significant genetic correlation (r_g) between AD and MDD ($r_g = -0.06$; $P = 0.2$), AD and BD ($r_g = 0.006$; $P = 0.9$), AD and SZ ($r_g = 0.04$; $P = 0.3$), and AD and ASD ($r_g = 0.0008$; $P = 0.99$). Only AD and ADHD had significant genetic correlation ($r_g = -0.23$; $P = 0.01$). After examining pleiotropic enrichment of AD given BD (and other disorders), we then performed cFDR to identify the shared loci for a given pair of traits. We identified two SNPs with a $cFDR_{(AD\&BD)} < 0.05$. *WAC(rs332183)*, $cFDR_{(AD\&BD)} = 0.030$, $Z_{(AD)} = -3.95$, $Z_{(BD)} = 3.97$) and *MTSS1L(rs56264804)*, $cFDR_{(AD\&BD)} = 0.012$, $Z_{(AD)} = -4.36$, $Z_{(BD)} = 4.19$) was associated with AD and BD with opposite direction of effect. *MTCH2(rs10838738)*, $cFDR_{(AD\&MDD)} = 0.007$, $Z_{(AD)} = -5.76$, $Z_{(MDD)} = -4.31$) was associated with AD and MDD with same direction of effect. *DDB2(rs11039131)*, $cFDR_{(AD\&SZ)} = 0.03$, $Z_{(AD)} = -5.11$, $Z_{(SZ)} = -3.88$) and *ADAM10(rs2555356)*, $cFDR_{(AD\&SZ)} = 0.012$, $Z_{(AD)} = -4.55$, $Z_{(SZ)} = -3.93$) was associated with AD and SZ with same direction of effect. We did not find any overlapping SNPs based on the conjunctive analysis of AD with ADHD or ASD. CC-GWAS identified 86 independent loci among AD and the 5 psychiatric disorders, of which 19 are CC-GWAS specific loci; 11 of which were not reported previously. 2SMR results did not support psychiatric disorders as causal factors for AD (MR Egger > 0.05).

Discussion: Overall, there is a polygenic overlap between AD and psychiatric disorders, suggesting shared pathogenesis. However, we failed to find any causal relationship between psychiatric disorders and AD.

Complex Traits Posters - Thursday

PB1401. Genetic overlap of idiopathic pulmonary fibrosis and hypertension.

Authors:

G. Parcesepe¹, R. Allen¹, B. Guillen-Guio², R. G. Jenkins^{3,4}, L. V. Wain^{1,5}, c. DEMISTIFI³; ¹Univ. of Leicester, Leicester, United Kingdom, ²Hosp. Univ.rio Ntra. Sra. de Candelaria, Santa Cruz de Tenerife, Spain, ³Univ. of Nottingham, Nottingham, United Kingdom, ⁴Nottingham BioMed. Res. Ctr., Nottingham, United Kingdom, ⁵Leicester Respiratory BioMed. Res. Ctr., Glenfield Hosp., Leicester, United Kingdom

Abstract Body:

Fibrosis is a feature of multiple chronic conditions. Idiopathic Pulmonary Fibrosis (IPF) is the most well-known fibrotic disease of the lung, whereby excess deposition of extracellular matrix impairs gas exchange and leads to respiratory failure. Up to 50% of individuals with IPF have co-morbid hypertension, defined using systolic and diastolic blood pressure (SBP, DBP). High blood pressure can lead to organ fibrosis or can be a consequence of artery stiffening due to fibrosis. Studies have implicated common processes, such as TGF- β signalling, in both IPF and blood pressure regulation.

Genome-wide association studies (GWAS) of blood pressure have identified >900 independent signals of association. GWAS of IPF risk have identified 20 independent signals. We hypothesised that there are shared genetic risk factors for IPF and hypertension that could be informative about shared fibrotic pathways.

We analysed genome-wide genetic correlation using LD score regression (LDSC), and locus-specific overlap, using the largest publicly available GWAS of SBP, DBP and IPF. Genome-wide genetic correlation was low (IPF with; SBP = -0.077, $p=0.02$; DBP = -0.027, $p=0.43$). 7 variants previously reported for association with IPF were also significantly associated ($P<1\times 10^{-5}$) with SBP or DBP. Variants near *MAD1L1* and *MAPT* increased risk of both IPF and hypertension, whilst variants near *TERC*, *FAM13A*, *TERT*, and *DEPTOR*, and at 17q22.1 had opposite directions of effect on risk of IPF and hypertension.

These findings support that there are shared fibrotic mechanisms between IPF and hypertension. The opposite effects of variants at specific loci highlight the need for caution when considering therapeutic targeting of these shared pathways.

Complex Traits Posters - Wednesday

PB1402. Genetic pleiotropy effects on kidney function and soluble receptor for advanced glycation end-products: The Long Life Family Study (LLFS).

Authors:

M. Feitosa¹, B. Thyagarajan², M. Wojczynski¹, S. Lin¹, A. Kuipers³, S. Acharya¹, A. Kulminski⁴, G. J. Patti¹, M. Brent¹, K. Christensen⁵, J. Zmuda³, M. Province¹; ¹Washington Univ Sch Med., St Louis, MO, ²Univ. of Minnesota, Minneapolis, MN, ³Univ of Pittsburgh, Pittsburgh, PA, ⁴Duke Univ, Durham, NC, ⁵Univ. of Southern Denmark, Odense, Denmark

Abstract Body:

Patients with chronic kidney disease (CKD) have increased oxidative stress and chronic inflammation, which may escalate the production of advanced glycation end-products (AGE). The estimated glomerular filtration rate (eGFR) is used for detecting and managing kidney diseases. Low eGFR and high circulating level of soluble receptor for AGE (sRAGE) are associated with aging, CKD, and cardiovascular risk. We estimated the eGFR using serum creatinine (eGFRcre) and cystatin C (eGFRcys) from CKD Epidemiology Collaboration (2021). We evaluated whether eGFRcre (and/or eGFRcys) share pleiotropic genetic factors with sRAGE, assessing whole-genome sequencing variants with minor allele count ≥ 20 in 4,182 individuals (age range: 24-110) from exceptional healthy-aging families from the LLFS (Wojczynski et al., 2021). As eGFRcre and eGFRcys are correlated negatively with sRAGE ($r=-0.25$, $P=1.4 \times 10^{-37}$, and $r=-0.30$, $P=2.7 \times 10^{-53}$, respectively), we employed correlated meta-analyses (CMA) (Province et al., 2013) to test whether combining genome-wide association (GWAS) P -values enhances the ability to detect variant sharing effects on these correlated traits. We considered a variant pleiotropic if the univariate GWA $P \leq 0.01$ and CMA $P \leq 5.0 \times 10^{-08}$. We identified 15 novel loci for eGFRcre (and/or eGFRcys) demonstrating pleiotropy with sRAGE, including *FAFI-CDKN2C-MIR4421*, *SH3GLB1-SELENOF*, *STK32B*, *TMEM144-RXF1*, *CREB5*, *CNTNAP2*, *LINC00707*, *LOC101928272-LINC02670*, *LINC02737-CNTN5*, *RIMBP2*, *POLRID-GSX1*, *NPAS3*, *LINC02301-SNORD3P3*, *CASC17-ROCR*, and *GPRI42-GPRC5C-LINC01987-LINC01973*. Some loci were reported as GWAS suggestive ($P < 10^{-7}$) for eGFRcre, CKD, diabetic kidney disease, blood urea nitrogen levels, and serum uric acid levels. Additionally, we identified loci harboring genes with roles in pathways, including CREB (cAMP response element-binding protein), PI3K-Akt signaling, integrin, and apoptotic signaling. Our findings show pleiotropic genetic associations with eGFR and sRAGE levels, which may explain part of the correlated genetic architecture between kidney function, oxidative stress, low-grade chronic inflammation, and their shared pathways in accelerated biological aging.

Complex Traits Posters - Thursday

PB1403. Genetic prediction of weight and waist circumference regain after weight loss with Intensive Lifestyle Intervention: A secondary analysis of the Look AHEAD trial.

Authors:

M. Revsbech Christiansen^{1,2}, T. O. Kilpeläinen¹, J. M. McCaffery²; ¹Novo Nordisk Fndn. Ctr. for Basic Metabolic Res., Univ. of Copenhagen, Copenhagen, Copenhagen, Denmark, ²Dept. of Allied Hlth.Sci., Univ. of Connecticut, Storrs, CT

Abstract Body:

Many people can achieve weight loss successfully. However, weight maintenance is a struggle, and most weight loss is regained within 5 years. Only few studies have examined whether genetic variants predict weight regain. Furthermore, studies tend to focus on weight and body mass index (BMI), but waist circumference (WC) also predicts cardiovascular morbidity and mortality. In this secondary data analysis of Look AHEAD we examine whether genetic risk for higher BMI or abdominal adiposity (WC or waist-to-hip ratio adjusted for BMI (WCadjBMI and WHRadjBMI)) predict BMI and waist circumference change after an initial 1-year weight loss. Look AHEAD is a randomized, controlled trial testing the impact of Intensive Lifestyle Intervention (ILI) compared to a control group on health outcomes among participants with overweight or obesity and type 2 diabetes. A subset of individuals randomized to ILI who lost at least 3% of their weight (White subset N= 709; Full sample N=1050) were included in this study. To assess the genetic risk, we used summary statistics for BMI, WHRadjBMI and WCadjBMI to construct genetic risk scores. Outcomes included the changes in BMI, WCadjBMI and WC from year 1 to years 2, 4 and 8. The models accounted for age, sex, baseline trait level, change in trait from baseline to year 1, and the 3 first genetic principal components for the full sample. Mean loss of BMI and WC in ILI were -3.22 and -7.70 cm at year 1; among ILI participants who lost 3% of their weight, mean changes in BMI and WC were 0.97 and 2.48cm at year 2, 1.92 and 4.88cm at year 4 and 2.04 and 6.67cm at year 8. In linear models, a genetic risk for increased WHRadjBMI predicted increased WCadjBMI in White ILI losers between years 1 and 2 ($\beta \pm SE = 1.02 \times 10^{-3} \pm 4.62 \times 10^{-4}$, $P = 0.027$), years 1 and 4 ($1.24 \times 10^{-3} \pm 5.16 \times 10^{-4}$, $P = 0.016$) and years 1 and 8 ($1.45 \times 10^{-3} \pm 5.33 \times 10^{-4}$, $P = 6.69 \times 10^{-3}$). The genetic risk score for WHRadjBMI also predicted WCadjBMI in the full sample for year 1 to 2 ($8.60 \times 10^{-4} \pm 3.75 \times 10^{-4}$, $P = 0.022$), year 1 to 4 ($1.10 \times 10^{-3} \pm 4.36 \times 10^{-4}$, $P = 0.012$) and year 1 to 8 ($1.50 \times 10^{-3} \pm 4.58 \times 10^{-4}$, $P = 1.09 \times 10^{-3}$). For WC alone, the WHRadjBMI genetic risk score was predictive of a WC change from year 1 to 2 in the White subset (0.0378 ± 0.0181 cm, $P = 0.037$). This translates to a 1.1cm difference in WC change from year 1 to 2 between groups stratified according to the 10th and 90th percentile of the WHRadjBMI GRS. These data show that a genetic risk for increased central adiposity is predictive for higher gain in waist circumference in years 1 to 8 after a 3% weight loss. The results imply that genetically predisposed subgroups may be at higher risk for WC increase and could benefit from additional intervention to maintain WC after a weight loss.

Complex Traits Posters - Wednesday

Ctr., Chicago, IL

Abstract Body:

Longitudinal change in memory performance can serve as a powerful endophenotype of Alzheimer's disease (AD) that accurately reflects the continuum of cognitive decline that occurs over the course of aging and disease. In the present study, we investigate the genetic architecture of memory performance leveraging psychometric-based techniques to harmonize memory scores in 20,205 non-Hispanic White (NHW) and 2,612 non-Hispanic Black (NHB) participants across 4 longitudinal cohorts of aging and AD (ACT, ADNI, NACC, ROSMAP). Longitudinal memory scores were available in 14,877 and 1,853 in NHW and NHB participants, respectively. Genome-wide association studies (GWAS) of baseline memory performance and memory decline were performed using linear regression, covarying for age, sex, and the first five principal components to control for unmeasured population stratification. Analyses were run in each cohort/ancestry group separately, then subsequently meta-analyzed. For both memory outcomes, strong association signals were observed at 5 known AD loci, including *APOE* (rs429358, both $p < 1.19 \times 10^{-58}$), *BINI* (rs6733739, both $p < 2.18 \times 10^{-9}$), *PICALM* (rs3851179, both $p < 2.87 \times 10^{-7}$), *CRI* (rs4844610, $p = 3.63 \times 10^{-9}$) and *CD2AP* (rs9473117, $p = 3.98 \times 10^{-6}$). In addition to these known loci, we identified 2 novel genome-wide significant loci in the longitudinal memory decline analysis on chromosome 1 (rs2760073, intronic *C1orf50*, $p = 4.77 \times 10^{-8}$) and chromosome 12 (rs78378232, intergenic, $p = 3.47 \times 10^{-8}$). The chromosome 1 locus (rs2760073) is an eQTL for *CCDC23*, *ERMAP*, and *LEPRE1* in whole blood (eqtlgen.org) and these genes are involved in axon development, cell adhesion mediation, and collagen synthesis, respectively. This large analysis of memory performance in a population that includes the full clinical and preclinical spectrum of AD highlights the utility of sensitive longitudinal measures to confirm known loci and identify novel genomic signals. Expanding this approach to include more cohorts enriched for cognitively normal participants may provide the opportunity to deconvolve the genetic architecture of age-related cognitive decline from the genetic architecture of disease.

Complex Traits Posters - Thursday

PB1405. Genetic profiling and improved predictive capability with protein-based risk scores for IBD and disease progression using UK Biobank data.

Authors:

X. Zeng¹, P. Charuworn¹, V. Watson¹, D. Neasham², O. Archangelidi², D. Ellwanger¹, B. Pei³, Y-P. Lai³, I. Eres¹, A. Rampersaud³, S. Wang¹, G. Kafatos², B. Gibson¹, M. van Lookeren Campagne¹, Y-H. Hsu³; ¹Amgen, South San Francisco, CA, ²Amgen, Thousand Oaks, CA, ³Amgen, Cambridge, MA

Abstract Body:

Inflammatory bowel disease (IBD) is a broad term that describes conditions characterized by chronic inflammation of the GI tract. In 20 - 30% of patients, IBD progresses in extent and behavior over time; however, given the unpredictability of disease development at diagnosis, it is difficult to identify patients who will eventually progress to more extensive disease. Identifying patients at risk for progression would help personalize medical management, targeting earlier aggressive interventions. While recent large-scale genome-wide association studies (GWAS) have successfully identified risk loci for IBD, efforts to understand the genetic mechanism for IBD progression have been less fruitful due to the lack of proper data sources. With longitudinal clinical data in over 500K genotyped subjects, the UK Biobank (UKBB) presents a promising resource for revealing the genetic basis of IBD progression.

In this study, 8,109 clinically diagnosed IBD subjects were identified in the UKBB based on electronic health medical records. Occurrence of progression related outcomes (including IBD related surgeries, colon cancer, and primary sclerosing cholangitis) were used to define patients with IBD progression. We identified 2,451 IBD progressors and 5,658 non-progressors.

Two GWAS strategies with different underlying hypotheses were implemented - logistic and ordinal GWAS. Logistic GWAS comparing IBD progressors versus non-progressors identified 20 novel risk loci that have not been implicated in IBD manifestation. In parallel, to identify genetic variants associated with IBD severity, we stratified the cohort into healthy, non-progressors, and progressors and performed ordinal GWAS; this analysis identified 22 genome-wide significant risk loci, including 13 that were also found to be associated with IBD risk, suggesting that the pathophysiological mechanisms involved in IBD progression may be shared with that of IBD manifestation. Overall, our analysis suggests that IBD manifestation and progression have both shared and unique genetic underpinnings.

Further, protein-based risk scores were derived for both IBD and disease progression using proteomics data obtained from the UK Biobank Pharma Proteomics Project for over 54K participants. The scores derived from panel proteins selected by Lasso regression have the best discriminative capacity in the testing cohort for IBD and disease progression with an AUC of 0.76 and 0.64, respectively. For IBD, we show that a poly-omics risk score model incorporating both proteomics and genomics data (AUC = 0.78) outperforms models derived solely from either genomics data (AUC = 0.66) or proteomics data (AUC = 0.76).

Complex Traits Posters - Wednesday

PB1406. Genetic Regulation of Gene Expression in HIV+ T Cells Associated With Control of HIV spVL in African Populations

Authors:

R. Tough^{1,2}, S. N. Gingras^{1,2}, J. F. Tuff², C. M. Card^{3,1}, D. M. Tang², P. J. McLaren^{2,1}; ¹Dept. of Med. Microbiol. and Infectious Diseases, Univ. of Manitoba, Winnipeg, MB, Canada, ²Natl. Lab. for HIV Genetics at JC Wilt Infectious Diseases Res. Ctr., Natl. Microbiol. Lab., Publ. Hlth. Agency of Canada, Winnipeg, MB, Canada, ³Natl. Lab. for HIV Immunology at JC Wilt Infectious Diseases Res. Ctr., Natl. Microbiol. Lab., Publ. Hlth. Agency of Canada, Winnipeg, MB, Canada

Abstract Body:

HIV set-point viral load (spVL), the amount of virus in the blood during the chronic phase of infection, is a strong determinant of disease progression and transmission potential. Previous genome-wide association studies show that ~25% of the variance in HIV spVL in the infected population is attributable to common host genetic variants, mainly in the CCR5 and class I HLA genes. However, the majority of these studies only include individuals of European ancestry thus omitting a substantial proportion of global genetic diversity. To address this gap, we recently conducted a genome-wide association study of HIV spVL in 3,879 individuals of African Ancestry and observed a novel locus on chromosome 1 that is significantly associated with decreased HIV spVL (top SNP rs59784663, $p = 6.4E-10$, $\beta = -0.3$). Associated variants at this locus are unique to populations of African ancestry and the region has not been previously shown to impact HIV spVL in Europeans. The locus includes four protein-coding genes; PRKAB2, FMO5, CHD1L and BCL9, however, the precise causal variant(s), causal gene and/or causal pathway are unknown. To test the association between the top SNP and gene expression, we selected individuals that are homozygous reference (N=12) or heterozygous (N=12) at rs59784663 and performed transcriptional profiling of stimulated (anti-CD3/CD28) and unstimulated primary CD4+ T cells, the major cellular target of HIV infection. We did not observe a significant relationship between rs59784663 genotype and any of the genes in the region. However, we did observe a trend towards lower relative expression of CHD1L in stimulated CD4+ T cells and PRKAB2/FMO5 in unstimulated CD4+ T cells in individuals carrying the variant allele. In a transcriptome-wide analysis, we observed dysregulation of key signaling pathways; such as upregulation of AKT activation (FDR $P < 0.025$) and DNA double strand break sensing (FDR $P < 0.022$) in stimulated CD4+ T cells and upregulation of TNFR1-induced NF κ B signaling pathway (FDR $P < 0.005$) in unstimulated CD4+ T cells in heterozygous individuals. These data suggest that variants in the chromosome 1 region may be acting in trans to regulate expression of genes involved in HIV pathogenesis and have implications for design of novel anti-HIV therapeutics.

Complex Traits Posters - Thursday

PB1407. Genetic regulation of gene expression in the frontal cortex across the human lifespan

Authors:

H. Young¹, A. de Pins¹, R. Signer², C. Seah¹, A. Cote³, L. Huckins¹; ¹Icahn Sch. of Med. at Mount Sinai, New York, NY, ²Icahn Sch. of Med. at Mount Sinai, Fort Collins, CO, ³Icahn Sch. of Med., New York, NY

Abstract Body:

Background Genome-wide association studies have identified a large number of loci associated with psychiatric disorders by amassing huge sample sizes and compiling samples across a large number of contexts and environments. While great for discovery, this approach can obscure important context-specific impacts of genetic variation. Expression quantitative trait loci (eQTLs) provide an opportunity to identify genomic variants that regulate gene expression in tissues of interest, here the frontal cortex. Genetic regulation of gene expression can be highly context-dependent, and thus to obtain a more full picture of the regulatory landscape we seek to incorporate context into the search for eQTLs. Here, we extend this approach to aging in order to uncover associations of age-dynamic regulation and probe how that regulation is associated with neuropsychiatric disorders.

Methods Leveraging seven post mortem frontal cortex datasets that span a wide range of ages throughout adulthood into advanced aging, we collected matched genotypic and transcriptomic data for 1,811 individuals in order to identify age-specific and age-dynamic eQTLs. We conduct age-stratified eQTL searches (broken down into decade-sized age bins: 40-49, 50-59, ... 90+, N range = 195 - 425) as well as analyses to detect age*SNP interaction effects. Colocalization analyses and clustering values derived from cubic spline interpolation are used to identify age-dynamic eQTLs, and those eQTLs are tested for colocalization with neuropsychiatric traits.

Results We identify 7,734 eGenes with a significant age*SNP interaction effect. Age-stratified eQTL searches found 3,393 eGenes had a significant eQTL in only one of the decade-stratified analyses and many other sets of eGenes were identified with distinct set membership between all six age-stratified analyses (significant in 2, 3, etc. different age ranges), indicating age-specific regulation. K-means clustering of cubic spline interpolation allowed for the grouping of eQTLs based on their temporal trajectories into sets and identified two out of six clusters with age-dynamic eQTLs effect size trajectories across the lifespan.

Discussion Our findings show the benefit of considering age a useful investigative tool instead of treating it as a confounding variable that must be controlled for. The incorporation of environmental context can lead to discovery of dynamic genetic regulation that is key to understand the full genetic architecture of psychiatric disorders.

Complex Traits Posters - Wednesday

PB1408. Genetic susceptibility for autoimmune diseases and white blood cell count variability.

Authors:

N. Vaitinadin¹, C. M. Stein¹, J. Mosley², V. Kawai³; ¹Vanderbilt Univ Med. Ctr., Nashville, TN, ²Vanderbilt Univ. Med. Ctr., Nashville, TN, ³Vanderbilt Univ Med Ctr., Nashville, TN

Abstract Body:

Background: Fluctuations in white blood cell (WBC) counts is a common clinical characteristic in autoimmune (AI) conditions. Whether a genetic predisposition to an AI disorder associates with WBC counts in the general population is not known. We evaluated whether polygenic predictors for 7 common AI diseases are associated with WBC count variability. **Methods:** Publicly available genome-wide association study (GWAS) summary statistics were used to develop SNP-based genetic instruments for 7 common AI diseases. We tested the associations between each genetic instrument and measured WBC counts with a two-sample inverse variance weighted method (IVWM) and SNP weighted associations derived from a GWAS for WBC counts. Effect size in the IVWM analysis represents change in log[WBC counts] per change in log odds-ratio of the AI disease. For those AI diseases with significant associations in the IVWM analysis, a linear regression analysis using polygenic risk scores (PRS) as predictors was performed to test for associations with measured WBC counts in community-based (ARIC, n=8926) and medical-center derived cohorts (BioVU, n=40,461). The PRS analyses were also stratified by sex, as the incidence of AI diseases often varies by sex. **Results:** In the IVWM analysis, systemic lupus erythematosus (SLE) (Beta= -0.05 [95% CI, -0.06, -0.03]), multiple sclerosis (MS) (Beta= -0.05 [-0.07, -0.02]), and rheumatoid arthritis (RA) (Beta= 0.02 [0.01, 0.03]) were significantly associated with WBC counts. PRS for these diseases showed associations with measured WBC counts in ARIC and BioVU, following the same direction of effect as the IVWM analysis. In ARIC, a higher PRS was associated with lower log-transformed WBC count for SLE (beta -0.01, 95% CI: -0.017, -0.005 per SD increase in the PRS) and MS (-0.01, 95% CI: -0.017, -0.005). In BioVU, the association estimates for each AI PRS were very similar to those from the ARIC cohort, except that the RA association was significant. The WBC changes were larger among females, compared to males, consistent with known differences in sex-specific incidence rates. **Conclusions:** A genetic predisposition to SLE, RA, and MS was significantly associated with WBC counts. The gender differences in effect size suggest a non-constitutive association between genetic predisposition and WBC counts. This, combined with the fact that associations were observed in populations where prevalence of these AI diseases is expected to be low, suggests that subclinical AI disease may be more common than would be expected in the general population.

Complex Traits Posters - Thursday

PB1409. Genetic Variability of *CYP2B6* Polymorphisms (785A>G, 64C>T and 516G>T) in Southwest Nigerian Population: Implications for Malaria Treatment

Authors:

S. Ademola, O. Bamikole, A. Dibia, Y. S. Imo, J. Etim, A-L. Ajige, O. K. Amodu; Univ. of Ibadan, Ibadan, Nigeria

Abstract Body:

Malaria remains a disease of public health importance in spite of the efforts made over the years to reduce its burden globally. It is responsible for most deaths among under 5 children in sub-Saharan Africa. Although there was recorded gains in malaria reduction, the COVID-19 pandemic stalled the progress due to disruption in malaria management and treatment provision. The artemisinin combination therapy (ACT) is the recommended first line treatment for *Plasmodium falciparum* malaria in Nigeria. However, single nucleotide polymorphisms of the cytochrome P450 2B6 gene (known for the primary induction of artemisinin) can affect the enzyme function as it either enhances, decreases, or abolishes its enzymatic activities depending on the drug substrates. This study investigated the frequency of commonly observed *CYP2B6* variants (516G>T {rs3745274}, 785A>G {rs2279343}, 64C>T {rs2279343}) and the association with malaria in a Yoruba population of Nigeria. Genotyping of *CYP2B6* genetic polymorphisms was carried out among 200 children using PCR-RFLP protocol. Statistical package for social sciences (SPSS) was used in analyzing demographic and clinical data. Genotypic & allelic frequencies were calculated, conformity with Hardy Weinberg equilibrium and associations were tested for under three different genetic models using Plink v1.90 and haploview 4.2. We observed a minor allelic frequency (MAF) of 0.12, 0.375, 0.423 for 785A>G, 64C>T & 516G>T allelic variant respectively. The Three SNPs were not in linkage disequilibrium, SNP variants 785A>G and 516G>T were in conformity with Hardy Weinberg equilibrium. The genotype distributions of 785A>G and 64C>T differed significantly across all malaria groups. Further analysis showed a statistically significant association ($P < 0.01$; $OR < 1$) of 785 A>G with malaria under the additive and dominant models. This finding indicates that some cytochrome p450 gene variants may confer protection against malaria development in addition to its drug metabolism functions. Further large-scale studies on *CYP2B6* variants are recommended to explore its impact in malaria development or susceptibility.

Complex Traits Posters - Wednesday

PB1410. Genetic variants in Olfactory Response Genes associated with Osteoarthritis progression to Hip or Knee Replacement among African and Hispanic American Veterans.

Authors:

A. Nair^{1,2}, V. Srinivasasainagendra^{2,3}, H. K. Tiwari³, M. M. Bamman^{2,4,5}, J. Richman^{2,6}, J. Singh^{2,7,8}, M-L. McDonald^{1,2,7,9}; ¹Div. of Pulmonary, Allergy and Critical Care Med., Dept. of Med., Sch. of Med., Univ. of Alabama at Birmingham (UAB), Birmingham, AL, ²Birmingham VA Hlth.care System (BVAHS), Birmingham, AL, ³Dept. of Biostatistics, Sch. of Publ. Hlth., UAB, Birmingham, AL, ⁴Dept. of Cell, Dev.al, and Integrative Biology, Sch. of Med. (UAB), Birmingham, AL, ⁵Florida Inst. for Human & Machine Cognition, Pensacola, FL, ⁶Dept. of Surgery, Sch. of Med., UAB, Birmingham, AL, ⁷Dept. of Epidemiology, Sch. of Publ. Hlth., UAB, Birmingham, AL, ⁸Div. of Rheumatology and Clinical Immunology, Dept. of Med. at the Sch. of Med., UAB, Birmingham, AL, ⁹Dept. of Genetics, Sch. of Med., UAB, Birmingham, AL

Abstract Body:

Background/Aims: Osteoarthritis (OA) is a progressive disease marked with increasing pain and mobility limitations necessitating total hip or knee replacement (THR/TKR). Veterans who undergo THR/TKR experience higher comorbidity, poor functional status and higher health care utilization. We aimed to identify genetic variants associated with THR/TKR.

Methods:Ancestry stratified genome wide association scans (GWAS) were performed among European White (EW: N=56,466), African American (AA: N=16,876) and Hispanic (HIS: N=5,579) Veterans from the Million Veteran Program (MVP) adjusting for age, sex, BMI and population structure. ICD9/ICD10 codes were used to identify THR/TKR cases and two sets of age matched controls: 1) Healthy set: no OA history and 2) Possible progressive set: have OA but notTHR/TKR.

Results: Using the healthy set for controls, no variant was significantly associated with THR/TKR at a level reaching genome-wide significance (GWS) among EUR or HIS Veterans. Two variants were significantly associated with THR/TKR among AA Veterans: 1) rs181133140 (OR=5.5, P=1.7x10⁻⁸, MAF=0.0006) intergenic to *OR52H1* and *OR52B6* genes which encode olfactory receptors 52H1 and 52B6; and 2) rs145338039 (OR=2.1, P=2.2x10⁻⁸, MAF=0.015) intronic to *FAM184A* gene which has been previously implicated in medulloblastoma. Using the possible progressive set as controls, several variants were significantly associated with THR/TKR among AA and HIS but not EUR Veterans. Among AA Veterans one variant in the UTR3 of *WFDC13* gene in the telomeric region of chromosome 20 and an intronic *HAOI* (Hydroxyacid Oxidase 1) variant were significantly associated. Among HIS Veterans a non-synonymous variant within *OR10G9* (olfactory receptor *10G9*) was associated with THR/TKR.

Conclusions: Variants in or near olfactory receptor genes were associated with THR/TKR in AFR and HIS Veterans. Olfactory loss is prevalent in aging populations often attributed to increased chronic diseases and medications. A direct link to OA or THR/TKR has not previously been reported. However, olfactory stimulation has been shown to mediate pain responses and progression to THR/TKR is largely motivated by increasing pain. Thus, it is possible that genetic variation in olfactory receptors influence pain perception in Veterans with OA increasing the necessity for THR/TKR.

Complex Traits Posters - Thursday

PB1411. Genetic variation in fatty acid amide hydrolase (*FAAH*) influences early drinking and smoking behaviors.

Authors:

A. Alsaafin¹, M. Chenoweth¹, M-P. Sylvestre², J. O'Loughlin², R. Tyndale³; ¹Univ. of Toronto, Toronto, ON, Canada, ²Université de Montréal, Montreal, QC, Canada, ³CAMH and Univ. of Toronto, Toronto, ON, Canada

Abstract Body:

Background: The endocannabinoid system plays a role in psychiatric disorders and drug dependence. Within the endocannabinoid system, genetically variable fatty acid amide hydrolase (FAAH) metabolizes endocannabinoids. Individuals with the C/A or A/A genotypes (A-group) of a common missense variant (rs324420; C>A; Pro129Thr) in *FAAH* have reduced enzyme activity compared to those with the C/C genotype (C-group). In animal studies, low FAAH activity is associated with alcohol and nicotine use, but in contrasting directions. Among human adults, those in the A- (vs. C-) group have an increased risk of harmful alcohol drinking (e.g., binge drinking days), but do not differ in risk for regular smoking or tobacco dependence. The associations between low FAAH activity (A-group) and early drinking and smoking behaviors during adolescence have not yet been investigated.

Methods: We studied European-ancestry participants from the Nicotine Dependence in Teens cohort. Adolescents were surveyed in a total of 20 cycles (from age ~12 to 17), then again during young adulthood (from age ~20 to 30). Hazard ratios (HR) were estimated to assess the association between genotype (C vs. A- group) and drinking initiation among baseline never-drinkers. Among those who initiated drinking, HR were estimated for attaining monthly, weekly, and daily drinking. The association between genotype and past-year binge drinking when participants were young adults was estimated using logistic regression. We estimated HR for smoking initiation according to genotype among baseline never-smokers, and from first inhalation to ICD-10 dependence among those who initiated smoking.

Results: Adolescents in the A- (vs. C-) group had a higher risk of drinking initiation (HR=1.39, 95% CI 1.09-1.77) and daily drinking (HR=2.24, 95% CI 1.05-4.76). As young adults, those in the A-group had higher odds of past-year binge drinking at ages 20 (odds ratio (OR)=2.18; 95% CI 1.38-3.45) and 30 (OR=1.66, 95% CI 1.13-2.45). An association between *FAAH* variation and smoking initiation was observed (HR=1.20, 95% CI 1.04-1.39). In contrast to early alcohol behaviors, those in the A- (vs. C-) group had generally slower or similar rates to early smoking outcomes (HR's range from 0.43 to 1.15). Sensitivity analyses showed robust findings when examining the three genotype groups separately (i.e., C/C vs. C/A vs. A/A).

Conclusions: Low FAAH activity (i.e., A-group) is a risk factor for drinking and smoking initiation and in the development of early harmful drinking. In contrast, low FAAH activity may protect against early smoking outcomes. *FAAH* variation appears to alter susceptibility to drug use.

Complex Traits Posters - Wednesday

PB1412. Genetically Informed Prediction of Short Term Parkinson's Disease Progression

Authors:

H. Javedani Sadaei¹, A. Cordova-Palomera², L. Jonghun², J. Padmanabhan², C. Shang-Fu¹, N. Wineinger¹, R. Dias¹, D. Prilutsky², S. Szalma², A. Torkamani¹; ¹Scripps Res. Translational Inst., La Jolla, CA, ²Takeda Dev. Ctr. Americas, San Diego, CA

Abstract Body:

Background: Parkinson's disease (PD) treatments modify disease symptoms but do not halt progression, characterized by slow and varied motor and non-motor changes overtime. Variation in PD progression hampers clinical research, resulting in long and expensive clinical trials prone to failure. Objective: Development of models for short-term PD progression prediction, which could be useful for informing individual-level disease management, and shortening the time required to detect disease-modifying drug effects in clinical studies. Methods: PD progressors were defined by an increase in MDS-UPDRS scores at 12-, 24-, and 36- months post-baseline. Using only baseline features, PD progression was separately predicted across all timepoints and MDS-UPDRS subparts in an optimized XGBoost framework. These predictions were combined into a meta-predictor for 12-month MDS UPDRS Total progression. Data from the Parkinson's Progression Markers Initiative (PPMI) were used for training with independent testing on the Parkinson's Disease Biomarkers Program (PDPB) cohort. Results: 12-month PD total progression was predicted with an F-measure 0.77, ROC AUC of 0.77, and PR AUC of 0.76 when tested on a hold-out PPMI set. When tested on PDPB we achieve a F-measure 0.75, ROC AUC of 0.74, and PR AUC of 0.73. Exclusion of genetic predictors led to the greatest loss in predictive accuracy; ROC AUC of 0.66, PR AUC of 0.66-0.68 for both PPMI and PDPB testing. Conclusions: Short-term PD progression can be predicted with a combination of survey-based, neuroimaging, physician examination, and genetic predictors. Dissection of the interplay between genetic risk, motor symptoms, non-motor symptoms, and longer-term expected rates of progression enable generalizable predictions.

Complex Traits Posters - Thursday

PB1413. Genetically-associated body-mass index, vitamin D levels, and age at puberty are not associated with Parkinson's Disease related phenotypes.

Authors:

E. Misicka, F. Briggs; Case Western Reserve Univ. Sch. of Med., Cleveland, OH

Abstract Body:

Background: Parkinson Disease (PD) is a neurodegenerative disorder affecting 1 million persons in the United States. There is an urgent need to characterize the biological mechanisms underlying PD onset and presentation as prevalence is expected to increase by 20% by 2030. Robustly investigating the effects of potential risk factors can be difficult due to the limited availability of epidemiologic data (i.e., there are conflicting findings for body mass index [BMI] and vitamin D [vitD] on PD risk). Fortunately, genetic instrumental variable (GIV) analyses can examine genetically driven causal relationships that may be confounded in epidemiologic studies. **Objective:** To investigate the relationships for factors associated with risk and presentation of other common neurodegenerative diseases and multiple PD phenotypes using Mendelian randomization (MR). **Methods:** MR is a form of GIV analysis where genome-wide association (GWA) summary statistics are utilized to investigate the relationship between exposure and outcome. Genetic variants associated with the exposure serve as GIVs. GIVs were selected from GWA studies for BMI (n=681,275), serum vitD levels (n=79,366), and age at puberty (AAP; n=329,245). GWA studies were also selected for PD phenotypes as outcomes, including risk (n=1.34×10⁶), age at onset (AAO; n=28,568), and binary and ratio measures of PD motor phenotype (MP, MPR; n=3,212). For each exposure, GIVs were clumped at a linkage disequilibrium threshold of $r^2 < 0.05$ using the 1000 Genomes EUR Reference Panel. Inverse variance weighted (IVW) meta-analysis was performed for each exposure on each outcome, alongside other MR approaches. Significant associations were investigated for horizontal pleiotropy using the MR-Egger intercept test. **Results:** Neither VitD (GIVs=6) nor AAP (GIVs=377) were significantly associated with any of the PD phenotypes (p>0.05). However, BMI (GIVs=656) was significantly associated with PD AAO under IVW meta-analysis ($\beta = -0.87$, p=0.018). A significance test of the MR-Egger intercept for the BMI-PD AAO association revealed that there were horizontally pleiotropic effects present (p=0.044). **Conclusions:** MR analyses do not implicate genetically-driven BMI or vitD as risk factors for PD, which adds resolution to conflicting epidemiological studies. AAP was also not associated with PD risk, which is in contrast to the relationship between AAP and multiple sclerosis risk. BMI, vitD and AAP were also not associated with PD presentation (MP, MPR, or AAO); however, an association between BMI and PD AAO appeared to be influenced by horizontal pleiotropy, and merits further investigation.

Complex Traits Posters - Wednesday

PB1414. Genetics determinants of Renin-Angiotensin-Aldosterone System (RAAS) in the Cooperative Health Research In South Tyrol study

Authors:

L. Foco¹, M. W. Arisido¹, E. Koenig¹, M-C. Zennaro², M. Poglitsch³, P. P. Pramstaller¹, C. Fuchsberger¹, C. Pattaro¹; ¹Inst. for Biomedicine, Eurac Res., Bolzano, Italy, ²Université Paris-Cité, PARCC, Inserm, Paris, France, ³Attoquant Diagnostics GmbH, Vienna, Austria

Abstract Body:

Background The Renin-Angiotensin Aldosterone system (RAAS) is the major player in the long-term blood pressure (BP) regulation. Following cleavage of angiotensinogen by renin, the resulting angiotensin I peptide is further converted to angiotensin II by the Angiotensin Converting Enzyme (ACE). Angiotensin II can then bind to its type 1 receptor, stimulating the production of aldosterone, a steroid hormone inducing sodium and water retention, thus raising BP. The RAAS is targeted by commonly used anti-hypertensive drugs, but despite its importance, little is still known about its genetics, partially due to the technical difficulties in the quantification of the involved biomarkers. **Methods** Using mass-spectrometry, we simultaneously quantified in serum equilibrium angiotensin I (eqAngI), angiotensin II (eqAngII) and aldosterone (Aldo) on 2105 participants to the Cooperative Health Research In South Tyrol study (CHRIS), who were either normotensive or under documented anti-hypertensive drug (AHD) treatment. We derived proxies of renin activity ($PRA-S=eqAngI+eqAngII$), angiotensin-converting enzyme activity ($ACE-S=eqAngII/eqAngI$) and adrenal gland function ($AA2-ratio=Aldo/eqAngII$). We tested association of these biomarkers with 1,085,897 SNPs imputed against a population specific whole-exome-sequencing-based panel, adjusting for age, sex, AHD, and assuming an additive genetic model, using Regenie v 3.1.1. **Results** ACE activity (ACE-S) was associated with variants spanning the ACE gene. The top association was seen at rs4363 ($p=2.8E-18$), already associated with serum ACE level, and we replicated the association with rs4343 ($p=6.7E-18$) and ACE activity described in an Asian population. We found strong evidence of association of eqAngII and adrenal function (AA2-ratio) with the missense/stop gained rs27044 in the ubiquitous endoplasmic reticulum aminopeptidase 1 (ERAP1, $p=8.2E-10$), involved in angiotensin II degradation. We observed a borderline association between aldosterone and the synonymous/non-coding transcript exon rs7275 at SMARCA4/LDLR ($p=5.9E-8$), previously related to lipid metabolism and coronary artery disease. **Conclusions** While some results await replication in an independent cohort, findings are consistent with known physiology, and shed light on undescribed mechanisms possibly involved in RAAS biology.

Complex Traits Posters - Wednesday

PB1415. Genetics of Gulf War illness, a genome wide association study

Authors:

J. Vahey^{1,2}, X. Qin², A. Stone³, W. C. Carter³, L. M. Griffin³, S. Pyarajan⁴, G. Turner⁴, C. Stafford², E. J. Gifford^{2,5}, K. J. Sims², C. Williams², E. Hauser^{6,2}; ¹Duke Univ., Durham, NC, ²Durham VA Med. Ctr., Durham, NC, ³Central Arkansas Veterans Hlth.care System, Little Rock, AR, ⁴VA Boston Hlth.care System, Boston, MA, ⁵Duke Margolis Ctr. for Hlth.Policy, Durham, NC, ⁶Duke Univ Med Ctr, Durham, NC

Abstract Body:

GWII is a set of debilitating symptoms afflicting 25-35% of US Veterans deployed in the 1990-91 Gulf War. The cause is unknown but is believed to be a complex mixture of military exposures and individual susceptibility. In the 30+ years since the war, a diagnostic definition, biomarkers and treatments remain elusive. Veterans continue to suffer major decrements to quality of life. The GWIECB was developed to perform genome-wide genetic analysis to explore underlying genetic susceptibility to GWII with the hope that enriched genes and associated genotypes may eventually help identify new biomarkers or treatments. Gifford et al. (Life Sciences 2021) applied the recommended GWII research definitions to the GWIECB. Based on the consistent association with deployment, the CDC Severe GWII case definition was chosen as the primary case definition for the analysis. Genotyping was done using Illumina Omni2.5-8v1.4 using standard protocols. Plink 1.9 was used for genetic data cleaning and analysis of 1,777,976 SNPs. GWAS was completed on 1,061 Veterans, using a logistic regression model, adjusting for age, sex, and ten genetic principal components (PCs) with 247 CDC Severe GWII cases (23.6%). Pathway analysis was performed using gene and gene set association, as implemented in MAGMA 1.6b, using the individual level data. Genome-wide significance was not reached by any gene in the association analysis. The top 10 genes in the gene-based association were SLC22A4, LANCL2, FAM172A, ZNF17, DPT, EPB41L1, ZNF516, ZNF804B, SCFD1, and ZNF394. SLC22A4 is an integral membrane transport protein that transports small organic cations. The top ten ranked gene sets reproduce prior work and are consistent with findings related to exposures thought to be implicated in GWII. The top result, response to cadmium ion (beta=0.43, p=2.36×10⁻⁴) suggests genetic susceptibility to heavy metals as a contributing factor. The 2nd and 3rd pathways, regulation of response to interferon gamma (beta=0.62, p=3.08×10⁻⁴) and regulation of autophagosome maturation (beta=0.81, p=3.35×10⁻⁴), reinforce neuroinflammation and neurodegeneration pathways in GWII. This unbiased genetic analysis of CDC Severe GWII suggests the need to incorporate environmental exposures in genetic models of GWII.

Complex Traits Posters - Wednesday

PB1416. *Genetics of ventricular septal defects: A novel genetic interaction between Sox7 and Wnt4 is associated with abnormal endocardial cushion morphogenesis*

Authors:

A. Hernandez-Garcia¹, K. Pendleton¹, S. Kim¹, Y. Li¹, K. Bum Jun¹, H. Zaveri¹, V. Jordan², C. Ljungberg^{3,4}, R. Chen¹, R. Lanz¹, D. Scott^{5,6}; ¹Baylor Coll. of Med., Houston, TX, ²Dept. of Molecular Physiology and Biophysics, Baylor Coll. of Med., Houston, TX, ³Dept. of Pediatrics, Baylor Coll. of Med., Houston, TX, ⁴Jan and Dan Duncan Neurological Res. Ctr. at Texas Children's Hosp., Houston, TX, ⁵Baylor Coll. Med, Houston, TX, ⁶Dept. of Molecular Physiology and Biophysics, Baylor Coll. of Med., Houston, TX

Abstract Body:

SOX7 is located in a region on chromosome 8p23.1 that is recurrently deleted in individuals with septal defects. *Sox7*^{-/-} embryos die of heart failure around E11.5 due to defects in vascular remodeling. These embryos have hypocellular endocardial cushions with severely reduced numbers of mesenchymal cells. We also observed a ventricular septal defect (VSD) in a rare *Sox7*^{lox/-};Tie2-Cre embryo that escaped early lethality. This led us to hypothesize that SOX7 plays a critical developmental role in the endocardium of the atrioventricular (AV) canal. We subsequently used AV explant studies to show that SOX7 deficiency leads to a severe reduction in endocardial-to-mesenchymal transition (EndMT). Since SOX7 is a transcription factor, we hypothesized that it functions in the endocardium by regulating the expression of EndMT-related genes. To identify these genes in an unbiased manner, we performed RNA-seq on pooled E9.5 hearts tubes harvested from *Sox7*^{-/-} embryos and their wild-type littermates. We found that *Wnt4* transcript levels were severely reduced, which we confirmed by RNA in situ hybridization. This was of particular interest since WNT4-deficiency causes VSDs in humans. We went on to perform *in silico* analyses that suggested that multiple SOX family binding sites exist in the predicted *Wnt4* promoter. We and others have proved that WNT4 is expressed in the endocardium and promotes EndMT by acting in a paracrine manner to increase the expression of BMP2 in the myocardium. Consistent with these findings, we found that *Bmp2* transcript levels were diminished in *Sox7*^{-/-} embryonic hearts. To verify if *Wnt4* interacts with *Sox7* to modulate EndMT process during the endocardial cushion development, we determined the density of mesenchymal cells in the endocardial cushions of E10.5 mouse embryos. Consistent with our hypothesis, *Wnt4*^{+/-}; *Sox7*^{+/-} double heterozygous had reduced numbers of mesenchymal cells in their endocardial cushions compared to controls, due to decreased levels of EndMT and mesenchymal cell proliferation. We conclude that SOX7 promotes EndMT in the developing AV canal by positively regulating *Wnt4* and *Bmp2* expression. Additionally, we have novel evidence that *Sox7* interacts genetically with *Wnt4* to modulate EndMT and mesenchymal cell proliferation in the endocardial cushions of the developing AV canal. These data also provide additional evidence that haploinsufficiency of *SOX7* contributes to the congenital heart defects seen in individuals with recurrent 8p23.1 microdeletions.

Complex Traits Posters - Thursday

PB1417. Genome scans of early childhood caries implicate bitter taste receptors

Authors:

E. Orlova¹, T. Dudding², J. M. Chernus³, R. N. Alotaibi⁴, S. Haworth², R. J. Crout⁵, M. Lee³, N. Mukhopadhyay⁶, E. Feingold¹, S. M. Levy⁷, D. W. McNeil⁵, B. Foxman⁸, R. J. Weyant³, N. J. Timpson⁹, M. L. Marazita¹⁰, J. R. Shaffer¹; ¹Univ of Pittsburgh, Pittsburgh, PA, ²Univ Bristol, Bristol, United Kingdom, ³Univ. of Pittsburgh, Pittsburgh, PA, ⁴King Saud Univ., Riyadh, Saudi Arabia, ⁵West Virginia Univ., Morgantown, WV, ⁶Univ Pittsburgh/Sch Dental Med, Pittsburgh, PA, ⁷Univ. of Iowa Coll. of Dentistry, Iowa City, IA, ⁸Univ. of Michigan, Ann Arbor, MI, ⁹Bristol Univ., Bristol, United Kingdom, ¹⁰Univ. of Pittsburgh, Ctr. for Craniofacial and Dental Genetics, Pittsburgh, PA

Abstract Body:

Although genetic risk factors are known to affect susceptibility to early childhood caries (ECC), few studies have focused on finding genetic determinants of ECC. Here we performed a meta-analysis of genome-wide association studies (GWAS) testing ~3.9 million genetic variants in five cohorts of children (aged up to 6 years, total N=2974, cohorts: COHRA1, COHRA2, Iowa Fluoride Study, Iowa Head Start, ALSPAC) using Stouffer's method, aiming to identify genes with potential roles in ECC biology. There was suggestive evidence for association (p -value $< 1 \times 10^{-5}$) at genetic regions and gene families previously associated with caries in primary and permanent dentition. There was also suggestive evidence for association with genetic regions related to tooth morphology, immune response to bacteria, nociception, periodontal disease, and others. We then integrated the meta-analysis results with gene expression data in a transcriptome-wide association study (TWAS). This approach identified 6 genes whose genetically predicted expression was associated with ECC (p -values $< 3.09 \times 10^{-6}$; *LINC02905*, *CDH17*, *TAS2R43*, *SMIM10L1*, *TAS2R14*, *NRAD1*). Some of the strongest associations were with genes encoding members of the bitter taste receptor family (TAS2R); other members of this family have previously been associated with caries in primary, mixed and permanent dentition. Of note, we identified the receptor encoded by *TAS2R14* (z -score 0.47; p -value = 1.06×10^{-6}), which stimulates rapid innate immunity and anti-microbial defense in response to molecules released by cariogenic bacteria *S. mutans* and *S. aureus*. The other gene transcripts identified by the TWAS did not have known biological relationships with caries. The transcript *CDH17* (z -score 1.74; p -value = 3.32×10^{-8}) stands out as one of the most significant and reliable associations. *CDH17* influences the permeability of the intestinal epithelium. These findings provide insight into ECC genetic architecture, underscore the importance of host-microbial interaction in caries risk, and identify novel risk genes for follow-up study.

Complex Traits Posters - Wednesday

PB1418. Genome sequencing in brain samples from the ROSMAP cohort to examine the relationship between telomere length, mitochondrial copy number, and β -amyloid

Authors:

M. Lynch¹, M. Taub², J. Farfel³, J. Yang³, D. Bennet³, R. Mathias⁴; ¹Johns Hopkins Univ., Baltimore, MD, ²Johns Hopkins, Baltimore, MD, ³Rush Med. Coll., Chicago, IL, ⁴Johns Hopkins Univ, Baltimore, MD

Abstract Body:

Telomere length (TL) changes regulation and mitochondrial DNA (mtDNA) alterations are well established hallmarks of aging and may have associations with cognitive phenotypes. Little is known about the relationship between TL and β -amyloid, especially in brain samples. Previously, the role of TL in Alzheimer's Disease (AD) has been studied in small sample size groups using leukocyte samples and few studies investigated AD related phenotypes including β -amyloid.

We examined N=256 DLPFC samples extracted from human aged (range: 71.3-108.2, mean: 88.6 years old) and AD brains from The Religious Orders Study (ROS), and the Rush Memory and Aging Project (MAP). In this sample, 43.4% were diagnosed with dementia and 28.5% with MCI. TL was estimated from whole genome sequencing data (WGS) by Telseq which has high correlation with Southern blot methods (Taub et al Cell Genomics 2022). Raw mtDNAcn estimates were calculated as $(covmt/covnuc) \times 2$ using mtDNA and nuclear DNA from the WGS data (Klein et al Molecular Neurodegeneration 2021).

We found TL and mtDNAcn measures to be positively correlated ($R=0.13$, $p=0.041$), even after adjustment for age and sex ($R=0.13$, $p=0.031$). While not significant, we found age of the samples to be negatively correlated with TL (~ 11 bp decrease/year, $p=0.29$) and males to have shorter TL than females (106bp shorter, $p=0.47$), consistent with prior knowledge. We did not find mtDNAcn to be significantly associated with age of sample (13.4 increase/year, $p=0.19$) or sex (92.2 higher in males, $p=0.53$). Previous studies have reported mixed results on the effect of aging and sex on mtDNAcn in brain samples.

In independent linear regression models, we identified a significant negative association ($\beta=-0.23$, $p=0.012$) between mtDNAcn and β -amyloid levels and between TL and β -amyloid levels ($\beta=-0.15$, $p=0.023$). Additionally, in a multivariate regression, we found both brain mtDNAcn and TL to be independently related to β -amyloid. Higher β -amyloid is associated with lower mtDNA copy number ($\beta=-0.21$, $p=0.024$), and lower telomere length ($\beta=-0.13$, $p=0.049$). We found these associations to be robust to cell composition; results did not change after adjusting for brain cell composition estimated from these same samples using bulk RNASequencing data.

These results suggest that higher β -amyloid levels are related to lower mtDNAcn and shorter TL in the DLPFC, and therefore that mtDNAcn and TL may be involved in AD pathogenesis. These findings suggest for the first time that the two genomic measures of aging in brain tissue (mtDNAcn and TL) may be independently related to AD pathogenesis.

Complex Traits Posters - Thursday

PB1419. Genome wide association study of clinically predicted suicide liability.

Authors:

A. Jespersen, O. Plana-Ripoll, J. Steinbach, C. Albiñana, J. McGrath, P. Mortensen, F. Privé, E. Agerbo, B. Vilhjálmsón; Aarhus Univ., Aarhus, Denmark

Abstract Body:

Suicide accounts for 1 in every 100 deaths worldwide, resulting in more than 700,000 deaths annually. Globally the number of suicides has decreased by 36% in the last 20 years whilst the Americas have seen a 17% increase in deaths by suicide. Although there is considerable evidence that attempted suicide and death by suicide have distinct aetiologies, they share risk factors, which include previous suicide attempt, depression, and alcohol use disorders.

Heritability estimates of suicidal behaviour range from 17% to 55% suggesting a significant genetic component to suicide risk. However, as suicides are fortunately relatively uncommon, genetic studies of suicidal behaviour suffer from insufficient number of genotyped cases and are generally underpowered. In this study, we aim to address this limitation by leveraging Danish electronic health care records to perform a GWAS of clinically predicted suicide liability. We achieve this by using health registers containing all hospital admissions, diagnoses, and prescriptions of the Danish population, to clinically predict death by suicide. In order to do this, we will first use a Danish population sample comprising 323,000 individuals, 869 of whom died by suicide, to train a penalised regression. The resulting weights will be used to clinically predict suicide liability in an independent sample of 134,000 genotyped individuals. We then perform a GWAS of the clinically predicted suicide liability and compare the genetic overlap with the most recent case-control GWAS of death by suicide (Docherty et al. 2020), as well as genetic correlations between clinically predicted suicide liability and major psychiatric disorders. We expect results from this study to shed light on the contribution of common genetic variants to the clinically predicted risk of death by suicide. The study will demonstrate the level of genetic similarity between clinically predicted death by suicide and observed death by suicide. Finally, this method of leveraging electronic health records for clinical prediction to increase power in genetic studies could pave the way for genetic studies of phenotypes otherwise suffering from low numbers of genotyped cases.

Complex Traits Posters - Wednesday

PB1420. Genome-wide analysis in over 1 million individuals reveals over 2,000 independent genetic signals for blood pressure

Authors:

J. Keaton¹, Z. Kamali², A. Vaez³, T. Xie⁴, A. Ani⁴, E. Evangelou⁵, J. Hellwege⁶, J. Denny⁷, D. Levy⁸, T. Edwards⁶, P. Munroe⁹, H. Snieder⁴, H. Warren¹⁰, Million Veterans Program, Lifelines Cohort Study, ICBP Consortium; ¹NIH/NHGRI, Bethesda, MD, ²Isfahan Univ. of Med. Sci. (IUMS), Isfahan, Iran, Islamic Republic of, ³Univ. of Groningen, Groningen, Groningen, Netherlands, ⁴Univ. of Groningen, Groningen, Netherlands, ⁵Imperial Coll. London, London, United Kingdom, ⁶Vanderbilt Univ. Med. Ctr., Nashville, TN, ⁷NIH, Kensington, MD, ⁸NHLBI/NIH, Framingham, MA, ⁹Queen Mary Univ. of London, London, United Kingdom, ¹⁰William Harvey Res. Inst., Barts and The London Sch. of Med., QMUL, London, United Kingdom

Abstract Body:

Hypertension is a leading cause of premature death affecting more than a billion individuals worldwide. Here we report on the genetic determinants of blood pressure (BP) traits (systolic, diastolic, and pulse pressure) in the largest single-stage genome-wide analysis to date (N=1,028,980 European-descent individuals). We identified 2,103 independent genetic signals ($P < 5 \times 10^{-8}$) for BP traits, including 113 novel loci. These associations explain ~40% of common SNP heritability of systolic and diastolic BP. Comparison of top versus bottom deciles of polygenic risk scores (PRS) based on these results reveal clinically meaningful differences in BP (12.9 mm Hg for systolic BP, 95% CI 11.5-14.2 mm Hg, $p = 9.08 \times 10^{-73}$) and hypertension risk (OR 5.41; 95% CI 4.12 to 7.10; $P = 9.71 \times 10^{-33}$) in an independent dataset. Compared with the area under the curve (AUC) for hypertension discrimination for a model with sex, age, BMI, and genetic ancestry, adding systolic and diastolic BP PRS increased discrimination from 0.791 (95% CI = 0.781-0.801) to 0.814 (95% CI = 0.805-0.824, delta AUC=0.023, $P = 2.27 \times 10^{-22}$). Our transcriptome-wide association study detected 2,793 BP colocalized associations with genetically-predicted expression of 1,070 genes in five cardiovascular tissues, of which 500 are previously unreported for BP traits. These findings represent an advance in our understanding of hypertension and highlight the role of increasingly large genomic studies for development of more accurate PRS, which may inform precision health research.

Complex Traits Posters - Thursday

PB1421*. Genome-wide association analyses of sepsis and septic shock in a large practice-based biobank

Authors:

L. Jiang¹, A. Oeser¹, A. Dickson², L. Daniel², N. Cox³, R. Tao³, C. Chung², W-Q. Wei⁴, M. Stein², Q. FENG⁵; ¹Vanderbilt Med. Ctr., Nashville, TN, ²Vanderbilt Univ. Med. Ctr., Nashville, TN, ³Vanderbilt Univ Med Ctr., Nashville, TN, ⁴Vanderbilt Univ, Nashville, TN, ⁵Vanderbilt Univ. Med. Ctr.I, Nashville, TN

Abstract Body:

Introduction: Sepsis accounts for one in every three in-hospital deaths and for 13% of hospital costs in the U.S. Classic twin studies of infections and recent genetic studies on COVID19 suggest that host genetics contribute to sepsis. However, we know little about genetic predictors of sepsis, especially in patients with infections. In the current study, we leveraged the de-identified electronic health records (EHRs) linked to DNA samples in the biobank at Vanderbilt (BioVU). We conducted GWAS on the risk of (1) sepsis and (2) septic shock in patients hospitalized with infections.

Methods: We identified 11,989 White, and 2,096 Black adults who (1) were admitted to Vanderbilt University Medical Center with an infection requiring antibiotics and (2) had genome-wide genotyping available. Sepsis was defined by the Sepsis-3 criteria of concurrent infection and organ dysfunction using diagnosis codes (ICD), procedure codes, lab tests, and keywords from the chart. Septic shock was defined by the ICD codes for septic shock/severe sepsis (995.92, 785.52, R65.20, and R65.21). We tested associations between genotypes and risk of sepsis or septic shock using logistic regression and adjustment for sex, age, age², and 10 PCs of ancestry to account for residual population structure.

Results: During the hospital stay, 3,546 White and 521 Black patients developed sepsis, including 1386 and 152 with septic shock, respectively. Among patients who developed sepsis, there were fewer women (46.5%) than men, and Black patients were younger (51.8±16.9 years) than White patients (58.2±15.9 years). In GWAS analyses, rs77960372-A was associated with an increased risk of septic shock in White patients (upstream of CD166; odds ratio [OR], 2.98; p=4.6×10⁻⁸); CD166 is a member of a subfamily of immunoglobulin receptors and it may be involved in inflammation through its regulation of members of the NF-κB family. There was a suggestive association with an increased risk of septic shock in Black patients for rs111587601-A (close to DYRK2; OR, 3.7; p=6.9×10⁻⁸); DYRK2 was previously reported to be part of an expression signature of 7 genes associated with outcomes in patients with sepsis.

Conclusion: In a GWAS on the risk of sepsis and septic shock in patients hospitalized with infections we identified two potential genetic signals close to CD166 and DYRK2 genes.

Complex Traits Posters - Wednesday

PB1422. Genome-wide association analysis of composite sleep scores in 413,904 individuals

Authors:

H. Wang¹, M. O. Goodman¹, J. M. Lane¹, H. S. Dashti², J. Chung¹, T. Sofer¹, S. M. Purcell¹, X. Zhu³, M. K. Rutter⁴, S. Redline¹, R. Saxena²; ¹Brigham and Women's Hosp., Harvard Med. Sch., Boston, MA, ²Massachusetts Gen. Hosp., Harvard Med. Sch., Boston, MA, ³Case Western Reserve Univ., Cleveland, OH, ⁴Manchester Univ., Manchester, United Kingdom

Abstract Body:

Recent genome-wide association studies (GWAS) of self-reported sleep traits have identified hundreds of genetic loci, often in genes and biological pathways that are shared across sleep phenotypes. Modeling the multiple dimensions of sleep may allow identification of common underlying genetic mechanisms and complement analyses of individual traits. Moreover, accounting for phenotypic and genetic correlations between traits has the potential to enhance signal in noisy measurements. To help identify the biological bases common to multiple sleep characteristics, we performed GWAS of two composite sleep scores derived from sleep questionnaires characterizing 413,904 individuals of European ancestry from the UK Biobank. Questionnaire items included information on self-reported sleep duration, chronotype, insomnia, snoring, and daytime sleepiness. We constructed an additive sleep score as a sum of up to five favorable sleep behaviors (having sleep duration of 7-8 hours, early chronotype, few insomnia symptoms, no snoring, and no excessive daytime sleepiness). We also performed principal component (PC) analysis to extract a composite sleep score (PC1) as the weighted sum explaining the highest proportion of the combined phenotypic variance. Higher PC1 value is interpretable as a sleep deficiency phenotype (shorter sleep duration, frequent insomnia symptoms, and excessive daytime sleepiness). Separate GWAS of additive and PC1 sleep scores identified, respectively, 7 and 15 novel loci, containing genes that function in nervous system development (*CNTN3*), mTORC1 signaling (*FNIP2*), and immune response pathways (*IGSF21* and *KLRG1*). Both composite sleep approaches revealed novel genetic mechanism of related sleep behaviors, while retaining clinical and biological interpretability. In the next step, we will construct an analogous heritability-maximizing composite sleep score, and study the genetic overlap between composite sleep scores with cardiometabolic, inflammatory, and psychiatric traits using genetic correlation and Mendelian randomization analyses.

Complex Traits Posters - Thursday

PB1423. Genome-wide association meta-analysis and burden of rare coding variants in African American patients with Acne

Authors:

A. Saeidian¹, H-Q. Qu², M. March², Y. Liu³, J. Glessner², H. Hakonarson⁴; ¹Ctr. for Applied Genomics, Children's Hosp. of Philadelphia, Philadelphia, PA, ²Children s Hosp. of Philadelphia, Philadelphia, PA, ³The children's Hosp. of philadelphia CHOP, Philadelphia, PA, ⁴Children's Hosp. of Philadelphia, Philadelphia, PA

Abstract Body:

While Acne is mostly a disorder of adolescence, it persists into middle age in a significant number of individuals. A broad range of evidence primarily from twin studies suggests that acne is a disorder of genetic susceptibility. Acne consists of a broad spectrum of diseases varying in the age of onset and resolution and in severity, type, and distribution of lesions that primarily impact facial skin. Here, we perform a GWAS meta-analysis and evaluated the aggregate contribution of predicted deleterious low-frequency and rare variants in the minority African American (AA) population. We performed a GWAS meta-analysis on blood-derived DNA of 4853 AA individuals, including 2811 males, 2011 females, and 22578 AA controls without acne. The cases and the controls are matched in age of diagnosis and sex. The samples are extensively stratified into sub-cohorts by coexisting obesity, polycystic ovary disease, a steroid medication, and specific combinations of >1 comorbid conditions. For rare variants, SNP-set Kernel Association Test (SKAT) was done in stratified sub-cohorts of a total of 5000 AA cases and controls sequenced by whole genome sequencing (WGS). We identified several candidate genes with the strongest enrichment ($P < 5E-08$ in GWAS and $P < 1E-06$ in WGS, respectively), results that are currently being replicated in independent samples of European populations. Further experimental study is being designed to clarify the functional mechanisms of the genes in acne, pending for validation results in European.

Complex Traits Posters - Wednesday

PB1424. Genome-wide association meta-analysis reveals 99 risk loci for pain susceptibility and pleiotropic relationships with psychiatric, metabolic, and immunological traits.

Authors:

E. Mocchi^{1,2,3}, K. Ward¹, S. Dorsey^{1,3}, S. Ament^{2,4}; ¹Dept. of Pain & Translational Symptom Sci., Univ. of Baltimore, Sch. of Nursing, Baltimore, MD, ²Inst. for Genome Sci., Sch. of Med., Univ. of Maryland, Baltimore, MD, ³Ctr. to Advance Chronic Pain Res. (CACPR), Univ. of Maryland Baltimore, Baltimore MD, Baltimore, MD, ⁴Dept. of Psychiatry, Univ. of Maryland Sch. of Med., Baltimore, MD

Abstract Body:

Chronic pain is at epidemic proportions in the United States, represents a significant burden on our public health system and is coincident with a growing opioid crisis. There are substantial individual differences in pain susceptibility, with patients who have seemingly identical injuries often reporting different pain intensities, likely explained by genetic factors.

We conducted a meta-analysis of genome-wide association study (GWAS) summary statistics from seventeen pain susceptibility traits in the UK Biobank. The selected traits included eight phenotypes describing types of pain experienced in the last month (headache, neck/shoulder, back, stomach/abdominal, hip, knee, pain all over the body and pain any), two phenotypes related to chronic pain lasting three months or longer (headache and back), five phenotypes related to the use of pain relief medications, and two phenotypes related to cardiovascular pain (chest pain and leg pain on walking). Combined analysis of the 17 selected pain related traits was carried out using the software PLEIO, which corrects for environmental correlations due to sample overlap. This analysis revealed 99 genome-wide significant risk loci, 65 of our 99 risk loci overlap loci from previous studies, while the remaining 34 loci are novel.

We used a leave-one-trait-out meta-analysis approach to evaluate the robustness of our results and the influence of each individual trait on the joint analysis. Thirty-seven of the 99 loci reached genome-wide significance in all leave-one-trait-out analyses, including many of those with the strongest joint p-values, e.g., 12q13.3 (P-value 6.8e-72; *LRP1*, *STAT6*), 1q22 (P-value 6.2e-29; *MEF2D*), and 17q21.31 (P-value 1.96e-28; *CRHRI*), while 22 regions were mostly driven by a single trait, among them 12p12.1 (P-value 3.56e-11; *SOX5*) for back pain, 20q11.22 (P-value 2.8e-17; *GDF5*) for knee pain and 7p14.1 (P-value 4.7e-17; *SUGCT*) for headache.

Risk loci were enriched for genes involved in neurological and inflammatory pathways. Furthermore, genetic correlations and two-sample Mendelian randomization indicated that depression, neuroticism, metabolic, cardiovascular and immunological traits mediate the risk of pain in these loci, with the strongest effects from neuropsychiatric (odds ratio=1.48; 95%CI:1.23-1.77; P-value=2.95E-05) and immunological traits (odds ratio=2.05; 95%CI:1.40-3.00; P-value=2.09E-04).

Our analyses suggest a complex genetic architecture linking genetically correlated pain phenotypes and related traits.

Complex Traits Posters - Thursday

PB1425. Genome-wide association of Copy Number Variation for Cleft Lip with or without Cleft Palate in families from a multi-ethnic study sample.

Authors:

N. Mukhopadhyay¹, E. Leslie², E. Feingold³, M. L. Marazita⁴; ¹Univ Pittsburgh/Sch Dental Med, Pittsburgh, PA, ²Emory Univ., Atlanta, GA, ³Univ of Pittsburgh, Pittsburgh, PA, ⁴Univ Pittsburgh, Ctr. for Craniofacial and Dental Genetics, Pittsburgh, PA

Abstract Body:

Orofacial clefts (OFCs) comprise one of the most common forms of birth defects worldwide, posing a large public health burden, due to the social, emotional and financial consequences for individuals affected with OFCs, their families, and society. Thus, identifying the etiologic factors for OFCs is vital for assessing risk, developing prevention methods, and determination of the extent of therapeutic and social support needed by affected individuals and families. OFCs vary by manifestation and severity, and are grouped broadly into cleft lip with or without cleft palate (CL/P) and cleft palate alone (CP). The majority of OFCs - 70% of CL/P and 50% of CP - occur without any other detectable cognitive or structural abnormality. Identifying the genetic causes of non-syndromic OFCs has been largely limited to the study of polymorphic markers such as SNPs; very few have explored the association between copy number variation (CNV) and OFC risk. Further, prior CNV studies were limited by the sample size and/or target regions analyzed. Our current study investigates whether the presence/absence of an abnormal copy number (specifically a deletion or duplication) is associated with non-syndromic CL/P. In our study, *de novo* and inherited CNVs are treated and analyzed similarly, under the assumption that both may be similarly disruptive to gene functioning. Subjects drawn from a multiethnic GWAS sample from the Pittsburgh Orofacial Cleft Study (POFC) are included in this study. CNVs were identified based on genotype intensities from a GWAS panel of SNPs, and the copy numbers at predetermined genomic coordinates located across the genome - normal vs. abnormal - analyzed within a variance-component based case-control GWAS framework. GWASs were run on the entire POFC sample, as well as subsets defined based on their ancestry. A strong association signal (most significant p-value ~ 10E-32) was observed within a region spanning a 50 KB region in 7p14.1 in the total POFC sample. The most strongly associated ancestry group was the Central and South American subset (p-value ~ 10E-26), with the European subset showing a modest association as well (p-value < 10E-05). In an earlier study of only European trios, *de novo* CNVs in this region were reported as being associated with CL/P risk. Thus our study confirms the earlier finding in Europeans, and extends the finding to trios from Central and South America. Fine-mapping and functional investigation of these and other potential associations are currently underway.

Complex Traits Posters - Wednesday

PB1426*. Genome-wide association of NASH and Mendelian randomization with plasma protein levels identifies putative protein changes resulting from disease.

Authors:

E. Smith¹, L. Sundararajan², S. Held², E. Sundaram², E. Uberbacher², M. Leuze², S. Badola³, R. Mikkilineni³, J. Schneider², D. Diogo³, L. Ekstrom², J. Stover², S. Szalma¹; ¹Takeda Dev. Ctr. Americas, Inc., San Diego, CA, ²Nashville BioSci.s, Nashville, TN, ³Takeda Dev. Ctr. Americas, Inc., Cambridge, MA

Abstract Body:

Nonalcoholic steatohepatitis (NASH) is estimated to affect 5% of adults in the United States, however only a fraction of those affected are diagnosed due to risks associated with liver biopsy. Currently, noninvasive blood biomarkers have been identified that can help identify patients that are likely have NASH, but have limitations in predicting stage or disease progression. Identifying proteins with levels that change as a result of disease could point to novel biomarkers or mechanisms in disease progression that could help diagnose and monitor patients with NASH. Recent advances in high throughput plasma proteomics now allows for profiling of 1000's of proteins in the plasma proteome. Large-scale studies, such as the UK Biobank Pharma Proteomics Project (UKB-PPP), are enabling well-powered Mendelian randomization studies that could identify causal links between disease and protein levels. To improve the genetic understanding of NASH and allow for Mendelian randomization analysis, we performed a genome-wide association study (GWAS) of non-alcoholic fatty liver disease (NAFLD) patients that we further classified as likely-NASH or likely non-alcoholic fatty liver (NAFL). NAFLD patients were identified from electronic health record data in participants of European ancestry in the BioVU database. Patients were classified as likely-NASH or likely-NAFL using a combination of diagnosis codes, biopsy reports, imaging reports, ALT measures, and keywords. Controls had no reported liver disease and were matched to cases by age and sex. Genome-wide association of 1,542 likely-NASH patients vs 6,538 control participants identified two previously reported loci: PNPLA3 and HSD17B13. We performed meta-analysis with a recently published NAFLD GWAS including NASH patients (Anstee et al.) and identified 4 additional loci that have been previously implicated in NASH: MARC1, GCKR, TRIB1, and TM6SF2. To identify proteins that might be affected as a result of NASH, we tested for association between the 6 lead variants and 1469 protein levels in 36,3741 unrelated participants of White British ancestry from the UKB-PPP. We performed two-sample Mendelian randomization and identified 108 proteins significantly associated using the weighted median test (FDR < 0.05). Significantly associated proteins were enriched for being metabolic enzymes and were highly expressed in liver hepatocytes. These results highlight the utility of large-scale proteomic studies for identifying putative biomarkers of disease and implicate a large number of proteins that may have utility in identifying patients with NASH or in monitoring disease course.

Complex Traits Posters - Thursday

PB1427. Genome-wide association studies identify genetic variants associated with comorbidities in atopic dermatitis

Authors:

A. Hartley¹, J. Saklatvala², R. Ramessur³, A. Budu-Aggrey¹, C. Smith³, S. Brown⁴, J. Min¹, N. Dand², L. Paternoster¹; ¹MRC-Integrative Epidemiology Unit, Population Hlth.Sci., Bristol Med. Sch., Bristol, United Kingdom, ²Dept. of Med. and Molecular Genetics, King's Coll. London, London, United Kingdom, ³St John's Inst. of Dermatology, King's Coll. London, London, United Kingdom, ⁴Ctr. for Genomic and Experimental Med., Inst. of Genetics and Cancer, Univ. of Edinburgh, Edinburgh, United Kingdom

Abstract Body:

Background: Atopic dermatitis (AD), also referred to as eczema, is a common skin condition with a substantial comorbid burden, including other atopic conditions (e.g. asthma and food allergy). To further elucidate the genetic aetiology of comorbidities in AD, we performed GWAS of relevant comorbidities stratified by AD status in UK Biobank.

Methods: Using the white European subset of UK Biobank, we analysed 36 comorbidities with a prevalence $\geq 2\%$ in UK Biobank, selected by expert review and epidemiological evidence. AD and comorbidities were identified based on self-report, hospital episode statistics, cancer and death registry data. GWAS were performed for each comorbidity, separately for 13,965 AD cases and 349,805 controls and we then performed an interaction Z-test to test for differences in SNP-comorbidity associations between cases and controls. Bolt linear mixed models were fitted on SNPs with a minor allele frequency ≥ 0.01 and an imputation INFO score ≥ 0.7 . Analyses were adjusted for age, sex and ten principal components.

Results: Sixty-nine independent genome-wide significant ($p \leq 5 \times 10^{-8}$) SNPs were identified across 20 comorbidities in the AD case population. Most of these SNPs displayed stronger associations with comorbidity in AD cases compared to controls, as evidenced by genome-wide significant p-values in the interaction test for 43 of these SNPs. Additionally, six SNPs with stronger effects in cases compared to controls, but with p-values $> 5 \times 10^{-8}$ in the case-only GWAS, were identified by the interaction test. Of the 49 SNPs associated with a condition more strongly amongst AD cases than controls, 22 SNPs were intronic, including *IGF1R* for congestive heart failure, *ST6GALNAC3* for type 2 diabetes and *ACE* for myocardial infarction.

In stratified analyses such as these, index-event bias may influence results. To assess the potential influence of index-event bias, we examined the SNP associations with AD in the latest 'Early Genetics and Lifecourse Epidemiology' consortium AD GWAS. Twenty-seven of the 49 SNPs showed no association with AD ($p > 0.05$), excluding the possibility of index-event bias. However, 18 SNPs were associated with AD ($p \leq 5 \times 10^{-8}$) and therefore interactions may be explained by this bias. These SNPs were associated with asthma and were mainly clustered around the strongly-replicated *FLG* locus on chromosome 1q21.3.

Conclusions: Our work has identified SNPs with potential roles in comorbidity associated with AD. A better understanding of the genetic mechanisms contributing to the burden of comorbidity in AD may in the future aid attempts to target these patient subgroups for more effective preventative or therapeutic strategies.

Complex Traits Posters - Wednesday

PB1428. Genome-wide association studies of human and rat body mass converge on a conserved molecular network.

Authors:

B. Leger¹, S. Wright¹, B. Rosenthal¹, J. Kreisberg¹, S. Liu¹, T. Jia¹, A. Chitre¹, O. Poleskaya¹, K. Holl², J. Gao¹, R. Cheng¹, A. Martinez³, G. Tony⁴, A. Gileta⁵, H. Chen⁶, S. Fligel⁷, P. Meyer⁸, T. Robinson⁷, L. Solberg-Woods⁹, T. Ideker¹, A. Palmer¹; ¹Univ. of California San Diego, La Jolla, CA, ²Med. Coll. of Wisconsin, Milwaukee, WI, ³The Univ. of Tennessee Hlth.Sci. Ctr., Memphis, TN, ⁴Univ. of Toronto, Toronto, ON, Canada, ⁵Univ. of Chicago, Chicago, IL, ⁶Univ. of Tennessee Hlth.Sci. Ctr., Memphis, TN, ⁷Univ. of Michigan, Ann Arbor, MI, ⁸Univ. of Buffalo, Buffalo, NY, ⁹Wake Forest Univ., Winston-Salem, NC

Abstract Body:

Translation of polygenic findings across species is critical for understanding the mechanisms driving normal and disease phenotypes, and for gaining clearer understanding of how well model organism paradigms recapitulate human biology. Here, we demonstrate a network genetic approach to identify the conserved and divergent mechanisms identified in GWASs for body mass index (BMI) in humans and rats. While the specific genes associated with BMI from GWAS show non-significant cross-species agreement, we show highly-significant alignment when analyzing the genes in the context of a network (PCNet, a network of 2.7 million physical and functional gene associations). In particular, we find that the conserved network highlights brain-expressed genes and mechanisms, including hormone regulation, epigenetic regulation, and cellular signaling. To clarify the unshared biology between the two species, we also identify divergent mechanisms for the two species using a similar approach. These disparate processes include water transport in rats, and additional epigenetic processes in humans. We validate these networks using functional studies in mice that are summarized by the Mouse Genome Database. This validation demonstrates conserved function across three distinct mammals evolutionarily separated by ~100M years. This study provides a roadmap for factoring any genotype-phenotype association carried out in multiple species into discrete sets of conserved and divergent molecular pathways and processes. Further, it is a novel method for clarifying whether studies in model organisms accurately model the polygenic signals identified by genetic studies in humans.

Complex Traits Posters - Thursday

PB1429. Genome-wide association study analysis of glucose response in oral glucose tolerance test (OGTT).

Authors:

V. Thaker¹, W. Gu², S. Cao², R. Salem²; ¹Columbia Univ Med Ctr, New York, NY, ²Univ. of California, San Diego, La Jolla, CA

Abstract Body:

The shape of the glucose response curve during an oral glucose tolerance test (OGTT), monophasic versus biphasic, identifies physiologically distinct group of individuals with differences in insulin secretion and β -cell sensitivity. The subjects with biphasic glucose curve, defined as a rebound of glucose following a nadir ≥ 0.025 mmol/L, have higher insulin sensitivity and β -cell function. The genetic variants linked with such glucose response have not been defined. **Method:** We performed a genome wide association study (GWAS) to identify genetic variants associated with biphasic profile using data from the Hyperglycemia and Adverse Pregnancy Outcome (HAPO) study retrieved from dbGaP. Eligible pregnant women from diverse ethnicities underwent a standard 75-g OGTT between 24-32 weeks gestation: Afro-Caribbean- (AC, n = 1345), European- (EA, n = 1507), Hispanic- (HL, n = 889), and Thai-Asian (TA, n= 1253) ancestry. Two glucose response outcomes were constructed: i) Quantitative: glucose-difference (Gluc-diff) between glucose levels at hours 2 and 1 of OGTT and ii) Binary: biphasic (Gluc-diff ≥ 0) vs. monophasic (Gluc-diff < 0). GWAS analyses were performed for each ancestry group using SAIGE, controlling for age, BMI, type 2 diabetes (T2D), and first three principal components. Ancestry specific results were combined using METAL and loci annotated using BioThings. **Results:** We identified 814 subjects with biphasic OGTT response (AC=299, EA=244, HL=131 and TA=140). The ancestry specific analyses identified an intronic variant rs10830963 in the melatonin receptor 1B (*MTNR1B*, $\beta=-6.67$, $p=4.51E-09$) with Gluc-diff in EA, that remained significant in transancestry meta-analysis ($p=2.37E-09$). *MTNR1B* is established gene for T2D and glycemia related traits. Known prioritized genes for suggestive threshold loci ($10E-6$) in transethnic metanalysis are involved in insulin biology/metabolic pathways: *ATXN1* (adipocyte differentiation, waist-hip ratio), *CNDP2* (diabetic nephropathy), *SGCZ* (T2D), *TCF12* (T2D), *NKAIN1* (BMI, BMI-adjusted hip ratio), *KIF17* (ciliary transcription factor) for binary outcome and *SGMS1* (lipid metabolism) for quantitative outcome. Other intergenic/intronic loci of unknown significance were also prioritized. **Conclusion:** Use of a novel phenotype for glucose regulation may identify additional loci and/or genes relevant to insulin biology/metabolism that may or may not be known with more traditional measures. Prior studies have validated the relevance of genes prioritized in gestational diabetes for general population; future replication studies are planned to establish their role in non-pregnant state.

Complex Traits Posters - Wednesday

PB1430*. Genome-wide association study for 233 circulating metabolic traits in 136,000 participants reveals extensive pleiotropy and novel associations.

Authors:

M. Karjalainen¹, S. Karthikeyan², E. Sliz¹, NMR Metabolomics and Genetics Consortium, M. Ala-Korpela¹, A. S. Butterworth², J. Kettunen¹; ¹Univ. of Oulu, Oulu, Finland, ²Univ. of Cambridge, Cambridge, United Kingdom

Abstract Body:

Introduction: Genome-wide association studies utilizing high-throughput metabolomics have identified multiple loci associated with circulating metabolic traits. Knowledge on the genetic determinants of systemic metabolism gives novel insights into the biological pathways affecting complex diseases. **Methods:** We performed a GWAS of 233 circulating metabolic traits quantified by nuclear magnetic resonance spectroscopy (NMR) in over 136,000 participants from 33 cohorts, thereby considerably expanding our previous GWAS which included 123 traits and 25,000 participants. GWAS was followed by multiple downstream analyses, including detailed characterization of metabolic profiles of lipid and lipoprotein-associated variants, characterization of disease associations of the metabolic trait-associated variants, and Mendelian randomization of twenty non-lipid traits. **Results:** Significant associations were identified for all 233 metabolic traits. Associations were detected at 276 genomic regions that corresponded to over 400 independent loci, which is a substantial improvement compared to our previous study which identified 62 loci. Novel loci were identified for multiple metabolic traits. As an example, associations at 26 loci were detected for glutamine, several of which were novel. Many loci showed extensive pleiotropy. Detailed characterization of metabolic profiles of 84 novel lipid- and lipoprotein-associated loci revealed that the metabolic profile of *TRIM5*, a novel coronary artery disease-associated locus, is similar to that of *HMGCR* whose effects are concordant to statin therapy. Many metabolic trait-associated variants associated with diseases. One such disease was intrahepatic cholestasis of pregnancy, whose genetic determinants and metabolic underpinnings were characterized here for the first time. Mendelian randomization analyses demonstrated causal relationships between non-lipid traits and diseases, implying, e.g., a causal association of acetoacetate (a ketone body) with hypertension. **Conclusions:** Our GWAS of 233 circulating metabolic traits revealed genetic associations in over 400 independent loci. The five-fold increase in sample size and doubling the number of metabolic traits compared to our previous NMR metabolomics GWAS resulted in a large increase in the number of significant associations, leading to a substantial improvement in understanding of genetic regulation of systemic metabolism. Extensive pleiotropy, novel associations and causal relationships were detected.

PB1431. Genome-Wide Association Study in a Rat Model of Temperament Identifies Multiple Loci for Exploratory Locomotion and Anxiety-Like Traits.

Authors:

A. Chitre¹, E. Hebda-Bauer², P. Blandino², K-M. Nguyen¹, P. Maras², F. Li², S. Flagel², A. Ozel², O. Polesskaya¹, R. Cheng¹, S. Watson, Jr.², J. Li³, A. A. Palmer⁴, H. Akil²; ¹Univ. of California San Diego, La Jolla, CA, ²Univ. of Michigan, Ann Arbor, MI, ³Univ Michigan, Ann Arbor, MI, ⁴Univ. of California San Diego, LA JOLLA, CA

Abstract Body:

Common genetic factors likely contribute to multiple psychiatric diseases including mood and substance use disorders. Certain stable, heritable traits reflecting temperament, termed externalizing or internalizing, play a large role in modulating vulnerability to these disorders. To model these heritable tendencies, we selectively bred rats for high and low exploration in a novel environment (bred High Responders (bHR) vs. Low Responders (bLR)). Although selective breeding has been carried on for tens of generations, the bHR and bLR retain significant genetic diversity, although the sites under the strongest selection are likely to be divergently fixed or nearly fixed when contrasting the bHR and bLR. To identify genes underlying the response to selection, we phenotyped and genotyped 538 rats from an F2 cross between bHR and bLR. The SNP heritability estimates for these behavioral traits ranged from 0.06 to 0.79. There were significant phenotypic and genetic correlations between tests that capture facets of exploratory locomotion and anxiety. Ten significant and conditionally independent loci for six behavioral traits were identified. Five of the six traits reflect different facets of exploratory locomotion that were captured by three behavioral tests. Distance traveled measures from the open field and the elevated plus maze map onto different loci and may, thus, represent different aspects of novelty-induced locomotor activity. The sixth behavior trait is the only anxiety-related trait mapping to a significant locus on chromosome 18 within which the *Pik3c3* gene is located. We also identified *Fancf* and *Gas2* as potential candidate genes that may drive the chromosome 1:107 Mb QTL for exploratory locomotion traits. The identification of a locomotor activity-related QTL on chromosome 7 encompassing the *Pkhd111* and *Trhr* genes is consistent with our finding of these genes being differentially expressed in the hippocampus of bHR vs. bLR rats. The strong heritability coupled with identification of several loci associated with exploratory locomotion and emotionality provide compelling support for this selectively bred rat model in discovering relatively large effect causal variants tied to elements of internalizing and externalizing behaviors relevant to psychiatric and substance use disorders.

PB1432. Genome-wide association study in mesial temporal lobe epilepsy with hippocampal sclerosis

Authors:

E. Bruxel^{1,2}, P. H. M. Magalhães^{1,2}, T. K. de Araujo^{1,2}, T. C. de Oliveira^{1,2}, M. K. M. Alvim^{1,2}, M. E. Morita-Sherman^{1,2}, R. Secolin^{1,2}, C. L. Yasuda¹, B. Leal³, J. Chaves³, A. M. Ferreira³, A. M. da Silva³, L. E. Betting⁴, K. Lin⁵, R. Walz⁵, M. R. Rodrigues⁶, T. Hünemeier⁶, L. V. Pereira⁷, A. C. Pereira⁸, F. Cendes^{1,2}, I. Lopes-Cendes^{1,2}; ¹Univ. of Campinas, Campinas, Brazil, ²Brazilian Inst. of NeuroSci. and Neurotechnology (BRAINN), Campinas, Brazil, ³Univ. of Porto, Porto, Portugal, ⁴São Paulo State Univ., Botucatu, Brazil, ⁵Federal Univ. of Santa Catarina, Florianópolis, Brazil, ⁶Univ. of São Paulo, São Paulo, Brazil, ⁷Univ. de São Paulo, São Paulo, Brazil, ⁸Harvard Med. Sch., Boston, MA

Abstract Body:

Introduction: Mesial temporal lobe epilepsy (MTLE) is a chronic neurological disorder characterized by the occurrence of spontaneous seizures initiated in the mesial temporal lobe structures. MTLE is a type of focal epilepsy frequently associated with a characteristic histopathological lesion denominated hippocampal sclerosis (HS). Many patients with MTLE+HS have severe epilepsy, which is often resistant to treatment with antiseizure medication. Recent genome-wide association metanalysis found suggestive evidence of association to two loci on chromosomes (ch)s 3q25.41 and 6q22.31 in patients with focal epilepsy and HS, and a locus on ch 2q24.3 for all focal epilepsies combined [1]; however, to our knowledge, these results have not been replicated. **Materials and Methods:** We studied 501 patients and 1.146 controls. Patients with MTLE+HS were ascertained in several epilepsy centers in Brazil and Portugal. All patients fulfilled the diagnostic criteria for MTLE+HS proposed by the International League Against Epilepsy. In addition, controls were ethnically matched to patients. We used the Affymetrix 6.0 array for SNP genotyping. **Results:** Principal component analyses showed no significant differences in the genomic composition of patients and controls and were used as covariates in the association study. After quality control, we used an additive model for the association to perform a logistic regression. We found four novel association signals at chs 7 ($p = 5.689e^{-10}$), 9 ($p = 2.68e^{-10}$), 12 ($p = 2.989e^{-10}$) and ch 14 ($p = 3.645e^{-8}$). **Discussion/Conclusion:** The SNPs associated with the phenotype are in introns and intergenic regions, suggesting that regulatory elements are likely to be involved in the genetic predisposition to MTLE+HS. Future steps in this project aim to perform local ancestry inference and integrate transcriptomic and epigenomic data to identify putative causal variants. **Funding:** Fundação de Amparo à Pesquisa do Estado de São Paulo (FAPESP), SP, Brazil. **Reference:** [1] International League Against Epilepsy Consortium on Complex Epilepsies. Nat Commun 9(1): 5269, 2018.

Complex Traits Posters - Thursday

PB1433. Genome-wide association study of diabetic retinopathy in the Million Veteran Program identifies four significant loci

Ctr., Decatur, GA, ⁵Emory Univ., Atlanta, GA, ⁶Providence VA Med. Ctr., Providence, RI, ⁷Phoenix VA Hlth.Care System, Phoenix, AZ, ⁸Arizona Univ., Phoenix, AZ, ⁹Massachusetts Gen. Hosp., Boston, MA, ¹⁰Broad Inst., Cambridge, MA, ¹¹Stanford Univ., Palo Alto, CA, ¹²VA Northeast Ohio Hlth.care System, Cleveland, OH, ¹³Case Western Reserve Univ., Cleveland, OH, ¹⁴Louis Stokes Cleveland VA Med. Ctr., Cleveland, OH, ¹⁵Cole Eye Inst., Cleveland Clinic, Cleveland, OH

Abstract Body:

Diabetic retinopathy (DR) is the leading cause of vision loss and preventable blindness in adults, affecting an estimated 93 million individuals worldwide. The course of diabetes and severity of complications vary substantially among individuals, and this variability is not fully explained by risk factors such as glycemic control. Several genome-wide association studies (GWAS) of DR have been conducted, and while significantly associated loci have been reported, few have replicated. We used a validated electronic health record algorithm to identify DR cases (proliferative, severe non-proliferative, moderate non-proliferative, and unspecified DR; total N = 33,627) and controls with diabetes but without retinopathy (N = 52,388) in the Million Veteran Program. GWAS of TOPMed imputed SNPs were conducted using logistic regression adjusting for age, sex, body mass index, hypertension status, duration of diabetes, and the top ten principal components. Analyses were stratified using the harmonized ancestry and race/ethnicity (HARE) approach and three groups were included in the present study: European (21,486 cases/35,986 controls), African American (8,559 cases/12,079 controls), and Hispanic (3,582 cases/4,323 controls). We identified one, two, and one genome-wide significant loci in the European, African American, and Hispanic populations, respectively. All genome-wide significant SNPs identified in the analysis of European ancestry individuals were located in the intronic regions of TCF7L2, a gene previously associated with type 2 diabetes. The African American analysis identified loci in the intronic regions of CNGB3 (rs7824288 (Odds ratio [OR] = 0.83 (95% confidence interval [CI] 0.78 - 0.88), p = 3.44x10⁻⁹) and ARHGAP29-AS1 (rs55937938 (OR = 1.29 (95% CI 1.18 - 1.41), p = 1.75x10⁻⁸)). The Hispanic analysis identified rs61833024, intergenic on chromosome one, (OR = 0.35 (95% CI 0.24 - 0.51), p = 2.71x10⁻⁸). While the significant locus identified in the European population may be a proxy for glycemic control, the loci identified in the Hispanic and African American analyses have not been previously associated with DR and their role is not yet defined. With the resources of the Million Veteran Program, we conducted the largest multi-ancestry GWAS of Hispanic, African American, and European populations to date, identifying three previously unreported loci associated with DR in populations underrepresented in genomic research.

Complex Traits Posters - Wednesday

PB1434. Genome-wide association study of longitudinal changes in motor symptomology in Parkinson's Disease

Authors:

W. Kim¹, F. Tao¹, S. Hall^{2,3}, O. Hansson^{2,3}, M. Nagle¹; ¹Genetics Guided Dementia Discovery (G2D2) Eisai Inc., Cambridge, MA, ²Dept. of Clinical Sci., Lund Univ., Malmo, Sweden, ³Memory Clinic, Skane Univ. Hosp., Malmo, Sweden

Abstract Body:

Introduction: To date, there are no therapeutics to slow the progression of Parkinson's Disease (PD), which would have tremendous impact for patients. While genome-wide association studies (GWAS) have identified genetic factors associated with risk of PD, genetic determinants of motor progression of PD remain largely unknown. At Eisai's G2D2 research institute, we apply human genetics to discover novel drug targets for neurodegenerative disease. Given our ongoing work, this study aims to identify the genetic influences of motor progression of PD in two longitudinal cohorts, Accelerating Medicines Partnership Parkinson's disease (AMP-PD) and Biomarkers For Identifying Neurodegenerative Disorders Early and Reliably (BioFINDER), and the published GWAS of progression of PD clinical endpoints in 12 longitudinal patient cohorts (Iwaki et al., 2019).

Methods: We examined seven PD clinical measures, including the Unified Parkinson's Disease Rating Scale (UPDRS) or Movement Disorder Society revised UPDRS Part I to IV and total score, modified Schwab & England activities of daily living scale, and Hoehn and Yahr (HY) staging scale. In AMP-PD and BioFINDER cohorts, genetic and longitudinal phenotype data were available on a total of 3,164 subjects with 19,540 observations for a median of 1.5 years. We derived a slope of longitudinal change using the linear mixed model with each subject's deviation as the random effect. We then regressed this slope estimate on an imputed genome-wide marker under an additive genetic model for each cohort. Age at baseline, sex, clinical site if needed, and principal components were included as covariates. We meta-analyzed 2 GWAS results from AMP-PD and BioFINDER and one published GWAS result from a total of 4,093 patients with 22,307 observations for a median of 3.81 years under the inverse-variance fixed model. We then performed candidate gene analysis focusing on 78 reported PD risk loci to determine whether genome-wide significant PD susceptibility loci are associated with the progression of PD clinical measures.

Results: We did not identify genetic loci reaching genome-wide significance in our meta-analysis. However, in the candidate gene analysis, rs12528068-T near *RIMS1* (Regulating Synaptic Membrane Exocytosis 1) was associated with the annual increase in HY score, passing the Bonferroni corrected p-value (Beta=0.27, P=6.26E-04, Minor allele frequency=0.29). This genetic locus was reported to be associated with an increased risk of PD (Beta=0.07, P=1.63E-10).

Conclusions: Our study identified a genetic locus associated with both susceptibility and progression of PD. Further study is required to replicate our findings.

Complex Traits Posters - Thursday

PB1435. Genome-wide association study of nephrotic syndrome replicates *APOLI* and MHC loci, while predicted gene expression analysis identifies *C4A*.

Authors:

J. Hellwege¹, J. H. Breeyear², E. S. Torstenson³, G. P. Jarvik⁴, O. Dikilitas⁵, I. J. Kullo⁵, R. Rowley⁶, K. Kiryluk⁷, K. Susztak⁸, T. L. Edwards¹; ¹Vanderbilt Univ. Med. Ctr., Nashville, TN, ²Vanderbilt Univ., Nashville, TN, ³Vanderbilt Univ. Med. Ctr., Nashville, TN, ⁴Univ Washington Med Ctr., Seattle, WA, ⁵Mayo Clinic, Rochester, MN, ⁶Natl. Human Genome Res. Inst., Bethesda, MD, ⁷Columbia Univ., New York, NY, ⁸Univ Pennsylvania, Philadelphia, PA

Abstract Body:

Nephrotic syndrome is characterized by heavy proteinuria (>3g/24 h), hypoalbuminemia, hyperlipidemia, and edema. The etiology of nephrotic syndrome is heterogeneous, with diverse renal pathophysiology leading to similar clinical manifestations, and prevalence varying by both age and race/ethnicity. Although some cases may be monogenic in origin, genome-wide association studies have identified common variation contributing to risk of nephrotic syndrome. We integrated imputed genotype data from Vanderbilt University's BioVU and the Electronic Medical Records and Genetics (eMERGE) network with summary statistics from Biobank Japan, UK Biobank and FinnGen, for a cross-ancestry total of 2,683 cases and 731,916 controls. Cases were identified by diagnostic codes for nephrotic syndrome, while controls were without renal disease diagnosis codes. Genetic associations with nephrotic syndrome status were modeled as a function of additive genotype, sex, and the top 10 principal components of ancestry, followed by inverse-variance weighted fixed-effects meta-analysis. Across SNPs passing quality filters and with minor allele frequency >0.01, 21 independent SNPs at 17 unique loci were significant at $p < 5 \times 10^{-8}$. The smallest p-value was found for rs2763980 ($p = 3.3 \times 10^{-16}$, odds ratio [OR] = 1.8) near *LSM2* in the class III MHC region on chromosome 6. The G1 variants of *APOLI* were also strongly associated ($p = 5.9 \times 10^{-16}$ and 9.2×10^{-16} , OR = 2.6), driven by African ancestry individuals in BioVU and eMERGE. *APOLI* is a well-known risk factor for various forms of kidney disease in African ancestry individuals, including nephrotic syndrome. Genetic correlations were estimated with LD score regression between nephrotic syndrome and estimated glomerular filtration rate (-0.3 [standard error (SE) = 0.2]), blood urea nitrogen (0.1 [SE = 0.1]), systolic blood pressure (0.2 [SE = 0.2]), and type 2 diabetes (0.7 [SE = 0.5]), but none were significant ($p > 0.1$). We also evaluated associations between nephrotic syndrome and genetically predicted gene expression using GTEx kidney cortex tissue models. One gene, *C4A*, was significant in this analysis ($p = 9 \times 10^{-11}$), with increased expression associated with decreased risk of nephrotic syndrome. Our results identified numerous loci associated with nephrotic syndrome, and suggest more shared genetic architecture with type 2 diabetes than with kidney function or blood pressure, which is consistent with diabetic kidney disease leading to nephrotic syndrome. This study provides insight into nephrotic syndrome through identification of genetic loci, shared genetic architecture, and translation to predicted renal gene expression.

Complex Traits Posters - Thursday

PB1437. Genome-wide association study of plasma amyloid β levels in older adults

Authors:

M. Aslam¹, K. Fan¹, B. Snitz¹, S. DeKosky², O. Lopez³, E. Feingold⁴, M. Kamboh⁴; ¹Univ. of Pittsburgh, Pittsburgh, PA, ²Univ. of Florida, Gainesville, FL, ³Univ. of Pittsburgh, Department of Neurology, PA, ⁴Univ of Pittsburgh, Pittsburgh, PA

Abstract Body:

In addition to the deposition of amyloid plaques in the brain, plasma levels of amyloid-beta ($A\beta$) are becoming of great interest as an important endophenotype for Alzheimer's disease (AD). Identification of genetic variants modulating plasma $A\beta$ levels could help to better understand the underlying pathways regulating $A\beta$ levels in plasma. Baseline plasma $A\beta_{40}$ and $A\beta_{42}$ levels were measured in approximately 3,000 older subjects (>75 years; 94% self-identified white), derived from the Ginkgo Evaluation of Memory (GEM) study. Plasma $A\beta_{42}/40$ ratio was calculated on subjects with both measurements. Genome-wide genotyping was performed on the available ~2,700 DNA samples using Illumina Infinium Multi-Ethnic Global-8 Kit followed by imputation through the Michigan imputation server. Genome-wide association analyses on $A\beta_{40}$, $A\beta_{42}$, and $A\beta_{42}/40$ ratio were performed on white subjects having both genotype and phenotype data. Analyses were performed using a linear regression framework implemented in PLINK, including age, sex, and the first four principal components of ancestry as covariates. FUMA GWAS (<https://fuma.ctglab.nl/>) was used for the pathway and gene-based analyses. A genome-wide significant signal was observed for plasma $A\beta_{42}$ levels on chromosome 19 in *KLHL26* (*rs11665980*, $\beta=0.06304$, $p=4.76E-08$). The same variant (*KLHL26/rs11665980*) was also associated with increased plasma $A\beta_{42}/40$ ratio ($\beta=0.06578$, $p=5.66E-08$). Interestingly, in the gene-based analysis *KLHL26* was the top gene for plasma $A\beta_{42}$ ($p=8.0914E-06$) and $A\beta_{42}/40$ ratio ($p=5.1024E-06$) and also showed association with $A\beta_{40}$ ($p=0.00071$). *KLHL26* belongs to *KLHL* family, which is involved in ubiquitin-mediated protein degradation, cytoskeletal rearrangement, and actin binding. In conclusion, our study has identified a novel *KLHL26* gene modulating plasma amyloid levels, which needs to be confirmed in independent and larger samples.

Complex Traits Posters - Wednesday

PB1438. Genome-wide association study of venous thromboembolism in women using combined oral contraceptives

Authors:

D-A. Trégouët¹, M. GERMAIN¹, P. Suchon², G. Munsch¹, N. Saut², D. Smadja³, J. Emmerich⁴, D. Bacq-Daian⁵, A. Boland⁵, J-F. Deleuze⁵, P-E. Morange²; ¹Bordeaux Population Hlth.Res. Ctr., INSERM U1219, Bordeaux, France, ²Aix Marseille Univ., La Timone Hosp., Marseille, France, ³Hematology Dept. and Biosurgical Res. Lab (Carpentier Fndn.), European Georges Pompidou Hosp., Assistance Publique Hôpitaux de Paris, Paris, France, ⁴Dept. of vascular medicine, Paris Saint-Joseph Hosp. Group, INSERM 1153, Paris, France, ⁵CNRGH, Evry, France

Abstract Body:

Millions of women worldwide use combined oral contraceptives (COC). In some age groups, more than 50% of women are using COC. COC use induces a prothrombotic state and associates with a ~five-fold increased risk of venous thromboembolism (VTE). In 2013, the pill scare has underlined the need for identifying at risk women before the first prescription of COC. However, no efficient and powerful tool is currently available to achieve this goal, in particularly because the exact underlying pathophysiological mechanisms are still not well characterized. To fill this gap and identify novel molecular players involved in COC induced VTE, we here performed the first genome-wide association study (GWAS) for VTE in COC users. Capitalizing on a sample of 964 women who developed VTE on COC and 662 COC users with no personal history of VTE, we tested the association with VTE of 10,442,711 single nucleotide polymorphisms (SNPs) with imputation criteria > 0.3 and minor allele frequency > 0.005 . One genome-wide association signal was observed at the known *ABO* locus (lead SNP rs505922, p-value = $5.28 \cdot 10^{-13}$). Haplotype analysis revealed that ABO blood A1 and B groups were associated with increased risk of VTE (OR = 1.80 [1.50 - 2.17], p = $9.4 \cdot 10^{-10}$; OR = 1.57 [1.19 - 2.08], p = $1.5 \cdot 10^{-3}$, respectively). Intriguingly, A2 blood group was found protective in this population (OR= 0.57 [0.35 - 0.92], p = 0.022). Of note, among the 4 additional loci (*DTHD1*, *IRF2*, *JADE2*, *SLC39A11*) that exhibited suggestive statistical association at $p < 10^{-6}$, two (*IRF2* and *JADE2*) have previously been found associated with plasma levels of Sex Hormone Binding Globulin (SHBG). Increased SHBG levels have already been observed in VTE patients under COC compared to healthy COC users, suggesting that genetically determined SHBG levels could serve as a biomarker for VTE in COC users. Polygenic risk score analyses are ongoing together with the replication of the *IRF2* and *JADE2* association in an independent sample of 735 VTE on COC and 735 women without VTE on COC.

Complex Traits Posters - Thursday

PB1439. Genome-wide association study on skin tags

Authors:

M. Liu¹, J. Lee¹, B. Riley-Gillis¹, N. Smaoui¹, J. F. Waring¹, M. Reppell¹, X. Zheng¹, S. Manson Brown², T. Cheng², R. Mehta², S. Peterson², A. Abbasi¹; ¹AbbVie Inc., North Chicago, IL, ²Allergan Aesthetics, Irvine, CA

Abstract Body:

Skin tags, also known as acrochordons, are common benign lesions that are more likely to develop as people age. Skin tags are mainly found where the skin folds, such as the armpits and the neck, which may be due to constant friction of skin. Although usually not painful, skin tags can impact self-image and self-esteem; therefore, understanding their etiology with a goal of avoidance or treatment merits effort. Aging, obesity and insulin resistance have been associated with skin tags, however, the biological mechanisms underlying this condition remains unknown. Moreover, as they typically manifest later in life, there could be a natural part of the aging process that is yet to be fully understood. To understand the genetic basis of skin tags a genome-wide association study (GWAS) for skin tags was run using a large-scale population cohort, UKBiobank. We created a case-control cohort using a combination of electronic health records (EHR) with 9,324 cases and 158,113 controls. The analysis was limited to participants of European ancestry and GWAS was performed using SAIGE mixed model and adjusted for age, sex, principal components, and relatedness in the mixed models. In total, we identified 3 loci for skin tags around the genes *HMCNI*, *TERT* and *ABCA1*. We found significant eQTL in skin-related sun-exposed and not-sun-exposed tissue for genes *HMCNI* and *TERT*. Interestingly, *HMCNI* has been shown to play a part in basement membrane organization of the skin. We will present genetic correlation and mendelian randomization with other obesity and skin-related traits to better understand the shared underlying biology. To our knowledge, this is the largest GWAS to date on the skin tag phenotype providing insights into the genetic contribution and biological processes involved.

Complex Traits Posters - Wednesday

PB1440. Genome-wide association study to identify genetic variants for obesity in Korean population

Authors:

S. Yang, Y. Kwak, M. Yuk, J. Lee, J. Youn, N. Song; Coll. of Pharmacy, Chungbuk Natl. Univ., Cheongju, Korea, Republic of

Abstract Body:

Background: Obesity is affected by approximately 40% of genetic factors. The previous genome-wide association studies (GWAS) for obesity have reported more than 15 genes and 100 genetic loci. But most of GWAS were performed in European and only about 20% of studies were researched in Asian. Asian have a difference in obesity criteria and might have different genetic variants from Europeans. We conducted a GWAS on obesity in Korean population to replicate previously reported genetic loci and identify novel genetic loci in East Asian.

Methods: From the Korean Genome and Epidemiology Study (KoGES) including the Health EXAminee (HEXA) study (n=58,690), the CARdioVascular disease Association Study (CAVAS, n=8,105), and the Ansan and Ansung study (n=5,493), a total of 72,288 study participants with epidemiological and genome-wide single nucleotide polymorphism (SNP) data were selected. Obesity was defined as a body mass index $\geq 25\text{kg/m}^2$ according to World Health Organization obesity classification for Asian. The previously identified 60 obesity susceptibility SNPs from the GWAS ($P < 5.0 \times 10^{-8}$) were selected for replication. In each cohort, we performed GWAS for obesity using multivariable logistic regression model with adjustment for age, sex, history of chronic diseases (i.e., diabetes, hypertension, and hyperlipidemia), and smoking status. Furthermore, the GWAS results of 3 cohorts were combined by a meta-analysis.

Results: Among the 60 SNPs previously identified by GWAS on obesity, 28 SNPs were statistically significantly replicated ($P < 0.05$), where 11 SNPs (rs633715, rs6752378, rs2030323, rs1421085, rs1558902, rs17817449, rs7185735, rs8043757, rs10871777, rs11152213, and rs17782313) had a nominal genome-wide significance ($P < 5.0 \times 10^{-8}$) in Korean population. In the meta-analysis of GWAS results for 3 cohort, we identified 69 SNPs (novel 65 SNPs and known 4 SNPs) associated with obesity ($P < 5.0 \times 10^{-8}$) showing extensive overlapping of genetic susceptibility regions (*FTO*, *ADCY3*, *BDNF*, *BDNF-AS*, *LINC00678*, *DNAJC27*, and *CRYZL2P-SEC16B*) previously identified in European. The most significant SNP for obesity was rs8050136 (16q12.2; $P = 2.2 \times 10^{-18}$) at well-known obesity gene *FTO*.

Conclusion: We identified 69 obesity-related SNPs in Korean population showing a similar aspect of obesity-associated genetic loci to European suggesting the worldwide obesity-risk genes of *FTO*, *ADCY3*, *BDNF*, *BDNF-AS*, *LINC00678*, *DNAJC27*, and *CRYZL2P-SEC16B*.

Hussman Inst. for Human Genomics, Univ. of Miami, Miami, FL, ⁹Dept. of Pathology and Lab. Med., Univ. of Pennsylvania, Philadelphia, PA, ¹⁰Dept. of Neurology, Columbia Univ., New York, NY, ¹¹Dept. of Biostatistics, Boston Univ. Sch. of Publ. Hlth., Boston, MA

Abstract Body:

Introduction: Alzheimer's disease (AD) is a progressive neurologic disorder with memory loss and dementia. Gene-environment interactions may explain missing heritability for AD. Cigarette smoking has been clearly implicated as a risk factor for AD in meta-analysis. We conducted a genome-wide (GW) study assessing the joint main and interaction effect with smoking to further investigate AD genetic architecture. **Methods:** A total of 20,687 non-Hispanic White (NHW; 7,821 cases and 12,866 controls) and 2,093 African American (AA; 761 cases and 1,332 controls) participants from the AD Genetic Consortium and the Framingham Heart Study who had lifetime smoking information available were analyzed. "Ever smoking" (i.e., past or current smoking) was considered to be a positive exposure. Across 33 datasets, we conducted a GW joint analysis (2 degrees of freedom [2DF] test) of the combined SNP main and SNP-by-smoking interaction effects. The joint effect was estimated using logistic regression and the F-Test. Age, sex, and principal components for population structure were included as covariates. Meta-analysis with METAL within ethnic background was conducted by combining p-values from the 2DF tests weighted based on sample size. **Results:** In addition to the known *APOE* locus, we identified two novel GW significant associations within *FHIT* (top SNP: rs2367086 minor allele frequency [MAF]=0.37, P=4.07×10⁻⁸, OR=1.05 in smokers, OR=1.01 in non-smokers, intronic, chromosome 3) in the NHW sample and within *SLC22A23* (top SNP: rs9392488 MAF=0.31, P=2.11×10⁻⁹, OR=1.24 in smokers, OR=0.58 in non-smokers, intronic, chromosome 6) in the AA sample. The minor alleles of rs2367086(T) and rs9392488(C) were significantly associated with decreased expression levels of *FHIT* (anterior cingulate cortex [P=3.40×10⁻⁴]) and *SLC22A23* (frontal cortex [P=0.036]) respectively in the GTEx database and also associated with increased methylation levels in blood at CpGs near the candidate genes (cg13679804 for rs2367086 [P=1.32×10⁻¹⁵⁵]; cg18842474 for rs9392488 [P=3.97×10⁻¹¹⁷]) in the GoDMC database. *FHIT*, which has also been implicated in a GWAS of blood total tau levels, encompasses the common fragile site FRA3B susceptible to carcinogen-induced damage leading to translocations and aberrant transcripts. *SLC22A23* codes for a transmembrane protein implicated in smoking cessation and resilience to AD. **Conclusion:** In this GW interaction study with smoking of AD, we identified two novel and promising ancestry-specific loci. Our findings highlight the value of considering environmental, genetic and ancestry-specific factors together towards a personalized medicine approach to AD.

Complex Traits Posters - Wednesday

PB1442. Genome-wide meta-analysis identifies a potential therapeutic targets for new loci and functional pathways influencing Alzheimer's disease risk

Authors:

J. Kim¹, S. Park¹, J. Cha¹, D-H. Park¹, H. Lim¹, J. Kim¹, S. Lee¹, H. Kim¹, W. Chung²; ¹Basgenbio Co., Ltd., Seoul, Korea, Republic of, ²Harvard Sch. of Publ. Hlth., Boston, MA

Abstract Body:

Alzheimer's disease (AD) has a complex causal pathway in which environmental characteristics and individual characteristics, such as aging and genetics, interact. In particular, the genetic factors involved in its pathogenesis are complex. Previous studies suggested that the pathogenesis of AD is influenced by multiple genetic components, rather than a single genetic factor. It may bring the benefits of GWAS-based research to identify biomarkers and potential therapeutic targets for AD. While previous studies on potential biomarkers and therapeutic targets have suggested genes (variants and locus), results may depend on the characteristics of the cohort used in each study, such as race, sample size, and the genomic data used for the analysis. In this study, we performed a GWAS analysis on AD using samples excluding non-white in the UK Biobank data. First, we selected a proxy AD group for people who do not have AD in consideration of the heritability of AD, such as whether the parents have AD, the timing of the onset of the parents, and the period of survival. It was confirmed that the GWAS results of the proxy AD group replicated the GWAS results of the clinical AD patient group in the previous studies. Next, a meta-GWAS was performed based on the recently reported AD research data. A total of 20 significant loci were identified, excluding the APOE gene region, and 4 significant novel loci of new AD were discovered. Four loci are coding regions for HS3ST1, ANK3, MADD, and CYYR1 genes, which have functional relationships directly or indirectly with AD. For functional annotation of new loci, the eQTL of the brain region for the corresponding SNP was checked in the GTEx portal, and functional evaluation was performed through colocalization. When single-tissue eQTLs for the corresponding SNPs were checked on the GTEx portal for functional annotation of new loci, three genes (HS3ST1, ANK3, and MADD) showed strong expression patterns in brain tissue and differences in expression according to genotypes. In the CYYR1, it was presented that the different expression levels in adipose and function evaluation were performed through colocalization. The results of this study are expected to serve as a basis for functional follow-up studies and may be utilized in pre-screening of potential risk groups for AD risk. In addition, it can provide research data for screening novel biomarkers of AD and targets for drug development. We anticipate that functional interpretation strategies and follow-up experiments will result in a comprehensive understanding of late-onset AD aetiology, which will serve as a solid foundation for the improvement of AD therapy.

Complex Traits Posters - Thursday

PB1443. Genome-wide meta-analysis identifies novel susceptibility loci for acne vulgaris

Authors:

M. Kals^{1,2}, M. Teder-Laving¹, A. Reigo¹, R. Ehin^{1,3,4}, T. Objärtel¹, M. Vaht¹, T. Nikopensius¹, A. Metspalu^{1,5}, K. Kingo^{6,7}, ¹Estonian Genome Ctr., Inst. of Genomics, Univ. of Tartu, Tartu, Estonia, ²Inst. for Molecular Med. Finland (FIMM), HiLIFE, Univ. of Helsinki, Helsinki, Finland, ³Inst. of Hlth. Technologies, Tallinn Technical Univ., Tallinn, Estonia, ⁴BioCC Ltd., Tallinn, Estonia, ⁵Inst. of Molecular and Cell Biology, Univ. of Tartu, Tartu, Estonia, ⁶Inst. of Clinical Med., Faculty of Med., Univ. of Tartu, Tartu, Estonia, ⁷Tartu Univ. Hosp., Tartu, Estonia

Abstract Body:

Acne vulgaris is a common inflammatory disease that primarily impacts facial skin in adolescence and in young adulthood, causing long-term psychosocial consequences. It is characterized by chronic inflammation of the pilosebaceous unit resulting from bacterial colonization of hair follicles by *Propionibacterium acnes*, androgen-induced increased sebum production, and altered keratinization. To undertake the analysis of genetic effects on outcome in acne, we performed a genome-wide meta-analysis comprising 34,422 individuals with acne and 364,991 controls from three independent cohorts with European ancestry (Estonian Biobank, FinnGen, and LifeLines). We identified four novel genome-wide significant loci: 11q12.2 (*FADS2*); 12q21.1 (*LGR5*); 17q25.3 (*FASN*); and 22q12.1 (*ZNRF3*) and replicated 19 previously implicated risk loci for European populations, bringing the total number of reported acne susceptibility loci to 50. We estimated that 9.4% of the phenotypic variance (SNP-based heritability) of acne was explained by common variation across the genome. Evaluation of polygenic risk scores (PRS) indicated a strong association with acne pathogenesis - individuals reporting acne had significantly higher mean acne PRSs than those who reported no acne. Furthermore, difference in PRS distributions was more significant in individuals with severe form of the disease, acne conglobata, compared to normal controls. Our findings highlight Wnt, p38 MAPK, and TGF β -mediated signaling pathways as key factors in genetic predisposition to acne vulgaris together with variation in fatty acid metabolism-related network of genes affecting the structure and maintenance of the hair follicle, and particularly the pilosebaceous unit. Understanding the genetic susceptibility factors and underlying biological pathways involved in the pathogenesis of acne will promote gaining insights for development of more effective acne treatment schemes.

PB1444. Genome-wide metabolite quantitative trait loci analysis in red blood cells from routine blood donors

Authors:

A. Moore¹, M. P. Busch², K. Dziewulska³, E. A. Hod⁴, J. C. Zimring³, A. D'Alessandro⁵, G. P. Page⁶, for the National Heart, Lung, and Blood Institute (NHLBI) Recipient Epidemiology Donor Evaluation Study; ¹RTI Intl., Durham, NC, ²Vitalant Res. Inst., San Francisco, CA, ³Univ. of Virginia, Charlottesville, VA, ⁴Columbia Univ. Med. Ctr., New York City, NY, ⁵Univ. of Colorado Denver-Anschutz Med. Campus, Aurora, CO, ⁶RTI Intl., Atlanta, GA

Abstract Body:

The Red Blood Cell (RBC)-Omics study, part of the larger NHLBI-funded Recipient Epidemiology and Donor Evaluation Study (REDS-III), aims to understand the genetic contribution to blood donor and RBC characteristics, and to outcomes in recipients of RBC from these donors. Previous work identified genetic and metabolic underpinnings to blood donation, storage, and transfusion outcomes, but none have yet linked the two bodies of work. We performed a pilot Genome-Wide Association (GWA) analysis using RBC-Omics study participants with generated untargeted metabolomics data to identify metabolite QTL (mQTL) in RBCs. RBC-Omics participants were recruited from four blood donation centers across the United States from among volunteer donors and oversampled for racial/ethnic diversity and high-frequency donors. Metabolomics data was generated from stored, frozen, leukoreduced RBC (LR-RBC) aliquots using ultra-high-pressure liquid chromatograph-mass spectrometry. 512 metabolites were assigned molecule names. As part of metabolite quality control and processing, we excluded metabolites after manual review (n=5), pharmaceuticals with implausible distributions (n=22), and high missingness (n=103). We imputed missing values in the remaining metabolites using quantile regression imputation of left-censored data, natural log-transformed the relatively quantified metabolites, and normalized values of each metabolite. We performed GWA analyses of 382 metabolites in 243 individuals imputed using the 1000 Genomes Project phase 3 all-ancestry reference panel. Analyses were conducted using ProbABEL and adjusted for sex, age, donation center, number of whole blood donations in the past two years, and first ten principal components of ancestry. Our preliminary results identified 423 independent loci associated with 132 metabolites ($p < 5 \times 10^{-8}$). Potentially novel locus-metabolite associations were identified for *FLVCR1* and choline; and for *LPCAT3* and the lysophosphatidylserines 16.0, 18.0, 18.1, and 18.2. These associations are supported by published rare disease and mouse studies. We confirm previous metabolite GWA results for associations including N(6)-Methyl-L-lysine and *PYROXD2*, and various carnitines and *SLC22A16*. We demonstrate that it is possible to perform metabolomics-scale GWA analyses with a modest, trans-ancestry sample size. Given the many published GWA reports linking top SNPs identified in the present analysis to various blood cell traits, careful follow-up is needed to characterize these associations found in a population enriched for repeat blood donors. These data will also provide insights into the system biology of RBCs.

Complex Traits Posters - Thursday

PB1445. Genome-wide Polygenic Risk Scores in Diabetes Risk Prediction: Results from the Asian Indian Diabetic Heart Study/Sikh Diabetes Study

Authors:

D. Sanghera; Univ. of Oklahoma Hlth.Sci. Ctr., Oklahoma City, OK

Abstract Body:

Background and Aims: Genome-wide polygenic risk scores (PRS) have shown high specificity and sensitivity in predicting type 2 diabetes (T2D) risk in Europeans. However, PRS-driven information on other ethnic groups is sparse, including Asian Indians (AI), who have a heightened risk for T2D. We examined the predictive efficacy of ancestry-derived (PRSAI) and European-derived (PRSEU) with a clinical risk score (CRS) of T2D.

Methods and Results: Weighted PRSs were computed using 63 variants from (Punjabi/Sikh) genome-wide association studies and 59 variants from European meta-analyses studies in 4,602 individuals (2,574 cases and 2,028 controls) of the Asian Indian Diabetic Heart Study/Sikh Diabetes Study. Ancestry-specific PRSAI showed 23.7% improved efficacy for T2D risk prediction over PRSEU. In sensitivity analysis, the area under the curve (AUC) for PRSAI and PRSEU was 0.79 and 0.72, respectively, after adjusting for CRS. Interestingly, the AUC remained unchanged on combining the PRS (AI+EU), i.e., 0.79, suggesting a superior performance of the ancestry-specific model. Additionally, PRSAI was also associated with the increased risk for glycosylated hemoglobin (HbA1c) (Beta=0.15, p=2.16x10⁻¹⁶) and decreased beta-cell function (HOMA-B) (Beta=-0.32, p=1.12x10⁻³²).

Conclusions: The ancestry-specific PRSAI demonstrated greater efficacy and a 9.7% enhanced AUC over PRSEU. More genetic evaluations on underserved non-European populations are required to increase the transferability of PRS across racial and ethnic groups and facilitate its smoother integration into clinical practice.

Complex Traits Posters - Wednesday

PB1446. Genome-Wide SNP Interaction Tests with Polygenic Risk Score for Ischemic Stroke Identifies Associations with Alzheimer Disease at *VCPKMT* and *KNDC1* by Age-Stratified Analysis

Authors:

J. Chung¹, X. Sun¹, X. Han¹, J. Mez¹, R. Mayeux², J. Haines³, M. Pericak-Vance⁴, G. Schellenberg⁵, K. Lunetta⁶, L. Farrer⁷; ¹Boston Univ., Boston, MA, ²Columbia Univ, New York, NY, ³Case Western Reserve Univ, Cleveland, OH, ⁴Univ. of Miami Miller Sch. of Med., Miami, FL, ⁵Univ Pennsylvania Sch Med, Philadelphia, PA, ⁶Boston Univ SPH Crosstown Ctr, Rm 313, Boston, MA, ⁷Boston Univ Sch Med, Boston, MA

Abstract Body:

Background: Amelioration of hypertension and other vascular risk factors has been associated with lower Alzheimer's disease (AD) risk. We aimed to identify genetic factors for AD influenced by cerebrovascular genetics using AD genome-wide association study (GWAS) with polygenic risk score (PRS) for ischemic stroke (IS). **Method:** We computed the IS PRS for European-ancestry individuals in GWAS datasets from Alzheimer's Disease Genetic Consortium and Framingham Heart Study (AD cases: 16,343, AD controls: 21,091) using the SNP-level effect estimates for IS from a MEGASTROKE GWAS. The PRS consisted of 1,438 SNPs pruned for linkage equilibrium ($r^2 < 0.4$) with minor allele frequency (MAF) $> 1\%$ and was normalized in each study. We evaluated the relationship between age (at onset for AD cases and at the last exam for controls) and the IS PRS. Next, we conducted genome-wide (GW) SNP-by-PRS interaction tests for AD in different age groups using logistic regression models adjusting for age, sex, and principal components of ancestry. Top findings were further evaluated using a transcriptome dataset in Religious Orders Study and Memory and Aging Project (ROSMAP). **Result:** We found a significant interaction effect between the IS PRS and age in all sample (OR=1.01, P=0.04) for AD. In particular, we observed significant associations between the IS PRS and AD in younger age groups defined using age cutoffs < 75 (OR=1.07, P=5.9x10⁻⁵) or < 80 (OR=1.04, P=0.01), but no association in older age groups > 75 (OR=0.98, P=0.16) or > 80 (OR=0.99, P=0.74). Following these observations, we tested GW SNP-by-PRS interactions in the age groups > 80 and < 75 and the entire sample. No genome-wide significant (GWS) interaction was detected in the total sample, but we identified GWS interactions near *VCPKMT* in the < 80 group (best SNP: rs4900982, MAF=0.44, interaction [INT] effect=-0.12, INT P=7.0x10⁻⁸) and within *KNDC1* in the > 75 group (best SNP: rs9419027, MAF=0.42, INT effect=0.13, INT P=3.3x10⁻⁸). In GTEx, rs4900982 and rs9419027 are significant expression SNPs for *VCPKMT* in the frontal cortex (P=5.0x10⁻³) and *KNDC1* in the caudate nucleus (P=5.0x10⁻⁵). In ROSMAP, we found a nominally significant association of AD risk with the interaction between *VCPKMT* expression and IS PRS among subjects < 80 (n=66, P=0.056), but not > 80 (n=572, P=0.75) or total sample (n=638, P=0.43). There were no significant interactions of the IS PRS with *KNDC1* in portion of the sample. **Conclusion:** We identified association of AD risk with interactions between two novel loci (*VCPKMT* and *KNDC1*) and IS PRS. We are evaluating the associations of these interactions with cognitive test scores and AD-related neuropathological traits.

Complex Traits Posters - Thursday

PB1447*. Genomic architecture of Autism Spectrum Disorder from comprehensive whole-genome sequence annotation.

Authors:

B. Trost¹, B. Thiruvahindrapuram¹, A. J. S. Chan², W. Engchuan¹, E. J. Higginbotham¹, J. L. Howe¹, L. O. Loureiro¹, M. S. Reuter¹, D. Roshandel¹, J. Whitney¹, M. Zarrei¹, M. Bookman³, C. Sondheimer¹, D. Glazer¹², D. M. Hartley⁷, S. W. Scherer¹; ¹The Hosp. for Sick Children, Toronto, ON, Canada, ²Children's Hosp. of Philadelphia, Philadelphia, PA, ³Verily Life Sci., San Francisco, CA, ⁴Hamad Bin Khalifa Univ., Doha, Qatar, ⁵Sidra Med., Doha, Qatar, ⁶UC San Diego, La Jolla, CA, ⁷Autism Speaks, Princeton, NJ, ⁸Children's Hosp. Los Angeles, Los Angeles, CA, ⁹BC Children's & Women's Hlth.Ctr, The Univ. of British Columbia, Vancouver, BC, Canada, ¹⁰DNASTack, Toronto, ON, Canada, ¹¹Holland Bloorview Kids Rehabilitation Hosp., Toronto, ON, Canada, ¹²Google, Mountain View, CA

Abstract Body:

Fully understanding the genetic factors involved in Autism Spectrum Disorder (ASD) requires whole-genome sequencing (WGS), which theoretically allows the detection of all types of genetic variants. With the aim of generating an unprecedented resource for resolving the genomic architecture underlying ASD, we analyzed genome sequences and phenotypic data from 5,100 individuals with ASD and 6,212 additional parents and siblings (total n=11,312) in the Autism Speaks MSSNG Project, as well as additional individuals from other WGS cohorts. WGS data and autism phenotyping were based on high-quality short-read sequencing (>30x coverage) and clinically accepted diagnostic measures for ASD, respectively. For initial discovery of ASD-associated genes, we used exonic sequence-level variants from MSSNG as well as whole-exome sequencing-based ASD data from SPARK and the Autism Sequencing Consortium (>18,000 trios plus additional cases and controls), identifying 135 ASD-associated protein-coding genes with false discovery rate <10%. Combined with ASD-associated genes curated from the literature, this list was used to guide the interpretation of all other variant types in WGS data from MSSNG and the Simons Simplex Collection (SSC; n=9,205). We identified ASD-associated rare variants in 789/5,100 individuals with ASD from MSSNG (15%) and 421/2,419 from SSC (17%). Considering the genomic architecture, 57% of ASD-associated rare variants were nuclear sequence-level variants, 41% were nuclear structural variants (SVs) (mainly copy number variants, but also including inversions, large insertions, uniparental isodisomies, and tandem repeat expansions), and 2% were mitochondrial variants. Several of the ASD-associated SVs would have been difficult to detect without WGS, including an inversion disrupting *SCN2A* and a nuclear mitochondrial insertion impacting *SYNGAP1*. Polygenic risk scores did not differ between children with ASD in multiplex families versus simplex, and rare, damaging recessive events were significantly depleted in multiplex families, collectively suggesting that rare, dominant variation plays a predominant role in multiplex ASD. Our study provides a guidebook for exploring genotype-phenotype correlations in the 15-20% of ASD families who carry ASD-associated rare variants, as well as an entry point to the larger and more diverse studies that will be required to dissect the etiology in the >80% of the ASD population that remains idiopathic. All data resulting from this study are available to the medical genomics research community in an open but protected manner.

Complex Traits Posters - Wednesday

PB1448. Genomic discovery with functional annotation of *CNTNAP5* in the phenotypic extremes of primary angle closure glaucoma

Authors:

S. Chakraborty, S. Saha Roy, J. Sarma, T. Ahmed, S. Bhattacharjee, M. Acharya; Natl. Inst. of BioMed. Genomics, Kalyani, India

Abstract Body:

Primary angle closure glaucoma (PACG) is one of the major leading causes of blindness. Several risk factors include narrow iridocorneal angle, and increased lens thickness, leading to shallow anterior chambers in anatomically predisposed eyes. Earlier, the two comprehensive GWAS on PACG case-control identified eight novel loci where control populations were included without considering any anatomically predisposed parameters. Indeed, in India, ~30% of people show a narrow iridocorneal angle, but from here only 0.5-1% of people develop PACG. To exclude heterogeneity, we conducted an age-dependent model of progressive angle closure GWAS where relatively early-onset PACG patients (PACG: age ≤ 50 years) compared with anatomically predisposed (narrow iridocorneal angle $< 15^\circ$) non-glaucomatous older individuals (PACS: age ≥ 60 years) to improve power to detect genetic factors for glaucomatous neurodegeneration. In our discovery phase, we identified genomic alterations using a genome-wide association study in 148 PACG and 92 PACS individuals. A total of 11 genome wide suggestive significant ($P < 1e^{-05}$) SNPs were found. Of them, 5 loci were mapped at *TLL2*, *CNTNAP5*, *TNF*, *PAPLN* and *MCCDI*. Genotype-phenotype correlation prioritized rs780010 of *CNTNAP5*, which was significantly associated with the cup to disc ratio ($P = 0.0024$), which is a clinical parameter directly correlated with glaucomatous neurodegeneration. Conditional analyses identify 13 loci of *CNTNAP5* associated with PACG. We further validated the sentinel SNP rs780010, with $P = 2.131e^{-06}$, in a separate replication cohort (PACG = 50; PACS = 39) and observed a significant association (odds ratio (OR) = 2.307, $P = 0.012$). Integrative bioinformatics analyses suggested higher retinal neuronal expression of *CNTNAP5* with active enhancer marks, which were subsequently validated through a luciferase assay. Further, translation blocker morpholinos against *cntnap5a* and *cntnap5b* were injected into zebrafish embryos at a single cell stage (2.5ng each). There were significant eye size reductions and retinal nerve thinning was observed in zebrafish morphants in comparison to 5 base mismatch-pair control morphants. In conclusion, genomic discovery results not only indicate a genomic association of the *CNTNAP5* with PACG but also imply that it may play a role in glaucomatous neurodegeneration. Further, functional annotation results lead us to hypothesize that *CNTNAP5* is the candidate gene to perturb the development of the neural retina, leading to reduced eye size and neurodegeneration of the retinal ganglion cells, thereby increasing the risk of PACG-associated vision loss.

Complex Traits Posters - Wednesday

PB1449. Genomic structural equation modeling to unravel kidney-specific variants from multiple biomarkers

Authors:

R. Fujii^{1,2,3}, C. Pattaro¹; ¹Eurac Res., Bolzano, Italy, ²Fujita Hlth.Univ., Toyoake, Japan, ³Nagoya Univ., Nagoya, Japan

Abstract Body:

Genome-wide association studies (GWAS) of kidney function have focused almost exclusively on the estimated glomerular filtration rate derived from serum creatinine (eGFR_{crea}), which may also reflect muscle mass metabolism. To identify kidney-specific loci, researchers typically compare the GWAS results with those from alternative kidney function markers such as cystatin C-based eGFR (eGFR_{cys}), uric acid (UA), and blood urea nitrogen (BUN). Assuming the existence of an underlying kidney function trait affecting the levels of multiple markers, we applied genomic structural equation modeling (GenomicSEM) combining publicly available univariate GWAS results of eGFR_{crea} (n=1,201,909), eGFR_{cys} (n=460,826), UA (n=457,690), and BUN (n=852,678) from the CKDGen Consortium. Z-scores of the results were compared against 424 lead variants of each locus in the previous GWAS for eGFR_{crea}. The merged summary statistics across four previous GWAS included >6,000,000 SNPs. The highest genetic correlation was observed between eGFR_{crea} and eGFR_{cys} ($r_g=.593$, $se=.041$), followed by eGFR_{cys}-UA ($r_g=-.393$, $se=.037$), eGFR_{cys}-BUN ($r_g=-.387$, $se=.042$), eGFR_{crea}-BUN ($r_g=-.364$, $se=.044$), eGFR_{crea}-UA ($r_g=-.217$, $se=.035$), and UA-BUN ($r_g=.211$, $se=.039$). Confirmatory factor analysis (CFA) showed good fitting (comparative fit index=.936, root mean square residual=.028) and identified factor loadings (λ) for each biomarker: $\lambda_{eGFR_{crea}}=.654$; $\lambda_{eGFR_{cys}}=.896$; $\lambda_{BUN}=-.405$; and $\lambda_{UA}=-.479$. Of the 373 available SNPs which were significant in the previous eGFR_{crea} GWAS, the absolute Z-score of the common latent kidney trait were bigger for 119 variants (31.9%). Of these, 112 variants (94.1%) showed significant effects on eGFR_{crea}, eGFR_{cys} and BUN, underlying their kidney function relevance. Among 254 variants with smaller absolute Z-score in the latent kidney trait analysis, only 86 (33.9%) were significantly associated with eGFR_{crea}, eGFR_{cys} and BUN. These findings highlight the strong enrichment of loci directly relevant to the kidney obtained with GenomicSEM. In the absence of a kidney function-specific marker, GenomicSEM analysis shows the potential to prioritize kidney function-relevant loci by combining multiple kidney-related biomarkers.

Complex Traits Posters - Thursday

PB1450. GenoPipeR: An Automated Pipeline for Predictive Modelling of Complex Phenotypes using Genome-wide Data

Authors:

V. Marshe¹, S. Elsheikh², E. Tio², M. Maciukiewicz³, A-C. Hauschild⁴, X. Men², D. Felsky², D. J. Mueller²; ¹Columbia Univ. Irving Med. Ctr., New York, NY, ²Ctr. for Addiction and Mental Hlth., Toronto, ON, Canada, ³Univ. Hosp. Zurich, Zurich, Switzerland, ⁴Dept. of Med. Informatics, Univ. Med. Ctr. Göttingen, Göttingen, Germany

Abstract Body:

Machine Learning (ML) offers novel opportunities for modelling complex traits using high-dimensional SNP data. However, rigorous ML analyses are challenging and require the integration of ML best practices with modality-specific expert knowledge. We present the *genoPipeR* R package: an automated, user-friendly ML pipeline for complex trait modelling using SNP and covariate data. In contrast to SNP-modelling pipelines with custom architectures, *genoPipeR* is a standardized, supporting *PLINK*-formatted files and allows the user to select among state-of-the-art ML models (R caret) and types of cross-validation (CV) for model selection and hyperparameter tuning. The pipeline automatically performs feature selection and modelling with consideration for genetic architecture. To evaluate *genoPipeR*, we built models for beta-amyloid levels and Alzheimer's disease consensus diagnosis, adjusted for demographic and batch covariates in the ROS/MAP cohort (N = 2,067). For genetic features, we prioritized across SNPs using PC-corrected genome-wide GLMs. A final set of the top 25 clinical and genetic features were selected based on non-zero elastic net coefficients and passed to model selection and hyperparameter tuning. We assessed seven models (GLM, CART, RF, GBM, linear/radial SVM, kernel PLS) and two CV types (5-fold vs. nested 5-fold). Final models were tested in a 30% holdout. For genome-wide models (9,329,439 SNPs before prioritization), the computational performance was reasonable (7-37 mins). For beta-amyloid levels, our best model was a non-nested GLM model ($RMSE = 0.99$, $MAE = 0.82$, $adj. R^2 = 0.17$; actual vs. predicted, Spearman $\rho = 0.42$, $p = 8.52 \times 10^{-18}$) including top features rs11728484, rs2215637, age at death, *APOE* rs1065853, and *ZDHHC21* rs113159914. Other model-selected SNPs were in *KCNT2*, *APOC1* and *APOE* $\epsilon 4$ (rs429358). Compared to a non-ML linear regression model including sex, age at death, batch effects and *APOE* $\epsilon 4$ status ($R^2 = 0.12$), our model achieved a 5% higher explained variance. A non-nested kernel PLS model showed the best performance for Alzheimer's disease status ($AUC = 0.68$; $Acc = 0.62$, $p = 4.01 \times 10^{-4}$; $Sens = 0.68$, $Spec = 0.65$). The top predictors were age at death, *APOE* rs429358, *NECTIN2* rs12972156, rs6956154, and *BCL2L14* rs1641717. Our analysis shows that *genoPipeR* can identify features at the genome-wide level that have previously been associated with a complex outcome, as well as potentially interesting features for further investigation. The pipeline is suitable for local and distributed computing settings, depending on the sample size, and integrates extensive post-processing, including publication-ready plots.

Complex Traits Posters - Wednesday

PB1451. Genotypic and Phenotypic Heterogeneity in Prader-Willi Syndrome: A Bangladeshi cohort study

Authors:

R. Mim¹, H. Akter^{1,2}, M. Rahman³, S. Sarker^{1,4}, M. Basiruzzaman^{1,5}, M. Chowdhury^{1,6}, M. Rahaman¹, T. Eshaque¹, M. Morshed¹, A. Islam^{1,7}, G. Kundu⁸, S. Kanta⁴, R. Biswas⁹, K. Coll., Dhaka, Bangladesh, Dhaka, Bangladesh, ¹¹Mohammed Bin Rashid Univ. of Med. and Hlth.Sci., Dubai, United Arab Emirates

Abstract Body:

Background: Prader-Willi syndrome (PWS) is a neurodevelopmental disease characterized by aberrant imprinted gene expression in the 15q11-13 region. Dysregulation of the genes located in this region shows variable clinical phenotypes such as Prader-Willi syndrome (PWS, #176270), Angelman syndrome (AS, #105830) and 15q11-q13 duplication syndrome (Dup15q syndrome, #608636). In this study, we applied chromosomal microarray analysis (CMA) to detect chromosomal abnormalities throughout the genome of the clinically suspected Prader-Willi syndrome patients.

Methods: We have conducted genome-wide CMA (642,824 probes spanning the genome) analysis for 6 clinically suspected Prader-Willi patients to identify chromosomal abnormalities (deletion/duplication/translocation and rearrangements). For the negative patient, we used Whole Exome Sequencing (WES) to uncover single nucleotide variants (SNVs), small insertion and deletion. We have used human genome build GRCH38/UCSC hg38 as reference. Variant classification analysis was conducted based on the American College of Medical Genetics (ACMG) guidelines.

Results: Out of the 6 patients, 5 patients were carrying different lengths of pathogenic deletion and duplication CNVs in the 15q11.2q13.1 region of chromosome 15. The overlapping region is 4.92Mb (Chr15:23370969-28289373). The diagnostic yield of CMA in clinically suspected Prader-Willi syndrome patients is 83.33%. No clinically relevant variants were found in one patient. This patient was further included in WES. From WES, we have found a variant of uncertain significance (VOUS) c.1642T>A (p.Tyr548Asn) in the *PPP2R5D* gene which is associated with Intellectual developmental disorder 35 (MRD35, #616355).

Conclusion: In Bangladesh, CMA and WES testing are not yet implemented in clinical practice as a first-tier diagnostic test for Prader-Willi syndrome. Our results from this study show the utility of CMA and WES for the precise genetic diagnosis and its integration in clinical practice.

Key words: Prader-Willi syndrome (PWS); Chromosomal microarray analysis (CMA); Whole Exome Sequencing (WES); Single nucleotide variants (SNVs); American College of Medical Genetics (ACMG).

Complex Traits Posters - Thursday

PB1452. Global analysis of RNA editing in Alzheimer's disease across multiple brain regions.

Authors:

E. Huang, M. Choudhury, X. Xiao; UCLA, Los Angeles, CA

Abstract Body:

RNA editing is a biological process that refers to the alteration of RNA transcripts through insertion, deletion, or substitution of nucleotides. The nucleotide changes induced by RNA editing events have been shown to regulate gene expression through a diverse range of mechanisms, such as altering protein-coding sequences, splice sites, and sequences related to microRNA gene-targeting. It is increasingly recognized that RNA editing is globally dysregulated in many neurological disorders. Here, we aim to gain a comprehensive understanding of the relationship between RNA editing and Alzheimer's Disease (AD) pathology. We utilized bulk RNA-seq data from two large-scale patient cohorts: the Mount Sinai Brain Bank (MSBB) study and the ROS/MAP project. Each cohort encompass samples from hundreds of individuals across multiple brain regions, including the prefrontal cortex, superior temporal gyrus, parahippocampal gyrus, and inferior frontal gyrus. Using a computational pipeline designed for de novo identification of editing sites and quantification of their corresponding editing levels, we identified over hundreds of thousands of editing sites in each brain region. Thousands of sites were found to have significantly different editing levels between AD and control samples, among which are protein-recoding sites in various genes that have been previously implicated in Alzheimer's Disease pathology. To better understand regulators of editing levels, we identified RNA binding proteins (RBPs) that significantly correlate with the editing levels across the samples in each brain region. Finally, we performed ordinal regression analyses to identify sites with editing levels that are strongly related to the severity of three measures of Alzheimer's Disease pathology: cognitive status, neurofibrillary tangle levels, and plaque density. Our work presents a systematic view of how RNA editing contributes to multiple facets of AD progression and emphasize the importance of its consideration in future studies that aim to better understand the disease's biological underpinnings.

Complex Traits Posters - Wednesday

PB1453. Global Long COVID Host Genetics Initiative identifies *FOXP4* locus as the first genetic risk factor associated to Long COVID

Authors:

V. Lammi¹, S. E. Jones¹, T. Nakanishi^{2,3}, Long COVID Host Genetics Initiative, H. M. Ollila^{1,4,5,6}; ¹Inst. for Molecular Med. Finland, University of Helsinki, Finland, ²McGill Univ., Montreal, QC, Canada, ³Kyoto-McGill Intl. Collaborative Sch. in Genomic Med., Graduate Sch. of Med., Kyoto Univ., Kyoto, Japan, ⁴Broad Inst. of MIT and Harvard, Cambridge, MA, ⁵Ctr. for Genomic Med., Massachusetts Gen. Hosp., Boston, MA, ⁶Anesthesia, Critical Care, and Pain Med., Massachusetts Gen. Hosp. and Harvard Med. Sch., Boston, MA

Abstract Body:

Introduction: While most people recover from COVID-19 within 3 months, a substantial proportion suffer from long-term post COVID-19 conditions or so-called “Long COVID”. The most common symptoms include fatigue, cognitive dysfunction and breathlessness, though symptoms can vary widely by proband, and severity can range from mild to debilitating. To understand the disease etiology and genetic liability behind Long COVID, we built a global working group under the COVID-19 Host Genetics Initiative.

Materials and methods: At present (data freeze 2), 20 studies from 14 countries representing six genetic ancestry groups contributed data to our meta-analyses. Long COVID was primarily captured using questionnaires, with Long COVID being defined as ‘any symptoms that cannot be explained by alternative diagnoses, or impact on everyday functioning, 3 months after the onset of COVID’. In studies with electronic health record (EHR) data, specific diagnosis codes for Post COVID-19 conditions (ICD-10 code U09(.9), or corresponding SNOMED codes) were used.

Results: We performed a GWAS meta-analysis comparing Long COVID cases (N=2,592) to population controls (N=942,312) and identified a genetic risk locus on chromosome 6 upstream of the *FOXP4* gene (rs9367106, P = 7.3e-9, OR = 1.6[1.4-1.9], minor allele frequency = 0.04). The lead variant is in linkage disequilibrium with another variant previously associated with COVID-19 severity (rs1886814, r²=0.62, D’=0.93), showing the same direction of effect for the risk haplotype. At present, none of the other reported lead variants for COVID-19 severity showed associations with Long COVID. In addition, comparing Long COVID cases (N=3,877) to COVID+ controls without Long COVID (N=28,446), showed a nominal association (rs9367106, P = 0.046, OR = 1.2[1.0-1.4]).

Conclusions: Our early findings indicate that *FOXP4* may affect susceptibility to Long COVID. The transcription factor (Forkhead box protein P4) encoded by *FOXP4* is involved, inter alia, in antigen-specific recall responses in T cells, and lung secretory epithelium regeneration. Thus, this association suggests a biological link for infection-related immunological memory and lung mucus functions with the development of Long COVID. Furthermore, our data support epidemiological findings that connect Long COVID with initial COVID-19 disease severity. The Long COVID Host Genetics Initiative is continuing to recruit additional studies from diverse ancestries and incorporate information from ongoing data collection efforts within existing contributors to better understand the genetic factors predisposing to Long COVID and to explore its effect on long-term health

Complex Traits Posters - Thursday

PB1454. GWAS and Polygenic prediction of anthropometric traits in sub-Saharan African populations

Authors:

Adebamowo¹, ACCME Research Group as part of the H3Africa Consortium; ¹Univ. of Maryland Sch. of Med., Baltimore, MD, ²Asokoro District Hosp., Abuja, Nigeria, ³Federal Med. Ctr. Keffi, Keffi, Nigeria, ⁴Wuse Gen. Hosp., Abuja, Nigeria, ⁵Univ. of Ibadan, Ibadan, Nigeria, ⁶NHGRI/CRGGH, Bethesda, MD, ⁷NIH/NHGRI, Bethesda, MD, ⁸Inst. of Human Virology Nigeria, Abuja, Nigeria, ⁹Garki Hosp. Abuja, Abuja, Nigeria, ¹⁰Univ. of Abuja Teaching Hosp., Abuja, Nigeria, ¹¹Natl. Hosp. Abuja, Abuja, Nigeria, ¹²Kubwa Gen. Hosp. Abuja, Abuja, Nigeria, ¹³NIH, Bethesda, MD

Abstract Body:

Background: Evidence suggests that polygenic risk scores (PRS) for complex traits which are currently mostly derived from European-ancestry (EA) populations perform poorly in other populations because of underrepresentation in the underlying genome-wide association studies (GWAS) data, differences in allele frequencies, and effect sizes (among other factors). **Methods:** We conducted GWAS, meta-analyses and gene-set analyses of height, body-mass index (BMI), and waist-hip ratio (WHR), and generated and compared PRS from EA (n~694,000), Multiethnic ancestry (MEA, n~49,300), African American and Afro-Caribbean ancestry (AA/AC, n~41,300) and Sub-Saharan African (AFR, n~14,000) populations. We used the African Collaborative Center for Microbiome and Genomics Research data (ACCME, n~15,000) for GWAS discovery and PRS target, and the Africa America Diabetes Mellitus study data (AADM, n~5,200), for GWAS replication and PRS validation. **Results:** The top replicated variants associated with each trait were in *HMGAI* (rs6937622, p=3.70 x 10⁻¹², for height), *MDGAI* (rs188795185, p=1.18 x 10⁻⁷, for BMI) and *HAAO* (rs140002152, p=1.95 x 10⁻⁹, for WHR) gene regions. The EA-derived PRS had the highest proportion of variance explained (R^2) for the selected anthropometric traits in SSA populations, compared to the MEA, AA/AC and AFR derived PRS. The ancestry-specific parameters for the best predictive PRS were EA ($R^2=2.39\%$, p=4.24x10⁻⁵⁶), AA ($R^2=2.08\%$, p=5.12x10⁻⁴⁹) and AFR ($R^2=0.54\%$, p=1.89x10⁻¹³) for height; EA ($R^2=1.21\%$, p=2.19x10⁻²⁸), AFR ($R^2=0.18\%$, p=2.49x10⁻⁰⁵) and MEA ($R^2=0.79\%$, p=4.30x10⁻¹⁹) for BMI; and EA ($R^2=0.59\%$, p=1.19x10⁻¹⁴), AFR ($R^2=0.06\%$, p=0.018) and MEA ($R^2=0.06\%$, p=0.013) for waist-hip ratio. The results of comparing participants in the highest PRS quantile versus those in the lowest quantile were consistent with these findings. **Conclusions:** PRS derived from large-scale EA populations had high predictability for anthropometric traits in SSA populations. For the selected anthropometric traits, PRS prediction R^2 improved with increasing sample size, indicating the need for more genomic data from diverse populations to serve as a basis for PRS.

Complex Traits Posters - Wednesday

PB1455. GWAS of the age-of-onset of type 1 diabetes reveals HTATIP2 as a novel T cell regulator.

Authors:

C. Cardinale¹, X. Chang², H. Qu², H. Hakonarson¹; ¹Children's Hosp. of Philadelphia, Philadelphia, PA, ²Children's Hosp. of Philadelphia, Philadelphia, PA

Abstract Body:

The age at which type 1 diabetes first presents is a parameter of clinical interest. We conducted a quantitative trait genome-wide association study of type 1 diabetes age-of-onset in a discovery cohort of 4,014 cases and a replication cohort of 493 cases. Two loci were genome-wide significant: the previously-identified signal in the human leukocyte antigen locus on chromosome 6, and a novel signal in the *NELL1* gene on chromosome 11. Bayesian fine-mapping nominates rs10833518 as the causal SNP, and homozygosity for the risk allele is associated with an average one-year earlier onset. The risk allele of this SNP is bound by an allele-specific protein complex in gel shift. Four genes in this locus are expressed in immune cells, and we used siRNA knock-down of these candidates with RNA-seq in primary human CD4⁺ T cells to determine that inhibition of HTATIP2 reduces expression of kinases, receptors, and transcription factors involved in signal transduction. Functionally, knock-down of HTATIP2 in these cells increases viability and reduces expression of activation markers. Taken together, we nominate HTATIP2 as a new type 1 diabetes risk gene acting via T cell regulation.

Complex Traits Posters - Thursday

PB1456. Heterozygous loss-of-function mutation in *SORL1* causes neuronal dysregulation of endosomal trafficking and processing of APP.

Authors:

B. DeRosa¹, S. Simon¹, B. Kunkle¹, R. Carney^{1,2}, M. Cuccaro^{1,3}, H. Cukier^{1,4}, J. Vance^{1,3,4}, M. Pericak-Vance^{1,3,4}, D. Dykxhoorn^{1,3}; ¹John P. Hussman Inst. for Human Genomics, Univ. of Miami Miller Sch. of Med., Miami, FL, ²Miami VA Med. Ctr., Miami, FL, ³Dr. John T. Macdonald Fndn. Dept. of Genetics, Univ. of Miami Miller Sch. of Med., Miami, FL, ⁴Dept. of Neurology, Univ. of Miami Miller Sch. of Med., Miami, FL

Abstract Body:

Dysregulation in endolysosomal trafficking has emerged as a key pathogenic process in both sporadic and inherited forms of Alzheimer's disease (AD). *SORL1*, is a top AD risk gene that encodes a sorting receptor involved in amyloid precursor protein (APP) endosomal trafficking and the secretion of amyloid- β ($A\beta$). *SORL1* rare protein-truncating variants have been found to be causal in late onset AD and are enriched in cases with early-onset AD (EOAD), with some families exhibiting autosomal-dominant patterns of inheritance. We previously identified siblings affected with EOAD that had a rare heterozygous frameshifting deletion in *SORL1* (c.4293delC; rs1343336951) that results in a truncated protein lacking ~30% of the C-terminus (p.C1431WfsX2). To further understand the role of *SORL1* in AD pathogenesis, we first derived induced pluripotent stem cell (iPSC) lines from the two EOAD-affected siblings bearing the c.4293delC mutation. Next, we created isogenic control iPSC lines via CRISPR/Cas9-mediated homology-directed repair knock-in of the wildtype allele. These iPSC lines were evaluated for pluripotency, genomic stability, and the lack of off-target genome editing resulting from the CRISPR-based gene correction. Once validated, the isogenic pairs of *SORL1*^{+/-} and deletion-corrected control iPSC lines were differentiated into cortical neurons. Our data show that heterozygous loss of *SORL1* function leads to enlarged endosomes and the accumulation of APP in early endosomes. Additionally, we observe *SORL1*^{+/-} neurons have increased levels of secreted A β 42, a pathogenic isoform of $A\beta$ that is highly fibrillogenic and enriched in senile plaques. In conclusion, our results indicate that loss of function in a single copy of *SORL1* is sufficient to induce neuronal defects in APP trafficking and processing and dysregulation of $A\beta$ production. This study broadens our understanding of the contribution of *SORL1* mutations to AD and provides insight into possible early neuropathogenic effects of EOAD-associated mutations. These data, together with similar findings in neurons with other EOAD gene loss-of-function mutations, support an important mechanistic role for disturbances in endosomal APP trafficking and $A\beta$ production in AD pathophysiology.

Complex Traits Posters - Wednesday

PB1457. Heterozygous *RYR2*, *ABCG8*, *PIK3C2G*, and *RASSF9* variants as the cause of premature coronary artery disease in five Iranian families.

Authors:

S. Mehvari¹, M. Asadnezhad¹, N. Karimian Fathi¹, F. Ghodrattpour¹, S. Saki², K. Hosseini³, S. Sadeghian³, M. Akbari⁴, R. Malekzadeh², R. Najafipour¹, **H. Najmabadi**¹, K. Kahrizi¹; ¹Genetics Res. Ctr., Univ. of Social Welfare and Rehabilitation Sci., Tehran, Iran, Islamic Republic of, ²Digestive Disease Res. Inst., Tehran Univ. of Med. Sci., Tehran, Iran, Islamic Republic of, ³Dept. of Cardiology, Tehran Heart Ctr., Tehran Univ. of Med. Sci., Tehran, Iran, Islamic Republic of, ⁴Women's Coll. Res. Inst., Univ. of Toronto, Toronto, ON, Canada

Abstract Body:

Background/Objective: Coronary artery disease (CAD), the major cause of death globally, is a complex multifactorial disorder influenced by both common and rare genetic variants. Several risk factors including family history has long been recognized to increase the risk of CAD development. In this study, we aimed to identify the potential rare disease-causing variants in an Iranian cohort of familial premature CAD (PCAD). **Methods:** Whole exome sequencing (WES) was performed on proband of each family followed by Sanger sequencing for confirmation of the results and co-segregation analysis. **Results:** We have hitherto identified heterozygous probably disease-causing variants in genes *RYR2*, *ABCG8*, *PIK3C2G*, and *RASSF9* in five unrelated families. Mutations in *RYR2* are known to cause cardiac arrhythmia and sudden cardiac death (SCD). We identified different heterozygous missense variants in *RYR2* gene in two families, i.e. c.5189C>T (p.Thr1730Met) and c.9778C>T (p.Arg3260Thr). The former was detected in a 58-year-old female with a history of chest pain and the onset of established CAD at 47 years of age. The second variant was identified in a female with a history of cardiac attacks twice, at 23 and 49 years old, with a positive history of SCD in her family. In the third family, we identified a heterozygous likely pathogenic (LP) variant, c.562G>C (p.Val188Lys), in *ABCG8* gene which is involved in sterol metabolism in a 38-year-old female with a history of chest pain, hyperlipidemia and the onset of established CAD at 33 years of age. In the other family in which the male proband presented with the onset of established CAD at the age of 48, we identified a novel heterozygous LP splice variant, c.3357+1G>T, in *PIK3C2G* gene which is involved in promoting AKT signaling, hence insulin signaling pathway, glucose homeostasis and glycogen synthesis. In the last family, we identified a frameshift variant, c.893_894del (p.Ile298LysfsTer2), in *RASSF9* gene in a 44-year-old male with a family history of PCAD. Finally, for apparently healthy heterozygous members of these families, coronary CT angiography confirmed the genotype and showed mild to/or moderate coronary stenosis. **Conclusion:** Rare variants could be responsible for the pathogenesis of PCAD in affected individuals with a positive family history of such disease. Identifying these variants can help to prevent CAD morbidity and mortality in asymptomatic patients. The findings of this study may contribute to a better understanding of the genetic components of CAD and reflect the need to take rare variants into consideration. However, further studies are needed to support the role of *PIK3C2G* and *RASSF9* genes in CAD development.

Complex Traits Posters - Thursday

PB1458. HLA Haplotype Analysis and Genome Wide Association Study of Nephrotic Syndrome in the Million Veteran Program

Authors:

A. Hung^{1,2}, G. Wang^{1,2}, H-C. Chen^{1,2}, E. Phillips¹, C. Chung^{1,2}, J. Hellwege^{1,2}, O. Wilson^{1,2}, B. R. Gorman³, S. Pyarajan^{4,5}, J. E. Huffman⁶, M. Salani¹, E. Fagan¹, C. Fang¹, J. Triozzi¹, E. Siew^{1,2}, Million Veteran Program, A. Bick^{7,1}, C. Robinson-Cohen¹, R. Tao^{1,2}; ¹Vanderbilt Univ. Med. Ctr., Nashville, TN, ²Nashville VA, Tennessee Valley Hlth.care System, Nashville, TN, ³VA Boston Hlth.care System, Boston, MA, ⁴VA Cooperative Studies Program, VA Boston Hlth.care System, Boston, MA, ⁵Dept. of Med., Brigham and Women's Hosp. and Harvard Sch. of Med., Boston, MA, ⁶Massachusetts Veterans Epidemiology Res. and Information Ctr., VA Boston Hlth.care System, Boston, MA, ⁷Vanderbilt, Nashville, TN

Abstract Body:

Nephrotic syndrome (NS), is characterized by massive urinary excretion of protein, is caused by damage to the glomerular filtration barrier, and leads to heightened morbidity and mortality and faster progression to ESRD. Discovery of new therapies is urgently needed.

We identified veterans with NS, 1640 European ancestry (EA), and 924 African ancestry (AA). Controls included individuals with GFR > 60 ml/min and a negative UA, 218,300 EA, and 61,921 (AA). We performed a GWAS using logistic regression, an additive model (MAF > 1%), imputed to the 1000 Genomes reference panel, adjusted for age, sex, and the 10 PCs, stratified by race. A second model also adjusted for diabetes. HLA haplotypes were built by the MVP Genomic core using HIBAG with estimated accuracy >90%. For HLA haplotypes additive and dominant models were performed we here report the results for the additive model. We used Bonferroni adjustment for p-values.

Mean age was 59 (SD14), 89% were males. 31% of the cases were AA compared to 20% of the controls. 67% of the cases had diabetes while only 25% of the controls. 178 patients had FSGS (6%), 77 (3%) membranous (29 had PLA2R +), 14 (0.5%) crescentic GN, 11 (0.4%) MPGN, 6 (2%) diffuse or mesangio-capillary, and 4 (1%) dense deposits. 86% were NS of unspecified morphology. Our GWAS results for the EA patients showed an extensive GWAS association with different components of the HLA (979 SNPs). In the haplotype analysis, there were two risk HLA haplotypes in EA participants without diabetes in HLA class II; DQA1*05:01 (p=1.19E-06)- DRB1*03:01 (p=0.0001) and there were four risk HLA haplotypes in EA participants with diabetes in both HLA class I & II; DQA1*05:01 (p=3.36E-06)- DRB1*03:01 (p=1.56E-05)- DPB1*01:01(6.25E-05) C*07:01(p=0.0001). No risk HLA haplotypes were identified in AA participants. Other independent loci associations in EA were: known: *TSBP1* (p=9.01x10-09), *APOM* (p=1.41x10-08), *PRRC2A* (p=1.52x 10-08). Novel: *TNF* (p=3.08x10-08), *TNXB* (p=1.47x10-08), *VWA7* (4.10x10-08), *NOTCH4* (1.65E-8). For AA patients, association were *APOLI*; (rs73885319 p= 1.59x10-09, rs60910145; p= 1.95x10-09), and *RNF2* (p= 4.82x10-08).

Our GWAS and HLA haplotype analyses confirmed the strong association known between HLA-DQA1 and NS in EA individuals, particularly for membranous. It also confirmed the association of other HLA haplotypes and NS supporting the role of the immune response in this clinical condition. Our study identified novel associations with Von Willebrand factor, Tenascin, and NS. In AA, we confirmed the association between *APOLI* and proteinuric diseases like FSGS.

Complex Traits Posters - Wednesday

PB1459. HLA in autoimmune encephalitis.

Authors:

T. K. de Araujo^{1,2}, D. C. Rosa¹, F. R. Torres¹, W. Watanabe³, C. L. Yasuda^{3,2}, A. C. Coan³, F. Cendes^{3,2}, I. Lopes-Cendes^{1,2}; ¹Dept. of Translational Med., Sch. of Med. Sci., Univ. of Campinas (UNICAMP), Campinas, SP, Brazil., Campinas, Brazil, ²Brazilian Inst. of NeuroSci. and Neurotechnology (BRAINN), Campinas, SP Brazil., Campinas, Brazil, Campinas, Brazil, ³Dept. of Neurology, Sch. of Med. Sci., Univ. of Campinas (UNICAMP), Campinas, SP, Brazil., Campinas, Brazil

Abstract Body:

Autoantibody-mediated forms of encephalitis (AE) include neurological disorders characterized by subacute memory loss, movement disorders, and focal seizures. The Human Leucocyte Antigen (HLA) genes are involved in susceptibility to more than 100 inflammatory, infectious, and autoimmune diseases. HLA is among the most polymorphic regions of the human genome and presents considerable diversity among populations. Given that there are still controversies regarding the role of specific HLA alleles in AE we aim to search for HLA associations in a cohort of well-characterized patients with AE. To date, we have evaluated 36 patients: 11 with anti-NMDA-R antibodies, 6 with anti-GAD65 antibodies, 6 with paraneoplastic encephalitis, 1 with LGI-1 antibodies, 2 with anti-TPO antibodies, 6 without antibodies detection, and 5 patients with Rasmussen encephalitis. We also included data from 297 ethnically matched controls. The DNA from these individuals was extracted from peripheral blood or saliva samples and was genotyped for HLA using next-generation sequencing technology. The DNA libraries were loaded onto a MiSeq Sequencer (Illumina), and the data were analyzed with the NGSengine v. 2.25 software (GenDx). HLA genotyping was reported at a six-digit level whenever technically possible for HLA -A, -B, -C, -DRB1, -DRB3, -DRB4, -DRB5, -DPA1, -DPB1, -DQA1, -DQB1, and -G, but for comparison with previous published work, we set the results to two digits. Statistical analysis of relative allele frequencies was performed using an Excel spreadsheet; p-value and odds ratio (OR) were calculated using the R studio. The most common HLA alleles in AE was *HLA-A*02:01P* (0.20), *HLA-B*07:02P* (0.14), *HLA-C*04:01P* (0.19), *HLA-DPA1*01:03P* (0.63), *HLA-DPB1*04:01P* (0.29), *HLA-DQA1*01:02P* (0.29), *HLA-DQB1*02:01P* (0.23), *HLA-DRB1*07:01P* (0.16), *HLA-G*01:01P* (0.66). Most interestingly, we found a significant difference in the frequency of *HLA-B*07:02P* allele when comparing patients to controls, p-value=0.01299, 95%CI:1.134062-6.477955, OR:2.839002. These results may indicate a potential role for HLA-B in the predisposition to AE in the population studied.

Complex Traits Posters - Thursday

PB1460. HLA types are associated with hundreds of complex traits and diseases in an ancestry-dependent manner

Authors:

M. D'Antonio¹, D. Perry¹, A. Massarat¹, J. Margoliash², M. Gymrek³, K. Frazer⁴; ¹Univ. of California, San Diego, LA JOLLA, CA, ²Univ. of California, San Diego, San Diego, CA, ³Univ California San Diego, La Jolla, CA, ⁴UC San Diego, SAN DIEGO, CA

Abstract Body:

The 4 Mb major histocompatibility (MHC) region on chromosome 6p21.3, which encodes the human leukocyte antigen (HLA) gene complex, is highly polymorphic, gene dense (383 genes), and exhibits strong linkage disequilibrium. Genome-wide association studies (GWAS) have identified many traits and diseases with significant associations in the MHC region; however, ~90% of GWAS have been performed on European individuals. Additionally, GWAS have primarily focused on common SNPs, and omitted analysis of whole HLA genes alleles (HLA types), which can be poorly tagged by SNPs. For these two reasons, we believe many genetic associations located in the MHC region have yet to be discovered. We utilized 479,806 individuals in the UK BioBank (UKBB), including 443,019 individuals of European, 7,746 South Asian, 7,745 African and 2,366 East Asian descent, as well as 18,931 admixed individuals. We examined associations between the genotypes of 346 imputed HLA types at 4-digit resolution (distinguishing nonsynonymous variants between alleles) for 11 HLA genes and >75,000 SNPs in the MHC region and 1,213 traits, including ICD9 and ICD10 codes and blood biochemistry markers, and observed genome-wide significant associations for 419 traits, including 60 associations that are European-specific, 44 that are African-specific and 70 that are East Asian-specific. This indicates that the MHC region has strong ancestry-specific components. To understand the differences between genetic associations for 4-digit HLA types and SNPs, we performed fine-mapping using SuSiE on each genome-wide significant trait and found 2,215 independent signals. For 37 signals, the variant with the strongest posterior inclusion probability was an HLA type, indicating that in certain cases HLA types explain more trait variation than each single SNP. These cases include the previously reported association between HLA-DRB1*01:03 and ulcerative colitis across all individuals, as well as multiple ancestry-specific associations, including: HLA-C*15:02 and kidney failure in Africans; HLA-DRB1*04:04 and aortic valve disorders in East Asians; HLA-B*35:01 and lymphocyte percentage in Europeans; and HLA-B*14:01 and C-reactive protein levels in South Asians. Our study shows that the MHC region is associated with hundreds of traits in an ancestry-specific fashion, and that many of these associations are likely driven by HLA types rather than single SNPs. Expanding HLA types from 4-digit to 8-digit resolution (which distinguish nonsynonymous, synonymous, and non-coding regulatory variants between alleles) will likely identify hundreds more associations with specific HLA gene alleles.

Hosp., Toronto, ON, Canada, ¹³Dynacare Med. Lab., Toronto, ON, Canada, ¹⁴Mackenzie Hlth., Toronto, ON, Canada

Abstract Body:

Background: The susceptibility and severity of COVID-19 caused by severe acute respiratory syndrome coronavirus (SARS-CoV-2) is tied closely to host genetic factors. Association studies have shown that genetic variants of the human leukocyte antigen (HLA) locus influence the progression of SARS-CoV-2 infections by affecting immune response pathways. This study intends to evaluate additional evidence for the role of Class I and II HLA allelic variation with COVID-19 outcomes including factors such as age and sex in a large prospective cohort. This study is part of the GENCOV initiative, which aims to examine the relationship between COVID-19 disease risk factors, host genetics, and antibody response. **Aim:** The aim of this study is to identify novel associations between HLA alleles and COVID-19 symptom severity and antibody response. **Methods:** The GENCOV cohort consists of 1438 individuals undergoing genome sequencing and serological analysis. Blood samples are collected during COVID-19 infection as well as at 1, 6, and 12 months after diagnosis for assessment of serial antibody titres (IgG, IgA, and IgM), isotypes, antigen targets, and viral neutralization. The bioinformatics tools Optitype and HLA-VBSeq were used to call HLA variants from genome data. **Results:** To date, serology results have been acquired from 1135 participants, with ~50% over age 50. Self-identified ancestry included White/European (70%), Middle Eastern (13%), Asian (11%), and Ashkenazi Jewish (9%). Among the cohort, 36% were hospitalized due to COVID-19 and 46% had at least one comorbidity, such as cardiac disease (7%), diabetes (5%), and cancer (4%). Optitype results for three HLA loci identified the highest frequency alleles among 778 participants as A*02:01 (42%), B*08:01 (13%), and C*04:01 (28%). Similarly, HLA-VBSeq analysis performed on 605 of the 778 participants identified the highest frequency alleles as A*02:01:01:01 (43%), B*35:01:01:05 (11%), and C*12:03:01:01 (71%). Previously, C*04:01 has been associated with severe COVID-19 outcomes resulting in intubation and hospitalizations. Regression tree analyses will be used to identify associations between HLA alleles and serological profiles (IgA, IgG, IgM), as well as characteristics such as sex, BMI, age, symptom severity, and disease comorbidities. Findings related to HLA associations will be presented at the conference. **Conclusion:** This study will evaluate the contribution of HLA genotype to COVID-19 symptom severity, antibody response and disease phenotypes to further elucidate potential host biological factors that influence variability in SARS-CoV-2 outcomes.

Complex Traits Posters - Thursday

PB1462. *HLA* associations with autoantibody-defined subgroups in idiopathic inflammatory myopathies

Authors:

L. Diaz-Gallo¹, V. Leclair^{1,2}, A. Galindo-Feria¹, S. Sarrafzadeh Zargaw¹, S. Rothwell³, O. Krystufkova⁴, H. Mann⁴, L. P. Diederichsen⁵, H. Andersson⁶, M. Klein⁴, S. Tansley⁷, N. McHugh⁷, J. A. Lamp³, J. Vencovsky⁴, H. Chinoy⁸, M. Holmqvist¹, M. Bianchi⁹, I. E. Lundberg¹, L. Padyukov¹; ¹Karolinska Inst.t, Stockholm, Sweden, ²Div. of Rheumatology, Jewish Gen. Hosp. Lady Davis Inst., Montreal, QC, Canada, ³Univ. of Manchester, Manchester, United Kingdom, ⁴Charles Univ., Prague, Czech Republic, ⁵Copenhagen Univ. Hosp., Copenhagen, Denmark, ⁶Oslo Univ. Hosp., Oslo, Norway, ⁷Univ. of Bath, Bath, United Kingdom, ⁸Manchester Univ. NHS, Manchester, United Kingdom, ⁹Uppsala Univ., Uppsala, Sweden

Abstract Body:

Objective: In idiopathic inflammatory myopathies (IIM), autoantibodies define specific phenotypes suggesting a role of the adaptive immunity in the disease mechanisms. Therefore, we explored the relationship between autoantibody-defined subgroups, including both myositis-specific and -associated autoantibodies (MSA/MAA) and *HLA* genetic variants.

Methods: We included 1348 patients with probable or possible IIM and determined the occurrence of: anti-Jo1, -PL7, -PL12, -EJ, -OJ, -SRP, -Mi2, -TIF1, -MDA5, -SAE1, -NXP2, -PM/Scl, -U1RNP and -Ro52 autoantibodies. We used cluster analysis to identify autoantibody-defined subgroups and estimated their associations with clinical manifestations, *HLA-DRB1*, *-DQA1*, *-DQB1*, alleles, and class II and I amino acid frequencies, using logistic regression.

Results: We identified eight subgroups with the following dominant autoantibodies (% of patients): 1) anti-Ro52 (10%), 2) -U1RNP (14%), 3) -PM/Scl (8%), 4) -Mi2 (5%), 5) -Jo1 (9%), 6) -Jo1/Ro52 (10%), 7) -TIF1 (6%) and 8) negative for tested autoantibodies (39%). *HLA-DRB1**11, *15, *-DQA1**03, and *-DQB1**03 alleles were more frequent in the anti-U1RNP dominated subgroup, while *HLA-DRB1**03, *-DQA1**05, and *-DQB1**02 alleles were overrepresented in the anti-PM/Scl dominated subgroup. For the anti-Mi2 dominated subgroup, *HLA-DRB1**07 had the strongest association signal. In the case of anti-TIF1 dominated subgroup, signals from class I (*HLA-C* and *-A*) were detected additionally to other signals from class II. Although *HLA-DRB1**03 was overrepresented in both the anti-Jo1 and anti-Jo1/Ro52 subgroups, *HLA-DQA1**05, *-DQB1**02 and aspartic acid in position 9 of HLA-B were increased only in the latter. Lastly, *HLA-DRB1**13, *-DQA1**01 and *-DQB1**06 alleles and tryptophan and arginine at position 152 of HLA-A were overrepresented in the subgroup negative for tested autoantibodies.

Conclusion: Distinct *HLA* class II and I associations were uncovered for each of the autoantibodies-defined IIM subgroups. Combining *HLA* genotype to autoantibody profiles in IIM can help to unravel some of the pathogenic mechanisms in different subgroups and suggest a role of the adaptive immune system in the production of autoantibodies in IIM.

Complex Traits Posters - Wednesday

PB1463. *HLA-DRB1*15:01* modifies sphingolipid levels in multiple sclerosis

Authors:

F. Briggs^{1,2}, E. Misicka¹, W. Tobin³, J. Oksenberg⁴, S. Gregory⁵; ¹Case Western Reserve Univ. Sch. of Med., Cleveland, OH, ²Cleveland Inst. for Computational Biology, Cleveland, OH, ³Mayo Clinic, Dept. of Neurology, Rochester, MN, ⁴Univ. California San Francisco, Weill Inst. for NeuroSci.s, Dept. of Neurology, San Francisco, CA, ⁵Duke Univ., Dept. of Neurology, Durham, NC

Abstract Body:

Background. Multiple sclerosis (MS) is an autoimmune disease and mediated, in part, by myelin-specific autoreactive T cells. The primary genetic risk locus for MS, *HLA-DRB1*15:01* (DR2b), encodes an MHC class II molecule involved in antigen presentation, with high affinity for myelin antigens. Recently, an *HLA-DQA1* variant (rs13211653A; significant linkage disequilibrium with DR2b: $D'=1$, $r^2=0.03$, $p<0.0001$) was associated with lower plasma levels of sphingomyelin (SM; $p<10^{-8}$). SM is a key component of myelin, and SM hydrolysis is the major pathway of ceramide (Cer) generation, and these sphingolipids (SLs) modulate many signaling pathways including neuronal cell death and T cell activity, and may play a prominent role in MS. **Objective.** To determine if DR2b differentially modifies SM and ceramide serum levels in MS. **Design/Methods.** Metabolomic profiling was conducted for 70 non-Hispanic white MS cases and 82 healthy controls (HCs) using untargeted HD4 global technology (Metabolon), and 29 SM and 9 Cer metabolites were discerned. MS cases were disease modifying therapy naïve (96%) or free (>90 days), ≤ 2 years of diagnosis, and <5 years of 1st symptom. HCs were age/sex frequency matched. DR2b carriage (dominant model) was determined by rs3135388A tagging SNP. Logistic regression models were conducted with main effects and an interaction term between DR2b carriage and each metabolite (normalized & standardized), adjusting for age, sex, smoking history, and BMI. The Simes method was used to control the false discovery rate. Stratified models were conducted for metabolites with significant interactions ($q<0.05$). **Results.** There were 54% and 46% of MS cases and 32% and 69% HCs were DR2b positive or negative, respectively; therefore, MS was associated with DR2b carriage in the study sample (OR=2.5; $p=0.007$). There were 18 (47%) significant DR2b x metabolites interactions for 15 SM and 3 Cer metabolites ($OR_{\text{Ixn}}<0.15$; $q<0.05$). In DR2b non-carriers, all metabolites were trending in association with MS (OR>2.3; $p<0.2$), and 9 metabolites (8 SM; 1 Cer) were significantly associated with MS status (OR: 2.7-11.2; $p<0.05$). The strongest associations with MS in DR2b non-carriers were for SM_{d18:1/22:1, d18:2/22:0, d16:1/24:1} (OR=11.2, $p=0.03$), SM_{d18:1/17:0, d17:1/18:0, d19:1/16:0} (OR=10.4, $p=0.0096$), and stearyl SM_{d18:1/18:0} (OR=8.1, $p=0.02$). Interestingly, no metabolite was associated with MS status in DR2b carriers. **Conclusions.** We observed significantly elevated serum levels of several SL metabolites in DR2b negative MS cases compared to HCs but not in DR2b positive individuals, and warrants further investigation. Replication analyses are underway.

Complex Traits Posters - Thursday

PB1464. Host Genetics in Resistance to COVID-19: Hints from recovered Brazilian superelderly

Authors:

M. de Castro¹, E. C. Castelli², M. S. Naslavsky¹, M. O. Scliar¹, N. S. B. Silva², R. N. Pereira², V. A. O. Ciriaco², C. F. B. de Castro², C. T. Mendes-Júnior³, D. Meyer¹, K. Nunes¹, L. R. B. H. N. Saldiva¹, M. Passos-Bueno¹, M. Zatz¹; ¹Univ. of Sao Paulo, Sao Paulo, Brazil, ²São Paulo State Univ. (UNESP), Botucatu, Brazil, ³Univ. of Sao Paulo, Ribeirão Preto, Brazil, ⁴Prevent Senior Inst., Sao Paulo, Brazil

Abstract Body:

Since the onset of COVID-19 pandemic, it has been suggested that the clinical variability caused by SARS-CoV-2 infection could be influenced by the host genotype. So far, most of the reported genetic variants responsible for the disease vulnerability are associated with immune response, involving type I IFN immunity and modulation; *HLA* cluster genes; inflammasome activation, genes of interleukins; and chemokines receptors. On the other hand, little is known about the resistance mechanisms against SARS-CoV-2 infection. Interestingly, although elderly people are at a significantly higher risk of having severe and lethal forms of COVID-19, some cases of still unvaccinated centenarians who have recovered from COVID-19 or remained asymptomatic despite SARS-Cov-2 exposition have been identified worldwide. Based on these observations and aiming to identify candidate genes associated with host resistance we investigated 100 Individuals older than 90 years recovered from COVID-19 (Group 90+ / n=100) with mild symptoms as compared to the other extreme group, 50 individuals younger than 60 years who died due to COVID-19 (Group 60- / n=50). SARS-CoV-2 infection was confirmed by RT-PCR test or histopathological analysis. Biological samples (peripheral blood from the elderly or skin fragments from the younger at autopsy) were collected to obtain DNA. Whole-exome sequencing (WES) followed by a state-of-the-art method was performed to call genotypes and haplotypes across the highly polymorphic major histocompatibility complex (MHC) region. We found that the super elderly group displayed a higher frequency of missense variants in the *MUC22* gene (which is a member of the mucins' family), as one of the strongest signals in the MHC region as compared to the severe COVID-19 group and the general elderly control population. Since the pro-inflammatory basal state in the elderly may enhance the susceptibility to severe COVID-19, we hypothesised that *MUC22* might play an important protective role against severe COVID-19, by reducing overactive immune responses in the senior population. Complex Traits Posters - Wednesday

PB1465. How are *APOE4*, changes in weight/BMI, and longevity related? Insights from a Causal Mediation Analysis.

Authors:

R. Holmes, H. Duan, K. Arbeev, D. Wu, A. Yashin, S. Ukraintseva, Biodemography of Aging Research Unit, Social Science Research Institute; Duke Univ., Durham, NC

Abstract Body:

Introduction: The $\epsilon 4$ allele of the *APOE* gene (*APOE4*) is known for its negative association with human longevity, though the mechanism is unclear. *APOE4* was also linked to changes in weight/BMI, and the latter itself was associated with survival in late life. This indicates a possibility that some of the *APOE4* effects on longevity may be attributed to aging changes in weight/BMI.

Method: To see if the negative association of *APOE4* with longevity is mediated by key characteristics of age-trajectories of weight/BMI, we performed a Causal Mediation Analysis in the Health and Retirement Study data. The $\epsilon 4$ allele carrying status (yes vs. no) was the *causal agent*. We used two binary *mediators*: (1) rate of changes in bodyweight (SlopeW) between ages 65 and 80 being below vs. above median value; and (2) age at reaching maximum BMI value (AgeMaxBMI) being younger vs. older than 75, and all individuals survived age 80. The *outcome* was a binary survival variable (survived age 85+ vs. died before 85). 3292 and 3020 individuals with AgeMaxBMI and SlopeW values, respectively, were included in the analysis. SAS procedure PROC CAUSALMED under counterfactual framework was used, controlling for smoking and education to address confounding. Log link was used to address the non-rare outcome situation. Mediation effects were evaluated by the Total Effect (TE) and Natural Indirect Effect (NIE).

Results: Younger AgeMaxBMI (below 75) was a significant mediator of negative *APOE4* effect on survival to ages 85+ in total sample, and in samples stratified by sex and race (p-values between 0.02-0.04). The $\epsilon 4$ carriers were 17%-21% more likely to die before age 85, compared to noncarriers, when considering the mediator effect (TE p-values 0.02-0.047, NIE p-values 0.006-0.008). The percentage of the total effect mediated by AgeMaxBMI was 21% for the overall sample (p=0.044), and varied between 21%-22% in strata (p-values 0.042-0.046). SlopeW was a significant mediator of the *APOE4* effect on survival 85+ in unstratified data, with chances of dying before age 85 being 22% higher for $\epsilon 4$ carriers vs. noncarriers (TE p-value = 0.02). Indirect effect was statistically significant (NIE p-value=0.015). Similar effects were observed for both sexes.

Conclusion: Results of our Causal Mediation Analysis suggest that carriers of the *APOE* $\epsilon 4$ allele may have lower chances of surviving to age 85 and beyond in part because they reach peak values of weight/BMI at younger ages, and decline faster afterwards, compared to non-carriers. These findings are in line with the idea that detrimental effects of *APOE4* on longevity may involve accelerated physical aging, and that *APOE4* can be a promising target for anti-aging interventions.

Complex Traits Posters - Thursday

PB1466*. Hypermethylation of *PM20D1* promoter is associated with atherosclerosis in Dominican Families

Authors:

L. Wang¹, N. Dueker², H. Zhao³, C. Dong⁴, D. Cabral⁵, R. Sacco⁵, S. Blanton⁴, C. Dong⁴, T. Rundek⁴; ¹Univ. of Miami, PALMETTO BAY, FL, ²Univ. of Miami Miller Sch. of Med., Miami, FL, ³Yale Univ. Sch. of Publ. Hlth., New Haven, CT, ⁴Univ Miami, Miami, FL, ⁵Univ. of Miami, Miami, FL

Abstract Body:

Introduction: Carotid intima-media thickness (cIMT) is a marker of atherosclerosis and a predictor of vascular disease. Traditional vascular risk factors, e.g., hypertension, smoking, cholesterol, obesity, diabetes, and genetic loci do not completely explain the variation in cIMT. We sought to identify epigenetic factors that may explain the remaining cIMT variability. **Methods:** Methylome-wide association analyses (MWAS) was performed in 61 Dominican families with 799 individuals. CpG methylation in blood-derived DNA was measured using the Human MethylationEPIC BeadChip. *ComBat* was used to remove batch effects. Linear mixed model analyses were performed regressing bifurcation cIMT on beta values for CpG sites, adjusting for age, sex, 1st ancestry principal component, and cell composition. Family was included as a random effect. Differentially methylated regions (DMRs) analysis was performed using Comb-p. Methylation-quantitative trait loci (m-QTL) analysis was done using linear mixed effects models implemented in the R package 'lmer4'. One-sample mendelian randomization (MR) analysis was performed using the R package 'systemfit.' **Results:** 29 DMRs were significantly associated with cIMT (Sidak $p < 0.05$), averaging 5 ± 2 CpGs per DMR. The strongest DMR (Sidak $p = 1.2 \times 10^{-13}$) overlapped with the promoter of *PM20D1*. All 11 CpGs within the *PM20D1* DMR were associated with cIMT ($\beta = 0.20 \sim 0.34$; $p = 0.0004 \sim 0.002$). *PM20D1* deficiency has been previously implicated in obesity and diabetes. In our cohort, the *PM20D1* methylation was not associated with obesity (BMI: $r = 0.02$, $p = 0.54$; waist-hip ratio: $r = 0.03$, $p = 0.42$), or diabetes ($p = 0.09$), suggesting that the association of *PM20D1* methylation with cIMT is not mediated by obesity or diabetes. Furthermore, all 11 CpGs are associated with cis variants nearby, e.g. cg14159672_rs1775147 ($\beta = 0.14$, $p = 5.53 \times 10^{-36}$), which is consistent with The Accessible Resource for Integrated Epigenomic Studies (ARIES, $\beta = 0.52$, $p = 2.21 \times 10^{-22}$). In addition, rs1775147 is an expression QTL for *PM20D1* in the peripheral blood ($p = 6.6 \times 10^{-11}$), suggesting hypermethylation of *PM20D1* DMR directs lower expression of the gene. MR analysis supported that the hypermethylation at the *PM20D1* promoter is causatively associated with cIMT ($p = 0.02$). **Conclusion:** *PM20D1* acts as endogenous uncouplers of mitochondrial respiration, which is a cytoprotective strategy against oxidative stressors. Reduced expression of *PM20D1* leads to reduced uncoupling and increased reactive oxygen species production. Taken together, our data suggest that hypermethylation of *PM20D1* is a novel mechanism of atherosclerosis probably via oxidative stress.

Complex Traits Posters - Wednesday

PB1467. Hypertension Prediction From Metabolomics For Two Cardiovascular Disease Cohorts and Transfer Learning of Resultant Models

Authors:

H. Gong¹, D. Nguyen², A. Gaye¹, G. Gibbons¹; ¹NIH, Bethesda, MD, ²NIH, Bethesda, MD

Abstract Body:

Background. We hypothesize that hypertension and other cardiovascular disease will have predictive signal in metabolomics data, since small molecules are known to mediate and be produced by those diseases. We investigated two cohorts, the MH-GRID (Minority Health Genomics and Translational Research Bio-Repository Database) cohort of blacks (n=165) and GENE-FORECAST (Genomics, Environmental Factors, and the Social Determinants of Cardiovascular Disease in Africans Americans) (n=534).

Data. We have GC-TOF metabolomics data from Plasma in both MH-GRID and GENE-FORECAST. The data is corrected for sample drift using SERRF (Systematical Error Removal using Random Forest), and batch corrected into the same multidimensional space using the ComBat empirical Bayes method.

Results. We generated a random forest model in MHGRID with an AUC of 0.76. That model applied to GENE-FORECAST data resulted in a 62.6% accuracy for hypertension prediction. Additionally, we found WGCNA metabolite modules that were significantly associated with triglycerides, glucose, HDL, and systolic blood pressure.

Complex Traits Posters - Thursday

PB1468. Identification of a locus associated with major depressive disorder in a Colombian population

Authors:

C. Lattig¹, M. M. Velásquez¹, L. C. Hernández¹, Á. Arenas¹, Y. Gómez¹, E. Ferro²; ¹Univ. de los Andes, Bogotá D.C, Colombia, ²Clínica Montserrat, Bogotá D.C, Colombia

Abstract Body:

Determining the genetic architecture of major depression is relevant for the understanding of this multifactorial and highly prevalent disorder as well as designing strategies of personalized medicine. Several genome-wide association studies (GWAS) have allowed the identification of variants that may confer risk of developing depressive phenotypes. However, most of them have focused on European populations, leaving underrepresented those of admixed ancestry, such as Latin Americans. The present study included a sample of 171 healthy controls and 169 cases with a primary diagnosis of major depression. After genotyping, which was performed through the Infinium Global Screening Array-24 v2.0 (Illumina), the data was filtered according to genotyping call rates, minor allele frequencies and Hardy-Weinberg equilibrium. Then a multivariate logistic regression analysis was performed (Plink 1.9) to identify common variants associated with the clinical phenotype. The results provide evidence of a locus potentially associated with the disorder and that is in linkage disequilibrium with variants located within the *CNTN5* gene. This gene codes for the human contactin-5 protein, which has a role in the formation and maintenance of neuronal connectivity during development and have been associated with depression and autism. Although with a limited sample size, this study included a strategy of deep phenotyping and provides insights into the genetic architecture of major depression in an admixed population, that could be useful for subsequent meta-analyses.

Complex Traits Posters - Wednesday

PB1469. Identification of genetic loci associated with peanut specific IgG4 in high risk children from the LEAP study

Authors:

K. Kanchan¹, J. Perry², G. Shankar¹, I. Ruczinski³, C. Baloh⁴, G. Du Toit⁵, G. Lack⁵, K. Cerosaletti⁶, G. Nepom⁶, R. Mathias¹; ¹Johns Hopkins Univ. Sch. of Med., Baltimore, MD, ²Univ. of Maryland Sch. of Med., Baltimore, MD, ³Bloomberg Sch. of Publ. Hlth. Johns Hopkins Univ., Baltimore, MD, ⁴The Immune Tolerance Network, Seattle, WA, ⁵King's Coll. London, and Guy's and St Thomas' NHS Fndn. Trust, London, United Kingdom, ⁶Benaroya Res. Inst. at Virginia Mason, Seattle, WA

Abstract Body:

Learning Early About Peanut Allergy (LEAP) was a prospective, randomized, clinical trial in young children at high risk of peanut allergy (PA), establishing that early peanut consumption is effective in preventing PA. LEAP participants were randomly assigned to dietary peanut consumption or avoidance, and levels of peanut-specific IgG4 (psIgG4) were measured in serum at multiple time points throughout the trial. The consumption group of the trial had increased levels of psIgG4. We aim to identify genetic determinants of psIgG4 among those consuming peanuts, to elucidate potential genetic mechanisms for tolerance to peanuts. Whole genome sequencing was carried out on all participants. Genome-wide association tests adjusting for genetic ancestry, age at baseline, and sex was performed on 10,830,622 variants for psIgG4 among the 267 consumption group participants at 60 months of age, the primary endpoint in the trial. We identified 45 variants with p-values below the suggestive genome-wide significance threshold of 1×10^{-5} , mapping to 17 genetic loci. These loci mapped to genes known to be associated with barrier function (e.g., *SEPT2* and *PNPLA1*) and previously documented PA genes (e.g., *HLA-DQA1* and *HLA-DQB1*). We performed fine-mapping for 16 of these novel loci using the colocalization approach coloc (the HLA locus on chr6 has been previously described) and tested for colocalization against eQTLs for genes +/-200kb around each sentinel variant from 54 tissues from the GTEx catalog. A chromosome 2 locus for psIgG4 colocalizes to regulatory evidence for *SEPT2* and a lncRNA gene *AC005104.3*. We identified two credible causal variants, rs115271170 (MAF=33%, posterior probability of colocalization > 97%) in the small intestine and rs1429386442 (MAF=10%, posterior probability of colocalization 98%-100%) in numerous gut tissues such as esophagus gastroesophageal junction, esophagus mucosa, esophagus muscularis, stomach, colon sigmoid, colon transverse, lung, and whole blood. *SEPT2* encodes Septin 2, which is required for correct formation and polarization of the epithelium and mediates epithelial barrier function. This novel locus, a determinant of the psIgG4 response to peanut consumption, offers further validation of the importance of barrier dysfunction in food allergy, and the value of looking for genetic underpinnings of food allergy in the context of environmental exposure to an allergen.

PB1470. Identification of genetic loci with divergent effects between Crohn's disease and ulcerative colitis.

Authors:

Y. Kim¹, S. Jung¹, H-S. Lee¹, D. Park¹, Y. Lee¹, S. Park¹, J. Baek¹, S. Hwang², S. Park², S-K. Yang², B. Ye², K. Song¹; ¹Dept. of Biochemistry and Molecular Biology, Univ. of Ulsan Coll. of Med., Seoul, Korea, Republic of, ²Dept. of Gastroenterology, Univ. of Ulsan Coll. of Med., Seoul, Korea, Republic of

Abstract Body:

Crohn's disease (CD) and ulcerative colitis (UC), the two main types of inflammatory bowel disease, show substantial differences in clinical course and the treatment response. Understanding the genetic factors underlying the distinct characteristics of the two diseases will be crucial for improving diagnosis and treatment. We performed a genome-wide association study (GWAS) between CD (n=2359) and UC (n=2175) in a Korean population, followed by replication in an independent samples of 772 CD and 619 UC cases. We used publicly available summary statistics (Liu et al., 2015; de Lange et al. 2017) for comparison with and replication of our results. Genetic correlation between CD and UC in the Korean population ($r_{gKOR}=0.17$) was significantly lower than that of a European population based on the publicly available summary statistics ($r_{gEUR}=0.60$, $Z\text{-score}=3.60$, $P=1.60\times 10^{-4}$). Through a meta-analysis of the GWAS, we identified 2 novel loci with divergent effects between CD and UC: rs9842650 in *CD200* at 3q13 and rs885026 in *NCOR2* at 12q24. In addition, the 7 established susceptibility loci (MHC, *TNFSF15*, *OTUD3*, *USP12*, *IL23R*, *FCHSD2*, and *RIPK2*) reached genome-wide significance. Of the 9 loci, 6 (MHC, *TNFSF15*, *OTUD3*, *USP12*, *IL23R*, and *CD200*) were replicated in the case-case GWAS (CC-GWAS) of European and/or East Asian populations using the summary statistics. Pathway analysis using MAGMA showed that the interferon-gamma mediated signaling ($P=1.16\times 10^{-8}$) and cytokine-mediated signaling pathway ($P=2.71\times 10^{-6}$) were associated with genes in the loci with divergent effects. The proportion of variance explained in CD-UC status by polygenic risk score analysis was up to 22.6% (Nagelkerke's R^2). The area under the receiver-operating characteristic curve value was 0.74, suggesting acceptable discrimination between CD and UC. CD-UC GWAS provides new insights into genetic differences between the two diseases with similar symptoms, which might be useful in improving their diagnosis and treatment. Future studies of large-scale data are needed to verify our observations in diverse populations.

PB1471. Identification of novel genetic variants for association with rheumatoid arthritis susceptibility in Pakistani population

Authors:

S. Ali¹, R. Fatima¹, A. Maigoro^{1,2}, M. Bashir¹, A. Kanwal¹, H. Sadia¹, A. Suhail¹, J. M. Malik³, S. Khurshid⁴; ¹COMSATS Univ. Islamabad, Islamabad, Pakistan, Islamabad, Pakistan, ²Chungnam Natl. Univ., Daejeon, Korea, Republic of, ³Rehmat Noor Clinic, Rawalpindi, Pakistan, ⁴Pakistan Inst. of Med. Sci., Islamabad, Pakistan

Abstract Body:

Rheumatoid arthritis (RA) is an autoimmune disease, primarily affecting synovial joints causing inflammation and joint degradation. RA is responsible for a considerable degree of morbidity. It is a complex disease with both genetic and environmental risk factors. In the present study, 740 participants (370 cases and 370 controls) of Pakistani descent were genotyped for 14 common variants in nine candidate genes. Prior informed written consent was sought from all the cases and controls. Genotyping of the selected variants was done through PCR-based techniques. The association of variants with RA susceptibility was statistically investigated through multivariate logistic regression analysis. This case-control study indicated some significant associations in the overall and sub-group analyses. The rs2275913, rs3819024 and rs8193036 of *IL17A*; rs2397084 of *IL17F*; rs11549465 and rs11549467 of *HIF1A*; rs1799983 of *NOS3*; rs874881 of *PADI4* and rs4803455 of *TGFB1* showed significant association with the modified RA risk. In the smoking status-based sub-group analysis, the rs3819024 and rs8193036 of *IL17A*; rs763780 and rs2397084 of *IL17F*; rs11549465 of *HIF1A*; rs1799983 of *NOS3* and rs874881 of *PADI4* were found to be associated with differential risk among smokers and non-smokers. Further sub-group analysis, on the basis of self-identified gender, revealed the significant associations of rs2275913 of *IL17A*; rs763780 of *IL17F*; rs11549465 of *HIF1A* and rs1800795 of *IL6*, with susceptibility to RA. In brief, the present study identifies novel common variants and also confirms some previously known associations for rheumatoid arthritis susceptibility.

Complex Traits Posters - Thursday

PB1472. Identification of platelet aggregation genetic determinants: Results from a cross-ancestry GWAS meta-analysis

Authors:

F. Thibord, M. V. Chan, B. B. Nkambule, A. Lachapelle, J. Grech, R. E. Pashek, J. A. Cunha, M-H. Chen, A. D. Johnson; NIH/NHLBI, Framingham, MA

Abstract Body:

Platelets can be activated in response to several endogenous agonists, such as collagen exposed at a site of vessel injury, resulting in aggregation and the formation of a platelet plug to preserve vascular integrity. However, platelet hyperactivity has been associated with an increased risk of cardiovascular disease, a major cause of mortality worldwide. As platelet reactivity is heritable, our aim was to identify genetic associations in a mixed population utilizing newly collected data.

Platelet reactivity was investigated using two assays: light transmission aggregometry (LTA) and multiplate impedance aggregometry (MP). Agonists used to induce platelet activation included ADP, collagen, ristocetin and TRAP-6 amide for MP, and arachidonic acid and epinephrine were additionally used for LTA. Analyses were conducted in up to 2901 participants of European ancestry from the Framingham Heart Study (FHS) and 262 individuals of multi-ancestry from the OMNI cohort. Genetic analyses were adjusted for relatedness, age, sex, aspirin use, and 10 principal components using a linear mixed model. Variants with minor allele frequency ≥ 0.01 and imputation quality ≥ 0.8 were included in the analysis. Results from FHS and OMNI were then meta-analyzed using a fixed-effect inverse variance weighted model, and associations with a concordant effect direction in both cohorts and reaching $P < 5 \times 10^{-8}$ were considered significant.

Our analyses revealed five significant signals: rs6510306-C with stimulation by epinephrine (*CEP89* intron, $P = 1.17 \times 10^{-9}$), rs72867273-G with TRAP-6 (intergenic, $P = 1.96 \times 10^{-9}$) and rs670337-C with collagen (intergenic, $P = 4.96 \times 10^{-8}$) in LTA, as well as the previously reported *ITGA2* and *ADRA2A* loci, associated with MP collagen and LTA epinephrine responses, respectively. Then, we investigated suggestive associations ($P < 10^{-5}$) that were previously reported to also influence the platelet transcriptome, using eQTL results from the CEDAR and GENESTAR studies. This analysis identified nine associations that also influenced the expression of the following genes in platelets: *SAP30L*, *PNP*, *TPMI*, *PYGB* and *NCOA3*, as well as the known *PEAR1*, *ITGA2*, *ADRA2A* and *GP6*.

In conclusion, our significant results, as well as our suggestive results combined with platelet eQTL data, point to novel molecules that influence platelet aggregation, which could help to develop new therapeutic strategies to reduce platelet hyperactivity. Future directions include expanding these analyses using other platelet assays, as well as additional analyses stratified by sex and anti-platelet medication use.

Complex Traits Posters - Wednesday

PB1473. Identification of shared genes and pathways between psychiatric GWAS and monogenic neurodevelopmental disorders

Authors:

P. Jansen^{1,2}, E. van Walree^{1,2}, S. de Lange³, D. Posthuma²; ¹Dept. of Human Genetics, Amsterdam UMC, Amsterdam, Netherlands, ²Dept. of Complex Trait Genetics, VU Univ., Amsterdam, Netherlands, ³Dept. of Complex Trait Genetics, VU Univ., Amsterdam, Netherlands, Amsterdam, Netherlands

Abstract Body:

Introduction: Large genome-wide association studies (GWAS) rapidly identified novel risk genes for psychiatric disorders. Mendelian neurodevelopmental disorders (NDD) caused by single gene mutations show overlapping behavioral symptomatology, however the extent to which genes are shared between psychiatric GWAS and monogenic NDD needs to be fully explored.

Methods: We carry out genetic overlap analyses between five large-scale psychiatric GWAS (ADHD, autism, bipolar disorder, depression, schizophrenia, sample size range: N=46,077–807,553) and monogenic neurodevelopmental disorders (NDDs). Consistent gene-mapping was done in FUMA for each GWAS. Overlap analyses were carried out with monogenic disease genes in the Developmental Disease Gene - Phenotype (DDG2P) database. Using various bioinformatic resources, we analyzed gene properties and gene-expression of genes implicated in psychiatric disorders, NDDs or both.

Results: We found strong and statistically significant enrichment of psychiatric GWAS genes in all monogenic NDDs (enrichment=1.18, $P=1.70 \times 10^{-5}$), and NDDs genes related to abnormal brain development (enrichment=1.39, $P=1.10 \times 10^{-9}$). Of all psychiatric disorders, ADHD showed the strongest overlap with NDDs ($P=0.009$), and bipolar the lowest ($P=0.96$). We show that differences in gene function (synaptic and neurogenesis), properties (pLI score, missense sensitivity) and expression patterns predict involvement of genes in psychiatric GWAS, NDD or overlapping in both. We observed that psychiatric GWAS genes are significantly more common in known copy number variant (CNV) regions that are associated with a high risk of psychiatric symptoms (8% of psychiatric genes located CNVs).

Conclusions: Our findings provide novel insights into partly shared genetic etiologies between polygenic psychiatric disease and monogenic NDDs, and highlight mechanisms and gene properties that explain overlap between seemingly separate monogenic and polygenic disease. These results show that GWAS can inform the search of novel NDD genes, whereas monogenic NDDs can aid in the interpretation of GWAS loci.

Complex Traits Posters - Thursday

PB1474. Identifying compounds to treat opiate use disorder by leveraging multi-omic data integration and multiple drug repurposing databases.

Authors:

J. Stratford¹, M. Carnes¹, M. Schu¹, B. Quach¹, C. Willis¹, R. Mathur¹, E. Johnson¹, J. Carter¹, T. Nolen¹, N. Vandergrift¹, T. Kosten², B. Webb¹; ¹RTI Intl., Research Triangle Park, NC, ²Baylor Coll. of Med., Houston, TX

Abstract Body:

Recently, specific genetic loci influencing opiate use disorder (OUD) risk have begun to be identified. Gene expression and network analyses offer additional insight beyond risk. However, even multi-domain investigations rarely focus on producing prioritized targets for translational studies. To address this gap, we constructed a framework to identify biological targets and pharmacotherapies for clinical repurposing studies. This is accomplished by 1) leveraging extant results, 2) performing cross-omic network-based analysis, 3) creating an integrated catalogue of results and biological targets, and 4) generating a prioritized list of existing candidate compounds for future repurposing studies. OUD results were collected including two large ($n=304,507$, $n=79,729$) independent genome-wide association studies (GWAS) and four post-mortem human brain gene expression (285 independent samples). Network analyses were performed using dense module GWAS (dmGWAS) to identify human brain specific protein-protein interaction (PPI) modules. Drug repurposing databases Pharos, Open Targets, Therapeutic Target Database (TTD), and DrugBank were queried for clinical status, safety, and target selectivity. Cross-omic and drug query results were integrated for all genes in the genome, allowing flexible filtering to identify candidate compounds for follow-up review. Gene expression meta-analysis and gene-level GWAS analyses revealed 2698 and 3 genes ($FDR < 0.05$), respectively. Network analysis detected 22 PPI modules containing 71 genes showing enrichment. For pilot drug repurposing analysis, we selected genes showing robust expression differences ($q < 0.01$, $n=605$), suggestive GWAS evidence ($q < 0.16$, $n=115$), and is in an enriched PPI module. 24 of 767 genes showed evidence across more than one domain with 6 of 24 being targeted by approved compounds including known targets OPRM1 and DRD2, as well as four additional actionable genes. Across the four repurposing databases, seven approved compounds were identified targeting the novel genes and represent repurposing candidates for follow-up and expert review. This study leveraged existing results and multiple resources to identify approved compounds that target genes associated with OUD. By querying multiple lines of evidence, the approach allows a) querying many genes of interest, b) detecting candidates missed using a single domain or resource, c) and produces a succinct summary to facilitate efficient expert review. Identifying larger pools of candidate pharmacotherapies and summarizing the supporting biological evidence bridges the gap between discovery and translational studies.

Complex Traits Posters - Wednesday

PB1475. Identifying Developmental Stuttering comorbidities using Electronic Health Records.

Authors:

A. Scartozzi¹, D. M. Shaw¹, H. G. Polikowsky¹, D. G. Pruett¹, H-H. Chen², L. E. Petty¹, R. L. Gordon², Y. Yu³, 23andMe Research Team, R. M. Jones², C. D. Huff³, S. Kraft⁴, J. E. Below²; ¹Vanderbilt Univ., Nashville, TN, ²Vanderbilt Univ. Med. Ctr., Nashville, TN, ³MD Anderson Cancer Ctr., Houston, TX, ⁴Wayne State Univ., Detroit, MI

Abstract Body:

Developmental stuttering is a common speech disorder (studies estimate at least a 5% lifetime prevalence) characterized by prolongations, blocks and repetitions of speech sounds. Although recent population studies have provided evidence for both its heritability and polygenicity, the genetic factors impacting stuttering risk remain largely uncharacterized. We leveraged Electronic Health Records (EHRs) to investigate stuttering comorbidities (i.e., the presence of one or more conditions that co-occur with stuttering). Investigating stuttering comorbidities can help us glean information about shared biology. The current study uses polygenic risk scores (PRS) and a phenome-wide association study (PheWAS) to identify comorbidities of stuttering risk within Vanderbilt's EHR-linked biobank (BioVU). We developed sex- and ancestry-specific PRS models using summary statistics provided by 23andMe, Inc. from a genome-wide association study of self-reported stuttering in more than 1 million individuals. PRS models were tested and validated using an independent and clinically ascertained cohort, the International Stuttering Project (ISP). The European-Male (EUR-M) PRS model was predictive of stuttering status in ISP European males and females. We applied our 23andMe EUR-M PRS model to European participants within BioVU, $N = 71,986$. We then performed a PheWAS to identify phenotypes comorbid with stuttering risk. Although no Bonferroni significant associations were identified, some of the top hits recapitulated previously identified comorbid traits. A prior study identified conditions impacting weight control as common comorbidities, and we also observed a strong association with obesity ($p = 1.33 \times 10^{-4}$). Similarly, prior studies have identified suicidal ideation as notably enriched in individuals with developmental stuttering, and suicidal ideation was among our top findings ($p = 1.14 \times 10^{-3}$). Finally, prior studies have noted that the atopic triad is a common stuttering comorbidity, and we identified respiratory complications as associated with developmental stuttering risk ($p = 4.53 \times 10^{-3}$). Future studies will examine sex-specific comorbidities and examine differences in comorbid phenotypes captured by PRS applied to other sex and ancestry groups. By understanding stuttering comorbidities, we hope to elucidate shared mechanisms that contribute to its pathophysiology and enable improvements in clinical care.

Complex Traits Posters - Thursday

PB1476. Identifying genetic variations that connect iron homeostasis to metabolic disease.

Authors:

S. Praggastis¹, B. Crowell¹, L. Ivanova¹, R. Center², G-R. DiscovEHR Collaboration², A. N. Economides¹, S. Hatsell¹, H. E. Lob¹, J. Bovijn³, L. Lotta⁴, T. De⁵; ¹Regeneron Pharmaceuticals, Tarrytown, NY, ²Regeneron Genetics Ctr., Tarrytown, NY, ³Regeneron Genetics Ctr., Oxford, United Kingdom, ⁴Regeneron, Tarrytown, NY, ⁵Regeneron Genetics Ctr., Chicago, IL

Abstract Body:

Individuals with genetic iron overload diseases, such as hemochromatosis, have a higher incidence of type 2 diabetes. Elevated serum levels of the iron biomarkers ferritin and transferrin are positively correlated with the development of type 2 diabetes in individuals without iron overload diseases. However, the molecular mechanism by which iron overload results in metabolic dysfunction remains unknown. The goal of this study was to identify biomarkers that correlate iron homeostasis with abnormal glucose levels. We performed large-scale exome-wide association analyses and a genome-wide association study (GWAS) of glucose, HbA1c, and iron-related biomarkers (N = 480,389), as well as of type 2 diabetes with 58,379 cases and 530,072 controls. We identified known iron homeostasis pathway members and novel associations to both iron overload and type 2 diabetes. Through our GWAS analyses we identified our top candidate variant associated with reduced iron levels and reduced glucose levels (UIBC, beta (95%CI) = 0.049 SD (0.035,0.063), p = 3.61 x 10⁻¹², Glucose, beta (95%CI) = -0.02 SD (-0.025,-0.017), p = 2.34 x 10⁻²⁴). This variant has been previously associated with iron biomarkers and is a multi-tissue expressed quantitative trait loci (eQTL) in *FADS1/FADS2*, that results in reduced expression of *FADS1*. *FADS1* plays a critical role in long chain polyunsaturated fatty acid synthesis, and hepatic knockdown of this gene improves glucose clearance and limits adipose tissue expansion *in vivo*. *In vitro* studies demonstrated that expression is induced by iron supplementation. Variants in the *FADS1* locus have been strongly associated with blood glucose levels in previous GWAS, however the mechanism underlying this association remains unclear. Our future efforts will be to study the mechanism in a mouse-model. The novel and potentially pleiotropic effect of this variant on iron and glucose levels may help to inform future drug development.

Complex Traits Posters - Wednesday

PB1477. Identifying Metabolomic Signatures of Genetic Liability to Type 2 Diabetes in East Asian Adolescents

Authors:

S. Chen¹, B. He¹, S. Luo¹, S. Lam², M. Kwok¹, C. Schooling^{1,3}, S. Au Yeung¹, G. Leung¹; ¹The Univ. of Hong Kong, Hong Kong, China, ²The Chinese Univ. of Hong Kong, Hong Kong, China, ³City Univ. of New York, New York, NY

Abstract Body:

Background East Asians have a higher burden of type 2 diabetes (T2D) compared to Europeans despite lower rates of obesity. Exploring adolescent metabolomic signatures associated with increased genetic liability to T2D in East Asians can help identify unexplored causal factors of T2D in this population. **Methods** Using the East-Asian-population-based “Children of 1997” birth cohort (n=3,251), we generated a weighted genetic risk score (GRS) based on 128 genetic variants associated with T2D in East Asians ($p < 5 \times 10^{-8}$). Multivariable linear regression was used to assess the association of GRS with Nuclear Magnetic Resonance (NMR)-derived metabolites measured from serum at 16-18 years old, adjusted for batch, age, sex, and 6 top principal components. **Result** Higher genetic liability to T2D (per SD higher GRS) was associated with higher leucine (0.039 standard deviation (SD), 95% CI 0.010 to 0.069), valine (0.035 SD, 95% CI 0.004 to 0.067) and total branched-chain amino acids (BCAA) (0.035 SD, 95% CI 0.004 to 0.065). We also found associations with higher ketones including acetoacetate (0.053 SD, 95% CI 0.018 to 0.087), 3-hydroxybutyrate (0.049 SD, 95% CI 0.015 to 0.083), and acetone (0.051 SD, 95% CI 0.017 to 0.085). However, all these associations did not withstand Bonferroni correction. As expected, genetic liability to T2D was associated with higher glucose (0.048 SD, 95% CI 0.014 to 0.082). **Conclusion** Genetic liability to T2D was potentially associated with higher BCAA and ketones in this East Asian adolescent population. Whether these signals are causal in the etiology of T2D in East Asians requires additional investigation.

Complex Traits Posters - Thursday

PB1478. Identifying novel gene dysregulation associated with opioid overdose death: a meta-analysis of differential gene expression in human prefrontal cortex.

Authors:

J. Carter¹, B. Quach¹, C. Willis¹, D. Hancock¹, J. Montalvo-Ortiz^{2,3}, R. Logan^{4,5}, C. Walss-Bass⁶, B. Maher⁷, E. Johnson^{1,8}, PGC-SUD Epigenetics Working Group; ¹RTI Intl., Research Triangle Park, NC, ²Yale Univ., Orange, CT, ³Clinical NeuroSci.s Div., Natl. Ctr. of PTSD, West Haven, CT, ⁴Dept. of Pharmacology and Experimental Therapeutics, Boston Univ. Sch. of Med., Boston, MA, ⁵Ctr. for Systems NeuroSci., Boston Univ., Boston, MA, ⁶Univ. of Texas Hlth.Sci. Ctr. at Houst, Houston, TX, ⁷Johns Hopkins Bloomberg Sch. of Publ. Hlth., Baltimore, MD, ⁸Fellow Program, Research Triangle Park, NC

Abstract Body:

Background: Of the U.S. population aged 12 and older, 10.1 million people misused opioids in 2019. In 2020, the U.S. saw the highest 12-month count of opioid overdose deaths (OOD) recorded, >70,000: a 40% increase since 2019. The opioid epidemic continues to be a tremendous burden, but our understanding of the neurogenetics of opioid addiction remains limited. Only recently have human postmortem brain studies of differential gene expression (DGE) associated with OOD been published: Corradin et al. 2022; Mendez et al. 2021; Seney et al. 2021; Sosnowski et al. 2022. The four independent studies had modest sample sizes (N=40-153 decedents), and none tested nominated genes for replication. Here we tested for cross-study replication and conducted a transcriptome-wide meta-analysis.

Methods: All studies had RNAseq data from human prefrontal cortex and DGE analysis by OOD status. We tested top genes reported by each study (gene N=138) for independent replication using a meta-analysis of the other three studies. In a discovery meta-analysis, we combined results from all four studies (Sample N=285 independent decedents; gene N=19,915) to identify OOD-associated genes. We used the weighted Fisher's test for all meta-analyses, and only genes with summary statistics in at least two studies were considered. Results: Among the 138 genes nominated across the four studies, 16 were independently replicated (Bonferroni adjusted $p < 3.6 \times 10^{-3}$), including *ARL4D*, *NPAS4*, and multiple *DUSP* and *EGR* genes. The discovery meta-analysis identified 47 associated genes at a Bonferroni corrected threshold ($p < 2.5 \times 10^{-6}$) and 875 genes with FDR <0.05. Top genes from the discovery meta-analysis included all significant genes from the replication analysis and additional genes both anticipated (e.g. *BDNF*, *FOSB*, *OPRK1*) and not anticipated (e.g., *TENT5A*, *ZNF254*) from model organism and neuroscience studies of addiction. Analyses of all three gene sets (16 replicated, 47 Bonferroni meta-analysis, and 875 FDR meta-analysis) showed significant enrichment for genes in the Orexin receptor pathway, with up to 25 of the 154 genes in this pathway (including *HCRTR2*) being association with OOD. Discussion: Independent replication and greatly increasing sample size through meta-analysis identified numerous robust associations with OOD. This large number of associations suggests broad gene dysregulation in the prefrontal cortex and highlights the Orexin receptor pathway as a key finding in humans, providing a clear link to more than a decade of model organism study of this pathway and addiction, including evidence of the orexin system as a promising target for opioid addiction treatment development.

Complex Traits Posters - Wednesday

PB1479*. Identifying phenotypic signatures of circulatory microRNAs

Authors:

R. Mustafa¹, M. Evangelou², M. Ghanbari³, A. Dehghan^{1,4,5}; ¹Dept. of Epidemiology and Biostatistics, Imperial Coll. London, London, United Kingdom, ²Dept. of Mathematics, Imperial Coll. London, London, United Kingdom, ³Dept. of Epidemiology, Erasmus MC, Rotterdam, Netherlands, ⁴Dementia Res. Inst., Imperial Coll. London, London, United Kingdom, ⁵MRC Ctr. of Environment and Hlth., Imperial Coll. London, London, United Kingdom

Abstract Body:

Plasma circulatory microRNAs (miRNAs) have the potential to act as disease biomarkers or therapeutic targets. Previous investigations on the role of miRNAs in complex phenotypes frequently focused on several well-known miRNAs or traits of interest, while their causality remains poorly understood. Here we investigated the associations of genetically determined miRNAs with a wide range of clinical phenotypes and assessed the causality. We measured 2,083 circulatory miRNAs in plasma samples of 2,178 participants in the population-based Rotterdam Study cohort using HTG EdgeSeq miRNA Whole Transcriptome Assay, followed by identification of cis-variants that affect miRNAs expression (cis-miR-eQTLs). Single cis-miR-eQTL or weighted genetic risk scores (miRNA-GRS) were used as a proxy for plasma circulatory miRNA levels in phenome-wide association studies (PheWAS) comprising 905 clinical diagnoses across 16 disease categories using hospital episode statistics data in the UK Biobank (N=423,419). Two-sample Mendelian randomisation (MR) was implemented to test for causality using the inverse-variance weighted method, with weighted median and MR-Egger as sensitivity analyses to rule out horizontal pleiotropy. Cis-miR-eQTLs were identified for 204 miRNAs consisting of single cis-miR-eQTLs for 85 miRNAs and multiple cis-miR-eQTLs to compute 119 miRNA-GRS. At FDR<0.05, we identified 29 associations for nine miRNAs with single cis-miR-eQTLs and 44 associations for 17 miRNA-GRS. We tested 37 out of 44 associations for miRNA with at least three cis-miR-eQTLs in MR-PheWAS, which suggested their potentially causal role in the observed associations. In particular, the associations between miR-329-3p and miR-543 with obesity-related traits were replicated using large genome-wide association studies consortia data. Collectively, our study highlights phenotypic signatures of circulatory miRNAs and potentially causal roles of several miRNAs in cardiometabolic traits.

Complex Traits Posters - Thursday

PB1480. Identifying Rare Variants Associated with Type 2 Diabetes Mellitus in GENNID: a Multiplex, Multiethnic, Family Study.

Authors:

L. Simon¹, J. Wan¹, K. Edwards¹, B. Wu², T. Norden-Krichmar¹, A. Freedland¹, S. Ferdos¹, S. Sohail¹, American Diabetes Association GENNID Study Group; ¹Univ. of California, Irvine, Irvine, CA, ²Univ. of Minnesota, Minneapolis, MN

Abstract Body:

Objective: Type 2 diabetes mellitus (T2DM) is an important global public health problem. T2DM prevalence differs by ethnicity in the US, with Black and Hispanic individuals having higher T2DM rates compared to Asians and Whites. While T2DM is a complex, polygenic disease with a strong genetic component, the thousands of variants found to be associated with T2DM through genome-wide association studies (GWAS) and linkage studies only explain a small percentage of the total heritability of T2DM. Complex composite risk measures that consider genetics such as common-variant genetic burden polygenic risk scores (PRS) have the potential to enhance T2DM risk prediction. Rare variants may have the potential to further improve the predictive power of PRS. Family-based studies can be especially useful for detecting and identifying rare variants because such variants can be enriched in an extended pedigree and segregate with the phenotype. We will leverage genetic data from the GENNID study to identify rare variants associated with T2DM in this family-based multiethnic population. Given that rare variants that segregate in a family are enriched compared to the general population, we expected to observe a higher frequency of these variants that would allow us to evaluate rare variant associations in T2DM and assess heterogeneity across GENNID ethnic groups.

Methods: The GENNID study target population consists of 1651 subjects in 340 families from African American (AA), European American (EA), Japanese American (JA) and Mexican American (MA) families. We first identified rare variants by parsing through GENNID data and compiling a list of variants present in each GENNID ethnic group that exhibited a MAF of <0.01. Identified novel variants and genes were compared across all GENNID ethnic groups to assess potential overlapping variants and genes of interest. We will use the RVFam statistical package within R to collapse each SNP within their respective genes using a logit-link generalized linear mixed effects model to test for associations between T2DM status and each genotyped SNP.

Results: We identified unique rare variants in each GENNID ethnic group: AA (248 subjects, 68 families, 20835 rare variants), EA (747, 158, 13799), JA (122, 16, 23584) and MA (534, 98, 22033) with minimal overlap.

Conclusions: Rare variants were identified in each GENNID ethnic group with minimal overlap. Future research will assess whether the addition of these rare variants into a traditional common-variant PRS model improves T2DM prediction in the GENNID target population. Collectively, these results and findings will help elucidate the role that rare variants play in T2DM risk quantification.

Complex Traits Posters - Wednesday

PB1481. Identifying shared genetic architecture across eye diseases using electronic health records

Authors:

A. Scalici¹, T. Miller-Fleming², J. HIRBO³, E. Knapik⁴, N. Cox²; ¹Vanderbilt Univ., Nashville, TN, ²Vanderbilt Univ Med Ctr., Nashville, TN, ³Vanderbilt Univ. Med. Ctr., Clarksville, TN, ⁴Vanderbilt Univ. Med. Ctr., Nashville, TN

Abstract Body:

Vascular and nerve defects in the eye are major contributors to vision loss. Both myopia and glaucoma are associated with optic nerve damage, however, genetic correlation studies of the two diseases have produced varying results. Genetic correlation studies rely on GWAS summary statistics for SNP associations that often have no causal relationship to the phenotype of interest. To gain greater insights into disease mechanisms, we used both transcriptomic and electronic health record (EHR) data to implement gene and phenome-based approaches. To broadly examine shared genetic architecture across all eye diseases, cases were defined as subjects with at least one eye disease phecode in their EHR. For each case, we identified five age-matched controls with no eye disease phecodes in their EHR. Using BioVU, Vanderbilt University Medical Center's DNA biobank, we performed a transcriptome-wide association study (TWAS) to identify shared transcriptional profiles across eye diseases (N=70,493). We identified two genes (GPX7 & AC016590.3) with altered predicted gene expression associated with eye disease status. To identify eye disease comorbidities, we conducted a phenome-wide association study (PheWAS) using age-matched eye disease cases and controls in an independent non-genotyped study population with at least three visits to VUMC in five years (N= 663,228). This PheWAS identified strong associations between eye disease, cerebrovascular disease, neurological and motor deficits, and diabetes. Using the effect estimates from the significantly associated phenome as weights, we constructed a phenotypic risk score (PheRS), representing a weighted sum of a subject's comorbidities. This PheRS is predictive of eye disease status and is associated with altered predicted gene expression (POU1F1, PAK1, AC091100.1, TDRKH, RPL41, NEU2). Employing both the gene and phenome-based approaches used in this study identified both known and novel genes related to eye disease. Further functional analyses of these genes can expand the known pathways involved in eye disease pathogenesis and give greater insight into shared disease mechanisms.

PB1482. Identifying the genetically dysregulated risk and preventative pathways in Alzheimer's disease

Authors:

X. Li¹, Y. Dai¹, A. Liu², B. S. Fernandes¹, Z. Zhao³; ¹UTHealth at Houston, Houston, TX, ²UTHealth., Houston, TX, ³Univ Texas HSC Houston, Houston, TX

Abstract Body:

Background: Alzheimer's disease (AD) is a common neurodegenerative disorder in the elderly, in which genetic factors play an important role. Polygenic risk scores (PRS) could estimate individual AD risk and guide early intervention. A considerable proportion of the older adults (≥ 75) carry a high AD risk but evade AD. On the other hand, many individuals with a low risk for AD eventually develop AD. We hypothesized that unknown counterfactors might be involved in reversing the PRS prediction, which might provide insights into AD pathogenesis and clinical intervention.

Methods: We built a computational framework to identify risk and preventative pathways in AD using PRS-based stratification. First, we calculated PRS (including and excluding the APOE region) based on AD GWAS summary statistics and a genotype dataset of 1,846 individuals from ROS/MAP, MSBB, and Mayo databases. Next, we subgrouped the individuals by their PRS, clinical and pathological diagnosis, including samples with high PRS (high-risk) vs. samples with low PRS (low-risk), and AD subjects vs. controls with similar PRS background. We then conducted a transcriptome-wide association study (TWAS) by differential analysis between groups, adjusting for sex, age, and the first five principle-component of individual genotypes in the following three models with/without the APOE region: 1) full-PRS and full-TWAS; 2) noAPOE-PRS and noAPOE-TWAS; 3) noAPOE-PRS and full-TWAS.

Results: Prediction performance of PRS including the APOE region has the highest AUC (clinical diagnosis: 0.81, pathological diagnosis: 0.73) with a set p-value threshold at 0.5. Excluding the APOE region in the PRS calculation led to a consistent decrease in AUC. Model 1 validated well-known AD-related pathways, including amyloid-beta formation, amyloid-beta clearance (preventative), tau protein binding, and astrocytes response to oxidative stress. In model 2, myelin maintenance (preventative) and microglia antigen processing were detected significantly enriched in the corresponding comparison, suggesting that they are AD-related pathways independent of the effort of APOE. In model 3, we replicated the APOE independent pathways from model 2 and part of the AD-related pathways identified in model 1.

Conclusion: We developed a framework to stratify individuals by their disease risk evaluated by PRS systematically. The TWAS-level comparisons among those groups identify the AD risk and preventative pathways, including many well-known pathways and pathways independent of specific components. The independent validation is warranted. This framework can be extended to other polygenic complex disorders.

Complex Traits Posters - Thursday

PB1483. Impact of Interleukin-4, Interleukin-13 Gene Polymorphisms and HLA-DQ Alleles on Genetic Susceptibility of Type-1 Diabetes Mellitus (T1DM) in Kuwaiti Children

Authors:

M. Haider¹, M. Al-Rushood¹, H. Alsharhan¹, M. A. Rasoul¹, M. Al-Mahdi², H. Al-Kandari³; ¹Kuwait Univ., Faculty of Med., Safat, Kuwait, ²Al-Adan Hosp., Al-Adan, Kuwait, ³Farwania Hosp., Farwania, Kuwait

Abstract Body:

Type-1 diabetes mellitus (T1DM) is a complex multifactorial disease in which both genetic and non-genetic factors are thought to interact and result in the disease onset. Cytokines play a crucial role in pathogenesis of autoimmune diseases possibly due to their effector and regulatory functions in immune and inflammatory responses. *IL4* gene (on chromosome 5q31-33) carries a single nucleotide polymorphism (SNP) in its promoter (-590C/T), which is associated with a number of autoimmune diseases. IL4 and IL13 are key components in induction of the Th2 lymphocyte phenotype and in the downregulation of Th1 lymphocyte phenotype. We determined the genotype frequency of *IL4* gene promoter polymorphism (-590C/T), *IL13* gene polymorphism p.(Arg130Glu) and HLA DQ alleles in Kuwaiti children with T1DM to investigate their role in genetic susceptibility. This study included 244 Kuwaiti children with T1DM and 200 controls. The criteria by International Society for Pediatric and Adolescent Diabetes (ISPAD) was used for the diagnosis of T1DM. The control subjects were healthy Kuwaitis; none had close relative with T1DM and were evaluated by a specialist. The genotypes for *IL4* (-590C/T) and *IL13* p.(Arg130Glu) gene polymorphisms were identified by PCR-RFLP methods. HLA-DQ alleles were determined by sequence-specific PCR method. The frequency of *IL4* (-590C/T) gene polymorphism showed a statistically significant difference between Kuwaiti T1DM patients and controls in the Dominant model of genetic analysis but not in the Co-dominant model in which the significant difference was detected only in the heterozygous state. For *IL13* gene polymorphism p.(Arg130Glu), a statistically significant difference between patients and controls was detected only for heterozygous genotype in the Co-dominant model but not in the Dominant model. In 55% T1DM patients, the HLA genotype was either DQ2/2 or in combination with a DQ8 allele. Collectively, 91% had either DQ2 or DQ8 alleles in different combinations. Amongst the T1DM patients with HLA-DQ2/2 genotype, 80% had CC, 15% had CT and 5% had TT genotype of the *IL4* gene polymorphism. In T1DM patients with DQ2/8 genotype, 69% had the CC, 22% had CT and 9% had TT genotype of the *IL4* gene polymorphism. Our data highlights the role of C-allele of *IL4* (-590C/T) and Q allele of *IL13* p.(Arg130Glu) gene polymorphisms along with HLA-DQ2 and DQ8 alleles in determining the genetic susceptibility of T1DM in Kuwaiti children.

Complex Traits Posters - Wednesday

PB1484. Improving Common Disease Risk Prediction with Clinical Risk Factors using Polygenic Scores in a Primary Care Physician Network of 35,000 Patients Followed for 16 years.

Authors:

R. Mandla^{1,2}, P. Schroeder^{1,2}, B. C. Porneala², J. C. Florez^{2,1,3}, J. M. Mercader^{1,2,3}, A. Leong^{2,1,3}; ¹Broad Inst Harvard & MIT, Cambridge, MA, ²Massachusetts Gen. Hosp., Boston, MA, ³Harvard Med. Sch., Boston, MA

Abstract Body:

Introduction:

Polygenic Scores (PS) can be used for risk prediction of common diseases with complex genetic architecture, e.g., coronary artery disease (CAD), type 2 diabetes (T2D), and chronic kidney disease (CKD). Yet, their informative value above clinical factors has not been established, as studies on their utility in longitudinal risk prediction in real-world clinical settings are limited.

Methods:

We identified patients of European ancestry receiving clinical care in the Mass General Brigham (MGB) Primary Care Physician (PCP) network with genetic data in the MGB Biobank. We extracted their demographic, medical history, and lab data in a 2-year window around their first encounter to construct clinical risk scores (CRS) for coronary heart disease (CHD) (Framingham CHD risk score: age, sex, smoking, total cholesterol, high density lipoprotein [HDL], systolic blood pressure [SBP], hypertension [HTN] treatment), T2D (Framingham T2D risk score: age, sex, family history of diabetes, BMI, SBP, HDL, triglycerides), and CKD (SCORED model - age, sex, and diagnoses of anemia, HTN, diabetes, CHD, congestive heart failure, peripheral vascular disease, and proteinuria). We used the PRS-CS method to calculate genome-wide PS from published genome-wide association study (GWAS) summary statistics. We then performed Cox models to estimate the effects of PS and CRS on incident disease over an observation time of up to 16 years, and compared model performance using hazard ratios per SD (HR (95% CI)), c-index, and likelihood-ratio tests (LRT).

Results:

Among 35,162 patients with genetic data, PS were significantly associated with incident disease (CHD: HR=1.22 (1.16-1.29), $p=2\times 10^{-13}$; T2D: HR=2.78 (2.53-3.05), $p=3\times 10^{-103}$; CKD: HR=1.49 (1.35-1.65), $p=2\times 10^{-14}$). For patients with both genetic and clinical data, adding PS to the CRS model significantly improved model performance (1,047 incident CHD cases: CRS only model -, c-index=0.735; combined model - c-index=0.742; LRT $p=9\times 10^{-12}$; 1,058 incident T2D cases: CRS only model - c-index=0.694; combined model - c-index=0.737; LRT $p=5\times 10^{-58}$; 827 incident CKD cases: CRS only model - c-index=0.819; combined model - CRS c-index=0.824; LRT $p=5\times 10^{-10}$).

Conclusions:

Adding genetic risk to clinical risk models modestly improved longitudinal prediction of genetically complex, common diseases in a large PCP network. The cost effectiveness of such incremental improvement may only be realized where genetic data has already become available.

Complex Traits Posters - Thursday

PB1485. Improving model predictivity and explainability by combining genotypes and immunophenotypes in SARS-CoV-2 infected people.

Authors:

A. Renieri^{1,2,3}, C. Fallerini^{1,2}, K. Zguro¹, G. Brunelli¹, G. Martelloni¹, M. Baldassarri^{1,2}, F. Fava^{1,2,3}, A. Degl'Innocenti¹, S. Furini¹, Y. Mueller⁴, GEN-COVID multicenter study, P. Katsikis⁴; ¹Med Biotech Hub and Competence Ctr., Dept. of Med. Biotechnologies, Univ. of Siena, Siena, Italy, ²Med. Genetics, Univ. of Siena, Siena, Italy, ³Genetica Medica, Azienda Ospedaliero-Universitaria Senese, Siena, Italy, ⁴Dept. of Immunology, Erasmus Univ. Med. Ctr., Rotterdam, Netherlands

Abstract Body:

We first demonstrated that coding variants contribute to COVID-19 severity with different weight and inverse correlation to allele frequency by the so-called post-Mendelian model (Fallerini et al 2021). We then modeled the COVID-19 disease in three different immuno-phenotypes by serum pro/anti-inflammatory, and anti-viral cytokine and anti-SARS-CoV-2 antibody measurements: i) low antibodies, ii) excess of inflammation, and iii) balanced immunotypes (Muller Y et al 2022). We now show here how the immunophenotype can be predicted from genotype and vice versa. “Low antibodies” phenotype patient group is characterised by heterozygosity of ultrarare (loss of function) variants in immunodeficiency genes, while “excess of inflammation” group is characterised by a combination of rare (>1/1000) or low frequency (>1% and <5%) (gain of function) variants in autoinflammatory genes and hypoandrogenic variants in sex development genes in males (not contrasting the excess of inflammation). We also demonstrated that individuals with an apparent “balanced immuno-phenotype” but severe COVID-19 are characterised by variants inducing susceptibility to thrombosis, therefore pointing to a third not immunomediated group of pathogenicity (see also abstract by Fallerini et al at this meeting). Finally, the post-Mendelian model has been improved by collapsing on gene category, according to allele frequency for separating likely gain and loss of function variants (such as immunodeficiency genes, autoinflammatory genes, sex development genes, thrombophilia genes etc) rather than single genes. This approach simplifies and therefore reduces the excess of genetic features, improving model predictivity and explainability.

Complex Traits Posters - Wednesday

PB1486. Improving the selection of variants included in polygenic risk scoring models

Authors:

C. Arehart¹, M. Lin², L. M. Evans¹, C. R. Gignoux²; ¹Univ. of Colorado, Boulder, CO, ²Univ. of Colorado Anschutz Med. Campus, Aurora, CO

Abstract Body:

Polygenic risk scores (PRSs) have become a central tool in human genetics research as they provide a prediction framework in which externally derived genetic associations are used to predict an individual's propensity towards a polygenic trait. The recent growth of large-scale genome-wide association studies (GWASs) has captured many additive weak effect sizes across the genome and has provided ample training datasets for PRS models. However, it has been noted that PRSs tend to differ in accuracy between ancestry groups and these disparities have the potential to exacerbate health inequality, especially for groups of non-European ancestry. There have been many efforts to build software that performs well across a multitude of traits. These software packages, such as PRS-CS and LDpred2 to name a few, provide efficient methods to account for linkage disequilibrium and compute PRSs. The computational costs (in terms of hardware constraints, time, and money), however, have become a primary limitation for these models. To circumvent these costs a simple solution has been to shrink the scope of genetic variants included in the model. As such, many PRS workflows subset the genome to the set of HapMap3 variants which has been noted for its manageable number of variants (1.1M) that are generally well imputed, cover the whole genome, and pass quality controls. This upstream filtering step has yet to be optimized in the context of PRS. We aimed to find a set of representative variants (of a similar size) that leads to better PRS accuracy across traits and ancestry groups. Through principal component analysis of datasets including imputation accuracy, fine-mapping scores, functional scores, GWAS significance, regulation of gene expression, methylation, and linkage disequilibrium, we identified a set of 1.5M "tag" variants for potentially improved PRS accuracy. These variants are generally common, functionally relevant, well-represented by multiple ancestry groups, and only overlap with 265K variants from HapMap3. In development of PRS to predict atrial fibrillation, we have noted an AUC = 0.62 [0.62, 0.63] when using these variants which is +0.01 compared to using HapMap3. We will extend this framework to other traits, across different ancestry groups, and replicate with biobanks outside the Colorado Center for Personalized Medicine. We anticipate improvements in accuracy of PRS prediction at a similar or larger scale to that observed in atrial fibrillation.

Complex Traits Posters - Wednesday

PB1487. In silico analysis to examine COPD genetic associations using scRNA-seq-based CRISPRi approach in iPSC derived alveolar type 2 (iPSC-AT2) cells

Authors:

V. Malik¹, R. Werder², E. K. Silverman¹, X. Zhou¹, A. A. Wilson², M. Cho¹; ¹Channing Div. of Network Med., Dept. of Med., Brigham & Women's Hosp., Boston, MA, ²Ctr. for Regenerative Med., Boston Univ., Boston, MA

Abstract Body:

Background: Genome-wide association studies (GWAS) have identified sets of genetic variants associated with impaired lung function and chronic obstructive pulmonary disease (COPD). Genetic signals are enriched in fetal lung and specific lung cell types, including alveolar type 2 cells (AT2). Prior work has identified AT2 relevant GWAS genes via variant-to-gene mapping and gene expression studies, but the functional implications of these genes is poorly understood. **Methods:** We performed single cell RNA sequencing (scRNA-seq) and data analysis in induced pluripotent stem cell derived alveolar type 2 cells (iPSC-AT2) with CRISPR interference (CRISPRi)-based knockdown of a set of genes identified from variant to gene mapping and AT2 gene expression: *DSP*, *HHIP*, *RBMS3* and *ADGRG6*. We examined patterns of differential expression between control and knockdown, and further examined differential pathway and transcription factor analysis for *DSP* and *ADGRG6* using a Seurat-PROGENy-DoRotheA-CARNIVAL integrated workflow. **Results:** Differential gene expression identified similarities between *DSP* and *ADGRG6* knockdown. Significant pathways included cellular senescence, FoxO signaling, cytoskeletal organization, focal adhesion, ECM receptor interaction, as well as Wnt, mTOR (only in *ADGRG6* knockdown) and TGF-beta signaling pathways. CARNIVAL was used to identify the main signaling pathways using PROGENy and DoRotheA activity scores and identified MAPK, TGF-beta and ATF2 signaling pathway alterations in both *DSP* and *ADGRG6* knockdown. Additionally, in *ADGRG6* but not *DSP* knockdown, CARNIVAL identified alteration of SMAD2/3/4 pathway, Wnt and PS1 pathways, whereas Nrf2-ARE pathway alteration was identified only in *DSP* knockdown. **Conclusion:** In a differential gene expression analysis of four COPD GWAS candidate genes using CRISPRi knockdown in an alveolar type 2 cells (iPSC-AT2) model, we identified transcriptomic similarities between *DSP* and *ADGRG6* knockdown, and identified shared pathways regulating cytoskeletal organization, cell-cell interaction, oxidative stress response and proliferation. These findings require further experimental validation. **Keywords:** scRNA-seq, CRISPR interference, induced pluripotent stem cells, alveolar type 2, COPD

Complex Traits Posters - Thursday

PB1488. Increased burden of pathogenic variants in known aortopathy genes in individuals with early onset thoracic aortic dissection

Authors:

D. Guo¹, I. Marin², M. Boerio¹, S. LeMaire³, S. Prakash¹, A. Estrera¹, H. Safi¹, J. Coselli³, M. Bamshad⁴, D. Nickerson⁵, D. Milewicz⁶; ¹UT McGovern Med. Sch. at Houston, Houston, TX, ²UT Hlth.Sci. Ctr. at Houston, Houston, TX, ³Texas Heart Inst. at St. Luke's Episcopal Hosp., Houston, TX, ⁴Univ. of Washington, Seattle, WA, ⁵Univ Washington Sch Med, Seattle, WA, ⁶Univ Texas McGovern Med Sch, Houston, TX

Abstract Body:

Acute aortic dissections are life-threatening events that are preventable if at-risk individuals are identified. Up to 20% of dissection cases have evidence of a pathogenic or likely pathogenic (P/LP) variant in the 11 genes identified and validated for heritable thoracic aortic disease (HTAD). To identify genetic factors that predispose individuals to early onset, sporadic dissections (ESTAD) in the absence of clinical features of HTAD (family history and syndromic features), we performed whole exome sequencing (WES) on two cohorts of patients with early age of onset of dissection (1st batch ≤56 years old and 2nd batch ≤60 years old; recruited from 2009 - 2019)) and gender, and hypertension-matched controls. In the 2nd batch, WES identified 7.9% of patients have P/LP variants in 11 known HTAD genes, which replicated the finding in the 1st batch of WES (9.3%); no P/LP variants were identified in the controls. *FBNI* had the highest burden of P/LP variants in both cohort despite the fact that the cases were screened for clinical features of Marfan syndrome. Interestingly, when the *FBNI* cases are removed, individuals recruited before 2014 (prior to genetic testing being readily available) had P/LP variants in *COL3A1*, *TGFBR1*, or *TGFBR2*, all genes that cause HTAD associated with syndromic features, while all of the patients recruited after 2014 had P/LP variants in genes that predispose to HTAD in the absence of syndromic features, primarily *ACTA2* (p = 0.027). These data imply that genetic testing is identifying individuals in known HTAD genes associated with syndromic features, whereas the lack of syndromic features leads to a lack of diagnosis of P/LP variants in genes that are not associated with syndromic features.

Complex Traits Posters - Thursday

PB1490. Increased frequency of predicted loss of function variants in *PKP2* in African ancestry individuals

Authors:

A. Winters, D. Smelser, H. S. Rao, E. Carruth, DiscovEHR Collaboration, D. J. Carey, C. M. Haggerty; Geisinger, Danville, PA

Abstract Body:

Arrhythmogenic right ventricular cardiomyopathy (ARVC) is an inherited cardiac condition that frequently presents with sudden death without prior clinical symptoms. Previous studies have found that variants in genes encoding desmosome proteins, including *PKP2*, account for about 50% of ARVC cases, however these variants have variable penetrance and expressivity. While prior studies have mostly been conducted in European ancestry populations, limited prior data have suggested a possible increased prevalence of desmosome variants in African ancestry individuals. To better understand the prevalence of these variants across ancestry groups, we evaluated the frequency of predicted loss of function (LOF) variants in *PKP2* across the MyCode population at Geisinger. Through the DiscovEHR collaboration, exome sequence data linked to longitudinal electronic health records are available for over 175,000 individuals. Consistent with prior findings, in MyCode we saw that *PKP2* LOF variants are more common in Black individuals, with 0.25% of self-reported Black vs 0.04% of self-reported White individuals carrying a predicted LOF variant. In the Genome Aggregation Database (gnomAD), the same difference in *PKP2* carrier frequency is seen; 0.26% of African ancestry vs 0.06% of European non-Finnish ancestry individuals are carriers. The same increased carrier frequency among African ancestry individuals is also observed in the All of Us database, a study of genetic variation across the US, with 0.29% of African ancestry vs 0.07% European ancestry individuals being *PKP2* carriers. We then leveraged the extensive phenotype data available for the MyCode population to compare Black to White *PKP2* LOF carriers on a variety of ARVC-related traits. We observed a non-significant trend of White carriers (18%) being more likely than Black carriers (10%) to have any ARVC-related phenotype including ventricular tachycardia or fibrillation or a history of cardiac arrest, arrhythmia, or cardiomyopathy (OR = 1.7 [95%CI: 0.2 - 15.6] adjusted for age and sex; p = 0.63). A similar non-significant trend was seen in All of Us, with European ancestry *PKP2* LOF carriers being more likely to have an ARVC-related trait compared to African ancestry carriers (OR = 2.9 [95%CI: 0.7 - 11.6] adjusted for age and sex; p = 0.14). This increased genetic prevalence associated with African ancestry without evidence of associated disease suggests phenotypic variation by ancestry. Future work is needed to uncover the genetic and/or environmental factors modifying these associations.

Complex Traits Posters - Wednesday

PB1491. Individuals with GCK-MODY are not at increased risk for common complications associated with T2D as measured by the Diabetes Complications Severity Index (DCSI)

Authors:

L. McEwen¹, E. K. Burrows¹, K. M. Schiabor Barrett¹, E. T. Cirulli¹, A. Bolze¹, J. J. Grzymalski^{2,3}, W. Lee¹, N. L. Washington¹; ¹Helix, San Mateo, CA, ²DRI, Reno, NV, ³Renown Inst. for Hlth.Innovation, Reno, NV

Abstract Body:

Introduction: It's known that those with GCK-MODY have elevated blood glucose measurements, are variably diagnosed with T2D, and may even start insulin or oral hypoglycaemic agents (metformin and glibenclamide) as a result. In GCK-MODY patients, these pharmacologic treatments have little to no effect on HbA1c levels, which are typically used to determine future risk for disease complications related to diabetes.

Objective: The lack of response in HbA1c to treatment supports the thinking that *GCK* carriers with slightly elevated glucose levels may actually not be diabetic in the traditional definition of the disease and may not benefit from being treated as such. To formalize these recommendations, studies comparing rates of complications associated with diabetes, instead of a diabetes diagnosis directly, in relevant *GCK* carriers and those with a T2D diagnosis must first be completed.

Methods: We calculated the Diabetes Complications Severity Index (DCSI) from available ICD-10 codes for over 370,000 UKB participants with baseline glucose measurements. The DCSI is a 13-point scale calculated from patient medical records designed to quantify the severity of diabetes-related complications and can be used to measure the adverse outcomes in people with diabetes. We compared DCSI scores by *GCK* carrier status (defined as carriers of rare coding variants in regions of the gene shown to be statistically associated via the "Power Window" method with high glucose levels), presence of a T2D diagnosis, and glucose levels across both groups.

Results: While we found that the mean DCSI score for T2D cases was significantly higher than that of controls (negative binomial regression $p=6.5e-277$), we found that *GCK* carriers did not have a corresponding increase in the DCSI scores despite their high prevalence of T2D diagnoses (28% of *GCK* carriers vs 10% in non-carriers). Additionally, looking specifically at individuals with glucose measurements falling at least 1 standard deviation above the mean, we see a significant reduction in DCSI scores when comparing *GCK* carriers to non-carriers ($p=0.004$).

Conclusion: Overall, our findings suggest the blood glucose threshold for a diabetes diagnosis may be different for GCK-MODY and that these individuals are not at risk for common complications associated with T2D based solely on carrier status or elevated glucose levels.

Ctr., BC Cancer Agency, Vancouver, BC, Canada, ¹¹Univ. of British Columbia, Vancouver, BC, Canada, ¹²BC Children's Hosp., Vancouver, BC, Canada

Abstract Body:

While Coronavirus Disease 2019 (COVID-19) is caused by infection with the RNA virus SARS-CoV-2, human genetic variation can modulate susceptibility to infection and the severity of the disease. To characterize these variations, support COVID-19 research across Canada and contribute to the international COVID-19 host genetics effort, Genome Canada and CGEn (Canada's National platform for genome sequencing and analysis) launched the HostSeq project. HostSeq is a national databank of whole genome sequences (WGS) and clinical data from 13 independent clinical and epidemiological studies enrolling SARS-CoV-2-infected participants from across Canada who are broadly consented for health-related research. By summer 2022, the total number of DNA samples received exceeded 9,000. Here, we introduce the HostSeq project and report preliminary results from genetic analysis using polygenic risk scores (PRS) to assess whether contributing variation to COVID-19 severity aligns with other international efforts. Samples were sequenced at 30X depth on Illumina's NovaSeq 6000 at the three CGEn sites and then processed together (including joint calling and data harmonization with detailed case report forms). Rigorous quality control protocols were followed for both sample and data quality. We calculated PRS with PRSice2 and analyzed the association of best-fit PRS with hospitalization status (adjusted by three genetic principal components, age, sex and age-squared). We used the COVID-19 Host Genetics Initiative (HGI v7) GWAS for PRS computation. The genomes that have been joint-called represent a diverse population structure covering 5 populations (N=2,992: 73% European, 7% East Asian, 6% Admixed American, 6% South Asian, 5% African, 3% other). The best-fit PRS (p-value threshold of 4.4e-51 using 1.1e6 SNPs) was significantly associated with hospitalization (p-value < 2.2e-16; N=1,069 after restricting analysis to participants with covariates in the European subset). These initial results provide support for the polygenicity of severe COVID-19 and demonstrate the alignment of the HostSeq databank with international COVID-19 research. HostSeq genomes and their harmonized clinical information are available to the global research community through a Data Access Agreement and summary data are available through publicly accessible data portals both at www.cgen.ca.

Complex Traits Posters - Wednesday

PB1493. Insights into pediatric inflammatory bowel disease subtypes using single-cell RNA-sequencing.

Authors:

M. R. Keever-Keigher¹, L. Harvey², V. Williams², J. J. Johnston¹, D. A. Louiselle², E. Grundberg¹, T. Pastinen¹, C. A. Friesen², C. Smail¹, V. Shakhnovich²; ¹Children's Mercy Res. Inst., Kansas City, MO, ²Children's Mercy Hosp., Kansas City, MO

Abstract Body:

Several chronic, painful, debilitating disorders of the gastrointestinal (GI) tract have origins in autoimmunity, and manifest as tissue damage from inappropriate overactivation of the inflammatory response in genetically predisposed individuals. One example is inflammatory bowel disease (IBD), which can be subclassified as Crohn's disease (CD) and ulcerative colitis (UC). IBD can overlap with other chronic inflammatory disorders associated with infiltration of eosinophils in tissues of the gastrointestinal tract, such as eosinophilic esophagitis (EoE) and eosinophilic duodenitis (EoD). The complex and multifactorial nature of IBD necessitates an approach that can begin to uncover the underlying molecular phenotypes contributing to the altered signaling pathways defining each IBD subtype and its overlap with eosinophilic disorders. In this study, we identified single-cell transcriptomic signatures of IBD subtypes in pediatric patients using peripheral blood mononuclear cells (PBMC). Single-cell RNA-sequencing (scRNA-seq) was performed on PBMCs isolated from the blood samples of treatment-naïve pediatric patients of differing diagnoses, including CD, UC, EoE, EoD, and controls with apparently healthy gastrointestinal tracts. A total of 39,622 cells from 35 individuals (7 CD, 9 EoD, 10 EoE, 3 UC, 6 controls) passed quality control measures. We identified 1,188 (FDR < 0.05) differentially expressed genes (DEGs) between IBD subtypes and controls across six distinct cell populations. We observed downregulation of estrogen Receptor 2 (ERS2) in CD4+ T cells for all IBD subtypes compared to controls, which is supported by previous findings showing ERS2 expression to be inversely correlated with IBD severity. Secretoglobin 3A1 (SCGB3A1) was the most strongly upregulated among all DEGs in CD4+ T cells, with greater expression in EoD individuals compared to controls. In mice, increased expression of Scgb3a1 has previously been associated with pathogenesis of inflammation and infiltration of eosinophils in the lungs. Ongoing work is currently underway to detect robust expression patterns between subtypes of IBD and to identify genes related to disease diagnosis and prognosis. Ultimately, we expect our pediatric IBD scRNA-seq resource will lead to IBD subtype-specific molecular signatures that could be used in the development of minimally invasive diagnostic assays and for drug response applications.

Complex Traits Posters - Thursday

PB1494. Integrating common and rare variants into a genetic risk score for Alzheimer's disease risk prediction.

Authors:

E. Suh¹, G. Lee¹, S-H. Jung², Z. Wen¹, L. Shen^{1,3}, D. Kim^{1,3}; ¹Dept. of Biostatistics, Epidemiology & Informatics, Perelman Sch. of Med., Univ. of Pennsylvania, Philadelphia, PA, ²Dept. of Digital Hlth., SAIHST, Sungkyunkwan Univ., Samsung Med. Ctr., Seoul, Korea, Republic of, ³Inst. for BioMed. Informatics, Univ. of Pennsylvania, Philadelphia, PA

Abstract Body:

Background: Polygenic risk scores (PRS) are commonly used to estimate an individual's risk for disease, recently including Alzheimer's disease (AD). However, PRS fails to demonstrate sufficient specificity and sensitivity in risk prediction and does not incorporate rare variants, which also influence AD risk. We generated a novel genetic risk score for Alzheimer's disease which combines a smaller set of more informative common and rare variants using known neuroimaging biomarkers to better predict those with high or low risk of disease, as well as mild cognitive impairment (MCI) conversion to AD. **Method:** Whole genome sequencing data of 1,704 patients were collected from the Alzheimer's Disease Neuroimaging Initiative (ADNI). Common variants of each patient were aggregated into a gene-based burden to enable smooth model estimation and gene-level interpretation. We then used SAIGE-GENE+ to conduct a gene burden rare variant analysis for each participant (minor allele frequency ≤ 0.01). The risk score was estimated based on common gene burdens exhibiting high correlations with neuroimaging biomarkers, FDG- and AV45-PET, and significantly associated rare loci from the corresponding rare variant analysis. PRS were generated with clumping and thresholding using PLINK. We compared the performances between our risk score and PRS on two tasks: cases vs controls classification and MCI conversion prediction. **Result:** Our risk score demonstrated better prediction performance and improved distinguishability between cases and controls over PRS. Our score also showed lower risk for controls and MCI non-converter patients and, conversely, higher risk for AD and MCI converter patients compared to PRS. Additionally, our score is well-calibrated compared to PRS—the number of predicted AD and MCI converter patients increased smoothly as the risk score increased. **Conclusion:** We proposed a novel approach to calculate an AD-specific genetic risk score that integrates both common and rare variants. The main advantage of this method is that it uses AD-relevant loci for calculation, yielding a score that is a better predictor of AD risk. Experiments demonstrated that this score enhances performance of prediction accuracy, calibration, and interpretability over PRS.

Complex Traits Posters - Wednesday

PB1495. Integrating Genomic Risk into Absolute Risk Estimates for Coronary Heart Disease.

Authors:

M. Hamed, S. Saadatagah, A. Sherafati, H. Bangash, A. Miller, A. Kamzabek, I. Kullo; Mayo Clinic, Rochester, MN

Abstract Body:

Introduction: There is increasing interest in integrating polygenic risk scores (PRS) in the clinical setting. In the electronic medical records and genomics network (eMERGE) IV project, PRS for 8 common diseases in adults, including coronary heart disease (CHD), are being implemented in the clinical setting.

Methods: The Pooled cohorts equation (PCE) is used for assessing the 10-year absolute risk for CHD, with guideline-based recommendations provided for those at elevated risk. PRS can be combined with the PCE, since it is orthogonal to clinical risk factors, to calculate an integrated score (IS) for participants \geq 40 years. The IS will be returned in person to participants who are in the top 5th percentile of the PRS or have monogenic risk, and by letter to those who have a family history of CHD. A validated PRS is available for the three main population groups in the US: European, African American and Latino. The European population PRS will be used for East and South Asian ancestry, as it had comparable performance in our validation analyses. A genome informed risk assessment (GIRA) profile that includes PRS, monogenic risk, family history and 10-year CHD risk derived from PCE will be compiled for each participant. The GIRA provides guideline-based recommendations to manage individuals at high risk for CHD and will be deployed in the electronic health record (EHR) with linkage to clinical decision support. Outcomes such as screening for CHD and initiation of statin therapy will be assessed after the return of results.

Conclusion: We describe a method for integrating PRS into absolute risk estimates for CHD, along with monogenic risk and family history in a GIRA report.

Complex Traits Posters - Thursday

PB1496. Integration Analysis of Multi-Omics Data for Osteoporosis Biomarker Discovery Identification

Authors:

C. Qiu, K. Su, X. Zhang, A. Liu; Tulane Univ., New Orleans, LA

Abstract Body:

Osteoporosis is an increasingly serious public health problem, which is characterized by low bone mineral density (BMD). To date, the functional roles of the most reported biomarker that are associated with BMD remain unclear. To increase the understanding of the biological mechanisms of BMD variation, it is necessary to leverage multiple dimensional datasets to capture the complexity of biological networks. The recent advent of high throughput technologies has created an opportunity for integrating multi-omics data to build a comprehensive and dynamic model of the molecular changes in osteoporosis. In this study, we generated the multi-omics datasets with three data types (mRNA, methylation, and metabolomics) from 903 subjects. Hip BMDs were examined by dual-energy x-ray absorptiometry (DXA). By focusing on potential interesting biomarkers (differentially expressed genes, differentially methylated CpG sites, and differential metabolites) generated from single-layer analysis, we applied a data integration analysis for biomarker discovery using latent components (DIABLO) to identify the key omics biomarkers for BMD variation. We identified a multi-omics signature of 12 mRNA biomarkers, 6 metabolomics biomarkers, 47 methylation biomarkers, respectively. Correlation analysis showed a strong correlation between mRNA and metabolomics omics. In addition, we performed pathway analysis and identified that several biomarkers (e.g., *PCAT1*) have been associated with BMD variation through previous genome-wide association studies. In conclusion, we reconstructed the biological network in a multi-omics level and identified several novel biomarkers that may mediate variation in the risk of osteoporosis. Our results highlighted the advantages of using integration analysis to add value to the traditional single-layer analysis.

Complex Traits Posters - Wednesday

PB1497. Integration network-based analyses and Mendelian Randomization to screen drug repurposing candidates for osteoporosis

Authors:

D-Y. Liu¹, J. Greenbaum², H. Shen³, H-W. Deng³; ¹Tulane Univ., new orleans, LA, ²Tulane Univ., New Orleans, LA, ³Tulane Univ, New Orleans, LA

Abstract Body:

Osteoporosis (OP) is a systemic disease due to an imbalance in bone remodeling and bone resorption, increased skeletal fragility, and fracture tendency resulting in a growing public health issue. However, there are several shortfalls associated with existing therapies available for OP treatment such as long-term safety, side effects, and low efficacy. Given chemical or clinical trials are expensive and inefficient to characterize the therapeutic properties of drugs, drug repurposing (DR) has emerged as a potential tool with low overall development costs and a shorter development timeline. In the present study, a computational network-based integrated mendelian randomization approach was developed to screen 7811 candidate drugs to be effectively repurposed against OP. First, we interrogated transcriptomic and epigenomic biomarkers using publicly available RNA/ DNA methylation datasets of patients (n=121) with bone mineral density (BMD) by Weighted Gene Correlation Network Analysis (WGCNA). WGCNA identified hub gene pathways that described functions related to myeloid cell differentiation, regulation of osteoblast differentiation, ossification, etc. Totally, 157 compounds were screened primarily based on drug-disease proximity distance between osteoporosis modules and drug target modules in a PPI network. To further investigate the drug candidate's efficacy for OP, we utilized targetable expression quantitative trait loci (eQTL) to mimic exposure to the drug candidate and examine the causal effect on BMD. Significant Mendelian randomization results for 50 drug candidates were observed to reduce OP risk, suggesting an underlying mechanism with genetic support. These findings revealed alterations in core genes and pathways for OP, which may be useful for drug discovery and compound prioritization. However, given that computational studies cannot fully recapitulate a clinical trial, further research is needed to evaluate the effectiveness of the identified compounds for osteoporosis treatment.

Complex Traits Posters - Thursday

PB1498. Integration of proteomics quantitative trait loci into genetic association analysis of stroke in the African American population

Authors:

Y. Cai¹, A. J. Molstad², D. Levy³, A. Reiner^{1,4}, S. Wei^{1,4}, C. Kooperberg^{1,4}, L. Hsu^{1,4}; ¹Fred Hutchinson Cancer Ctr., Seattle, WA, ²Univ. of Florida, Gainesville, FL, ³Natl. Heart, Lung, and Blood Inst., Bethesda, MD, ⁴Univ. of Washington, Seattle, WA

Abstract Body:

Stroke is the third leading cause of death among African American (AA) people and the incidence rate is almost double that of European American (EA) people. Genome-wide studies suggest that there is a substantial genetic contribution (estimated heritability ~35%) to stroke risk in African ancestry populations; however, few variants have been identified to date. Recently, substantial efforts have been devoted to studying the association of genetic variation with proteomics, which is then used to inform genetic association for novel discovery. Most of the data in these studies have focused on populations of European ancestry and little has been done in AAs. The objective of this study is to identify variants predicting protein levels in AA participants, and to integrate this functional information into genetic association analysis of stroke in AAs.

We used OLINK Proteomics data on 1472 proteins for 1,537 AA and 883 EA participants from the Women's Health Initiative, and an additional 1062 EA participants from the Framingham Heart Study. We performed genome-wide analyses for each protein and identified proteomic quantitative trait loci (pQTL) using matrix eQTL. We undertook a two-stage discovery and replication design with 1,237 AA and 1,645 EA participants for discovery and 300 AA and 300 EA participants for replication. We adjusted for age, body mass index, smoking status, plate, batch effect, 10 genetic principal components and 20 PEER factors to account for hidden batch or technological effects in proteomic measurements. We set the genome-wide significance threshold 5×10^{-8} in the discovery set (for both cis- and trans- pQTLs), and for replication we used Bonferroni correction based on the number of pQTLs that passed the genome-wide significance threshold in the discovery stage. After pruning out correlated SNPs ($R^2 > 0.2$), a total of 1,678 pQTLs (538 proteins) for AAs were identified in discovery and 65.3% were replicated. For the EA population, a total of 1,153 pQTLs (367 proteins) were identified in the discovery and 50.5% were replicated. Among the 1096 replicated pQTLs in AA, we identified 758 unique pQTLs that were not present in EA results. These AA-specific pQTLs will help inform novel genetic regulations of protein expression in AA people.

Preliminary analysis also shows evidence of stroke-associated SNPs that are linked to discovered pQTLs. Four of 67 known SNPs for stroke were also AA pQTLs. The GWAS analysis of stroke from the MegaStroke study showed a significant enrichment in AA pQTLs. In future work, we plan to assess the genetic association of pQTLs with stroke risk in AA, and provide genetic insights for stroke risk in AA populations.

Complex Traits Posters - Wednesday

PB1499*. Integrative analyses to identify plausible target genes on Alzheimer's Disease genes with genetic evidence

Authors:

Y. Leung¹, B. Kunkle², B. Vardarajan³, E. Marcora⁴, E. Blue⁵, P. Kuksa¹, R. M. Cores⁶, A. DeStefano⁷, R. Mayeux³, L. Farrer⁸, A. Goate⁴, L-S. Wang¹, G. Schellenberg⁹, Alzheimer's Disease Sequencing Project; ¹Univ. of Pennsylvania, Philadelphia, PA, ²Univ. of Miami, Miami, FL, ³Columbia Univ, New York, NY, ⁴Icahn Sch. of Med. at Mount Sinai, New York, NY, ⁵Univ. of Washington, Seattle, WA, ⁶Gladstone Inst.s for Neurological Disease and Data Sci. and Biotechnology, San Francisco, CA, ⁷Boston Univ Sch Med., Boston, MA, ⁸Boston Univ Sch Med, Boston, MA, ⁹Univ Pennsylvania Sch Med, Philadelphia, PA

Abstract Body:

Many publications report genes or loci altering risk or causes Alzheimer's Disease (AD). The quality of evidence presented is highly variable. To clarify which loci are valid versus potential false positives, the Alzheimer's Disease Sequencing Project Gene Verification Committee (GVC) was formed to **review evidence for published GWAS loci, and evidence if a specific gene is causal for AD**. The GVC first performed a literature search to select publications for developing **structured criteria for evaluating genetic evidence**. A **tier system** was developed (tier 1-7) to identify the quality of evidence, with tier 1 loci having the highest quality of evidence supporting an association. We divided published results into **2 phenotype classes**: 1) Class 1 - AD case definitions are based on clinical and/or neuropathology data (most rigorous class); 2) Class 2: both clinical/neuropathological defined AD and dementia are cases, where the phenotype is inferred by family history using questionnaire (e.g. proxy cases from the UK Biobank). We reviewed 176 variants from 7 papers and found 144 tier 1 loci. Of these, 23 are from Class 1 and 130 are from Class 2. For 36 loci, 2 independent association signals highlighted the same locus. We identified causal genes in 2 ways. First, expert review found 20 genes supported by both genetic (GWAS or linkage exists) and functional evidence. These include *APP*, *PSEN1/2*. Then, we performed integrative analyses of association signals using **OpenTargets, AMP-AD Agora and INFERNO** to identify plausible causal genes. OpenTargets performs systematic drug target prioritization via the variant to gene score. The Agora platform hosts evidence (based on AMP-AD brain data) for whether genes are related to AD. INFERNO unbiasedly identifies the tissue/cell types in which the regulation occurs. These **3 gene ranking methods are complementary to each other** as the model and data used vary. By analyzing 176, we found 9 variants targeting the same gene by all 3 methods, suggesting these genes have the highest confidence of being a true causal gene in AD. These include *ABCA7*, *CRI*, *ACE*, *BIN1*, and *CLU*. Besides, 4 genes (*ABCA7*, *RIN3*, *GPC2* and *NDUFS2*) were identified in the brain with proteomics or metabolomics support. These 8 genes serve as potential therapeutic targets for AD. Retrospective analyses show that therapeutic targets supported by genetic evidence are 2-3x more likely to succeed compared to targets without genetic findings support. Thus, genetic gene discovery work for AD is a valid source of therapeutic targets. Yet, before significant resources are invested in drug development, evidence supporting a causal gene needs to be critically evaluated.

Complex Traits Posters - Thursday

PB1500*. Integrative analysis of large-scale multi-ancestry genome-wide association study and single-cell omics data provides high-resolution insight of cell-types in the pathogenesis of type 2 diabetes.

Abstract Body:

Type 2 diabetes (T2D) is a common metabolic disorder characterized by impaired glucose homeostasis affecting more than 400 million people worldwide. To gain insight into the pathophysiology of the disease, we integrated summary statistics from the largest multi-ancestry genome-wide association study (GWAS) of T2D (2,535,601 individuals including 428,452 cases) with publicly available single-cell chromatin accessibility (ATAC-seq) and transcriptome (RNA-seq) data from human adult and fetal tissues. We began by conducting joint analysis of the T2D GWAS summary statistics and ATAC-seq data of 222 distinct cell types from DESCARTES and CATLAS using fGWAS. ATAC-seq peaks in seventeen cell types, including adipocytes and endocrine/exocrine cells in the pancreas (alpha, beta, delta, gamma, acinar and ductal cells) and gastrointestinal tract (goblet, chief and enterochromaffin cells), were significantly enriched in T2D associations (false discovery rate (FDR) $q < 0.05$). We identified more than 100 independent T2D signals mapping to cell-type-specific ATAC-seq peaks that were computationally predicted to interact with gene promoters (for example, *HNF4A* and *WNT11* in beta cells, *HK1* and *HSPB7* in delta and gamma cells, and *ADH4* and *ADH1C* in adipocytes). T2D signals in cell-type-specific ATAC-seq peaks were jointly associated with fasting glucose adjusted for body mass index (FGadjBMI) and liver fat ($P = 0.000187$ and 0.0190 , respectively). T2D-risk alleles at signals mapping to ATAC-seq peaks in adult beta cells and fetal islet cells were associated with increased FGadjBMI and liver fat. We then conducted gene-set enrichment analysis using the T2D GWAS

summary statistics and 700 cell-type signature gene sets identified by multiple single-cell transcriptomic studies. Twelve gene sets were significantly enriched in T2D associations (FDR $q < 0.05$), including signatures for pancreatic islet endocrine cells ($P = 7.93 \times 10^{-11}$) and endocrine cells in the gastrointestinal tract such as G cells ($P = 0.000603$) and enterochromaffin cells ($P = 0.000742$). Taken together, these complementary approaches using single-cell chromatin accessibility and transcriptome data highlighted a potential role of secretory cells in the gastrointestinal tract, which is involved in the mechanism of action of widely used incretin-based medications for T2D, as well as pancreatic islet cells in the pathogenesis of the disease. Our study showcases the use of integrated analysis of large-scale GWAS and single-cell omics data to provide high-resolution insights into the pathophysiology of the disease.

Complex Traits Posters - Wednesday

PB1501. Integrative genomic and transcriptomic analyses revealed new driver variants associated with progression of the non-alcoholic fatty liver disease

Authors:

D. Kim^{1,2}, J-H. Choi¹, Y-H. Baek³, J-S. Jeong⁴, S-Y. Han⁵, Y. Lee⁶, G. Park⁷, Y-S. Lee⁷, H. Woo^{1,2}; ¹Dept. of Physiology, Ajou Univ. Sch. of Med., Suwon, Korea, Republic of, ²Dept. of BioMed. Cancer Ctr., Goyang, Korea, Republic of, ⁷Div. of Rare Cancer, Res. Inst., Natl. Cancer Ctr., Goyang, Korea, Republic of

Abstract Body:

Non-alcoholic fatty liver disease (NAFLD) is a broad spectrum of liver diseases ranging from non-alcoholic fatty liver (NAFL) to non-alcoholic steatohepatitis (NASH). In this study, to obtain an integrative insight into genomic and transcriptomic alterations during NAFLD progression, we performed RNA-Seq profiling (n=146) and whole exome sequencing from the biopsied tissue samples (n=132). Cluster analysis of the transcriptome revealed the three subtypes of NAFLD, which showed distinct genetic variants and pathological findings. We report that macrophage activity was associated with the transcriptomic subtypes, showing the altered macrophage repertoire plays a critical role in NAFLD progression. The findings could be verified using independent data of the whole genome sequencing (WGS) from the PBMC samples (n=94). In addition, we identified the candidate genes whose variants were correlated with transcriptional deregulation and macrophage activity across the subtypes. In conclusion, our results could demonstrate a deeper molecular-level understanding, providing novel targets for the diagnosis and treatment of NAFLD progression.

Complex Traits Posters - Wednesday

PB1502. Interactions between Valley Fever and genetic ancestry: does genetic ancestry affect risk of developing disseminated coccidioidomycosis?

Authors:

S. Spendlove^{1,2}, S. L. Jensen^{2,3}, D. Orellana², A. V. Stephens⁴, G. R. Thompson^{5,6,7}, R. H. Johnson^{8,9}, A. Heidari^{8,9}, R. Kuran^{8,9}, M. Butte^{3,4}, V. A. Abstract Body:

Coccidioidomycosis is a fungal infection endemic to the American Southwest. While most patients are asymptomatic after infection or develop only a respiratory infection, a small proportion of individuals develop severe disseminated coccidioidomycosis (DCM), which is associated with significant morbidity and mortality and requires prolonged antifungal treatment. The factors that contribute to an individual's risk for developing DCM are multifactorial, however, the genetic basis of this risk remains unclear. Previous studies have shown that self-identified race and ethnicity (SIRE) is associated with risk of DCM, including a higher risk of DCM in individuals identified as African-American, Latino or Filipino. The previous epidemiological research has used race and ethnicity, which is a social construct and not always equivalent to genetic ancestry. While race is based on an individual's external appearance and how they identify, genetic ancestry is based on where individuals' genetic data cluster with reference populations. In this study we use a merged cohort of 479 individuals from the UC Davis Center for Valley Fever and 87 individuals from the Valley Fever Institute at Kern Medical, who have differing severity of coccidioidomycosis. We show that having 20% or more of one's genetic ancestry clustering with the genetics of individuals from the African continent is associated with a 16.3 odds of DCM. Meanwhile having 20% or more genetic ancestry clustering with the genetics of individuals from Europe gives a decreased odds of 0.2. We also use GWAS and admixture mapping methods to identify any areas of the genome that may be transmitting this risk in some individuals. This project will allow us to leverage genetic biomarkers to identify individuals at the highest risk for DCM and who would benefit from early-treatment with immunomodulatory therapies.

Complex Traits Posters - Wednesday

PB1504. Interplay of age and Alzheimer's disease diagnosis in estimating heritability

Authors:

G. Leonenko¹, E. Baker¹, J. Hardy², V. Escott-Price¹; ¹Cardiff Univ., Cardiff, United Kingdom, ²UCL Inst. of Neurology, London, United Kingdom

Abstract Body:

The genetic contribution to a phenotype is frequently measured by heritability, the proportion of trait variation explained by genetic differences. Both Alzheimer's disease (AD) and ageing have a strong genetic component. Substantial heterogeneity of SNP-based heritability estimates of AD have been reported. We aimed to investigate these estimates in a number of different data cohorts to determine if we can identify a consistent estimate of the AD heritability. We investigate the sources of this heterogeneity in two cohorts a) clinically assessed cases and population-based controls from the UK Biobank and b) pathologically confirmed cases and controls, and calculate heritability with genome-wide complex trait analysis (GCTA) software. The cohorts vary by sample size, age of cases and controls and the definition of AD and control phenotypes. We compute heritability in four settings a) for all common (minor allele frequency >5%) SNPs, b) excluding APOE region, c) excluding both APOE region and genome-wide association study (GWAS) hits, and d) using gene-set specific SNPs that were identified as being associated with AD. We find that heritability estimates vary between 30-47% with 5% population prevalence when accounting for population structure. It drops substantially when additionally adjusting for age in the age-mismatched cohort but remains almost unchanged in the pathology confirmed cohort of cases and controls (46%). The heritability estimates decrease by 5-10% when the APOE region is removed. In conclusion, substantial variability in the AD SNP-based heritability estimates may be caused by incorrect adjustment for age in the age-mismatched cohorts. The heritability remains almost unchanged in the pathology confirmed cohorts independently of age adjustment.

Complex Traits Posters - Thursday

PB1505. Interrogation of shared genetic architecture of infectious disease traits and Alzheimer's disease

Authors:

R. Sale¹, D. Zhou², E. R. Gamazon³; ¹Vanderbilt Univ., Nashville, TN, ²Vanderbilt Genetics Inst., Nashville, TN, ³VUMC Clare Hall, Univ. of Cambridge, Nashville, TN

Abstract Body:

Alzheimer's Disease (AD) is a progressive, neurodegenerative disorder characterized by pathological hallmarks including amyloid beta plaques and neurofibrillary tau tangles that contribute to neuronal death. Accumulation of these neuropathological hallmarks may occur years before symptom onset, making it difficult to determine a causal relationship between AD neuropathology and cognitive decline. Amyloid beta oligomerization and amyloid beta generation are part of the innate immune system and integral to pathogen entrapment and clearance. Furthermore, studies have also shown that elevated brain microbe levels correlate with AD. This has led to the hypothesis that increased microbial burden exacerbates beta amyloid deposition and contributes to AD progression. However, there are many barriers to measuring microbial susceptibility, progression, and burden and linking these measurements to AD in a longitudinal cohort. Independent studies have determined that genetics influence AD development and microbial susceptibility, infection, and adverse outcomes. However, there is limited understanding of how risk loci associated with microbial infection and adverse outcomes may influence neurodegenerative diseases such as AD. The purpose of this study is to determine the genetic architecture of infectious disease traits, and determine shared genetic architecture between infectious disease traits and AD. We have obtained 90,000 individuals from the BioVU database, Vanderbilt University's deidentified electronic healthcare record (EHR) coupled to genomic information, who have been determined as either a case or control for an infectious disease trait (defined using ICD9 and ICD10 billing codes). We conducted GWAS on the individual infectious disease traits and performed LD Score regression analysis and Mendelian Randomization analysis to determine: 1.) the correlation between the genetics of AD and an individual infectious disease trait and 2.) determine causality between the genetics of an infectious disease trait and AD. These analyses determine the relationship between the genetics of infectious disease and AD and provide additional insight into AD risk and susceptibility.

Complex Traits Posters - Wednesday

PB1506. Intragenic loci within *TOMM40* modulate *APOE* expression in human microglia

Authors:

A. M Ramirez¹, O. Oron², L. Wang¹, M. Vasquez², B. DeRosa¹, K. Celis³, j. young⁴, K. Nuytemans⁵, J. Vance¹, D. Dykxhoorn¹; ¹Univ. of Miami, Miami, FL, ²Hussman Inst. for human genomics, Miami, FL, ³Univ Miami, Miami, FL, ⁴Univ. of miami, Miami, FL, ⁵John P. Hussman Inst. for Human Genomics, Miami, FL

Abstract Body:

Previously we demonstrated that the ancestry-related risk for Late Onset Alzheimer's Disease is driven by a local genomic region (termed Local Ancestry; LA) around *APOEε4*. Furthermore, we showed that the expression of *APOE* is higher in the brain of individuals bearing European LA compared to those with African LA. In a follow-up study, utilizing reporter assays and Capture-C data we located, within the European LA, two intronic loci in the *TOMM40* gene (named B10 and B13) that increased *APOE* expression in microglia and astrocytes. Here, we used CRISPR interference/activation (CRISPRi/a) to validate the regulatory role of these two regions in *APOE* expression and identify the specific subregion responsible for the interaction between *TOMM40* and the *APOE* promoter. Human Microglial Clone 3 (HMC3) CRISPRi/a lines were produced by transducing inducible dCas9-VP64 (Activator), dCas9-KRAB (Interferer) or dCas9 (control) using lentiviral vectors. To direct the dCas9 constructs to our regions of interest, we generated multiplex vectors that encode four single-guide RNAs (sgRNAs) targeting either B10 or B13 loci. We used 4 different sgRNAs in each case to ensure full coverage of the tested regions (~850bp/loci). Additionally, we constructed multiplex vectors including only 3 out of the 4 sgRNAs targeted at the B10 locus, as well as a non-targeting vector control bearing polyT tracts to truncate the expression of the scaffold RNAs. We then transduced each of the multiplex vectors into the HMC3 CRISPRi/a lines. We induced expression of the dCas9 constructs for 2 or 6 days with Doxycycline. RNA was extracted and the expression of *APOE* and close by genes (e.g. *TOMM40*) was measured by qRT-PCR. *APOE* expression significantly increased when targeting B10 or B13 with dCas9-VP64 after two days of Doxycycline treatment. Six days after treatment the significance persisted only when targeting B10. No significant changes in *APOE* expression were observed when inducing dCas9-KRAB. The upregulated *APOE* expression was reduced by leaving the first ~200bp of B10 untargeted in the dCas9-VP64 line, suggesting this area is key to modulate *APOE* expression. These preliminary results support our previous findings that regions B10 and B13 may house regulatory elements that modulate *APOE* expression and, show the potential location of a ~200bp cis-active element within B10 that could be driving the modulatory effects of European LA on *APOE*. While dCas9-VP64 increased *APOE* expression, dCas9-KRAB did not show repression presumably due to the already low basal levels of *APOE* in these cells. The expression of *TOMM40* did not vary across cell lines supporting that the effect observed is *APOE* specific.

Complex Traits Posters - Thursday

PB1507. Investigating the cellular and molecular response to hyperglycemia in iPSC-derived cardiomyocytes

Authors:

O. Johnson¹, E. Matthews¹, J. Gutierrez¹, M. Ward²; ¹the Univ. of Texas Med. Branch, Galveston, TX, ²Univ. of Texas Med. Branch, Galveston, TX

Abstract Body:

An estimated 451 million individuals worldwide are diagnosed with diabetes mellitus. Hyperglycemia is both a diagnostic hallmark and promoter of various diabetes-related pathologies. In cardiovascular tissue, prolonged hyperglycemia can lead to a type of cardiovascular disease (CVD) called diabetic cardiomyopathy (DCM) in some individuals. Because most CVDs are irreversible, understanding susceptibility to DCM is critical to early diagnosis and risk mitigation. Individual susceptibility to DCM can be assessed before the onset of cardiac pathology by determining genetic risk. Gene-by-environment (GxE) interactions, differential responses to the same environmental perturbation between cells of different genotypes, can be utilized to find disease-relevant variants that may inform genetic risk to DCM. To identify these interactions and understand the genetic and mechanistic basis for DCM, we have developed an *in vitro* cardiomyocyte model using three genotyped induced Pluripotent Stem Cell (iPSC) lines derived from both male and female healthy individuals to test the effects of hyperglycemia on the molecular and cellular response to glucose in iPSC-derived cardiomyocytes (iPSC-CM). Given that increased blood glucose concentrations are associated with increased risk of the development of DCM in diabetic individuals, we use glucose as an environmental perturbation relevant to DCM to identify functional variants. We can reliably differentiate beating iPSC-CMs at purities greater than 85%, as measured by the expression of cardiac-specific troponin T. Glucose exposure at hypoglycemic, physiologic and hyperglycemic concentrations reveals differences in gene expression within two hours. In the hyperglycemic condition we observe increased mRNA expression of known glucose response genes, such as *TXNIP*, which is also implicated in DCM. Several gene expression changes are maintained following week-long glucose exposure times; however a handful of known glucose response genes, including *SLC2A4*, show the opposite direction of effect over time, suggesting gene-regulatory changes mediating the differences between early and late responses. Early gene expression changes coincide with cellular changes affecting cardiomyocyte function whereby iPSC-CMs exposed to hyperglycemic conditions display arrhythmic effects determined by calcium flux measurements, and increased mitochondrial ROS production. Using this model, we plan to measure the global transcriptional, epigenetic and cellular response to glucose across individuals and correlate these changes with each individual's genetic variants to gain insight into DCM susceptibility.

Complex Traits Posters - Thursday

PB1508*. Investigating the influence of genetic ancestry on gene-environment interactions on polygenic risk score and acculturation: Results from the Hispanic Community Health Study/Study of Latinos.

Authors:

J. Sharma¹, C. McArdle², M. Graff³, C. Isasi⁴, M. Daviglus⁵, G. A. Talavera⁶, K. North³, L. Fernandez-Rhodes², G. L. Wojcik¹; ¹Dept. of Epidemiology, Johns Hopkins Bloomberg Sch. of Publ. Hlth., Baltimore, MD, ²Dept. of Biobehavioral Hlth., Coll. of Hlth. and Human Dev., The Pennsylvania State Univ., University Park, PA, ³Dept. of Epidemiology, Gillings Sch. of Global Publ. Hlth., Univ. of North Carolina at Chapel Hill, Chapel Hill, NC, ⁴Dept. of Epidemiology and Population Hlth., Albert Einstein Coll. of Med., Bronx, New York City, NY, ⁵Inst. for Minority Hlth. Res., Univ. of Illinois at Chicago, Chicago, IL, ⁶Dept. of Psychology, San Diego State Univ., San Diego, CA

Abstract Body:

Background: Many analyses of Hispanic/Latino groups in epidemiologic research aggregate participants into an assumed homogenous sample, despite diversity in the genetic makeup, environmental conditions, and sociocultural patterns in Hispanic/Latino groups. Using the Hispanic Community Health Study/Study of Latinos (HCHS/SOL), we examined the role of self-identified background group and genetic ancestry proportions in gene-diet and gene-acculturation interactions on the relationship between BMI and a BMI polygenic risk score (PRS_{BMI}).

Methods: Univariate and multivariable generalized linear models were executed using complex survey weights to understand heterogeneity in the distributions of several environmental variables identified a priori by McArdle et al. (2021). To understand the influence of both indigenous to the Americas (AME) ancestry and background group identity on the relationship between BMI and PRS_{BMI}, we used 3 modeling comparisons: 1) full model with and without AME ancestry proportion, 2) full model stratified by AME ancestry quartile, and 3) full model stratified by both background group and AME ancestry tertile. Key gene-environment interactions were PRS-diet and PRS-age at immigration.

Results: After complex survey weighting, 7,075 analytical samples remained, representing 6 background groups: 602 Central Americans, 1,717 Cubans, 636 Dominicans, 2,560 Mexicans, 1,157 Puerto Ricans, and 403 South Americans. Heterogeneity, assessed through t- and chi-squared tests, persisted in the distributions of key sociocultural, environmental, and health-related variables among participants after stratifying by self-identified background group and in univariate regressions with AME ancestry. The performance of the PRS_{BMI} decreased with increasing AME ancestry proportion. Statistically significant GxE interactions did not retain significance upon stratification by ancestry quartile and by both ancestry tertile and background, except for PRS-age at immigration interactions in the first tertiles of Mexican ($\beta = -1.33$, $p < 0.01$) and Dominican ($\beta = 4.11$, $p = 0.004$) groups and in the second tertile of the Central American group ($\beta = -3.11$, $p = 0.049$).

Conclusions: The BMI - PRS_{BMI} relationship and its interactions with age at immigration and diet varied significantly in both direction and statistical significance between AME ancestry tertiles of various background groups. Future analyses incorporating gene-environment interactions should account for different modifying effects of sociocultural variables between Hispanic/Latino background groups in addition to genetic ancestry.

Complex Traits Posters - Wednesday

PB1509. Irina St. Louis

Authors:

I. St. Louis; Johns Hopkins, Baltimore, MD

Abstract Body:

Recombination-activating gene 2 (RAG2) encodes the protein subunit RAG2 of the RAG1/2 endonuclease complex. This complex is well-known for its critical role in generating the diversity of B and T cell receptors. Mutations that impact the function of RAG2 in vitro, in an animal model, and in humans result in impaired V(D)J recombination activity, and various forms of severe combined immunodeficiency (SCID). In this study, I performed database mining and evaluated the molecular epidemiology of the SNP rs121918573 (a C>T missense mutation) and examined its potential impact on RAG2 function. Rs121918573 was mapped to the putative zinc-binding site within the plant homeodomain (PHD) region of RAG2. The effect of SNP on RAG2 protein structure was analyzed via a three-dimensional structure prediction model and the impact of a Cys478Tyr mutation on zinc-dependent binding to DNA was visualized. The I-TASSER server was used for the structural prediction of the SNP effect on both DNA and peptide binding. Predictive analyses of the effects of rs121918573 mutation alone showed evidence of destabilization on the PHD region of the protein but otherwise showed no impact on RAG2 expression. This study provides extensive data mining and bioinformatics analysis of the genomic location of rs121918573 and the predictive effect on the RAG2 gene and protein structure.

Complex Traits Posters - Thursday

PB1510. Is Whole-Blood Cell Mitochondrial Copy Number Lower in Chronic Obstructive Pulmonary Disease in the NHLBI trans-omics for precision medicine (TOPMED) Program?

Authors:

A. Rocco¹, X. Liu², H. Rossiter³, R. Casaburi³, M. Cho⁴, M. Irvin¹, H. Tiwari⁵, C. Liu², D. DeMeo⁶, M-L. McDonald¹; ¹Univ. of Alabama at Birmingham, Birmingham, AL, ²Boston Univ., Boston, MA, ³The Lundquist Inst. at Harbor-UCLA Med. Ctr., Torrance, CA, ⁴Brigham and Women's Hosp., Duxbury, MA, ⁵Univ Alabama at Birmingham, Birmingham, AL, ⁶Harvard Med. Sch., Boston, MA

Abstract Body:

RATIONALE: Chronic obstructive pulmonary disease (COPD) is the fourth leading cause of the death in the United States. With age, the prevalence of COPD increases while mitochondrial copy number (mtCN) tends to decrease. Lower whole blood mtCN is associated with increased systemic oxidative stress. Cigarette smoking, the primary risk factor for COPD, is known to contribute to oxidative stress. We postulated mtCN would be lower in COPD patients than current or former smoker controls without COPD.

METHODS: Analyses were performed on DNA from whole-genome sequencing of whole blood of 3,785 participants in three studies: SPIROMICS (373 COPD, 291 controls), ECLIPSE (2,006 COPD, 315 controls) and Framingham Heart Study (FHS) (167 COPD, 633 controls). mtCN was estimated using fastMitoCalc. In each study, linear regression models were used to test the relationship between mtCN as predictor for COPD and adjusted for age, sex, and smoking pack-years. In FHS, the model was also adjusted for current smoking. Fixed effect meta-analysis was performed among the three studies using the R library meta.

RESULTS: In SPIROMICS, participants with greater mtCN were less likely to have COPD (OR= 0.996, P=0.02). The relationship direction between mtCN and COPD was consistent in ECLIPSE (OR_{ECLIPSE}= 0.999, P_{ECLIPSE}= 0.88) and FHS (OR_{FHS}=0.887, P_{FHS}= 0.26) but did not reach P<0.05. Meta-analysis of the three studies indicated, although effect directions were consistent, there was moderate heterogeneity in effect and the meta-analysis result was not significant (OR_{meta}=0.999, CI= 0.9965-1.0007, P=0.20, I²=50.8%).

CONCLUSION: We demonstrate that COPD participants in SPIROMICS were slightly more likely to have lower mtCN than current or former controls. However, this finding was not replicated in ECLIPSE and FHS. We analyzed data from three large studies with state-of-the-art whole-genome sequencing and note significant degree of effect size heterogeneity. Additional research will be performed to understand whether factors such as white blood cell counts as well as factors related to COPD pathology or severity such as degree of lung function decline, percent emphysema and chronic bronchitis account for effect size heterogeneity among the three studies.

Complex Traits Posters - Wednesday

PB1511. Isoform usage differences in schizophrenia.

Authors:

P. Giusti-Rodriguez¹, A. Abrantes², N. Ancalade², S. Sekle², F. Memic³, A. Dijkstra⁴, E. Tseng⁵, G. Sheynkman⁶, J. Hjerling-Leffler³, A. B. Smit⁴, P. Sullivan^{7,3}; ¹Univ. of Florida Coll. of Med., Gainesville, FL, ²Univ. of North Carolina, Chapel Hill, NC, ³Karolinska Inst.t, Stockholm, Sweden, ⁴Amsterdam UMC, Amsterdam, Netherlands, ⁵Pacific BioSci.s, Menlo Park, CA, ⁶Univ. of Virginia, Charlottesville, VA, ⁷Univ North Carolina, Chapel Hill, NC

Abstract Body:

The genetic architecture of schizophrenia is dominated by common variants of small effects, similar to most complex human traits. The majority of the schizophrenia GWAS SNPs reside in non-coding regions where they could act through a variety of regulatory mechanisms, including alternative splicing, which could result in differential isoform usage in schizophrenia cases compared to healthy controls. The brain expresses the most diverse repertoire of isoforms, yet our understanding of brain-specific isoform expression and the mechanisms of their regulation by RNA binding proteins (RBPs) are incomplete. Rbfox1 is an RNA binding protein that regulates splicing. The gene that encodes it, *RBFOX1*, is located on a GWAS locus for schizophrenia and major depressive disorder, and mutations of *RBFOX1* have been linked to autism and epilepsy. Furthermore, gene-set analysis of schizophrenia GWAS findings has shown an enrichment for genes with a binding site for Rbfox1 and Rbfox2, another important splicing factor. Long-read RNA-sequencing technologies have made dramatic improvements in throughput, accuracy, access, and cost. Our study aims to generate a comprehensive isoform survey of human dorsolateral prefrontal cortex (DLPFC) and to identify potential isoform level differences in schizophrenia cases and controls. We generated long-read RNA-sequencing data from post-mortem human DLPFC from schizophrenia cases (n=10) and controls (n=15) using the PacBio Sequel II system. We also generated complementary short-read RNA-seq data to examine isoform abundances. We used published and in-house pipelines to generate a comprehensive isoform survey of human DLPFC and to compare differential isoform usage in DLPFC from schizophrenia cases vs healthy controls. We identified differential isoform usage (DIU) in DLPFC from schizophrenia cases compared to healthy controls using established and in-house pipelines (IsoSeq, Cupcake, SQANTI3, IsoAnnot, and DiffSplice) and contextualized these findings at the transcript- and gene-level using pathway and network analyses. Our findings support DIU as a regulatory mechanism at play in the pathophysiology of schizophrenia. DIU may reveal schizophrenia-associated isoforms that impact protein-protein interactions (PPIs) and could nominate actionable targets.

Complex Traits Posters - Thursday

PB1512*. Key discoveries of the genetic basis of stuttering.

Authors:

D. Pruett¹, H. Polikowsky¹, D. Shaw¹, A. Scartozzi¹, H-H. Chen¹, L. Petty¹, R. Gordon², Y. Yu³, 23andMe Research Team, C. Huff⁴, S. Kraft⁵, J. Below², R. Jones¹; ¹Vanderbilt Univ., Nashville, TN, ²Vanderbilt Univ. Med. Ctr., Nashville, TN, ³UT MD Anderson Cancer Ctr., Houston, TX, ⁴U.T. MD Anderson Cancer Ctr, Houston, TX, ⁵Wayne State Univ., Detroit, MI

Abstract Body:

Developmental stuttering is a speech condition characterized by syllable repetitions, prolongations, and involuntarily pauses. Despite a prevalence of ~1%, the cause of stuttering is unknown. Heritability studies have established that a genetic component for stuttering exists; however, the genetic factors impacting stuttering risk remain largely uncharacterized. This study utilizes the results of self-reported stuttering from a sample of more than 1 million individuals to further elucidate the genetic basis of stuttering. We conducted a GWAS in individuals genotyped by 23andMe, Inc. Cases were defined as those who self-reported ever having a stammer or a stutter (N=99,776), with all other individuals considered controls, comprising a total of 1,123,019 participants of African American, East Asian, European, and Admixed American ancestry. We performed ancestry and sex-specific association studies, which assumed an additive model for allelic effects and included age, five principal components, and genotype platforms as covariates. These 8 independent GWAS identified twenty-four loci that reached genome-wide significance. One significant risk variant ($p = 3.81 \times 10^{-16}$) was identified in the European-female (rs13107325, RAF= 8.13%, OR = 1.11) GWAS for a missense variant in *SLC39A8*, a gene encoding solute-carrier proteins critical for cellular transport in mitochondria. Additional loci identified significant variant signals that implicated genes *DCC*, *SRPK2*, *NMUR2*, *TSHZ2*, *MITF*, *VRK2*, *CAMTA1*, *MYO16*, *MMAB*, *CTNND2*, *SEMA6D*, *IRS2*, *COL14A1*, *PTPRQ*, *SHISA2*, *CYTH4*, *SORCSI*, and *RGCC* as contributing to stuttering risk. We conducted an enrichment test for gene modules using genes associated with variant signals. Gene modules comprised groups of functionally related gene modules Gerring et al. identified from GTEx tissue gene expression data. Gene module enrichment analysis identified enrichment for modules in multiple tissue models (e.g. pancreas, heart atrial appendage, esophagus mucosa etc.), implicating stuttering associated genes in biological processes such as metabolism, nervous system development, and cell signaling. These results highlight that stuttering risk factors are complex and polygenic and suggest that genetic variation impacts population-level stuttering risk. This large population study provides novel evidence for a neurological origin of stuttering, which may lead to improved treatment of disordered speech.

Complex Traits Posters - Wednesday

PB1513. Known Alzheimer disease candidate variants influence the severity of neuropathologic lesions underlying Alzheimer disease and related dementias.

Authors:

D. Godrich¹, J. Pasteris¹, E. Martin², G. Schellenberg³, M. Pericak-Vance², M. Cuccaro⁴, W. Scott¹, T. Montine⁵, G. Beecham¹, The Alzheimer's Disease Genetics Consortium; ¹Univ. of Miami, Miami, FL, ²Univ. of Miami Miller Sch. of Med., Miami, FL, ³Univ Pennsylvania Sch Med, Philadelphia, PA, ⁴John P. Hussman Inst. for Human Genomics, Miami, FL, ⁵Stanford Univ., Palo Alto, CA

Abstract Body:

Introduction: The hallmark neuropathologic lesions underlying Alzheimer disease (AD) include neurofibrillary tangles and amyloid plaques. However, these AD lesions seldom appear in isolation; instead, they often co-occur with AD related dementia (ADRD) lesions including lewy bodies (LB), cerebral amyloid angiopathy (CAA), arteriolosclerosis (ARTE), hippocampal sclerosis (HS), vascular brain injury (VBI), and TAR DNA-binding protein 43 (TDP-43). While AD genetics has been well studied, the genetics of the lesions underlying AD/ADRD has been largely overlooked. Herein, we report on the effect of known AD variants on AD and ADRD lesions, instead of a binary clinical diagnosis of AD. **Methods.** We used the National Alzheimer's Coordinating Center dataset, identifying 4,972 autopsied individuals with neuropathology and genetic data. Lesions were ranked ordinally based on increasing severity. We pulled 23 known AD-associated SNPs from a recent AD GWAS of clinically defined AD [Kunkle, 2019]. We used ordinal logistic regression models to test for associations between AD candidate SNPs and lesion severity, adjusting for age at death and sex. Finally, we investigated the combined effect of the independent variants, excluding *APOE*, by constructing genetic risk scores (GRSs). **Results.** Regression models showed 10 of the 23 previously identified variants were strongly associated with severity of tangles: *CRI*, *BINI*, *INPP5D*, *MEF2C*, *TREM2*, *PICALM*, *SORL1*, *ACE*, *APOE*, *CASS4* and of plaques: all the same besides *MEF2C* but including *FERMT2*. The ADRD neuropathologic lesions also showed some associations with known AD variants. We found *APOE* to be highly associated with CAA, LBs, HS, and TDP-43, but not ARTE or VBI. Severity of LBs and ARTE was associated with *BINI*, but of opposite effect in ARTE. CAA was associated with *PICALM* and *ACE*. HS was associated with *TREM2* and VBI with *CASS4*, but both of opposite effect from the AD lesions. TDP-43 showed a strong association with *ACE*. Finally, we found the GRS to be predictive only for the AD lesions and LBs. **Conclusions.** We showed that there was some overlap in the known AD variants that were shared in the ADRD lesions. Interestingly, although the AD lesions and CAA are correlated, there does not seem to be a highly shared genetic architecture, besides *APOE*, in these lesions. Additionally, the lack of association of *APOE* and other AD variants with the vascular lesions (ARTE and VBI) may suggest that even though these lesions frequently co-occur, their genetic profiles may differ. Finally, the lack of predictive value of the GRS in the ADRD lesions suggests that there is a need to improve our understanding of the genetic landscape of ADRD.

Complex Traits Posters - Thursday

PB1514*. Large scale genome-wide association study highlights the causality of vasospastic angina

Authors:

K. Hikino¹, S. Koyama¹, K. Ito¹, M. Koido², T. Matsumura³, R. Kurosawa⁴, K. Tomizuka⁴, Y. Koike¹, S. Ito¹, Y. Momozawa⁴, T. Morisaki⁵, Y. Kamatani⁶, The Biobank Japan Project, T. Mushiroda¹, C. TERAO⁴; ¹RIKEN Ctr. for Integrative Med. Sci., Yokohama, Japan, ²RIKEN Ctr. for Integrative Med. Sci., Yokohama, Kanagawa, Japan, ³Jichi Med. Univ., Tochigi, Japan, ⁴RIKEN Ctr. for Integrative Med. Sci., Yokohama, Japan, ⁵The Univ. of Tokyo, Inst Med Sci, Minato-ku, Tokyo, Japan, ⁶The Univ. of Tokyo, Minato-ku, Japan

Abstract Body:

Background: Vasospastic angina (VSA) results from coronary artery spasm and is more common in East Asians. VSA is an important disease that can lead to fatal conditions such as myocardial infarction and sudden death, but the genetic factors that may cause the disease have not yet been fully explored on a genome-wide level. Methods: A genome-wide association study (GWAS) of VSA was performed using the BioBank Japan (BBJ) data with 5,242 cases and 150,352 controls in total. The effect sizes of previously reported coronary artery disease (CAD) -susceptible loci were then compared between those with VSA and non-VSA CADs. Additionally, we compared the effect size of the variants associated with VSA with those of other CADs, which were also analyzed separately based on sex and age. Finally, we analyzed the mortality from AMI in patients who did not originally have CAD by using subsequent follow-up data. Results: We identified that rs112735431, a missense deleterious variant in *RNF213* gene (p.R4810K) in chromosome 17, had strong associations with VSA in all discovery, replication, and combined studies [odds ratio (OR): 2.98, 95% confidence interval (CI) 2.29 - 3.88, $p = 5.3 \times 10^{-16}$ in combined study]. This variant is an Asian-specific, low-frequency variant that has been experimentally linked to reduced angiogenesis and is a well-known cause of Moyamoya disease (a highly prevalent vascular disease in East Asians). Most of the previously reported CAD-associated variants showed higher absolute effect sizes in non-VSA CAD than in VSA, but only rs112735431 showed higher effect size in VSA. The effect sizes of rs112735431 in VSA were also distinctly different when compared to those in other CADs. Furthermore, in VSA patients, homozygous carriers of rs112735431 showed a penetrating association (OR: 13.80, 95%CI: 3.55 - 53.65, $p = 1.5 \times 10^{-4}$) compared to the expected heterozygous carriers in the additive model. In stratified analyses, consistent with epidemiologic findings, the risk allele for rs112735431 was more strongly associated in males (omnibus $p = 0.035$) and in the younger age group. Finally, a strikingly high fatality rate in AMI was observed in follow-up data in risk allele carriers of rs112735431, who did not have CAD at the time of BBJ enrollment (Hazard ratio:2.91, 95%CI: 1.65 - 5.12, $p = 2.1 \times 10^{-4}$). Conclusions: The rare missense variants in *RNF213*, rs112735431, identified in this first large-scale GWAS of VSA may be partially responsible for the high frequency of VSA in East Asian populations. The association between rs112735431 and high mortality from AMI may indicate a strong contribution of vascular cell dysfunction to the progression to AMI via coronary spasm.

Complex Traits Posters - Wednesday

PB1515. Large-scale chromatin accessibility fine-mapping of blood lipids GWAS loci in human liver cell types.

Authors:

B. Wenz¹, S. Ramdas¹, M. Caliskan², M. Dudek¹, K. Creasy¹, R. Aubin¹, J. Judd³, D. Xin¹, K. Olthoff¹, A. Shaked⁴, P. Camara¹, S. Grant⁵, D. Rader⁶, C. Brown¹; ¹Univ. of Pennsylvania, Philadelphia, PA, ²Daiichi Sankyo, Chesterfield, NJ, ³Stanford Univ., Stanford, CA, ⁴Hosp Univ Pennsylvania, Philadelphia, PA, ⁵Children's Hosp. of Philadelphia/Univ. of Pennsylvania, Philadelphia, PA, ⁶Univ of Pennsylvania, Philadelphia, PA

Abstract Body:

Genome wide association studies (GWAS) have identified thousands of genetic loci associated with a variety of common, complex human traits. For the vast majority of these loci, however, the true causal variant, target gene, and mechanism of action leading to these associations remain unclear. Most GWAS variants have high levels of linkage disequilibrium (LD) and/or fall in non-coding genomic regions, complicating fine-mapping and mechanistic studies. The impact of genetic variants that are associated with gene expression has been well-studied, suggesting that gene expression regulation plays a causal role at many complex trait associated loci. However, the upstream impacts of genetic variation on transcription factor binding and chromatin accessibility has not been comprehensively investigated. We assessed the landscape of chromatin accessibility in 189 human liver tissue samples using ATAC-seq. We identify more than two million regions of open chromatin in the human liver, many of which exhibit tissue specific regulatory activity. The depth of these data allowed for nucleotide resolution transcription factor footprinting to infer transcription factor binding sites (TFBS) in our samples. Integration of single nucleus RNA sequencing (snRNA-seq) from a subset of human liver samples has enabled prediction of TF binding, chromatin accessibility, and gene expression in specific liver cell types. Combined with whole genome sequence data from these samples, we identified thousands of cis-regulatory elements whose chromatin accessibility is associated with local genotypes, called chromatin accessibility quantitative trait loci (caQTLs). At dozens of blood lipids GWAS loci, we achieve cell type specific single nucleotide resolution to identify the specific TF binding site disturbed that leads to a co-localized caQTL, eQTL, and GWAS signal, which allows us to generate specific molecular hypotheses about the mechanisms leading to disease. Integration of chromatin conformation capture data generated in liver cell models allows us to test many of these hypotheses. These findings highlight the benefits of integrating multiple cellular traits for the identification and characterization of disease-causing variants and contribute to basic understanding of genetic and epigenetic regulation of gene expression in human liver tissue.

Complex Traits Posters - Thursday

PB1516. Large-scale exome sequencing identifies common and rare coding variants contributing to tinnitus

Authors:

A. Ayer¹, GHS-RGC DiscovEHR Collaboration, Regeneron Genetics Center, M. Drummond², G. Coppola¹, K. Praveen¹; ¹Regeneron Genetics Ctr., Tarrytown, NY, ²Regeneron Pharmaceuticals, Tarrytown, NY

Abstract Body:

Tinnitus, defined as the perception of sound without external stimulus, is a highly prevalent condition that affects 10-20% of the adult population worldwide. Chronic or severe tinnitus may negatively impact quality of life and has been associated with depression, anxiety, insomnia, cognitive impairment and psychiatric diagnoses. Current treatment options are limited to symptom management via noise suppressing devices and therapy focused on coping techniques, with little ability to target the causal pathways of the disorder. Identifying genes associated with tinnitus can elucidate relevant biological pathways, which may then be targeted to treat the underlying biological causes of tinnitus. We performed genome-wide and exome-wide association analyses of tinnitus in the largest such study to date in Europeans, including 27,409 cases and 566,160 controls from UK Biobank, Geisinger DiscovEHR, the Malmö Diet and Cancer Study, Mount Sinai's BioMe Personalized Medicine Cohort, Penn Medicine Biobank, and FinnGen. Cases were defined using self-reported and medical record diagnoses of tinnitus and controls excluded individuals diagnosed with hearing loss, which is highly correlated with tinnitus. We identified 13 loci associated with tinnitus, 3 of which are also hearing loss risk loci (*NID2*, *CTBP2* and *CRIP3*). In rare (minor allele frequency < 1%) variant analyses, we identified genome-wide significant associations with intronic variants in *CACNA1A* and *NFE2L2*. We also observed associations with missense variants in *SYNJ2* (Thr656Met; OR=1.42; p=3e-08), *COL11A2* (Phe80Ser; OR=11.29; p=2e-09) and aggregates of predicted loss-of-function variants within *KLHDC7B* (OR=2.06; p=5e-08) and *TRIOBP* (OR=1.89, p=3E-07), all of which have previously been associated with hearing loss in humans. *COL11A2* mutations can cause Stickler syndrome and tinnitus can be a symptom in affected individuals. Our results suggest that *SYNJ2* and *KLHDC7B* variants, which are associated with increased risk for hearing loss, may also confer a risk for tinnitus that likely accompanies the loss of hearing in carriers. Our analysis has identified novel common variant associations and is the first to interrogate the contribution of rare variants to tinnitus.

Complex Traits Posters - Wednesday

PB1517. Leveraging aggregation of juvenile idiopathic arthritis in large pedigrees to investigate susceptibility genes.

Authors:

C. Avery¹, J. F. Bohnsack², A. Hersh², S. Thompson³, M. Sudman³, S. Prahalad⁴, L. Jorde¹; ¹Dept. of Human Genetics, Univ. of Utah Sch. of Med., Salt Lake City, UT, ²Dept. of Pediatrics, Univ. of Utah Sch. of Med., Salt Lake City, UT, ³Div. of Human Genetics, Dept. of Pediatrics, Cincinnati Children's Hosp. Med. Ctr. & Univ. of Cincinnati, Cincinnati, OH, ⁴Dept. of Pediatrics, Emory Univ. Sch. of Med., Atlanta, GA

Abstract Body:

Juvenile idiopathic arthritis (JIA) is a complex rheumatic disease, affecting approximately 1 in 1000 children. While the etiology of JIA is largely unknown, genetic factors have been predicted to contribute to the development of JIA. Familial studies have estimated that the relative risk of JIA for siblings of probands is approximately 11.6x that of the general population. However, clinical heterogeneity and low disease prevalence have impeded investigation of heritable risk factors. Recent genome-wide association studies have suggested that up to 22 genes are associated with JIA susceptibility but are limited by their capacity to detect rare variants with high-effect size. Pedigree-based studies minimize genetic heterogeneity and target variants that are rare in the population but enriched in high-risk families. This study utilizes whole genome sequencing in 22 small multiplex pedigrees to identify genes harboring excess burden, and 10 large multi-generational pedigrees to identify segregating shared genomic segments (SGS) from a common founder to identify coding or regulatory risk variants for a dominant mode of inheritance. In our small multiplex pedigrees, we have identified a candidate coding variant in *ACVRI*, a component of BMP signaling, and a recessive candidate variant in *FOXPI*, recently implicated in a meta-GWAS of JIA. In our large pedigrees, SGS analysis identified several interesting segregating loci shared in cases and longer than one would expect by chance, including a genome-wide significant region flanking the HLA (1.8 Mb) and several genome-wide suggestive loci, including a 2 Mb region on chromosome 12 that includes *PARPBP* (PARP-1 binding protein), which positively regulates PARP-1. Interestingly, PARP-1 is a known regulator of various inflammatory disorders. These initial findings have the potential to refine and build upon previous efforts to identify heritable susceptibility to JIA, highlight key biological processes in JIA progression, and address the contribution of rare variants to JIA risk.

Complex Traits Posters - Thursday

PB1518. Leveraging genetic variation to evaluate risk factors and therapeutic opportunities for aortic valve stenosis: a mendelian randomization analysis.

Authors:

H. Urquijo¹, R. J. Richardson², T. R. Gaunt¹, T. G. Richardson¹; ¹MRC Integrative Epidemiology Unit (IEU), Bristol, United Kingdom, ²Faculty of Life Sci., Sch. of Physiology, Pharmacology and NeuroSci., Bristol, United Kingdom

Abstract Body:

Aims: Aortic valve stenosis (AVS) is an increasingly prevalent disease with no pharmacotherapies available. In this study, we used mendelian randomization (MR) to estimate the genetically predicted effects of established and emerging risk factors on AVS risk, as well as evaluate drug repurposing opportunities.

Methods and Results: Univariable MR analyses using genetic data of up to 462,927 UK Biobank participants supported previous MR findings indicating several established risk factors, such as elevated blood pressure and lipoprotein lipids, increase AVS risk. We additionally identified calcium (OR=1.26 per SD increase, 95% CI=1.10-1.43, $P=7 \times 10^{-4}$) and lifetime smoking (OR=1.92 per SD increase, 95% CI=1.55-2.39, $P=5 \times 10^{-9}$) as risk factors for AVS. Applying the same analysis on coronary artery disease (CAD) risk found comparable estimates with the notable exception of calcium which provided limited evidence of an effect on CAD (OR=1.06, 95% CI=0.97-1.15, $P=0.23$). Multivariable MR provided evidence that apolipoprotein B is the predominating lipoprotein trait increasing AVS risk when conditioned on low density lipoprotein cholesterol (LDL-C) and triglycerides. Finally, we found a genetically predicted effect of inhibition of antihypertensive target *ADRB1* on lower AVS risk. LDL-C lowering target *PCSK9*, lipoprotein(a) lowering target *LPA* and triglyceride lowering targets *ANGPTL4* and *LPL* also were genetically predicted to lower AVS risk.

Conclusions: We provide a comprehensive evaluation of modifiable risk factors driving the increased healthcare burden of AVS, which should be considered in risk stratification and prevention strategies. Furthermore, our findings provide valuable insight into the prioritisation of the pharmacotherapies which may yield clinical benefit towards treating AVS.

Complex Traits Posters - Wednesday

PB1519. Leveraging spatial patterns in the distribution of dental caries to resolve genetic heterogeneity.

Authors:

S. Haworth¹, J. R. Shaffer², A. Esberg³, P. Lundberg⁴, K. Divaris⁵, M. Marazita⁶, I. Johansson³; ¹Bristol Dental Sch., Univ. of Bristol, Bristol, United Kingdom, ²Ctr. for Craniofacial and Dental Genetics, Dept. of Oral and Craniofacial Sci., Sch. of Dental Med., Univ. of Pittsburgh; Dept. of Human Genetics, Sch. of Publ. Hlth., Univ. of Pittsburgh, Pittsburgh, PA, ³Section of Cariology, Dept. of Odontology, Umeå Univ., Umeå, Sweden, ⁴Section of Molecular Periodontology, Dept. of Odontology, Umeå Univ., Umeå, Sweden, ⁵Div. of Pediatric and Publ. Hlth., Adams Sch. of Dentistry, Univ. of North Carolina at Chapel Hill, Chapel Hill, NC, ⁶Ctr. for Craniofacial and Dental Genetics, Dept. of Oral and Craniofacial Sci., Sch. of Dental Med., Univ. of Pittsburgh, Pittsburgh, PA

Abstract Body:

Objective:

Dental caries (i.e., tooth decay) is a common disease with an incompletely understood genetic basis. The distribution of caries-affected tooth surfaces in the mouth follows recognizable spatial patterns, where groups of tooth surfaces have similar caries experience (termed caries clusters). We aimed to test whether analysis of these clusters would yield improved insight into the genetic basis of caries experience.

Methods:

The study included Swedish adults from the SIMPLER and VIKING studies. Quantitative traits were derived for five different caries clusters using electronic dental records and results of previously published cluster analysis. For each trait, genome-wide association statistics were generated and results from the studies were combined using fixed effects meta-analysis. SNP-based heritability estimates and estimates of genetic correlation between pairs of traits were estimated using the SumHer method, implemented in LDAK5.2.

Results:

Analysis included 18,819 adults, with mean age 74 years in SIMPLER and 64 years in VIKING. The caries traits were moderately heritable, with estimates of SNP-heritability between 0.12 and 0.20. At the genome-wide level, the caries clusters captured traits with distinct genetic profiles. As an example, the cluster representing caries in the occlusal surfaces of molar teeth had little genetic overlap with the other caries clusters (rg estimates between -0.39 and +0.11).

Differences in genetic architecture were also seen at the single variant level. As an illustration we examined the effects of rs1122171, a common variant located near *PITX1* which has previously been reported to associate with caries in adults. This variant had strong effects on caries in upper incisor teeth (0.079 standard deviations per T allele, $P=1.3 \times 10^{-11}$) but weak effects on caries in the occlusal surfaces of molar teeth (0.019 standard deviations per T allele, $P=0.071$)

Conclusion:

Different genetic risk loci are associated with caries experience at different tooth surfaces. Leveraging spatial patterns through clustering provides one way to resolve heterogeneity in the genetic architecture of caries. This may be useful to boost statistical power or provide more precise understanding of different disease mechanisms at different sites in the mouth. Genome-wide analysis of these caries clusters will now be included in GLIDE2.0, the second round of the oral and dental health GWAS consortium.

Complex Traits Posters - Thursday

PB1520. Leveraging the nutritional geometry framework to dissect the impact of macronutrient composition on metabolic function and gene regulation in fat tissue

Authors:

K. Farris¹, A. Crean², D. Sobreira¹, R. Barrès³, S. Simpson², M. Nobrega¹; ¹Univ. of Chicago, Chicago, IL, ²Univ. of Sydney, Sydney, Australia, ³Univ. of Copenhagen, Copenhagen, Denmark

Abstract Body:

Changes in macronutrient composition, even in the absence of changes in caloric intake, can have significant impacts on metabolic health and lifespan in mice. However, the functional and molecular underpinnings of these changes remain largely unexplored. Using the nutritional geometry framework, we have measured the impact of ten different isocaloric ratios of proteins, carbohydrates, and fat on metabolic function and gene regulation in fat tissue in mice. We can therefore dissect the impact of individual macronutrients on changes in gene regulation across the diets and identify possible mechanisms underlying the observed metabolic changes. Across the ten diets, we saw significant changes in metabolic measures such as body weight and glucose tolerance and identified 5,644 differentially expressed (DE) genes and 4,308 differentially spliced (DS) exons. The gene regulation changes we observed were predominately correlated with fat content in the diets, although there were still substantial contributions from protein and carbohydrate content. Further, the significant expression and splicing changes occurred in largely different genes, with only 967 genes being acted on by both modes of regulation, indicating that expression and splicing regulation are likely involved in separate processes in response to changes in macronutrient composition. To explore this further, we performed gene ontology (GO) analysis on sets of DE or DS genes that respond to each macronutrient. We found different GO terms enriched in response to the different macronutrients and modes of gene regulation. For example, in the set of DE genes with a significant positive correlation with fat content, the top GO term was cilium organization. In investigating this signal further, we found that it was being driven in part by 9 DE genes that were all associated with Bardet-Biedl syndrome (BBS). BBS is a rare autosomal recessive ciliopathy whose symptoms include obesity. Mouse knockouts of BBS-associated genes have demonstrated an association between some BBS genes and increased food intake. However, to our knowledge BBS-associated genes have not previously been associated with response to diet. We did not find cilium organization as a top GO term for the other macronutrient response groups, demonstrating the power of the nutritional geometry framework to provide novel insights into the gene regulatory response to changes in diet. By disentangling the response to individual macronutrients, we can provide novel insights into potential mechanisms underlying the overarching metabolic changes that are observed in response to changes in macronutrient composition.

Complex Traits Posters - Wednesday

PB1521. Limited effect of Y chromosome variation on coronary artery disease and mortality in UK Biobank.

Authors:

J. Wilson¹, P. R. Timmers²; ¹Univ Edinburgh, Edinburgh, United Kingdom, ²Univ. of Edinburgh, Edinburgh, United Kingdom

Abstract Body:

The effect of genetic variation in the male-specific region of the Y chromosome (MSY) on coronary artery disease and cardiovascular risk factors has been disputed. We systematically assessed the association of MSY genetic variation on these traits using a kin-cohort analysis of family disease history in the largest sample to date.

We tested 90 MSY haplogroups against coronary artery disease, hypertension, blood pressure, classical lipid levels, and all-cause mortality in up to 152,186 unrelated, genomically British individuals from UK Biobank. Unlike previous studies, we did not adjust for heritable lifestyle factors (to avoid collider bias), and instead adjusted for geographical variables and socioeconomic deprivation, given the link between MSY haplogroups and geography. For family history traits, subject MSY haplogroups were tested against father and mother disease as validation and negative control, respectively. Our models find little evidence for an effect of any MSY haplogroup on cardiovascular risk in participants. Parental models confirm these findings.

Kin-cohort analysis of the Y chromosome uniquely allows for discoveries in subjects to be validated using family history data. Despite our large sample size, improved models, and parental validation, there is little evidence to suggest cardiovascular risk in UK Biobank is influenced by genetic variation in MSY.

Complex Traits Posters - Wednesday

PB1522. Longitudinal transcriptomic profiling of IBD patients reveals therapeutic decision-making determinants of drug response.

Authors:

L. Cervera Seco¹, M. Sanchez-Mayor¹, A. M. Corraliza^{2,3}, A. Salas^{2,3}, J. Panes^{2,3}, U. Marigorta^{1,4}; ¹Integrative Genomics Lab, Ctr. for Cooperative Res. in BioSci.s (CIC bioGUNE), Basque Res. and Technology Alliance (BRTA), Bizkaia Technology Park, Derio, Spain, ²Dept. of Gastroenterology, IDIBAPS, Hosp. Clínic, Barcelona, Spain, ³Centro de Investigación Biomédica en Red de Enfermedades Hepática y Digestivas (CIBERehd), Barcelona, Spain, ⁴IKERBASQUE, Basque Fndn. for Sci., Bilbao, Spain

Abstract Body:

Inflammatory Bowel Disease (IBD) is a complex immune-mediated inflammatory disease that triggers a series of recurrent relapse-remission phases, leading to a chronic inflammation of the gut, and ultimately to severe outcomes like surgery. Although association studies have made deep inroads into the genetic component associated with diagnosis, our understanding of the factors contributing to drug response remains especially poor. Primary response to biological drugs is low, and secondary loss of response is prevalent. Even if the remission rates are low (around 30% of patients), the therapeutic repertoire available for clinicians will be expanding in the immediate years. It is therefore pressing to develop an understanding of the determinants of response to individual treatments with advanced therapies in IBD patients.

We have carried out a longitudinal follow-up including 147 patients from whom we obtained 264 intestinal biopsy and 119 blood RNA-seq samples. Our study includes samples from patients treated with the three main biological drugs approved, namely infliximab ("anti-TNF"), ustekinumab ("anti-IL12/IL23") and vedolizumab ("anti- α 4 β 7 integrin"), with 248, 47, and 88 samples, respectively. We also have around 3 timepoints (0, 14 and 46 weeks) for a total of 232, 92, and 59 samples, respectively. A first exploratory analysis using the full dataset confirms that tissue and, to a lesser extent, disease subtype are the main determinants of transcriptomic variability among IBD patients. Regarding drug response across time, ustekinumab response is associated with pathways related to extracellular recognition, whereas infliximab is putatively involved in translation- and general immune-related pathways. Interestingly, ustekinumab alters a particularly low number of genes across time points, suggesting that patients are not efficiently responding, or that gene modulation takes place at a slow rate. To improve our understanding of individual response to treatment, we carried out trend analyses based on connectivity scores that serve to classify patients into responders and non-responders. This allows uncovering new biological pathways associated to drug response profiles in particular patients. Besides providing a renewed understanding of the molecular effects of biological drugs, we propose that the creation of personalized models to explain longitudinal response to treatment is feasible and a promising venue to develop therapeutic positioning guidelines of biological drugs in IBD.

Complex Traits Posters - Thursday

PB1523. Loss of chromosome Y in leukocytes as a risk factor for critical COVID-19 in men.

Authors:

B. Bruhn-Olszewska¹, H. Davies¹, D. Sarkisyan¹, U. Juhas², E. Rychlicka-Buniowska², M. Wójcik², M. Horbacz², M. Jakalski², P. Olszewski², J. Orzechowski Westholm³, A. Smialowska³, K. Wierzba², A. Torinsson Naluai⁴, N. Jern⁴, L-M. Andersson⁴, J. Järhult¹, N. Filipowicz², E. Tiensuu Janson¹, S. Rubertsson¹, M. Lipcsey¹, M. Gisslen⁴, M. Hultstrom¹, R. Frithiof¹, J. Dumanski¹; ¹Uppsala Univ., Uppsala, Sweden, ²Med. Univ. of Gdansk, Gdansk, Poland, ³Stockholm Univ., Stockholm, Sweden, ⁴Univ. of Gothenburg, Gothenburg, Sweden

Abstract Body:

COVID-19 pandemic, which has a prominent social and economic impact worldwide, is characterized by a bias towards higher severity and mortality in males. The loss of chromosome Y (LOY) is a male-specific factor, associated with age-related diseases, cancer, and all-cause mortality in males. Recent studies demonstrated that LOY has a significant impact on the transcription of immune genes in leukocytes. Therefore, in this study, we tested the hypothesis that LOY is a plausible factor responsible for the severity of COVID-19 infection in males. We re-analyzed publicly available scRNA-seq data of PBMC samples collected from critically ill male patients and identified low-density neutrophils (LDNs) as the cell type most affected with LOY. These results, were confirmed by ddPCR in sorted leukocytes from the newly collected cohort, consisting of 211 men with severe COVID-19, showing that LOY above 5% cut-off was present in 46% of LDNs, 32% of granulocytes, and 29% of monocytes samples. In particular, LDNs occur in patients with severe COVID-19 and contribute to the hypercoagulable state of the disease. Remarkably, we demonstrate that LOY level is significantly associated with COVID-19 severity and mortality classified by the WHO grade. The analysis revealed that the level of LOY was higher in the whole blood of patients who died due to COVID-19, compared to the survivors. Similarly, critically ill patients with WHO grade 10 had significantly more LOY than patients with WHO grade 9 and 6. Moreover, the percentage of LOY in sorted subpopulations of leukocytes correlated with clinical variables including increased thrombocyte and decreased erythrocyte counts, as well as increased levels of IL-4 and IL-5. Interestingly, the follow-up analysis of recovered patients revealed a decrease in the number of LDNs and monocytes accompanied by a reduction of LOY level in PBMC, suggesting that LOY could be a consequence of emergency myelopoiesis. Collectively, our results imply that LOY is associated with the dysregulation of immune genes as well as in the shift in the composition of leukocyte subsets and might be involved in the generation of poor outcomes for men with COVID-19. Our results might also be relevant for other common viral infections showing similar male bias.

Complex Traits Posters - Wednesday

PB1524*. Loss-of-function variants association study highlights potential new causal genes implicated in blood pressure regulation

Authors:

E. Lecluze¹, G. Lettre²; ¹Montreal Heart Inst., Montréal, QC, Canada, ²Université de Montréal, Montreal, QC, Canada

Abstract Body:

Hypertension is a widely spread cardiovascular disease, affecting 1.28 billion peoples worldwide and leads to the death of 7.5 million people each year. Blood pressure (BP) is tightly regulated by a complex network relying on the kidney, the brain, the heart, the blood vessels, and the endocrine system, and influenced by environmental and genetic factors. For more than a decade, genome-wide associations studies (GWAS) performed in millions of individuals have associated over 1,400 SNPs with BP variation. However, how these genetic associations can highlight new genes and pathophysiological mechanisms remain elusive. Rarer variants can have large effect size on BP, but the GWAS design tend to ignore them. Among these, many coding variants are predicted to impair gene function by modifying the sequence of the encoded protein, and association of such variants directly incriminates important regulators of the trait. In this study, we focused our analyses on rare loss-of-function variants to highlight novel genes that may be implicated in BP regulation. We performed an association study with rare loss-of-function (LoF) variants in the 500,000 whole-exome sequencing dataset of the UK Biobank. We used additive and recessive models to test for association, as well as a burden gene-based test that aggregates the effect of rare LoF variants (minor allele frequency (MAF) ≤ 5 in the same gene. This led to the association of some well-known regulators of blood pressure, such as *NOS3*, implicated in nitric oxide production, a vasodilator (gene-based test, diastolic blood pressure, P-value= 1.1×10^{-8}). *FES* loss-of-function variants are also associated with BP variation (gene-based test, systolic blood pressure (SBP), P-value= 1.2×10^{-7}). *FES* encodes a tyrosine kinase controlling cell differentiation and adhesion; the gene has never been implicated in BP regulation, but the locus carries common non-coding SNPs associated with BP and coronary artery disease. *CASP9* is also a new gene of interest, as the frameshift variant rs2234723 (MAF=21%) is associated with the trait (additive test SBP, P-value= 3.5×10^{-11} ; $\beta = -0.3$). It lies in a complex locus (chr1:15429787-15677590) of several genes associated with glomerular filtration rate and SBP. Even though they have predicted loss-of-function variants, none of them are significant in our analysis, suggesting that *CASP9* may be the causal BP gene at this locus. Our focus on loss-of-function variants associated with BP directly incriminate potential causal genes that may be implicated in its regulation, setting the stage for future functional studies to better understand these potentially novel pathophysiological mechanisms.

Complex Traits Posters - Thursday

PB1525. Lung-specific alternative splicing is a shared etiological risk for COVID-19 severity and chronic respiratory diseases.

Authors:

T. Nakanishi¹, Y. Farjoun², S. Zhou³, B. Richards⁴; ¹McGill Univ., Montréal, QC, Canada, ²Lady Davis Inst., JGH, Montreal, QC, Canada, ³Lady Davis Inst. of Jewish Gen. Hosp., Montreal, QC, Canada, ⁴McGill Univ., Montreal, QC, Canada

Abstract Body:

Despite the successful development of vaccines and treatments, a striking number of individuals are still suffering from COVID-19, which requires us to identify mechanistic targets for therapeutic development and/or drug repurposing. Alternative Splicing (AS) is an essential mechanism for generating tissue-specific functional diversity in the form of protein isoforms, and it has been implicated that AS plays an important role in the immune response to infections. However, the causal role of AS in COVID-19 pathogenesis and its potential therapeutic relevance are not fully understood. Here, we show the etiological evidence of lung-specific AS for COVID-19 using a Mendelian Randomization (MR) approach and we demonstrate its shared genetic mechanisms with other chronic respiratory diseases. We first obtained the *cis*-regulatory genetic determinants of 8,201 gene splicing (*cis*-sQTLs) of 4,477 genes in lung and whole blood, the two most relevant tissues for acute SARS-CoV-2 infection, from GTEx Consortium. We then performed two-sample MR to assess whether these *cis*-sQTLs were associated with COVID-19 outcomes in the GWASs from the COVID-19 Host Genetics Initiative, encompassing up to 219,692 COVID-19 cases. In addition to the replication of our previous findings with *OAS1*, we identified that AS in *ATP11A*, *DPP9*, and *NPNT* in lung, rather than their total RNA levels, were associated with COVID-19 severity. Specifically, decreased use of alternative splice junctions, chr13:112875941-112880546 (hg38) in *ATP11A* and chr19:4714337-4717615 in *DPP9*, and increased use of alternative splice junction, chr4:105898001-105927336 in *NPNT* afford these associations. Colocalization analyses supported shared genetic signals of COVID-19 severity with idiopathic pulmonary fibrosis in the *ATP11A* and *DPP9* loci, and that with chronic obstructive lung disease in the *NPNT* locus. Taken together, our study suggests the shared etiological importance of AS in lung between COVID-19 and other chronic respiratory diseases. Given the tissue-specific nature of AS, those mechanism could be prioritized for drug discovery which may act in a tissue-specific manner. We anticipate our findings will motivate the ongoing effort to map the disease-relevant AS to the corresponding isoform or protein product, by means of emerging technologies such as long-read sequencing and high-throughput protein quantification.

PB1526. Machine learning in COVID-19 phenotype prediction

Authors:

G. Novelli¹, S. Casali², V. Colona¹, D. Cocciadiferro³, V. Favalli², R. Giannini¹, A. Latini¹, M. D'Apice⁴, V. Ferradini¹, M. Andreoni¹, P. Rogliani¹, F. Leonardis¹, M. Perrone¹, I. Qunti⁵, A. Novelli⁶, M. Biancolella¹; ¹Tor Vergata Univ, Rome, Rome, Italy, ²Bases Italia S.r.l., Campospinoso, Italy, ³Bambino Gesù Hosp. Rome, Rome, Italy, ⁴Tor Vergata Univ, Hosp. Rome, Rome, Italy, ⁵Sapienza Univ, Rome, Rome, Italy, ⁶Bambino Gesù Hosp., Rome, Rome, Italy

Abstract Body:

Since the beginning of the pandemic, numerous clinical, genetic and social COVID-19-related studies have been performed. Data science plays a key role in the identification of molecular mechanisms underpinning virus-host interaction, which represents a major challenge in a proactive perspective of precision medicine and to promote sustainable and rational public health interventions. In the present study, we trained a Random Forest classification model on target genetic data (variants identified by WES and functional analysis) to predict host response to SARS-CoV-2 infection. The dataset was composed by 128 samples and subsequently split in test and validation datasets, following a stratified k-fold cross-validation approach. The two target classes, representing disease severity (severe disease vs asymptomatic), were slightly imbalanced, with severe disease cases being overrepresented. After data cleaning and basic parameters tuning, model average classification accuracy was 0.77. In a second experiment, we included age and gender as basic clinical features for our machine learning model: average classification accuracy increased to 0.84. However, age distribution turned to be imbalanced, with a high percentage of the samples being seventy-five years old or older. Further data are needed to clarify the possible interplay between genetic and clinical features. However, this study demonstrates the development and application of Machine Learning (ML) to host-genome with integrative analyses, that allows not only to optimize polygenic risk score analysis, but also to refine the stratification of COVID-19 patients, to estimate an accurate prognosis and to set individual and targeted therapeutic approaches. This study was also supported by a grant of Regione Lazio (Italy, Progetti di Gruppi di Ricerca 2020 A0375-2020-36663 GecoBiomark).

Complex Traits Posters - Thursday

PB1527*. Machine learning-based classification of Age-related Macular Degeneration using gene expression profiles

Authors:

R. Ratnapriya¹, H. Nakajima¹, A. Barman²; ¹Baylor Coll. of Med., Houston, TX, ²Rice Univ., Houston, TX

Abstract Body:

Genome-wide association studies (GWAS) in humans have established a strong genetic component of AMD that is mostly driven by common variants. However, the progress in translating genetic findings into understanding disease pathways and mechanisms has been very slow. Gene expression dysregulation is emerging as a dominant model in complex diseases. However, accessing the transcriptome profiles in large disease and non-disease cohorts are challenging, which present significant limitation in identifying genes and pathways involved in the disease process using existing methods such as differential gene expression analysis. In this study, we apply machine learning (ML) methods to uncover gene expression signatures associated with Age-related Macular Degeneration (AMD). We use RNAseq data from 453 donor retina belonging to normal and AMD patients that were used to train and test different ML models for AMD classification. We investigated three feature selection methods and tested seven machine learning models to find the best model. To train the models, the data was randomly split into 70% training data and 30% test data. The training data was then further split for a 10-fold cross validation repeated 5 times. Sensitivity, specificity, accuracy, and Area under the receiver operating characteristics (ROC) curve were used to compare the performance of the machine learning models. We used a combination of biclustering plots, pathways analysis and co-expression regulation networks to identify the candidate genes relevant to AMD biology. Most classifiers achieved 60-80% accuracy in differentiating the advanced AMD from controls based on 81 genes/features. These features were enriched for genes in immune response, complement and extracellular matrix and connected to known AMD genes through co-expression networks and gene expression correlation. Our work demonstrates the merits of ML algorithms for disease classification and suggests the key role of gene expression changes in AMD despite a small patient population. Gene regulatory networks are sufficiently interconnected with individual genes having a small impact on the disease outcome. Thus, our method provides an opportunity to regain the holistic view of the AMD that is lost in experimentally tested reductionist approaches.

Complex Traits Posters - Wednesday

PB1528. Mapping Autism Spectrum Disorder Endophenotypes to Genomic Regions in Thousands of Families

Authors:

N. Stockham, K. Paskov, B. Chrisman, J-Y. Jung, D. P. Wall; Stanford Univ., Stanford, CA

Abstract Body:

The genetic architecture of Autism Spectrum Disorder (ASD) is multifaceted and unresolved despite consistently high heritability estimates. Recent studies with extremely large sample sizes have associated a few common variants and many high-effect ultra-rare variants with ASD diagnosis status but leave the genetic etiology of the vast majority of ASD diagnoses unexplained. A possible explanation for this lack of discovery is that there are several etiologically distinct forms of ASD and grouping these distinct forms under one diagnosis status obscures the genomic elements relevant to each etiology; therefore, ASD must be studied at the level of detailed psychiatric endophenotype while integrating information across the entire genome. In this work we attempt to map to specific genomic regions the psychiatric endophenotypes described by the subdomains (Reciprocal Social Interaction (RSI), Restricted Repetitive and Stereotyped Behavior (RRSB), Communication (COM)) of the Autism Diagnostic Interview-Revised (ADIR) and the closely related Social Communication Questionnaire (SCQ). Due to recombination siblings share varying fractions of chromosomal material that are Identical-By-Descent (IBD) from each parent. We hypothesized that increased sibling IBD fraction would entail decreased sibling differences in the molecular mechanisms relevant to ASD, and therefore decrease the sibling differences in ASD phenotypes. To determine which chromosomes are most relevant to different ASD endophenotypes, we applied a modified Haseman-Elston regression to seventeen hundred sibling pairs with concordant ASD diagnosis status from the two largest family-based ASD cohorts: the Autism Genetic Research Exchange/Hartwell (AGRE/iHART) collection and Simons Foundation SPARK (SPARK). The RSI endophenotype regression yielded the strongest genetic signal in both SPARK and AGRE/iHART cohorts, with chromosome 15 passing conservative permutation tests in SPARK and AGRE/iHART. In contrast, neither the RRSB nor COM subdomains could be mapped to a chromosome in both cohorts. The highlighting of chromosome 15 is particularly interesting given that chromosome 15q11-13 is the known causal loci for Angelman Syndrome and Prader-Willi Syndrome; genetic imprinting disorders that share many social behavior phenotypes with ASD. By focusing on detailed phenotypic and genomic differences between sibling pairs, we shift focus from searching for causal genetic variants in unrelated ASD cases to discovering the molecular mechanisms most relevant to ASD phenotypes.

Complex Traits Posters - Wednesday

PB1529. Metabolomic signatures of body mass index in the Hispanic Community Health Study/ Study of Latinos (HCHS/SOL)

Authors:

V. Buchanan¹, H. Highland², B. Yu³, C. L. Avery¹, S. Buyske⁴, J. Cai⁵, M. Daviglus⁶, A. Howard⁵, C. R. Isasi⁷, R. Kaplan⁷, R. J. F. Loos⁸, Q. Qi⁷, R. Rohde⁵, J. I. Rotter⁹, L. Van Horn¹⁰, E. Boerwinkle³, K. E. North¹¹, K. Young¹¹; ¹Univ. of North Carolina - Chapel Hill, Chapel Hill, NC, ²Univ North Carolina at Chapel Hill, Chapel Hill, NC, ³Univ. of Texas Hlth.Sci. Ctr. at Houston, Houston, TX, ⁴Rutgers Univ, Piscataway, NJ, ⁵Univ. of North Carolina, Chapel Hill, NC, ⁶Univ. of Illinois Coll. of Med., Chicago, IL, ⁷Albert Einstein Coll. of Med., Bronx, NY, ⁸Univ. of Copenhagen, Copenhagen, Denmark, ⁹Lundquist Inst., Harbor-UCLA Med Ctr, Torrance, CA, ¹⁰Northwestern Univ., Chicago, IL, ¹¹Univ North Carolina, Chapel Hill, NC

Abstract Body:

The public health burden of obesity is substantial, but the underlying etiology and metabolic dysfunction remains unclear, especially in underrepresented Hispanic/Latino populations who may be disproportionately affected. To address this gap, we aim to identify metabolites associated with body mass index (BMI) in the Hispanic Community Health Study/Study of Latinos (HCHS/SOL), a large, community-based prospective cohort from randomly selected households at 4 US study centers. Exams, interviews, and fasting blood draws were conducted at in-person baseline visits (2008-2011). A total of 3972 genotyped participants were randomly selected for metabolomic profiling using an untargeted platform. We investigated cross-sectional associations between Blom-transformed metabolites and BMI, adjusting for age, study center, background group, smoking status, and principal components of ancestry, stratified by sex (SUGEN), and meta-analyzed (SAS 9.4) across strata. We then conducted pathway analyses (MetaboAnalyst 5.0) for the significantly associated metabolites. Data for 687 known metabolites and BMI were available for 3667 individuals (mean age: 45.6 years, 57% female). We identified Bonferroni-corrected significant associations ($p < 0.05/687$) for 256 metabolites in the meta-analysis, 147 of which were positively and 109 negatively associated with BMI; to our knowledge, 39 (15%) were novel. Among the most strongly associated metabolites were: tyrosine ($\beta = 2.104$, $SE = 0.093$, $p < 1E-16$), found in high protein foods and previously associated with obesity and insulin resistance; glucose ($\beta = 1.209$, $SE = 0.100$, $p < 1E-16$), associated with obesity and diabetes; and histidine ($\beta = -1.119$, $SE = 0.099$, $p < 1E-16$), associated with decreased insulin resistance and BMI and may suppress inflammatory cytokines in adipocytes. The caffeine metabolism pathway was significantly overrepresented (FDR-corrected $p = 1.82E-2$). Positive and negative associations of caffeine and obesity traits have been shown; caffeine was positively associated with BMI in our stratified and meta-analyzed ($\beta = 0.885$, $SE = 0.101$, $p < 1E-16$) results.

Caffeine consumption may occur via sugar sweetened beverages and weight loss supplements. Using data from multiple visits and analyses that assess for metabolites that mediate the genetic effects of BMI and obesity may help disentangle the complex relationship between obesity and caffeine. Results are expected to facilitate understanding of metabolic dysregulation associated with excess adiposity in diverse, highly admixed populations and may provide novel insights concerning metabolic and physiologic mechanisms underlying obesity.

Complex Traits Posters - Thursday

PB1530. Metabolomics profiling upranks the role of natural steroids and phenylalanine metabolism over oxidative stress in insulin resistance amongst lean subjects.

Authors:

I. Diboun¹, L. Al-Mansoori², O. Albagha³, K. Fakhro⁴, Y. Mokrab¹, M. A. Elrayess²; ¹Sidra Med., Doha, Qatar, ²Qatar Univ., Doha, Qatar, ³Hamad Bin Khalifa Univ., Doha, Qatar, ⁴Sidra Med. and Res. Ctr., Doha, Qatar, Qatar

Abstract Body:

Insulin resistance (IR) is a prediabetic condition characterized by a loss of normal Insulin Sensitivity (IS) whereby an elevated insulin level is required to trigger glucose absorption from the blood. IR is strongly associated with obesity, but it is also occasionally observed amongst lean individuals. This study aims to characterize the metabolic correlates of IR in healthy lean to shed light on the underlying mechanisms. In this cross-sectional study, clinical and metabolic data were obtained for 200 lean healthy females (100 IR and 100 IS) from Qatar Biobank and another set of 107 obese subjects (41 IR and 20 IS) from local hospitals in Qatar. Linear models using metabolite levels comparing IR versus IS revealed upregulation of anabolic steroids, for both lean and obese including Androsterone Glucoronide and Epiandrosterone in addition to derivatives of Phenylalanine including the microbiota-product 1-Carboxyethylphenylalanine. Conversely, interaction analysis looking at differential IR/IS effects between obese and lean revealed that levels of long chain unsaturated fatty acids and markers of oxidative stress, including 2-Hydroxybutyrate, were uniquely elevated amongst obese IR but not lean IR, in comparison to their respective baseline levels in IS. These results were confirmed at a more global level using multivariate analysis whereby an Orthogonal Partial Least Square classifier trained on lean IR/IS was able to only marginally, though significantly, distinguish IR/IS from the obese cohort (Area Under the Curve (AUC) from Receiver Operating Characteristic Curve (ROC) analysis=0.68, pvalue=0.02). Elastic-Net-Regularized Generalized Linear Model was used to select a subset of 20 best predictor metabolites of IR in the lean and ROC analysis suggested a high discriminant capacity (AUC=0.93), in comparison to a similar classifier trained entirely on phenotypic traits (AUC=0.73). Amongst the predictor set of metabolites selected were Phenylalanine derivatives, steroids, xenobiotics (PFOS and Piperidinone), Glucose and metabolic traces of Lysine metabolism. Our data suggest an interplay of potentially genetic and environmental factors underlying IR in the lean population as evident in the enrichment in natural steroids but also food-derived amino acids including lysine and phenylalanine as well as xenobiotics. Importantly, our study suggests a different profile of risk factors to IR in the lean in comparison to obese subjects where IR is thought to be primarily associated with oxidative stress. Our subset of predictive IR metabolites in lean presumably healthy individuals may hold clinical value, hence its validation is well warranted.

Design and Evaluation, SAIHST, Sungkyunkwan Univ., South Korea, Seoul, Korea, Republic of

Abstract Body:

Dyslipidemia is defined as a disruption in lipid metabolism that affects the concentration of lipids in the blood, is a modifiable risk factor for cardiovascular disease. The intestinal microbiota has been reported to play a regulatory role in host lipid metabolism. The human gut microbiome harbors various antibacterial resistant genes (ARG). However, the role of gut resistome in the dyslipidemia patient is still unclear. Here we analyze the antibiotic resistance genes of gut microbiota from 1,026 patients with dyslipidemia and 618 healthy subjects. We used metagenomic approach to address differentially abundant species and the variation in ARGs profiles. Total ARG abundance was significantly higher in dyslipidemia patients than in healthy subjects (Wilcoxon rank-sum test; $p < 0.05$). Overall, tetracycline, multidrug-resistance, and beta-lactamase were the most abundant ARG classes in all subjects. However, aminoglycoside, phenicol, and fluoroquinolones were significantly more abundant in dyslipidemia than in healthy control ($p < 0.05$). The abundance of *tetQ* was the only ARG type significantly higher in dyslipidemia, while *tetW*, *tet40*, and *CblA-1* in healthy subjects were higher than in dyslipidemia. Similarly, *Prevotella* was differentially more abundant in dyslipidemia patients, and *Prevotella copri* and *Bacteroides plebeius* were significantly high in dyslipidemia patients. The *Prevotella* was negatively correlated with most ARGs except the *tetQ*. Similarly, *tetQ* was positively correlated with *Prevotella* genera and negatively correlated with other genera. Overall, more than eight bacterial genera were positively correlated with most ARGs in dyslipidemia, while only four genera were in healthy subjects. In dyslipidemia patients, the level of total cholesterol and low-density lipoproteins (LDL) cholesterol were negatively correlated with total ARGs, while aminoglycoside was positively correlated with LDL cholesterol. In conclusion, the taxonomic and ARGs of gut bacteria in dyslipidemia patients were significantly altered compared with healthy subjects. Further studies are required to investigate the role of *Prevotella* and tetracycline-resistant genes in dyslipidemia patients. This research was supported by a National Research Foundation of Korea (NRF) grant funded by the Korean government (MSIT) (2020R1A2C1012931).

Abstract Body:

Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disease. Selective vulnerability of energy-intensive motor neurons (MNs) has fostered speculation that mitochondrial function is a determinant of ALS. Previously, the position of mitochondrial function in the pathogenic cascade leading to neurotoxicity has been unclear. We separated upstream genetic determinants of mitochondrial function, including genetic variation within the mitochondrial genome or autosomes; from downstream changeable factors including mitochondrial copy number (mtCN) and MN gene expression. We discovered that functionally validated mitochondrial haplotypes are a determinant of ALS survival but not ALS risk. Loss-of-function genetic variants within, and reduced MN expression of, ACADM and DNA2 lead to shorter ALS survival; both genes impact mitochondrial function. MtCN responds dynamically to the onset of ALS independent of mitochondrial haplotype, and is also significantly correlated with disease severity. We conclude that mitochondrial function impacts ALS progression but not risk; our findings have therapeutic implications.

Complex Traits Posters - Wednesday

PB1533. Mitochondrial *TXNRD2* and *ME3* genetic risk scores are associated with specific primary open-angle glaucoma phenotypes

Authors:

I. Aboobakar¹, T. Kinzy², Y. Zhao¹, B. Fan³, L. Pasquale⁴, J. Cooke Bailey⁵, J. Wiggs⁶, NEIGHBORHOOD Consortium; ¹Mass Eye and Ear, Boston, MA, ²Case Western Reserve Univ., Cleveland, OH, ³Harvard Med Sch, Massachusetts Eye & Ear Infirmary, Boston, MA, ⁴Mount Sinai Hlth. System, New York, NY, ⁵Case Western Reserve Univ, Cleveland, OH, ⁶Harvard Med Sch, MEEI, Boston, MA

Abstract Body:

Purpose: Genetic variants in regions that include the mitochondrial genes *TXNRD2* and *ME3* are associated with primary open-angle glaucoma (POAG) in genome-wide association studies (GWAS). These genes may functionally contribute to POAG development by altering NADPH levels and oxidative stress response. To assess their clinical impact, we investigated whether *TXNRD2* and *ME3* genetic risk scores (GRSs) are associated with specific glaucoma phenotypes. **Methods:** 2617 POAG cases and 2634 controls from the NEIGHBORHOOD consortium were studied. All POAG-associated single nucleotide polymorphisms (SNPs) in the *TXNRD2* and *ME3* loci were identified using GWAS data ($p < 0.05$). Of these, 20 *TXNRD2* and 24 *ME3* SNPs were selected after adjusting for linkage disequilibrium. The correlation between SNP effect size and gene expression levels was investigated using the Gene-Tissue Expression (GTEx) database. GRSs were constructed for each individual using the unweighted sum of *TXNRD2*, *ME3*, and *TXNRD2+ME3* combined risk alleles. Age and gender-adjusted odds ratios (ORs) for POAG diagnosis were calculated per decile for each GRS. Additionally, the clinical features of POAG cases in the top 1, 5, and 10% of each GRS were compared to the bottom 1, 5, and 10%, respectively. **Main Outcome Measures:** POAG OR per GRS decile; maximal intraocular pressure (IOP) and prevalence of paracentral visual field loss among POAG cases with high vs. low GRSs. **Results:** Increased SNP effect size strongly correlated with higher *TXNRD2* and lower *ME3* expression levels ($r = 0.72$ and -0.97 , respectively). Individuals in decile 10 of *TXNRD2+ME3* GRS had the highest odds of POAG diagnosis (OR=1.79, 95% CI 1.39-2.30, $p < 0.001$). POAG cases in the top 1% of *TXNRD2* GRS had higher mean maximal IOP compared to the bottom 1% (19.9 mmHg vs 15.6 mmHg, $p = 0.01$). POAG cases in the top 1% of *ME3* and *TXNRD2+ME3* GRS had higher prevalence of paracentral field loss compared to the bottom 1% (72.7-89% vs 14.3-33%, $p = 0.02$ and 0.01 , respectively). **Conclusions:** Individuals with higher GRSs have higher odds of POAG diagnosis, with a greater effect seen for *TXNRD2+ME3* combined compared to either gene alone. Moreover, POAG patients with higher GRSs have higher IOP and greater prevalence of paracentral field loss. These data suggest that *TXNRD2* and *ME3* functionally contribute to POAG development and disease severity, potentially through a mechanism involving NADPH levels and mitochondrial dysfunction.

Complex Traits Posters - Thursday

PB1534. Modeling cardiac cell developmental trajectories at high temporal resolution.

Authors:

E. McIntire, K. Rhodes, K. Barr, M. DeMille, B. Umans, J. Burnett, N. Gonzales, Y. Gilad; The Univ. of Chicago, Chicago, IL

Abstract Body:

Cardiovascular disease (CVD) is the leading cause of mortality worldwide and has the highest economic impact of all physical noncommunicable diseases. Genetic variants modulate susceptibility in nearly all types of CVD. Most variants are noncoding, suggesting that gene regulation plays an integral role in mediating disease outcomes. However, pathogenic regulatory events are highly context dependent and may only occur during specific developmental stages, in specific cell types, or when certain environmental conditions are met. The specificity of gene regulation has made its characterization challenging, especially in cell types exclusive to early development. Induced pluripotent stem cells (iPSCs), which can be differentiated into cardiomyocytes and other disease-relevant cell types, have provided valuable insights into developmental gene regulation and its impact on CVD. For example, a timecourse study of cardiomyocyte differentiation discovered that even fleeting gene regulatory effects that occur at intermediate developmental stages can be associated with CVD-related outcomes in adults. However, these timecourse experiments are limited to examining a discrete number of collection time points, which are only snapshots of a highly dynamic process. Here, we have developed a new iPSC-derived cardiac organoid model that allows us to study gene regulation at unprecedented temporal resolution. We aggregated iPSCs to form three-dimensional embryoid bodies (EBs) that are guided to a cardiac fate over 9 days. Using scRNA-seq data from 7,286 cardiac EB cells collected from three individuals, we used unsupervised clustering and marker gene expression to uncover 11 known cell types (cardiac progenitor cells, proliferating cells, cardiomyocytes, fibroblasts, myofibroblasts, primitive endoderm, foregut, epicardium, endocardium, ectoderm, and neural crest). Our cell type annotations are consistent with those obtained using external scRNA-seq reference data collected from primary fetal tissue, indicating that cardiac EBs have transcriptional profiles resembling those observed in human fetal cells. Finally, we combined our cardiac EB data with single-cell data collected in a 16-day timecourse study of cardiomyocyte differentiation. All cell types observed in the extended timecourse study are present in a single collection of cardiac EBs, from pluripotent cells to differentiated cardiomyocytes. In other words, cardiac EBs effectively condense a differentiation timecourse experiment into a single culture system.

Complex Traits Posters - Thursday

PB1535. Modeling gene by environment interactions in post-traumatic stress disorder using hiPSC-derived neurons

Authors:

C. Seah¹, T. Rusielewicz², H. Bader³, C. Xu³, H. Young¹, R. Signer¹, A. dePins¹, P. Deans⁴, M. Breen¹, D. Paull², K. Brennand⁴, L. Huckins¹, R. Yehuda³; ¹Icahn Sch. of Med. at Mount Sinai, New York, NY, ²New York Stem Cell Fndn., New York, NY, ³James J. Peters Dept. of VA Med. Ctr., New York, NY, ⁴Yale Univ., New Haven, CT

Abstract Body:

Post-traumatic stress disorder (PTSD) is a debilitating disorder that is underdiagnosed and under-treated. Better identification of genetic and environmental elements of PTSD susceptibility and resilience is important to mitigate disorder burden. Integrating genomic loci with traumatic exposures may further elucidate gene by environment interactions that influence PTSD susceptibility. To test this, we performed an expression quantitative trait loci (eQTLs) analysis to identify SNPs that alter nearby mRNA expression across two PTSD-relevant cell types treated with the synthetic glucocorticoid hydrocortisone (HCort). eQTLs associate SNPs with nearby expression changes in a context-dependent manner and thus capture genetically- and environmentally-regulated expression. Our approach aimed to reveal cell type-specific and stress-dynamic eQTLs that may offer insight into the combined genetically- and stress-regulated contributions to PTSD. Fibroblasts from combat-exposed veterans with PTSD (n=20) and without (n=20), were used to generate two types of human induced pluripotent stem cell (hiPSC)-derived neurons- glutamatergic and GABAergic, and treated with two doses of HCort. Transcriptomic analysis of PTSD-specific HCort-response was conducted, then we identified eQTLs with interactive effects of genetically and HCort-regulated expression across cell types. We performed gene set enrichment of interactive eGenes for GWAS Catalog reported traits. We identified 675 and 374 unique eGenes in GABA-ergic and glutamatergic neurons, respectively, with a SNP by HCort interaction. These genes enrich in GWAS catalog genes including generalized epilepsy (p=9.65E-08), bipolar disorder (p=9.36E-06), and body mass index (p=1.48E-07), traits associated with stress and glucocorticoid response. Genes with particularly strong interactions include *PNPLA2* (p=5.6E-04), *LRP8* (p=6.59E-04), and *MXD4* (p=4.16E-04), which have been associated with chronic defeat stress, learning/memory formation, and amygdala signatures in a PTSD-like mouse model, respectively. eGenes in GABAergic and glutamatergic neurons differentially enrich in inflammatory, metabolic, and neuropsychiatric traits, indicating their differential role in response to acute stressors. Our preliminary data suggests that integration of genetics and stress signatures identifies genes associated with genetically regulated stress response in two major cell types implicated in psychiatric disorders. Further fine-mapping of eQTLs to disorder-relevant GWAS and validation in human cohorts may elucidate disorder relevance of these signatures.

Complex Traits Posters - Wednesday

PB1536. Modification of coronary artery disease clinical risk factors by coronary artery disease polygenic risk score

Authors:

B. Truong^{1,2}, Y. Ruan^{1,2}, S. Haidermota^{1,2}, A. Patel^{2,2}, I. Surakka¹, W. Hornsby^{1,2}, S. Lee^{3,4}, P. Natarajan^{1,2}; ¹Broad Inst. of MIT and Harvard, Cambridge, MA, ²Massachusetts Gen. Hosp., Boston, MA, ³Australian Ctr. for Precision Hlth., Univ. of South Australia Cancer Res. Inst., Univ. of South Australia, Adelaide, Australia, ⁴UniSA Allied Hlth.and Human Performance, Univ. of South Australia, Adelaide, Australia

Abstract Body:

Importance Clinical risk factors and coronary artery disease (CAD) polygenic risk score (PRS) complementarily predict risk for CAD. The extent to which the relationships between clinical risk factors and CAD are altered by CAD PRS is not well understood. **Objective** Determine whether the interactions between clinical risk factors and CAD PRS further explain risk for incident CAD. **Design, setting and participants** Participants were of European ancestry from the UK Biobank with incident CAD. Externally-trained genome-wide CAD PRS was generated and then applied to participants. Clinical risk factors, including type 2 diabetes (T2D), family history of heart disease, ever and current smoker, systolic and diastolic blood pressure (SDP and DBP), body mass index (BMI), lipoprotein(a), total cholesterol, low-density lipoprotein cholesterol (LDL-C), high-density lipoprotein cholesterol (HDL-C) and C-reactive protein (CRP), were ascertained at baseline. **Main Outcomes and Measures** Cox proportional hazards models were fitted to examine the CAD effects of CAD PRS, risk factors and their statistical interactions. Next, the PRS and risk factors were stratified to investigate the attributable risk of clinical risk factors. **Results** A total of 357,144 individuals (196,643 [55.1%] female, mean [standard deviation (SD)] age 57.2 [7.9] years) of European ancestry without prevalent CAD were included. During a median of 11.1 years of follow-up (interquartile range, 10.4-14.1 years), 21,971 individuals developed incident CAD (6.2%). CAD PRS was associated with 1.35-fold (95% CI 1.332-1.368) risk per SD for incident CAD. The prognostic relevance of these risk factors is relatively diminished for those with high CAD PRS: type 2 diabetes ($HR_{interaction} 0.91$, 95% $CI_{interaction} 0.88-0.94$, $P_{interaction} 1.14 \times 10^{-7}$), body mass index ($HR_{interaction} 0.97$, 95% $CI_{interaction} 0.96-0.98$, $P_{interaction} 2.91 \times 10^{-5}$) and C-reactive protein ($HR_{interaction} 0.98$, 95% $CI_{interaction} 0.96-0.99$, $P_{interaction} 9.35 \times 10^{-4}$). However, high CAD PRS yielded joint risk increases with low-density lipoprotein cholesterol ($HR_{interaction} 1.05$, 95% $CI_{interaction} 1.04-1.06$, $P_{interaction} 4.04 \times 10^{-13}$) and total cholesterol ($HR_{interaction} 1.05$, 95% $CI_{interaction} 1.03-1.06$, $P_{interaction} 4.38 \times 10^{-12}$). **Conclusion** CAD PRS is associated with incident CAD, and its application improves the interpretation of the prognostic relevance of several clinical risk factors.

Complex Traits Posters - Thursday

PB1537. Molecular and clinical characterisation of Polish Temple syndrome patients with 14q32 alterations

Authors:

D. Jurkiewicz¹, A. Madej-Pilarczyk¹, A. Swiader-Lesniak², K. Fraczak¹, P. Halat-Wolska¹, D. Siestrzykowska¹, D. Piekutowska-Abramczuk¹, M. Pelc¹, B. Chalupczynska¹, E. Ciara¹, K. Chrzanoska¹; ¹Dept. of Med. Genetics, The Children's Mem. Hlth.Inst., Warsaw, Poland, ²Dept. of Anthropology, The Children's Mem. Hlth.Inst., Warsaw, Poland

Abstract Body:

Temple syndrome (TS14) is an imprinting disorder characterised by pre- and postnatal short stature with small hands and feet, muscular hypotonia and feeding problems in early infancy followed by weight gain, premature puberty and in some cases speech delay and mild mental retardation. TS14 is caused by genetic/epigenetic abnormalities within the imprinted chromosomal region 14q32. It may show overlapping phenotype with Silver-Russell syndrome (SRS).

Here, we present clinical and molecular data of three patients with TS14. Molecular investigations were performed on leukocyte DNA and included methylation sensitive multiplex ligation-dependent probe amplification (MS-MLPA) and microsatellite analyses (MSA). In two patients maternal UPD of chromosome 14 [upd(14)mat] was found and in the third patient *MEG3*:TSS-DMR loss of methylation (LOM) was identified. Analysis of several imprinted *loci* in the patient with LOM excluded the presence of Multilocus Imprinting Disturbances (MLID). Patients demonstrated typical clinical TS14 features, however in one patient with upd(14)mat mild intellectual disability was present.

The investigations allowed to define the type of a 14q32 defect and confirm the diagnosis of TS14 in examined patients. A complex molecular approach to analyse 14q32 region is required for accurate diagnosis of TS14 allowing the recurrence risk determination and proper genetic counselling. The study corroborates that SRS should be considered in differential diagnosis with TS14 and shows efficacy of the applied diagnostic approach.

The study was supported by CMHI project S180/2019 and partly by MEiN projects: 7071/IB/SN/2020, 7088/II-KDM/SN/2020.

Complex Traits Posters - Thursday

PB1539. Molecular epidemiologic and family history evidence suggests that myalgic encephalomyelitis (ME)/chronic fatigue syndrome (CFS) may be an autoimmune disorder.

Authors:

R. Moslehi¹, A. Kumar¹, A. Dzutsev²; ¹Univ. at Albany, Albany, NY, ²NCI, NIH, Bethesda, MD

Abstract Body:

Background: Myalgic encephalomyelitis (ME)/chronic fatigue syndrome (CFS) is a complex disabling disorder with no known etiology or approved treatment. Estimates of the prevalence suggest that up to 3.4 million Americans may be afflicted. It has been suggested that ME/CFS may be triggered by an infectious illness including COVID-19, hence the prediction that 10 million new cases of ME/CFS may be diagnosed globally by the end of this pandemic. It is imperative to identify risk factors and underlying biologic mechanisms for ME/CFS. To this end, we conducted a molecular epidemiologic study to explore the link between ME/CFS, autoimmune disease (AID), and cancer. Methods: Our clinic-based case-control study involved 59 carefully selected ME/CFS patients and 54 appropriately matched healthy controls. We compared cases and controls with respect to the following: 1. prevalence of AID and cancer among their first-degree relatives, 2. prevalence of epidemiologic factors, and 3. serum levels of 48 cytokines. Statistical methods used were logistic regression and cumulative incidence analysis to calculate odds ratios (OR), relative risks (RR), 95% confidence intervals (CI) and p-values. We also used machine learning approaches to study the predictive power of serum cytokine levels in ME/CFS. Results: Our analysis revealed that ME/CFS cases were five times more likely than controls to have a family history of AID (OR=5.30, p=0.002). The life-time risk of AID among first-degree relatives of cases was significantly higher compared to the relatives of controls (RR=2.68, p=0.02). First-degree relatives of cases also had a significantly higher risk of early-onset (diagnosed <60 years of age) cancer compared to the relatives of controls (RR=2.24, p=0.03). Comparison of epidemiologic factors identified certain risk factors for ME/CFS such as history of allergies requiring medication (OR=6.00, 95%CI:2.52-14.28, p<0.0001) and exposure to contaminants (OR=4.35, 95%CI:1.96-9.65, p=0.0002). Our analysis identified a cytokine profile of ME/CFS, which classified patients with 84% accuracy (kappa=0.68, p=0.025, sensitivity=0.75, and specificity=1.00) in random forest models. Two cytokines, Interleukin-27 (IL27) and Macrophage inflammatory protein-1 alpha (MIP1- α), were found to be the most predictive biomarkers for ME/CFS. Both are involved in inflammatory processes and MIP1- α has been linked to other AIDs. Conclusions: Findings from our multidimensional analysis of pedigree, epidemiologic, and molecular data provide the most objective evidence to date that ME/CFS may be an AID. Our findings provide etiologic clues and druggable targets for treatment of ME/CFS.

Complex Traits Posters - Wednesday

PB1540. Molecular states during acute COVID-19 reveal distinct etiologies of long-term sequelae.

Authors:

R. Thompson¹, N. W. Simons¹, L. Wilkins¹, E. Cheng¹, D. M. Del Valle¹, G. E. Hoffman¹, C. Cervia², D. Yuan³, The Mount Sinai COVID-19 Biobank Team, J. R. Heath³, O. Boyman², S. Kim-schulze¹, R. Sebra¹, M. Merad¹, S. Gnjatic¹, E. E. Schadt¹, A. W. Charney¹, N. Beckmann¹; ¹Icahn Sch. of Med. at Mount Sinai, New York, NY, ²Univ. of Zurich, Zurich, Switzerland, ³Inst. for Systems Biology, Seattle, WA

Abstract Body:

Post-acute sequelae of SARS-CoV-2 (PASC) infection are debilitating, clinically heterogeneous, and of unknown molecular etiology. While the development of PASC is presumed to be rooted in the acute phase of COVID-19, direct causal links have yet to be established. A transcriptome-wide investigation was performed in a diverse cohort of 165 acutely infected hospitalized patients followed clinically into the post-acute period. We developed a method for modeling cell-type-specific gene expression patterns in bulk RNA-seq data using an interaction term between the phenotype of interest and the estimated cell type fractions. We validated our model by showing significant overlap between cell-type-specific differentially expressed genes for each cell type and published marker genes for that cell type; as well as by applying the model to an independent single-cell RNA-seq data set and showing significant positive correlations between the log fold changes from our model and those obtained by analyzing each cell type separately. We then used this model to identify distinct gene expression signatures of PASC in whole blood during acute infection, with innate and adaptive immune cell types implicated in different sequelae. Two clusters of sequelae exhibited divergent plasma-cell-specific gene-expression patterns. Sleep problems, nausea/diarrhea/vomiting, smell/taste problems, and skin rash were all associated with higher expression of immunoglobulin-related genes, while lung problems and pneumonia were both associated with lower expression of such genes. Furthermore, these expression patterns were dependent on anti-spike antibody titers for 3 of the sequelae (lung problems, pneumonia, and skin rash), directly linking them to the host response to SARS-CoV-2 infection. The downregulation of immunoglobulin genes associated with the other 3 symptoms independently of anti-spike antibody titers was validated in an independent cohort by the observation of lower total immunoglobulin titers in subjects with PASC. Incorporation of molecular data from acute phase enabled the detection of multiple etiologies of PASC beyond what can be discerned using only clinical data, emphasizing that acute phase molecular data is essential for a complete characterization of PASC as well as introducing the possibility for discovery of predictive biomarkers and development of precision treatment and prevention strategies for specific sequelae. Altogether, multiple etiologies of PASC were already detectable during SARS-CoV-2 infection, directly linking PASC with the acute host response to the virus and providing early insights into their development.

Complex Traits Posters - Thursday

PB1542*. Multi-ancestry HLA allele calling using whole-exome sequencing in the UK Biobank reveals 353 novel genome-wide significant HLA alleles associated with 11 auto-immune phenotypes

Authors:

G. Butler-Laporte; McGill Univ., Montréal, QC, Canada

Abstract Body:

The HLA is a highly polymorphic region associated with many immune and inflammatory diseases. SNP-based association studies cannot capture all its genetic variation, making them underpowered at this locus. HLA gene allele imputation can alleviate this problem. However, this can still be imprecise, especially in individuals of ancestries less represented in the imputation panel. Hence, HLA associations might still be missed.

Here, we use the UK Biobank 450,000 whole-exome sequences (WES) to directly call HLA alleles at 19 protein-coding genes and 11 pseudogenes using the HLA-HD software and the IMGT/HLA database (v3.45.0). When comparing previously imputed HLA alleles available in the UK Biobank to our results, imputed class I HLA genes achieved a biallelic 2-digit accuracy match of 82-83%. For class II genes, match rate decreased to 75% at *DPBI*, to as low as 0.2% at *DRB5*, suggesting that HLA sequencing improved HLA allele accuracy considerably.

We next performed HLA association studies of 11 known immune-mediated phenotypes: ankylosing spondylitis, asthma, immune thyroid disorders, coeliac disease, Crohn's, multiple sclerosis, polymyalgia rheumatica, psoriasis, rheumatoid arthritis, type I diabetes, and ulcerative colitis. Firth regression was performed for each allele-phenotype pair using REGENIE, first separately by continental ancestry followed by meta-analysis. At 4-digit HLA accuracy, we found 405 significant associations ($p < 5 \times 10^{-8}/11$), of which 353 were novel. These included 368 alleles in protein-coding genes (316 novel) and 37 in pseudogenes.

We then evaluated the predictive power of HLA calling on 7 of these traits to construct polygenic risk scores (PRSs) by combining LDpred results with imputed or called HLA alleles using XGboost. While adding HLA alleles to the PRS increased accuracy (AUC increased up to 0.157 in coeliac disease), both imputed and called alleles PRSs performed well. However, of the 250 pairs of 6-digit HLA alleles comparisons between equivalent 4-digit alleles, there were 34 with significantly different effect sizes ($p < 0.05/250$), including 20 in opposing effect direction. For example, *DR4*01:01:01* was associated with a 0.88-fold decrease in the odds of psoriasis (95% CI: 0.85-0.91, $p = 4.5 \times 10^{-13}$), but *DR4*01:01:02* increased the odds 2.43-fold (95% CI: 2.30-2.57, $p = 7.3 \times 10^{-206}$).

To conclude, WES HLA allele calling increases power of HLA association studies, especially at higher allele digit accuracy, where non-coding variants play a role in phenotype. This resource will be made available to all researchers through the UK Biobank return of results program.

Complex Traits Posters - Wednesday

PB1543. Multi-ancestry meta-analysis of asthma improves polygenic risk prediction across populations

Authors:

K. Tsuo^{1,2,3}, W. Zhou^{2,3}, Y. Wang^{2,3}, M. Kanai^{3,2,1,4}, S. Namba⁴, R. Gupta^{1,2,3}, L. Majara⁵, L. Nkambule^{2,3}, T. Morisaki⁶, Y. Okada^{4,7}, B. Neale^{2,3}, Global Biobank Meta-analysis Initiative, M. Daly^{2,3,8}, A. Martin^{2,3}; ¹Harvard Med. Sch., Boston, MA, ²Massachusetts Gen. Hosp., Boston, MA, ³Broad Inst. of MIT and Harvard, Cambridge, MA, ⁴Osaka Univ. Graduate Sch. of Med., Suita, Japan, ⁵Univ. of Cape Town, Cape Town, South Africa, ⁶The Univ. of Tokyo, Inst Med Sci, Minato-ku, Tokyo, Japan, ⁷RIKEN Ctr. for Integrative Med. Sci., Yokohama, Japan, ⁸Univ. of Helsinki, Helsinki, Finland

Abstract Body:

Asthma poses a significant global health burden as one of the most common chronic diseases worldwide. Risk prediction models of asthma can help inform prevention, intervention, and management strategies, but current models rely mostly on a limited range of clinical, environmental exposure, and family history factors and have modest clinical value. To investigate the potential utility of applying genetic risk factors for asthma risk prediction, we leveraged the largest genome-wide association study of asthma to date from the Global Biobank Meta-analysis Initiative (GBMI), which included 18 biobanks of diverse genetic ancestry groups and more than 1.8 million participants (153,763 cases, of which 28,492 were of non-European ancestry), to construct polygenic risk scores (PRS) for asthma. We applied a multi-ancestry Bayesian PRS construction method, PRS-CSx, to five different ancestry-specific meta-analyses from European (EUR), African (AFR), East Asian (EAS), Central and South Asian (CSA), and Admixed American (AMR) populations in GBMI. We evaluated the prediction accuracy of the multi-ancestry PRS, measured by variance explained on the liability scale (liability-scale R^2), in independent datasets with individuals of AFR, EUR, EAS, and CSA ancestries. In all target populations, the multi-ancestry PRS derived from GBMI had greater predictive accuracy compared to the PRS derived from a previous multi-ancestry asthma meta-analysis from the Trans-National Asthma Genetic Consortium, which included smaller sample sizes from populations of EUR and non-EUR ancestries (19,954 and 3,994 cases, respectively). In the non-EUR populations specifically, we observed an 8-fold increase in liability-scale R^2 in the AFR population, and a 4- and 3-fold increase in the CSA and EAS populations, respectively. We observed a 2-fold increase in liability-scale R^2 in the EUR cohort. To further interrogate the utility of polygenic risk prediction for different asthma subtypes, which may have both shared and distinct genetic risk factors, we utilize age of onset information available in some participating biobanks in GBMI to assess the performance of the PRS in childhood- and adult-onset asthma cohorts separately. In summary, we demonstrate that leveraging association data from larger and more diverse cohorts, together with a multi-ancestry PRS construction approach, delivers substantial improvements in PRS prediction accuracy for asthma, particularly in populations of non-European ancestries.

Abstract Body:

The human X chromosome is ~155 million base pairs long and represents 5% of the genome harboring more than 1600 genes, but has been under-investigated in Genome-wide association studies (GWAS). Understanding the contribution of X chromosome variation to polygenic traits and diseases is limited because association results for the X are often omitted due to the analytical technical challenges arising from incomplete inactivation of X chromosome in females and hemizyosity in males. In the GIANT consortium, we aimed to identify the variants on the X chromosome that contribute to adult human height by performing an X-chromosome wide fixed effect meta-analysis. In our initial analyses, we included data from females in 97 studies that included 1.8 million variants and a total sample size of 220K individuals from 5 major population groups (European, African-American, Hispanic, East-Asian and South-Asian). All studies were corrected for relatedness using linear mixed models and markers were filtered for low imputation quality and minor allele counts. We identified 12 independent signals that are more than 500kb apart and reach genome-wide significant p-values (5×10^{-8}). These signals are in the non-PAR region of the X chromosome and located near genes such as ATRX, PGK1 and FAAH2. For comparison, meta-analysis of same studies in chromosome 7 which is similar in size to the X chromosome resulted in 25 genome-wide significant signals that were 500kb apart. In ongoing work we will dramatically expand our sample size by including additional studies and also analyze male specific X chromosome data. This work will help us understand the role of common genetic variation in polygenic traits attributable to the X chromosome and could partially explain sex-specific genetic differences in polygenic traits such as height.

Complex Traits Posters - Thursday

PB1545. Multiple HLA haplotypes and a variant altering immunogenicity of minor histocompatibility antigen epitopes encoded by *CTSH* are associated with age at type 1 diabetes diagnosis.

Authors:

D. Roshandel¹, A. Spiliopoulou^{2,3}, S. McGurnaghan³, S. B. Bull^{4,5}, P. M. McKeigue², H. M. Colhoun³, A. D. Paterson^{1,5}; ¹Genetics and Genome Biology Program, The Hosp. for Sick Children, Toronto, ON, Canada, ²Usher Inst. of Population Hlth.Sci. and Informatics, Univ. of Edinburgh, Edinburgh, United Kingdom, ³Inst. of Genetics and Cancer, Univ. of Edinburgh, Edinburgh, United Kingdom, ⁴Lunenfeld-Tanenbaum Res. Inst., Sinai Hlth., Toronto, ON, Canada, ⁵Dalla Lana Sch. of Publ. Hlth., Univ. of Toronto, Toronto, ON, Canada

Abstract Body:

Type 1 diabetes (T1D) is typically considered a disease with onset in childhood or young adulthood, but it can present throughout the lifespan. Genome-wide association studies (GWAS) have identified 78 loci associated with T1D susceptibility. However, genetics of T1D age at diagnosis (AAD) has received little attention. Here, we performed a large meta-GWAS of T1D AAD including subjects diagnosed later in life compared to previous studies, genotyped on Illumina chips with extensive whole genome coverage and imputed to TOPMed. 7,923 unrelated European subjects with T1D from five studies were included: the Scottish Diabetes Research Network Type 1 Bioresource (SDRNT1BIO, n = 5,349, AAD mean = 23 yrs), Diabetes Control and Complications Trial (DCCT, n = 1,304, AAD mean = 21 yrs), Coronary Artery Calcification in Type 1 Diabetes (CACTI, n = 529, AAD mean = 13 yrs), Pittsburgh Epidemiology of Diabetes Complications (EDC, n = 150, AAD mean = 8 yrs) and Wisconsin Epidemiologic Study of Diabetic Retinopathy (WESDR, n = 591, AAD mean = 14 yrs). Variants with minor allele frequency >0.01 and high imputation quality (INFO >0.80) were included in the meta-GWAS (n = 8,154,710). HLA imputation was performed using TOPMed multi-ethnic HLA reference panel on Michigan imputation server. AAD was square root transformed and sex was included as a covariate in the model. Meta-GWAS analysis was performed using METAL v1.5 weighting effect sizes using the inverse of the standard errors. Multiple single nucleotide polymorphisms (SNPs) in the HLA region (top SNP: Chr6:32706117 (build GRCh38), T>C, $\beta = 0.28$, $p = 2.9E-37$) and an indel on Chr 15 (Chr15:78943251, TGTT>, $\beta = 0.21$, $p = 3.8E-8$) reached the genome-wide significance threshold ($p < 5E-8$). The indel is in high linkage disequilibrium ($r^2 > 0.8$) with rs2289702 (chr15:78944951, C>T, Gly12Arg) within *CTSH*. *CTSH* encodes two minor histocompatibility antigen epitopes: HLA-A*3101 and HLA-A*3303. The immunogenicity of both epitopes depends on the Arg residue and its substitution with Gly completely eliminates their binding to their corresponding HLA molecules. In the HLA imputation, multiple HLA class II haplotypes including *HLA-DQB1*03:02* ($\beta = 0.27$, $p = 2.3E-25$) and *HLA-A*24:02* class I haplotype ($\beta = 0.22$, $p = 4.9E-10$) were associated with AAD. A few known T1D loci were associated with AAD at nominal level ($p < 0.05$) but the majority of them were not associated at all. The results indicate that most T1D susceptibility loci do not affect AAD and the two identified loci for AAD are both involved in the immune system. Genetic studies can provide insight into heterogeneity within clinically-defined types.

Complex Traits Posters - Wednesday

PB1546. Multi-tissue splicing transcriptome-wide association study identifies 25 new candidate susceptibility genes and a new risk region for Alzheimer's disease

Authors:

G. Gao¹, J. McClellan¹, E. Wu², A. P. Wingo³, T. S. Wingo³, H. Im²; ¹Dept. of Publ. Hlth.Sci., Univ. of Chicago, Chicago, IL, ²Section of Genetic Med., Univ. of Chicago, Chicago, IL, ³Emory Univ. Sch. of Med., Atlanta, GA

Abstract Body:

Genome-wide association studies (GWAS) and transcriptome-wide association studies (TWAS) have discovered numerous genomic loci and genes, respectively, associated with Alzheimer's disease (AD); yet the causal genes are incompletely identified. We performed a joint intron splicing-based TWAS analysis for AD that combined information from multiple excised introns in a gene across multiple brain tissues by an aggregated Cauchy association test (ACAT). Specifically, the ACAT method constructed a test statistic by combining p-values of splicing TWAS for single introns and single tissues. We used splicing prediction models trained in 12 brain tissues in the GTEx (v8) data and summary statistics from genome-wide AD meta-analysis of results from 1) a genome wide association study by proxy (GWAX) (53,042 proxy cases, and 355,900 controls); and 2) AD case-control GWAS of 21,982 cases with diagnosed AD and 41,944 controls.

We identified 65 genes at 17 loci significantly associated with AD at the Bonferroni threshold. Among them, 24 genes at 10 loci were novel, having not been reported by previous TWAS or implicated by previous GWAS. To further determine which of the identified genes more likely to be causal, we performed a gene-based fine-mapping of TWAS by using the software package FOCUS. Among the 24 genes, seven genes at three loci were in credible sets at a nominal confidence level of 90% and had high posterior inclusion probabilities (PIPs) equal to or close to 1.0. The seven genes are: GATS (PIP=1) at locus 7q22.1; five genes HLA-DRB6 (PIP=1), HLA-DRB5 (PIP=1), XXbac-BPG154L12.4 (PIP=1), XXbac-BPG154L12.5 (PIP=1), and COL11A2 (PIP= 0.979) at locus 6p21.32; and UFC1 at locus 1q23.3. These genes are very likely causal. In addition, we performed joint splicing TWAS analysis by using the summary statistics only from the diagnosed AD case-control GWAS (without using proxy cases, see above). We identified a novel gene ELL in a novel locus (19p13.11), which was more than 5Mb away from previous published GWAS index SNPs. In summary, we identified 25 new candidate susceptibility genes for AD at 11 loci; one locus is in a novel risk region. These 25 novel susceptibility genes are promising targets for future mechanistic studies to understand how differentially spliced genes cause Alzheimer's disease.

Complex Traits Posters - Thursday

PB1547*. Multi-tissue transcriptome-wide association study (TWAS) uncovers 10 novel genes associated with multiple ageing outcomes.

Authors:

G. Navoly, O. Giannakopoulou, S. Mueller, L. Partridge, N. Alic, K. Kuchenbaecker; UCL, London, United Kingdom

Abstract Body:

Ageing brings about increased disease susceptibility. The rate at which an individual ages is partly determined by their genetic make-up. Previous genome-wide association studies (GWAS) identified only a few genome-wide significant loci, affecting lifespan. An alternative approach is through a gene-based association analysis called transcriptome-wide association study (TWAS), which integrates GWAS with gene expression data (eQTL), to model the association between gene expression levels and ageing. In this study, we performed a multi-tissue TWAS on human lifespan, using >1 million parental lifespans from the UK Biobank and the LifeGen Consortium, using S-MultiXcan software. We conducted two validation TWAS on two different ageing outcomes: longevity and healthspan (morbidity-free lifespan). We also performed TWAS fine-mapping, using FOGS software, to identify putative causal gene candidates. Finally, to assess the transferability of ageing-related findings from model organisms to humans, we tested for enrichment of genes in hallmark pathways: in the RAS, TORC1 and IIS pathways. We identified 563 genes whose expression was associated with parental lifespan (FDR <0.1), out of which, 137 novel genes were also associated with at least one other ageing outcome: longevity or healthspan (replication threshold $p < 0.05$). 10 of these novel genes, including *TOMM40*, *HTR3B*, *VARS*, *VWA7* and *COASY*, were associated with all the three ageing outcomes. The *HTR3B* gene, encoding a receptor for serotonin, has a function in cognition and memory, and has been linked to pathways in ageing. Furthermore, the 563 genes associated with parental lifespan were located in 109 physically distant (+/- 100kb) clusters. We used FOGS fine-mapping tool to identify likely causal genes for the 109 multi-gene clusters and successfully resolved several loci to one likely target gene (PIP >0.8 of being putatively causal), including *TOMM40*, *FES*, *PSMA4*, *IREB2*. Our analysis assessing the transferability of previous findings from model organisms to humans replicated several key genes of the RAS, TORC1 and IIS pathways, including well-established longevity genes *FOXO3* and *SESNI*. We showed successful application of the TWAS approach to validate previous GWAS findings, and to identify several novel genes associated with multiple ageing outcomes. Finally, our results support the key role of hallmark pathways in ageing in humans.

Complex Traits Posters - Wednesday

PB1548. Multitrait analysis genome-wide association study of atherosclerosis phenotypes

Abstract Body:

While over 300 genetic loci associated with coronary artery disease (CAD) have been discovered, genome-wide association studies (GWAS) of other atherosclerosis phenotypes have been less successful. Measures of atherosclerosis, such as coronary artery calcification (CAC) and carotid intima media thickness (cIMT), relate more closely to the specific pathophysiological mechanisms that lead to CAD and are highly correlated with CAD and other cardiometabolic risk factors. Our objective is to leverage these correlations to detect shared genetic loci for atherosclerosis phenotypes. Summary statistics from GWAS of 7 atherosclerosis phenotypes (CAD, cIMT, CAC, arterial stiffness index(ASI)) or cardiometabolic risk factors (type 2 diabetes, low density lipoprotein cholesterol (LDL-C), systolic blood pressure (SBP)) were combined to perform 24 separate multi-trait GWAS using N-GWAMA. A total of 1,183 pleiotropic genetic variants met the GWAS significance threshold of 5×10^{-8} and 925 met a Bonferroni-corrected significance threshold of 2.1×10^{-9} . Of the 925 variants, 575 were novel for at least one atherosclerosis phenotype (CAD: 146, CAC:217, cIMT:307, ASI:172). Most variants detected for atherosclerosis phenotypes were identified in loci with known associations with SBP, LDL-C, and type 2 diabetes. Using HyPrColoc, newly identified atherosclerosis variants that met the multi-trait significance threshold were further evaluated to identify clusters of traits with evidence of a shared causal variant. Sixteen novel variants for CAD and atherosclerosis measures also colocalized ($P_{RPA} > 80\%$) with clusters of cardiometabolic risk factors near or in genes whose known function could lead to excess CAD (*ABCB11*, *ADRB1*, *ASTN2*, *ATP1B3*, *BCL2*, *E2F3*, *FAIM2*, *HBSIL*, *HMGN2P25*, *KDM4B*, *PDGFC*, *PPARA*, *RPS6KB1*, *SLC24A3*, *SRRMI*, *Y_RNA*). For example, rs853777 near *ABCB11* was significantly associated with SBP, cIMT, CAD, and identified as a shared causal variant across CAD and SBP. While *ABCB11* has never been associated with atherosclerosis or SBP before, it is a known LDL-C and glucose locus, with a potential role in regulating liver function. Similarly, rs7776054 in *HBSIL* was significantly associated with CAD and ASI, and colocalized with LDL-C. Per GTEx, rs7776054 is a significant eQTL and sQTL of *HBSIL* in arterial and musculoskeletal tissue, and the gene has an important role in hemoglobin concentration. Thus, multi-trait GWAS of atherosclerosis identified loci not yet detected in single-trait GWAS with potential insights into the shared biological mechanisms leading to atherosclerosis and CAD.

Complex Traits Posters - Wednesday

PB1549. Multi-trait rare variant analysis of cardiometabolic traits

Authors:

W. Bone, A. Verma, T. G. Drivas, Y. Bradford, Penn Medicine Biobank, Regeneron Genetics Center, B. F. Voight, M. D. Ritchie; Univ. of Pennsylvania, Philadelphia, PA

Abstract Body:

Rare variant association tests on biobank cohorts have shown enormous promise to characterize the contribution of genetics to human traits. These experiments have shown strong evidence that rare protein-coding variants contribute to the risk of many common complex diseases. However, tests for rare variants carry several technical challenges: owing to the variant frequency, they suffer from a lack of power, and are quite sensitive to population stratification which can generate false positives. To address these challenges, we have implemented a framework to perform multi-trait association test of rare variant burden. Multi-trait methods using correlated traits have been previously shown to increase statistical power for discovery, and the use of burden tests and including common variant, rare variant, and local variant principal components as covariates can mitigate the impact of population stratification. This framework is capable of performing these experiments using both quantitative and binary traits. We have performed a proof-of-concept multi-trait rare variant analysis of lipid levels, using high-density lipoprotein, low-density lipoprotein, and triglycerides, as well as a liver enzymes multi-trait rare variant analysis, using alanine transaminase, aspartate transaminase, and alkaline phosphatase in the Penn Medicine Biobank (PMBB) 45K cohort. For circulating lipid level, we replicated five genes (*ABCA1*, *ANGPTL3*, *APOC3*, *LDLR*, and *PCSK9*) previously identified in an analysis of 200K exomes of UK Biobank (UKBB, Jurgens et al., 2021) and from 300K samples from the Global Lipids Genetics Consortium cohort (Lou et al., 2020). In the liver enzymes analysis, we detected three genes previously identified as likely causal genes at loci identified by genome-wide association studies (GWAS; *ALPL*, *GPLDI*, and *GPT*) as well as one gene not previously reported, *ANKRD36C*. We plan to extend this effort to perform a series of multi-trait scans for cardiometabolic rare variant in PMBB and UKBB to identify genes that modify coronary artery disease risk, type 2 diabetes risk and the quantitative traits that are associated and potentially causal for these diseases, including lipid levels and anthropometric traits. These experiments will give us a better understanding of the contribution of rare-coding variation to cardiometabolic disease and the pleiotropy between cardiometabolic traits. These experiments could also identify novel therapeutic targets. An advantage of these multi-trait rare variant association analyses over GWAS is that the results point directly to the potential therapeutic target gene.

Complex Traits Posters - Thursday

PB1550. Multivariate GWAS of 3D cranial vault shape in multi-ethnic and admixed children

Authors:

s. Goovaerts^{1,2}, H. Hoskens^{1,2}, R. J. Eller³, A. M. Musolf⁴, M. Yuan^{1,2}, N. Herrick³, S. Naqvi⁵, M. Lee⁶, H. L. Szabo-Rogers⁶, P. A. Romitti⁷, S. A. Boyadjiev⁸, J. R. Shaffer⁶, M. D. Indianapolis, Indianapolis, IN, ⁴Rutgers Univ., Piscataway, NJ, ⁵Stanford Univ. Sch. of Med., Stanford, CA, ⁶Univ. of Pittsburgh, Pittsburgh, PA, ⁷Univ. of Iowa, Iowa City, IA, ⁸Univ. of California Davis, Sacramento, CA, ⁹Penn State Univ., University Park, PA, ¹⁰Murdoch Childrens Res. Inst., Melbourne, Australia

Abstract Body:

Genome-wide studies have now identified several hundred loci associated with quantitative measures of human facial shape. Other regions of the craniofacial complex, by comparison, have received relatively little attention. The cranial vault - the portion of the skull that surrounds the cerebral cortex and cerebellum - is highly variable, has strong clinical relevance, and shows high heritability. Nevertheless, very little is known about the genetic basis of normal-range vault shape. Moreover, most genetic studies of craniofacial traits lack ethnic diversity, which can hamper discovery efforts. Here, we conducted a multivariate GWAS of 3D cranial vault shape extracted from magnetic resonance images in 4198 European ancestry and 2570 non-European ancestry (mostly admixed) children. By adjusting 3D cranial vault shape for both global and local genetic ancestry components, individuals that consist of up to a 3-way admixture component (having European, African, and American ancestry) could be included in a single genome-wide scan with boosted sample size and power while keeping Type I Error regulated. This yielded 30 independent genome-wide significant genetic loci, of which 20 were replicated in a dataset of 16,947 individuals from the UK Biobank. Amongst these loci, include transcription factors and growth factors known to play a role in craniofacial development (TBX15, DLX6, ALX1), brain development/morphology (ZEB2, RSPO2, RSPO3), and cranial suture morphogenesis (RUNX2, FGF10, FGF18, SHH). Collectively, our GWAS hits were enriched for processes related to skeletal development and showed elevated levels of transcription in cranial neural crest cells, suggesting a role during early craniofacial development. Most of the discovered loci were also implicated in disorders that result in abnormal craniofacial development in humans and/or model systems. More specifically, we found that our signals near BMP2, BBS9, and ZIC2 were also significantly associated (after correcting for multiple testing) with non-syndromic sagittal craniosynostosis in a case-parent trio dataset of 189 probands. These results affirm that common variation near genes implicated in abnormal craniofacial development also contribute to normal variation with regards to cranial shape and the craniofacial complex in general.

Complex Traits Posters - Wednesday

PB1551. Natural language processing and modelling of clinical brain disease trajectories

Authors:

I. Holtman¹, N. Mekkes¹, M. Groot², A. Rozemuller³, I. Huitinga⁴; ¹Univ. Med. Ctr. Groningen, Groningen, Netherlands, ²The Netherlands Brain Bank, Netherlands Inst. for NeuroSci., Amsterdam, The Netherlands, Amsterdam, Netherlands, ³Amsterdam Med. Ctr. location VUmc, Amsterdam, Netherlands, ⁴Netherlands Inst. for NeuroSci., Amsterdam, Netherlands

Abstract Body:

The brain is a highly complex organ that consists of many intricately linked substructures and cell types and is susceptible to a wide range of brain disorders. Many brain disorders show considerable overlap in clinical manifestations, genetic risk factors, and pathophysiological mechanisms, suggesting a complex relationship between clinical symptoms, neuropathology, and genetic susceptibility both within and between clinical diagnosis. Brain diseases are often wrongly diagnosed, as up to 30% show a mismatch between a clinical and neuropathologically based diagnosis. A better delineation of the relationships between these disorders might enable improved diagnosis, better prognosis, and personalized therapeutic interventions. This clearly illustrates the need for a cross-diagnostic, data-driven approach. To this end, we recently established the Netherlands Neurogenetics Database which aims to integrate the extensive clinical, and neuropathological data of the Netherlands Brain Bank (NBB) with genetics data from a large number of donors. A first aim of this project is to convert a large corpus of clinical history data, consisting of medical summaries made by medically trained staff of the NBB, into standardized clinical disease trajectories. For this, we aimed to identify and define clinical signs and symptoms associated with brain disorders. We identified 90 signs and symptoms, divided over 14 groupings, within 5 domains, such as ‘memory impairment’ and ‘hallucinations’. Different Natural Language Processing (NLP) models, including Google BERT, were trained and optimized with Optuna to identify these signs and symptoms in individual sentences in the clinical history data. After Optuna optimization, BERT and T5 were able to reliably identify most signs and symptoms with a micro-F1 score above 0.9. Out of the 90 attributes, 81 reached an F1 score of 0.8 or higher in the best performing BERT model. The final model was used to predict signs and symptoms in the full corpus. We subsequently compiled the attributes according to the main neuropathological diagnoses from the NBB and identified clear disease-associated signs and symptom profiles, supporting the validity of this approach. In addition, we were able to identify signs and symptoms that differ between disease subtypes, which might help to distinguish brain-disorder subtypes. Finally, these clinical attributes, in conjunction with polygenic risk scores were used to model the temporal aspects of disease progression, and to train machine learning models to more reliably predict neuropathological diagnosis.

Complex Traits Posters - Thursday

PB1552. Neurobiological pathways underlying opioid addiction identified by systems biology multi-omic gene integration.

Authors:

K. Sullivan¹, D. Kainer¹, M. Lane², M. R. Garvin¹, A. Townsend², B. C. Quach³, C. Willis³, N. C. Gaddis³, R. Mathur³, O. Corradin⁴, B. S. Maher⁵, P. C. Scacheri⁶, S. Sanchez-Roige⁷, A. A. Palmer⁷, V. Troiani⁸, E. Chesler⁹, D. B. Hancock³, E. O. Johnson³, D. A. Jacobson¹; ¹Oak Ridge Natl. Lab., Oak Ridge, TN, ²Univ. of Tennessee-Knoxville, Knoxville, TN, ³RTI Intl., Research Triangle Park, NC, ⁴MIT, Cambridge, MA, ⁵Johns Hopkins Bloomberg Sch. of Publ. Hlth., Baltimore, MD, ⁶Case Western Reserve Univ., Cleveland, OH, ⁷UCSD, La Jolla, CA, ⁸Geisinger Hlth.System, Danville, PA, ⁹The Jackson Lab., Bar Harbor, ME

Abstract Body:

Recent genome-wide association studies (GWAS) and omic-wide gene dysregulation studies in postmortem human brains have begun to robustly identify variants and genes associated with opioid addiction (OA). Linking OA genes to neurobiological pathways is critical to elucidating biological drivers underlying the observed associations and providing hypotheses for biological context-aware functional experiments. We applied a novel systems biology approach to connect OA-associated genes using a multiplex network with network layers from distinct types of biological experimental evidence, including six brain region-specific gene expression networks constructed using explainable artificial intelligence and RNA-seq data. Our initial analysis focused on 15 OA-associated genes: five GWAS-derived genes (*OPRM1*, *FURIN*, *KDM4A*, *PPP6C*, *PTPRF*), five differentially expressed genes (DEGs; *DUSP4*, *DUSP6*, *EGR4*, *ETV5*, *NPAS4*) from postmortem dorsolateral prefrontal cortex (dlPFC), and five genes from opioid-related epigenetic alterations to the dlPFC, including H3K27 hypoacetylation by ChIP-seq (*ASTN2*, *DUSP4*, *ENOX1*, *GABBR2*, *KCNMA1*) and DNA hypermethylation (*NTN1*). Using network mining algorithms, we identified a strong level of functional connection among these genes, with a high level of gene recovery (AUC=0.93) and a tight network of only 96 additional genes needed to connect all 15 OA-associated genes. Novel connections between genes were observed, including a scaffolding protein (*FLNA*) binding to both *OPRM1* and *FURIN*. Results also included multiple functional links between genes that modulate MAPK signaling (*DUSP4*, *DUSP6*, and *PPP6C*), which responds to morphine exposure. We then expanded our analysis to 182 OA-associated genes, including genes from recently characterized GWAS loci, differentially expressed proteins from the dlPFC using LC/MS proteomics, and additional DEGs from postmortem nucleus accumbens (NAc) and dlPFC. We used our recently developed systems biology tool GRIN (Gene set Refinement using Interacting Networks) to identify the genes that were most biologically interrelated among OA-associated genes in the dlPFC and NAc. Using gene set enrichment analysis from genes retained by GRIN with the larger 182 gene set, we confirmed the involvement of the MAPK signaling pathway in OA and identified a novel enrichment for transcriptional repression that was not identified prior to GRIN. Integrating these multi-omic datasets using AI-derived networks, we linked seemingly disparate single omics findings to neurobiological pathways in multiple brain regions, supporting a new conceptual model of the interplay of genes underlying OA.

Complex Traits Posters - Thursday

PB1553. Neuroimmunogenic architecture in brains of Alzheimer's disease at single-cell resolution

Authors:

Y. Chen¹, R. Dai², C. LIU³, H. Huang⁴; ¹broad Inst., Cambridge, MA, ²SUNY Upstate Med. Univ., Syracuse, NY, ⁴MGH, Boston, MA

Abstract Body:

Recent studies emphasized the crucial role of neuroinflammation in Alzheimer's disease (AD) pathogenesis. However, the expression of immune-related genes (IRGs) and possible regulatory mechanisms involved in major brain cell types of AD remain unclear. With the development of single-cell technology, we are equipped to dissect neuroinflammation at the cell type level in AD. For this study, we investigated IRGs changes in the major brain cell types using single-nucleus RNA-seq data from the Religious Orders Study and Memory and Aging Project (ROSMAP) study with 80,600 cells in the cortex across 48 individuals (24 patients and 24 matched controls).

We curated the IRGs from eight databases using uniform criteria. In total, we characterized 1,821 IRGs expressions across five major cell types in brains: excitatory neurons (Ex), inhibitory neurons (In), astrocytes (Ast), oligodendrocytes (Oli), and microglia (Mic). 1,698 IRGs were retained after data preprocessing and covariates adjustment. Differential gene expression was calculated using the linear mixed-effect model. We identified differentially expressed IRGs in each cell type (Ex: 32, In: 182, Ast: 12, Mic: 32, Oli: 78). Notably, CD81 showed significant differential expression across cell types, including microglia, astrocyte, and oligodendrocytes.

To decipher cell-cell interactions and communication changes in AD patients, we calculated the intercellular communication probability using Cellchat. We found all the brain cell types contained active cell-cell interaction of the immune pathways (IR-CCI). Furthermore, only patients' inhibitory neuron showed less IR-CCI than controls. We also ranked all the significant immune-related signaling pathways based on their differences between AD and controls. For example, we found that IL-4 signaling is more active in patients with AD than in controls.

Lastly, we conducted the single-cell eQTL analysis and identified variants affecting gene expression of IRG in these five major brain cell types. The GWAS signals were highly enriched in the microglia IRG-eQTL SNPs (enrichment = 2.3728; p.value = 3.71E-9) and neuron IRG-eQTL SNPs (enrichment = 1.7514; p.value = 0.0002).

In conclusion, we found that immune gene dysregulation events are widely present in major brain cell types in AD patients. Microglia and intercellular communication of neuroimmunity were highlighted in the AD brain for the neuroimmune dysregulation. Our work uncovers the neuroimmunogenic architecture in major human brain cells of AD patients, which will inform our understanding of the underlying mechanism of AD.

PB1554. Neuronal Assay for Investigating Circadian Rhythm Defects in Prader-Willi and Schaaf-Yang Syndrome

Authors:

A. Victor¹, C. Ramanathan², A. Liu³, Y. Shen³, L. Reiter¹; ¹Univ Tennessee HSC, Memphis, TN, ²Univ. of Memphis, Memphis, TN, ³Univ. of Florida, Gainesville, FL

Abstract Body:

Prader-Willi syndrome (PWS) is a neurodevelopmental disorder defined by a range of phenotypes, including developmental delay, intellectual disability, sleep disorders and increased autism risk. PWS is an imprinting disorder caused by a loss of paternal expression of critical genes in the 15q11.2-q13 regions, including *MAGEL2*, *SNRPN/SNURF*, and *SNORD116*. PWS patients are known to suffer from various sleep disorders, including sleep-disordered breathing and central hypersomnolence. The suprachiasmatic nucleus (SCN), within the hypothalamus, controls the circadian rhythms of many biological processes. Mouse models of PWS have alterations in their circadian rhythms, including REM sleep alterations and defects in rhythmic DNA methylation. While in cultured cells, *Magel2* was found to regulate *Bmal1* and *Per2*, both critical genes in the circadian pathway. Schaaf-Yang syndrome (SYS), a disorder with overlapping phenotypes in common with PWS, results from truncating mutations in the *MAGEL2* gene. Here, we investigated the expression of key Clock gene, *Per2*, across time in dental pulp stem cell (DPSC) patient-derived neurons from PWS, SYS and neurotypical control subjects. We have established the largest collection of DPSC lines from the deciduous teeth of PWS subjects (46 total). We regularly differentiate these stem cells into cortical-like neurons for molecular and functional studies. To investigate the circadian rhythms of PWS and SYS patients, we established DPSC cell lines harboring a *Per2* promoter-driven luciferase reporter (*Per2:Luc*) cell line to assess in vitro circadian bioluminescence rhythm. The reporter stem cells were differentiated for 4-weeks to achieve a mature neuronal reporter cell line. Using a Lumicycle instrument, which measures luciferase activity across time, we were able to observe the circadian bioluminescence rhythms of these patient derived neuronal cell lines across several days. We observed a shorter period length of bioluminescence rhythms from the PWS and SYS neurons compared with the neurotypical control neurons. We aim to use this assay to further examine the defective circadian rhythms in PWS and SYS and to perform drug screens in order to rescue these circadian defects.

Complex Traits Posters - Wednesday

PB1555. NGS testing and risk stratification of malignant cardiac arrhythmias

Authors:

N. Kokalj Vokac^{1,2}, Š. Stangler Herodež^{1,2}, D. Krgović^{1,2}, D. Vokač^{1,2}; ¹Univ. Medical Ctr. Maribor, Maribor, Slovenia, ²Med. Faculty, Univ. Maribor, Maribor, Slovenia

Abstract Body:

Cardiac arrhythmias are frequent in patients with nonischemic cardiomyopathy (CMP) and can precipitate sudden cardiac death (SCD) before symptoms set up. In majority malignant cardiac arrhythmias are nonspecific consequence of advanced hearth disease although in many cases could present a primary onset and proceed overt heart before structural and electrical remodeling. In the clinical practice risk stratification criteria for prophylactic implantable cardioverter defibrillator implantation (ICD) are mostly dependent on structural heart diseases exclusion and arrhythmogenic substrate approval by use of standard invasive and noninvasive clinical tests on the other hand nonspecific ECG changes in asymptomatic patients or patients with modest clinical signs many times are overlooked in these a routine new generation genetic testing (NGS) could be important for better clinical decision. Using NGS 202 patients age 51,2±19,4 Y patients were tested 83 with syncope or after aborted sudden death; 55 with converted ventricular tachyarrhythmia or ventricular fibrillation without structural heart disease and patients suspected for development of overt cardiomyopathy with modest symptoms or borderline cardiac diagnostic tests for recognition of arrhythmogenic cardiomyopathy; 63 patient with overt or high degree probability for relapse VT an ICD implantation and 21 patient with RF ablation procedure. NGS analysis was performed using the TruSight Cardio Sequencing Kit (Illumina, Inc., San Diego, CA, USA) on Illumina MiSeq platform. Data analysis was performed with MiSeq Reporter software 2.5.42.5 according to BWA Enrichment disc workflow. Variant Studio (Illumina, Inc., San Diego, CA, USA) software and open-access bioinformatic tools and databases were used for analysis and interpretation of variants obtained in VCF file. In study, we established molecular genetic disorder in 33% of the study population. Significant proportion 12,4 % of pathogenic and 20,8 % of VOUS variants were analyzed. In the group of patients with VOUS, 16.1% were highly clinically significant. In our presentation genotype - phenotype correlation is discussed for clinically pathological cases which according to NGS analyzes were classified as VOUS. Emphasis is placed on the importance of the results of NGS analyzes in defining the clinical condition and risk stratification with awareness of early cardiomyopathy detection, aggressive treatment and SCD prevention is of great clinical significance.

Complex Traits Posters - Thursday

PB1556. Non-desmosomal genes in Arrhythmogenic Cardiomyopathy: genetic variants rating

Authors:

M. Bueno Marinas, R. Celeghin, M. Cason, R. Bariani, M. De Gaspari, S. Rizzo, G. Thiene, M. Perazzolo Marra, D. Corrado, C. Basso, B. Bauce, K. Pilichou; Dept. Cardiac-Thoracic-Vascular Sci. and Publ. Hlth.. Univ. of Padua, Padua, Italy

Abstract Body:

Background. Arrhythmogenic Cardiomyopathy (AC) is an inherited disorder of the myocardium with a highly heterogeneous clinical presentation including life-threatening arrhythmias at risk of sudden death. Genetic testing impacts greatly in reaching AC diagnosis, but gene-disease associations has yet to be determined for the increasing number of genes included in clinical panels. **Methods.** Genetic variant re-appraisal was undertaken in most relevant non-desmosomal disease genes, based on current adjudication guidance, identified in 320 unrelated Italian AC patients who did not carry pathogenic/likely pathogenic (P/LP) variants in desmosome-coding genes and reported literature data. **Results.** In our cohort, 28 rare genetic variants in non-desmosomal genes were identified in 30 patients, of which 17 *FLNC* (Filamin C), 7 *DES* (Desmin), 2 *TMEM43* (Transmembrane protein 43), and 2 *CDH2* (Cadherin-2). No P/LP variants were found in *PLN* (Phospholamban) and *TJPI* (Tight junction protein-1) genes. Gene-based burden analysis, including P/LP variants reported in literature, showed significant enrichment only for *TMEM43* (3.52-fold), *DES* (9.55-fold), *PLN* (117.8-fold) and *FLNC* (93.22-fold). Evolutionary conservation analysis made evident a positive selection pressure (Ka/Ks ratio >1) for *CDH2* and *TJPI*, indicating that missense variants impact less the protein structure. Genotype-phenotype correlation highlighted 71% and 89% of left-dominant AC in *FLNC* and *DES* carriers, respectively. **Conclusion.** Genes lacking robust clinical and genetic evidences impact greatly the number of variants-of-unknown-significance detected and should be removed from clinical AC-targeted genetic panels since the findings cannot drive clinical decision-making. About two thirds of non- desmosomal P/LP variants occur in *FLNC* leading to fully-penetrant left-dominant AC.

Complex Traits Posters - Wednesday

PB1557. Non-Mendelian inheritance patterns and extreme deviation rates of CGG repeats in autism

Authors:

F. Kooy¹, D. Annear¹, A. Sanchis-Juan², L. Raymond³, G. Vandeweyer⁴; ¹University of Antwerp, Antwerp, Belgium, ²Univ. of Cambridge, Cambridge, United Kingdom, ³University of Cambridge, Cambridge, United Kingdom, ⁴Univ. of Antwerp, Antwerp, Belgium

Abstract Body:

Short tandem repeats (STRs) are tracts of DNA where short nucleotide motifs are repeated in a head-to-tail fashion. To date, greater than 30 STR-associated disorders have been described. Here, we explored the inheritance patterns of CGG trinucleotide STRs and the inheritance differences between autism-affected probands and their unaffected siblings. We utilized ExpansionHunter, to determine the genomic CGG-repeat length genotypes across a total cohort of 1978 trios and 114 quads.

Across the 6063 analysed CGG loci, 11,885,983 individual parent-to-child repeat genotypes were determined, and a total of 23,391,708 CGG-repeat transmissions were observed. Of all STR genotypes, most were monogenic across the proband, mother, and father. 15.6% of genotypes were informative, where the parental genotypes were different or heterozygous, but the proband genotype was reflective. However, 4.4% of CGG STR transmissions resulted in a deviating proband genotype. Deviation events were witnessed at 5881 of the CGG loci with an expansion-to-contraction ratio of 1.65.

This research not only solidifies previous findings surrounding STRs but specifically demonstrates new characteristics of CGG STRs. The mutation rate was strongly dependent on both the genomic location as well as intergenic positioning. While the largest portion of CGG-repeats is localised within genes, the regions that displayed the highest rates of CGG repeat mutation were the intergenic and immediate 5'-upstream regions. We solidify the idea that repeat variation rate is proportional to repeat length, however, we refine this concept and demonstrate how smaller repeats more readily demonstrate a greater degree of size variation and take on additional repeat units.

Interestingly, we observed that CGG STRs did not segregate based on Mendelian principles. The shorter repeat allele length is typically selected and reflected in offspring. Furthermore, this trend appears to magnify as the repeat length difference increases between the two parental repeat alleles. While almost all CGG STRs were determined to be polymorphic, we see how the repeats fall within an increasingly variable continuum, with a distinct subset of hypermutable CGG STRs that cluster in specific genetic regions and locations linked to neurological function and development. Some hypermutable CGG repeats then appear to be involved in autism spectrum disorder as we observe significantly higher rates and degrees of CGG repeat expansion in these regions among autism affected individuals versus their unaffected siblings. This may suggest that CGG STRs are explicitly linked to neurodevelopmental function and disorders.

Complex Traits Posters - Thursday

PB1558. Not one and done: A rare finding of two deleterious variants contributing to the onset of rhabdomyolysis.

Authors:

A. Kunovac¹, N. Berman², C. Munro², R. O. Rosti¹, X. Wang³, L. A. Berenbrok⁴, M. Massart²; ¹UPMC Genome Ctr., Pittsburgh, PA, ²UPMC Primary Care Precision Med., Dept. of Family Med., Pittsburgh, PA, ³AiLife Diagnostics, Pearland, TX, ⁴Univ. of Pittsburgh Sch. of Pharmacy, Pittsburgh, PA

Abstract Body:

Introduction: In the United States, approximately 26,000 cases of rhabdomyolysis are reported annually. Many genetic factors have been identified as contributing to the onset of rhabdomyolysis including metabolic myopathies, channelopathies, and mitochondrial disorders.

Case Presentation: This is a case of a 29-year-old male with recurrent episodes of rhabdomyolysis, resulting in multiple hospitalizations. Laboratory and metabolic evaluations did not reveal a cause. A traditional rhabdomyolysis panel determined that the patient was heterozygous for *RYRI* (AD) c.1589G>A (p.R530H), a likely pathogenic variant, and heterozygous for *PFKM* (AR) c.352G>C (p.G118R), a variant of uncertain significance. Cascade testing of his family members determined that his mother and brother were found to carry the same *RYRI* variant but did not report any symptoms. The patient returned to clinic eight months later. He continued to have more frequent episodes with additional hospitalization with CK levels ranging from 140 to >22,000 U/L. Notably, he also had low associated blood glucose levels that ranged from 69 to 89 mg/dL. The decision was made to advance to Whole Exome Sequencing (WES) due to incomplete explanation of the patient's recurrent symptoms. In addition to confirming that the patient was heterozygous for the *RYRI* and *PFKM* variants, a deep intronic variant, c.936+218G>A, in the *PFKM* gene was identified. This led our team to hypothesize that the severity of the patient's rhabdomyolysis could be the product of the *PFKM* pathway or a combination of the compounded mutations in both the *RYRI* and *PFKM* genes as an alternative explanation. The two *PFKM* variants were not found through targeted genetic testing in the mother, indicating that the patient either inherited these variants from the father in cis or possibly one or both variants are *de novo*. Testing of the father is pending. To the best of our knowledge, this is the first documented case of a patient with mutations in two different genes in a reported case of rhabdomyolysis.

Discussion: The results substantiate the idea that additional genetic testing, such as WES, should be considered when an initial genetic diagnosis is not aligning with the patient's symptoms. With approximately 5% of WES cases resulting in a dual diagnosis, individual panel tests could miss such a finding. Furthermore, in challenging cases such as the one presented herein, we propose that it is more cost-effective and therefore beneficial to both the patient and the healthcare system to perform WES rather than symptomatically treating patients over multiple hospital admissions.

Complex Traits Posters - Wednesday

PB1559. Novel Insights into Pediatric Scoliosis Revealed by Genome-wide Association Study and Whole Exome Sequencing

Authors:

H-Q. Qu¹, J. Qu¹, C. Vaccaro², X. Chang³, F. Mentch⁴, J. Garifallou¹, F. Mafra⁵, K. Nguyen⁶, M. March¹, R. Pellegrino⁷, J. Glessner¹, H. Hakonarson⁸; ¹Children s Hosp. of Philadelphia, Philadelphia, PA, ²The Children s Hosp. of Philadelphia, Philadelphia, PA, ³CHOP, Bryn Mawr, PA, ⁴Childrens Hosp. of Philadelphia, Philadelphia, PA, ⁵The Childrens Hosp. of Philadelphia, Philadelphia, PA, ⁶Children's Hosp. of Philadelphia, Phila, PA, ⁷The Children s Hosp. of Philadelphia, Philaldelphia, PA, ⁸Children's Hosp. of Philadelphia, Philadelphia, PA

Abstract Body:

The etiology of pediatric scoliosis remains obscure. Etiologically, pediatric scoliosis has been linked to central nervous system development with the theory of asynchronous neuro-osseous growth. To investigate the complex nature of pediatric scoliosis, we sought to acquire insight into the molecular mechanisms of pediatric scoliosis pathogenesis through genomic approaches, including genome-wide association study (GWAS) and whole exome sequencing (WES). The GWAS was performed on an African American cohort including 1,386 unrelated scoliosis cases and 8,942 controls, and a European American cohort with 2,833 scoliosis cases and 11,672 controls. We uncovered 25 genes showing replicable genome-wide significance by gene-based association study in both cohorts. Shared genetic susceptibility of pediatric scoliosis and autistic disorder/mental disorders was observed from common genetic variants, suggesting there is enrichment of genes in scoliosis patients with significant roles in the development and function of the central and peripheral nervous systems. Our pediatric scoliosis results also suggest adrenocortical role based on common variants of the phosphodiesterase 11A gene (*PDE11A*), involved in cAMP and cGMP signaling in adrenal cortex. The WES was performed in an African American cohort including 310 unrelated cases and 4,032 unrelated controls, and a European American cohort with 489 cases and 3,392 controls. Mutation burden was tested using the Test Rare vAriants with Public Data (TRAPD) algorithm, which we have optimized with normalized genome coverage and internal controls, as a powerful approach for rare causal variants with effects in the same directions. A total of 20 genes showed replicable genome-wide significance by mutation burden study in both cohorts. Genes related to muscular disorders are highlighted by the burden of rare coding variants in scoliosis patients, with or without the diagnosis of neuromuscular scoliosis. In summary, this study unveiled a new view of the panorama of the molecular mechanisms of pediatric scoliosis pathogenesis, represented by 25 genes identified by GWAS, and 20 genes identified by WES, with replicable genome-wide significance. As genetic susceptibility of pediatric scoliosis appears to overlap with central and peripheral nervous system disorders as well as neuroendocrine dysfunctions, causal effects from rare coding variants related to genetic scoliosis may also contribute to muscular, neurologic, and neuroendocrine defects, suggesting significant heterogeneity of the resulting phenotypes.

Complex Traits Posters - Thursday

PB1560. Obesity genomic loci are heterogeneously associated with lipid profiles in ancestrally diverse *Population Architecture using Genomics and Epidemiology (PAGE)* study.

Authors:

D. Kim¹, M. Graff¹, H. M. Highland¹, R. A. J. Smit², Z. Wang², Y. Cai³, M. Kim³, C. L. Avery¹, P. Gordon-Larsen¹, R. C. Kaplan⁴, J. E. Manson⁵, E. Marouli⁶, M. Fornage⁷, C. Gignoux⁸, C. A. Haiman⁹, S. Buyske¹⁰, T. C. Matise¹⁰, C. Kooperberg³, U. Peters³, R. J. F. Loos², K. E. North¹; ¹Gillings Sch. of Global Publ. Hlth., Univ. of North Carolina at Chapel Hill, Chapel Hill, NC, ²Icahn Sch. of Med. at Mount Sinai, New York, NY, ³Fred Hutchinson Cancer Ctr., Seattle, WA, ⁴Albert Einstein Coll. of Med., New York, NY, ⁵Harvard T. H. Chan Sch. of Publ. Hlth., Boston, MA, ⁶Barts and The London Sch. of Med. and Dentistry, Queen Mary Univ. of London, London, United Kingdom, ⁷Univ. of Texas Hlth.Sci. Ctr. at Houston, Houston, TX, ⁸Univ. of Colorado, Denver, CO, ⁹Univ. of Southern California, Los Angeles, CA, ¹⁰Rutgers Univ., Piscataway, NJ

Abstract Body:

Obesity has a heterogeneous impact on cardiovascular disease (CVD), in particular for lipid traits and across diverse populations. In this study, we utilized genetic variation to define the heterogeneous impact of obesity on CVD and to gain insight into the underlying biology that connects the metabolic disturbances of obesity to CVD. We estimated local genetic correlations between obesity (assessed by body mass index (BMI)) and lipid levels to identify loci associated with obesity and low dyslipidemia risk (Ob/LDR loci) and loci associated with obesity and high dyslipidemia risk (Ob/HDR loci) in 56,681 (34% European, 30% Hispanics, 28% African, and 8% others) *Population Architecture using Genomics and Epidemiology (PAGE)* study participants. We conducted pair-wise local genetic correlation analyses between BMI and three lipid traits (high-density lipoprotein (HDL), low-density lipoprotein (LDL), and triglycerides (TG)) across 2,495 approximately LD-independent segments of the genome using *LAVA*. We utilized publicly available UK Biobank GWAS summary statistics (<http://www.nealelab.is/uk-biobank/>) of BMI (N~355K) and lipid traits (N~300K). We filtered the loci with statistically significant ($p < 0.05/2,495$) local heritability for both BMI and a lipid trait and identified loci with statistically significant ($p < 0.05/\text{number of tested loci}$) local genetic correlation coefficients (r_g). Ob/LDR loci displayed $r_g > 0$ for BMI-HDL and $r_g < 0$ for BMI-LDL and BMI-TG. Ob/HDR loci displayed $r_g < 0$ for BMI-HDL and $r_g > 0$ for BMI-LDL and BMI-TG. To further investigate the discovered loci, we constructed Ob/LDR and Ob/HDR loci-based BMI polygenic scores (PGS) - using SNP weights modeled from PRS-CS - and assessed the association between the PGS and BMI or continuous lipid levels in the PAGE samples. We identified 19 (14 unique) Ob/LDR loci (BMI-HDL: 5, BMI-LDL: 5, and BMI-TG: 9) - 6 were previously identified - and 83 (66 unique) Ob/HDR loci (BMI-HDL: 58, BMI-LDL: 4, and BMI-TG: 21). In the ancestry-combined results, Ob/LDR loci-based BMI PGS were significantly associated ($p < 0.05$) with both BMI and the lipid trait in a hypothesized way (β s for BMI > 0 for all three pairs, β for HDL > 0 , β s for LDL and TG < 0). Ob/HDR loci-based BMI PGS were significantly associated with BMI ($\beta > 0$) and HDL ($\beta < 0$). The identification and replication of genetically correlated obesity-lipid loci further support the importance of using genetics to define the heterogeneous impact of obesity on dyslipidemia and downstream CVD. Our study findings support and extend previous findings from European studies. Further analyses will be conducted to identify the causal variants and genes underlying these loci.

Complex Traits Posters - Wednesday

PB1561. Opportunities in national SARS-CoV-2 genomic surveillance programs for accelerating study on human genetic determinants of differential COVID-19 severity

Authors:

T. Szemes^{1,2}, T. Sladeczek¹, T. Adamik¹, M. Gaziova³, M. Nemeč¹, J. Turna¹, J. Radvanszky¹, A. Kalinakova⁴, D. Rusnakova^{2,1}, T. Sedlackova¹, M. Bohmer^{1,4}, J. Budis^{1,5}; ¹Comenius Univ. Sci. Park, Bratislava, Slovakia, ²Comenius Univ., Faculty of Natural Sci., Bratislava, Slovakia, ³Comenius Univ., Faculty of Mathematics, Physics and Informatics, Bratislava, Slovakia, ⁴Publ. Hlth. Authority of the Slovak Republic, Bratislava, Slovakia, ⁵Slovak Ctr. of Scientific and Technical Information, Bratislava, Slovakia

Abstract Body:

In March 2020 the World Health Organisation announced global pandemic of SARS-CoV-2 virus with major impact on healthcare and economy in virtually all countries in the world. SARS-CoV-2 is a cause of COVID19 which, based on pathogen-host interaction, can lead to highly variable outcomes. Along with known risk factors for severe forms like age, comorbidities, genetic factors were studied but with limited success.

Unprecedented efforts in pathogen surveillance of clinical COVID-19 cases by genome sequencing of the virus in almost all countries started to aid pandemic management. More than 10 million viral genomes have been published so far. In our country, weekly genomic surveillance of SARS-CoV-2 genomes was launched in March 2021.

Due to inclusion of new NGS laboratories Public Health authority in this surveillance programme, as well as our core sequencing laboratory with 10 years experience, there were different levels of experience with laboratory procedures, but more importantly with NGS bioinformatics and result reporting. Due to this obstacle and a growing number of sequenced samples, we developed a centralized information system for organizing the national COVID-19 sequencing effort. The system with abbreviated name NarCoS is utilized to transfer id and metadata for all planned samples, to define sequencing runs for all labs, to analyze sequencing runs and to batch evaluate and report results to national register as well as to GISAID, ENA/GenBank and Tessa. Currently all facilities use ARCTIC PCR protocol based genome enrichment of the virus and sequencing on Illumina NGS platforms. Our core laboratory contributed by sequencing approx. half of all SARS-CoV-2 sequences.

Unfortunately, only in a very limited number of our cases, the human genome was also a target for analysis. Exome sequencing was carried out in two cases of in utero lethality of the fetus after COVID-19 induced in late stages of pregnancy to rule out genetic causes. We propose to extend pathogen genomic surveillance programs to focus also on human genomic variability as this can lead to valuable knowledge on genetic risk factors and polygenic risks to stratify population groups according to their genetic risks. Different sample types for SARS-CoV-2 tests are suitable for analysis of different levels of human genome variation. Adding the exome analysis could be done by modification of library preparation protocols, which are carried out within SARS-CoV-2 sequencing, without time penalty. It is also technically possible to extend integrated information systems like ours to allow a comprehensive analysis of human exomes. Naturally, ethical and data privacy issues need to be addressed.

Complex Traits Posters - Thursday

PB1562. Osteoarthritis has high genetic heritability in 488,421 multi-ancestry participants from MVP and the UK Biobank.

Authors:

A. Wilson¹, V. Srinivasasainagendra², A. Nair¹, A. Rocco¹, J. Chiles¹, J. Richman³, S. Pyarajan⁴, H. Tiwari², D. Speed⁵, M. Bamman⁶, J. Singh³, M-L. McDonald¹; ¹Univ. of Alabama at Birmingham, Div. of Pulmonary, Allergy, and Critical Care Med., Birmingham, AL, ²Univ. of Alabama at Birmingham, Sch. of Publ. Hlth., Biostatistics, Birmingham, AL, ³Birmingham VA Hlth.care System (BVAHS), Birmingham, AL, ⁴Partners Hlth.Care, Lexington, MA, ⁵Aarhus Univ., Aarhus, Denmark, ⁶Florida Inst. for Human and Machine Cognition, Pensacola, FL

Abstract Body:

Introduction Osteoarthritis (OA) is a progressive joint disease with a poorly understood etiology. Disease management is limited primarily to symptom management (e.g., pain, inflammation). The societal and patient-centered impacts of OA among United States Veterans are profound with healthcare costs for treatment exceeding \$880 million annually. To establish more comprehensive insights into the allelic spectra of OA, we estimated heritability using summary statistics from ancestry stratified GWASes of 488,421 United States Veterans who participated in the Million Veteran Program (MVP) and participants from the UK Biobank (UKB). **Methods** Genotype data for MVP and UKB was generated from DNA typed on customized Affymetrix Axiom biobank arrays for common and rare variants. Standard quality control procedures were implemented to ensure high quality SNP and DNA samples were analyzed. HARE was used to classify subjects into major ancestry groups. OA heritability was estimated in MVP and UKB ancestry groups with $\geq 10,000$ subjects (MVP: European (EUR), African American (AFR), Hispanic (HIS)); and UKB: EUR). Heritability was calculated using the baseline linkage disequilibrium-linkage disequilibrium adjusted kinships (BLD-LDAK) method which relies on a restricted maximum likelihood algorithm. In addition, the BLD-LDAK model provides estimates of heritability stratified by categories of annotated SNPs (i.e., intronic or promotor regions of the genome) that can be used estimate the unique influence for each category on heritability. **Results** In MVP, heritability of OA was highest among Veterans of HIS descent ($h^2= 51.3\%$, $SD= 8.7\%$), followed by AFR ($h^2= 29.0\%$, $SD= 3.2\%$), and EUR ($h^2= 19.0\%$, $SD= 1.4\%$). In UKB, the heritability of OA in EUR was 7.8% ($SD= 0.8\%$). In MVP, heritability of OA was most heavily influenced by SNPs annotated to the hyper-sensitive site 2 (HS2) super-enhancer, transcription factor coding, and DNAase 1 hypersensitive site regions, in EUR, AFR, and HIS, respectfully. In MVP EUR, heritability was most heavily influenced by SNPs annotated to intronic regions. Among all ancestry groups in MVP and UKB, heritability was enriched for SNPs annotated to HS2 super-enhancer regions. **Conclusions** We demonstrate OA is highly heritable among MVP and UKB participants, with heritability estimates greater than 30%. SNPs annotated to HS2 super-enhancer regions, enriched among all MVP and UKB ancestry groups, could serve as potential biomarkers or drug targets to improve health outcomes in OA. Future directions include the investigation of SNPs in the most heavily influential annotation groups to determine whether they are of direct functional significance in OA.

Complex Traits Posters - Wednesday

PB1563. Overexpression screen of chromosome 21 genes reveals modulators of Sonic hedgehog signaling relevant to Down syndrome.

Authors:

A. Moyer¹, F-X. Fernandez², Y. Li³, D. Klinedinst³, L. Florea³, S. Thyme¹, R. Reeves³; ¹Univ. of Alabama at Birmingham, Birmingham, AL, ²Univ. of Arizona, Tucson, AZ, ³Johns Hopkins Sch. of Med., Baltimore, MD

Abstract Body:

Dysregulation of Sonic hedgehog (SHH) signaling may contribute to multiple Down syndrome-associated phenotypes, including cerebellar hypoplasia, congenital heart defects, craniofacial and skeletal dysmorphologies, and Hirschsprung disease. However, despite evidence that activation of SHH signaling rescues Down syndrome-associated phenotypes in cellular and mouse models, chromosome 21 does not encode any canonical components of the SHH pathway. To identify chromosome 21 genes that inhibit SHH signaling, we overexpressed 163 chromosome 21 cDNAs in a series of in vitro and in vivo screens. Chromosome 21 cDNAs that affected SHH signaling in two luciferase reporter lines (Shh-LIGHT2 and SmoA1-LIGHT) and in developing zebrafish embryos were further screened in a SHH-dependent cell-based assay of osteoblast differentiation. Next, cDNAs that consistently up- or downregulated SHH signaling were overexpressed in primary cerebellar granule cell precursors using lentiviral transduction. Our series of screens identified four candidate genes (*B3GALT5*, *ETS2*, *HMGNI*, and *MIS18A*) that inhibit the proliferation of granule cell precursors when overexpressed, which is a finding that is directly relevant to Down syndrome-associated cerebellar hypoplasia. We also confirmed overexpression of trisomic candidate genes with bulk RNA-seq of postnatal day 6 (P6) cerebellum in four Ts65Dn pups (stock #001924), four TcMAC21 pups (stock #035561), and eight euploid littermates. Our study indicates that overexpression of some chromosome 21 genes, including *DYRK1A*, activates SHH signaling whereas overexpression of other genes, such as *HMGNI* and *MIS18A*, inhibits SHH signaling. Moreover, overexpression of genes involved in chromatin structure and mitosis, but not genes previously implicated in ciliogenesis, regulates the SHH pathway. Because identifying which chromosome 21 genes modulate SHH signaling in vivo may suggest new therapeutic avenues for ameliorating Down syndrome phenotypes, we are currently assessing overexpression of top candidate cDNAs using zebrafish reporters of SHH activity.

Complex Traits Posters - Thursday

PB1564*. Parsing Transcriptomic and Variant Signatures in Tetrapartite Brain Regions Uncover a Collection of Novel Genes in the Neuropeptide-Neurotransmitter Axis Conferring Addiction Risk

Authors:

A. Veerappa, C. Guda; Univ. of Nebraska Med. Ctr., Omaha, NE

Abstract Body:

Chronic substance abuse is a neuropsychiatric disorder involving persistent craving, pleasure, and reward, ultimately progressing to addiction. The midbrain controls hunger, reward, and pleasure traits, whereas the dorsolateral prefrontal cortex (DLPFC) controls craving, decision making, and tolerance traits. In contrast, Nucleus Accumbens (NAc) controls feeding, sexual, reward, stress-related, and drug self-administration behaviors, while amygdala regulates emotion and memory. To understand these complex and dynamic events in the background of substance use disorders (SUDs), we performed transcriptome and variant calling approaches combined with a multi-pronged strategy involving transcriptome clustering, classification, and variant filtering. Distinct transcriptomic signatures were observed that were unique and shared across groups. Significant upregulations of genes *CSF3*, *GADD45B*, *SOCS3*, and *NPAS4* were observed in all three regions of midbrain, DLPFC, NAc and amygdala highlighting the presence of their respective traits (motivation, reward memory, and tolerance) in long-lasting maladaptations of neurocircuitry due to chronic substance abuse. Distinct mutational spectrum in genes *CCKAR*, *NPAS4*, *TACR1*, *TENM2*, *EGF*, *GRM4*, and *NPY2R* were identified in the regulatory axis conferring susceptibility towards experimentation, substance use, reward, tolerance, and dependency. By unraveling the transcriptomic and mutational signatures between midbrain, DLPFC, NAc and amygdala, our study advances the understanding of the biology of substance use and its progression towards addiction, providing potential stage-specific testable targets.

Complex Traits Posters - Wednesday

PB1565. Partitioned polygenetic risk scores of adipocyte marker genes and sex-specific GWAS variants explain sex-specific differences in abdominal obesity

Authors:

H. Huang^{1,2}, A. Kar¹, M. Deal¹, M. Alvarez¹, K. Mohlke³, K. Pietiläinen^{4,5}, M. Laakso⁶, J. Sinsheimer^{1,7}, P. Pajukanta^{1,2,8}; ¹Dept. of Human Genetics, David Geffen Sch. of Med. at UCLA, Los Angeles, CA, ²Bioinformatics InterDept.al Program, UCLA, Los Angeles, CA, ³Dept. of Genetics, Univ. of North Carolina at Chapel Hill, Chapel Hill, NC, ⁴Obesity Res. Unit, Res. Program for Clinical and Molecular Metabolism, Faculty of Med., Univ. of Helsinki, Helsinki, Finland, ⁵Obesity Ctr., Endocrinology, Abdominal Ctr., Helsinki Univ. Central Hosp. and Univ. of Helsinki, Helsinki, Finland, ⁶Dept. of Med., Univ. of Eastern Finland and Kuopio Univ. Hosp., Kuopio, Finland, ⁷Dept. of Computational Med., David Geffen Sch. of Med. at UCLA, Los Angeles, CA, ⁸Inst. for Precision Hlth.at UCLA, Los Angeles, CA

Abstract Body:

Abdominal obesity is a common sex-stratified complex disorder, investigated using waist-hip ratio adjusted for body mass index (WHRadjBMI) as a proxy. Previous genome-wide association studies (GWAS) have identified sex-specific loci and shown that WHRadjBMI GWAS loci are enriched for genes expressed in adipose tissue, suggesting that partitioning polygenetic risk scores (PRS) by sex based on both genetic and adipose cell-type-specific genes can inform us about the key genomic loci and genes driving the sex differences in abdominal obesity. To this end, we compared sex-stratified WHRadjBMI PRSs built using lassosum with split-validation on 3 sets of SNPs in the UK Biobank with 50% partitioning of the unrelated Europeans: 1) SNPs in cis-regions of sex-specific adipocyte marker genes, 2) sex-specific WHRadjBMI GWAS SNPs, and 3) full genome. To first identify sex-specific adipocyte marker genes, we assigned adipocyte marker genes in adipose single-nucleus RNA sequencing (snRNA-seq) data (n=15 Finns; 60% female), followed by replications (n=6 Finns; 50% female). We discovered 31 replicated sex-specific adipocyte marker genes, and built sex-specific adipocyte (SSA) PRSs using all SNPs (MAF>1%) in the cis-regions (+/-500kb) of these 31 genes (~117k SNPs), which explain 0.377% and 0.0642% of WHRadjBMI variance in females vs males. Next, we retrieved WHRadjBMI GWAS SNPs that are significant in females ($p < 5 \times 10^{-8}$) but not even nominally significant in males ($p \geq 0.05$) (4,002 unclumped SNPs), and vice versa (516 unclumped SNPs), from the GIANT Consortium GWAS summary statistics. These sex-specific GWAS (SSG) PRSs explain 4.46% of WHRadjBMI variance in females and 0.442% in males. When comparing these two partitioned PRSs, SSAs and SSGs, to the full genome (~8M SNPs), that explains 9.53% of WHRadjBMI variance in females and 2.77% in males, the female SSA PRS explains 2.77 times more of WHRadjBMI variance than expected by the number of covered loci, and the female SSG PRS, built with only 4,002 SNPs, explains almost half of the WHRadjBMI variance in the full genome PRS. The majority (81%) of the 31 SSA genes are correlated with insulin resistance (Q-value<0.05 for the Matsuda index) in the METSIM adipose bulk RNA-seq cohort (n=335). The adjacent and overlapped genes of the clumped SSG SNPs are enriched for a rheumatoid arthritis pathway (FDR=0.0294) by Webgestalt, and the SSG SNPs for 8 TF motifs by HOMER. Overall, we discover that the 31 adipocyte marker gene regions and sex-stratified GWAS loci explain more of abdominal obesity variance in females (4.84%) than males (0.51%), suggesting a larger role of environment and gene-environment interactions in male abdominal obesity.

PB1566. Patterns of human germline hypermutability identified with whole-genome sequencing

Authors:

S. Dong¹, A. Ljungdahl², G. B. Schwartz³, J. An⁴, D. Werling⁵, S. Sanders²; ¹Univ California San Francisco, San Francisco, CA, ²Univ. of California San Francisco, San Francisco, CA, ³Ann & Robert H. Lurie Children's Hosp. of Chicago, Chicago, IL, ⁴Korea Univ., Seoul, Korea, Republic of, ⁵Univ. of Wisconsin-Madison, Madison, WI

Abstract Body:

Germline mutations generate the substrate of evolution, however, a subset of these mutations lead to human disorders, including neurodevelopmental delay. Thus, factors such as parental age that influence germline mutation rate can have widespread impacts on childhood morbidity and mortality.

Here we report the detection of three individuals exhibiting germline hypermutability in an independent cohort including 3,736 offspring from 1,868 quartet families (two parents, two offspring) with whole-genome sequencing of blood-derived DNA, validated independently with PCR and Sanger sequencing. Two brothers both exhibit a three-fold excess of germline *de novo* single nucleotide variants (SNVs) enriched for paternal origin (96%) with similar mutational profiles and signatures (COSMIC signature SBS37) though no specific mutations are shared. This observation strongly suggests the presence of a risk factor in the father's germline, however phenotypic data did not report prior cancer diagnoses or use of chemotherapeutic medications. Analysis of the paternal WGS data did not identify a causal variant in a gene related to DNA repair of cancer risk.

The third offspring was found to have a novel pattern of postzygotic germline hypermutability. Unlike all previously reported cases, the excess mutations were predominantly small insertions and deletions (indels) with no clear bias in parental origin. The indels are enriched by COSMIC signature ID2 (T/A homopolymers). Analysis of the allele balance reveals a higher-than-expected fraction of both *de novo* SNVs and indels arising postzygotically, suggesting that the mechanism was not exclusive to indels. Finally, by leveraging the family-based two offspring design of the cohort to compare mutation rates between siblings, we demonstrate that, aside from paternal age, shared genetic or environmental factors have minimal contribution to population-wide germline mutation rates, suggesting that the germline may exhibit relative protection from mutagenesis.

PB1567. Pediatric Manifestations of Genetic Risk Factors for Polycystic Ovary Syndrome

Authors:

J. Zhu^{1,2,3}, A. U. Eliassen^{4,5}, I. M. Aris⁶, S. E. Stinson⁷, J-C. Holm^{7,8}, T. Hansen⁷, M-F. Hivert⁶, K. Bønnelykke⁴, J. N. Hirschhorn^{1,2,3,9}, Y-M. Chan^{1,2,3}; ¹Div. of Endocrinology, Boston Children's Hosp., Boston, MA, ²Programs in Metabolism and Med. and Population Genetics, The Broad Inst. of MIT and Harvard, Cambridge, MA, ³Dept. of Pediatrics, Harvard Med. Sch., Boston, MA, ⁴Copenhagen Prospective Studies on Asthma in Childhood Res. Ctr. (COPSAC), Copenhagen, Denmark, ⁵Dept. of Hlth. Technology, Section for Bioinformatics, Technical Univ. of Denmark, Kongens Lyngby, Denmark, ⁶Div. of Chronic Disease Res. Across the Lifecourse, Dept. of Population Med., Harvard Med. Sch., Harvard Univ. and Harvard Pilgrim Hlth. Care Inst., Boston, MA, ⁷Novo Nordisk Fndn. Ctr. for Basic Metabolic Res., Faculty of Hlth. and Med. Sci., Univ. of Copenhagen, Copenhagen, Denmark, ⁸The Children's Obesity Clinic, Dept. of Pediatrics, Copenhagen Univ. Hosp., Holbæk, Denmark, ⁹Dept. of Genetics, Harvard Med. Sch., Boston, MA

Abstract Body:

Background: Polycystic ovary syndrome (PCOS) is a common polygenic disorder of reproductive-age women that is associated with ovulatory dysfunction (irregular periods), hyperandrogenism (increased levels and/or action of androgens such as testosterone), and cardiometabolic dysfunction (e.g., obesity and abnormal lipid levels). However, it is not known whether genetic risk factors for PCOS have manifestations in children. Proposed childhood precursors to PCOS include obesity and premature adrenarche, a common but poorly understood condition with early production of androgens from the adrenal glands. Indeed, girls with premature adrenarche often have a maternal history of PCOS, suggesting shared causal factors across these conditions. A polygenic risk score (PRS) from PCOS-associated genetic variants can be used to identify childhood precursors of this disorder. **Methods:** We used PRS-CS (continuous shrinkage) to optimize a PRS for PCOS in women from the UK Biobank, then to calculate PCOS PRSs for 5,968 children in the Avon Longitudinal Study of Parents and Children (ALSPAC). We used linear regression to assess for associations of the PCOS PRS with a proxy for premature adrenarche (age at pubarche, i.e., first appearance of pubic hair) and with measures of adiposity (body mass index [BMI] and total and trunk fat-mass indices) at ages 4 to 19 years. We sought to replicate associations between PCOS PRS and BMI in Copenhagen Prospective Studies on Asthma in Childhood (COPSAC; N=450), Project Viva (N=512), and The HOLBAEK Study (N=4,005). **Results:** Children who carried a high PCOS PRS had a younger age at pubarche (estimated effect size per 1 SD increase in PRS=-1.0 month, $p=0.001$), higher BMI SD score (SDS) as early as 7 years of age (estimated effect size per 1 SD increase in PRS=+0.04 BMI SDS, $p=0.003$), and higher total-body and trunk fat mass indices at 9 years of age (estimated effect size per 1 SD increase in PRS=+0.017, $p=7 \times 10^{-8}$ and +0.009, $p=3 \times 10^{-8}$, respectively). The association between PCOS PRS and BMI SDS replicated in Project Viva and HOLBAEK but not in COPSAC (estimated effects per 1 SD increase in PRS = +0.15, +0.15 and -0.05, 1-tailed $p=0.0023$, 5×10^{-10} and 0.17, respectively). **Conclusions:** PCOS genetic risk factors are associated with cardiometabolic and androgenic phenotypes in children. Thus, genetic risk factors for PCOS, a disorder of reproductive-age women, can result in early perturbations in yet-to-be-determined biological pathways that underlie PCOS in children. Future dissection of the underlying molecular pathways will inform strategies to prevent, halt, and reverse these perturbations before the development of PCOS and its related conditions.

PB1568. Perceived benefits and barriers to implementing polygenic risk scores in primary care: results of a national physician survey

Authors:

J. Vassy^{1,2,3}, B. Kerman⁴, A. A. Lemke⁵, M. Clayman^{6,7}, K. MacIsaac¹, E. Harris¹, A. Antwi⁸, T. Yi⁸, C. A. Brunette⁹; ¹Harvard Med. Sch. at VA Boston Hlth.care System, Boston, MA, ²Brigham and Women's Hosp., Boston, MA, ³Precision Population Hlth., Ariadne Labs, Boston, MA, ⁴Brigham and Womens Hosp., Boston, MA, ⁵Norton Children's Res. Inst., Affiliated with the Univ. of Louisville Sch. of Med., Louisville, KY, ⁶UMass Chan Med. Sch., Worcester, MA, ⁷Ctr. for Hlth.care Organization & Implementation Res., Bedford, MA, ⁸VA Boston Hlth.care System, Boston, MA, ⁹VA Boston Hlth.care System, Mission, KS

Abstract Body:

Background: Implementation of polygenic risk scores (PRS) into routine preventive medicine will depend in part on the clinical utility and barriers primary care physicians (PCPs) perceive to their use. Methods: We used a national online survey to ask PCPs about 1) their perceived utility of PRS for individual preventive actions; 2) their perceived benefits of PRS; and 3) their perceived barriers to PRS implementation. We performed latent class analysis (LCA) of the responses to identify unique subgroups of PCPs based on similarities and differences in response patterns. Results: Among 369 PCP respondents nationally (open rate 10.8%; participation rate 96.3%; completion rate 92.9%), mean (SD) age was 55.1 (13.0) years; 137 (37.3%) were women; mean (SD) time since medical school graduation was 27.3 (13.3) years; 73 (19.9%), 12 (3.2%), and 232 (63.2%) reported Asian, Black/African American, and White race, respectively; and 15 (4.1%) reported Latinx/Hispanic ethnicity. The majority (63%-93%) agreed they would use PRS for all 3 classes of preventive actions queried (disease screening procedures, preventive medications, and lifestyle modification), except for using a low-risk PRS to identify patients who might be able to delay/discontinue lifestyle modification (41% agreeing). Across composite scores associated with the 3 classes of preventive actions, respondents endorsed stronger preference for taking earlier/more intensive action for high-risk patients than with delaying/discontinuing action for low-risk patients (signed rank $p < 0.001$). Respondents most often chose out-of-pocket costs (48%), lack of clinical guidelines (24%), and patient insurance discrimination (22%) as extreme barriers to PRS implementation. LCA identified 3 subclasses of PCP respondents. Skeptics ($n=83$, 22.6%) endorsed less agreement with individual clinical utilities, saw patient anxiety and insurance discrimination as significant barriers, and agreed less often that PRS could help patients make better health decisions. Learners ($n=134$, 36.5%) and believers (150, 40.9%) generally expressed similar levels of agreement that PRS had utility for preventive actions and that PRS could be useful for patient decision-making. Compared with believers, however, learners perceived greater barriers to the clinical use of PRS and were most likely to see the lack of clinical guidelines for PRS as a significant barrier. Conclusion: Variation in how PCPs perceive the benefits and barriers for the clinical implementation of PRS suggests tailoring implementation strategies to specific needs and concerns.

Complex Traits Posters - Thursday

PB1569. Performance of externally developed polygenic risk scores in the All of Us Research Program Database

Authors:

L. Hull¹, B. Truong², P. Natarajan¹; ¹Massachusetts Gen. Hosp., Boston, MA, ²Broad Inst. of MIT and Harvard, Cambridge, MA

Abstract Body:

Background: Polygenic risk scores (PRS) have been developed and validated in diverse datasets globally. The All of Us (AoU) Research Program is a novel biobank recruiting diverse U.S. adults. We described the performance of PRS in AoU, using coronary artery disease (CAD), celiac disease, and body mass index (BMI) as examples.

Methods: The Polygenic Score (PGS) Catalog contains a repository of PRS developed to date, including metadata allowing for these scores to be replicated. We computed 26 CAD scores, 10 celiac disease scores and 22 BMI scores for the AoU participants with genetic data available in the V5 data release. We evaluated common predicted genetic ancestries available in AoU with probability higher than 90% and the PGS Catalog including European, African, East Asian and Latino/Admixed American.

For each ancestry, we performed quality control for the genotype data in AoU, we removed variants with genotype rate <95%, Hardy-Weinberg equilibrium p-value <10⁻¹⁴ and minor allele frequency <1%. CAD and celiac cases were defined using diagnostic codes; CAD cases also included those with relevant procedural codes or self-reported personal history of MI or CAD. BMI came from direct measurements of non-pregnant participants. The prediction accuracy was estimated by Nagelkerke R² for disease phenotypes and partial R² for continuous phenotypes adjusted for age, sex and 10 principal components of ancestry.

Results: The prediction performance for CAD and celiac disease, respectively, were 0.026 (95% CI 0.02-0.031) and 1x10⁻⁴ (95% CI 0 - 2.8x10⁻⁴) for European, 0.006 (95% CI 0.001-0.012) and 9.2x10⁻⁵ (95% CI 0 - 2.4x10⁻⁴) for African, 0.019 (95% CI 0-0.044) and 7.4x10⁻³ (95% CI 4.1x10⁻⁴ - 1.4x10⁻²) East Asian, and 0.015 (95% CI 0.006-0.025) and 1.74x10⁻⁴ (95% CI 0 - 5.3x10⁻⁴) for Latino/Admixed American. For body mass index, we observed that the partial R² for European, African, East Asian, and Latino/Admixed American were 0.118 (95% CI 0.113-0.123), 0.022 (95% CI 0.018-0.026), 0.07 (95% CI 0.054-0.087) and 0.075 (95% CI 0.067-0.082), respectively.

Conclusion: We highlighted the utility of PGS catalog to estimate PRS in a novel independent sample, demonstrating a variety of performances by different methods. Benchmarking PRS allows for direct comparison of performance measures in diverse populations.

Complex Traits Posters - Wednesday

PB1570. Phenome-wide analyses with nonsynonymous variants in *SOS2* demonstrate remarkable pleiotropic associations in the UK Biobank

Authors:

S. Bruse, D. Jakubosky, G. McInnes, B. Gonzalez, Z. Romer, N. Karra, A. Leverentz, B. Cajes, O. Gottesman; Empirico Inc., San Diego, CA

Abstract Body:

Large-scale biobanks linked with rich phenotypic information enable the unbiased evaluation of associations between sequence variants and thousands of phenotypes. Such phenome-wide association studies (PheWAS) can improve our understanding of the biological functions of a given gene and facilitate the prioritization of potential therapeutic targets by revealing pleiotropic associations across comorbidities and with diseases previously considered distinct. Utilizing data from 452,401 individuals in the UK Biobank, we identified two independent missense variants (P191R, AAF=0.01 and L183F, AAF=0.001) located in the same domain of the *SOS2* protein, that individually and collectively demonstrate protective associations across a broad range of cardiometabolic diseases and traits in a PheWAS. A burden test aggregating carriers of these two variants is significantly associated with decreased urate ($p=6.17E-14$, $\beta=-0.009$), increased eGFR ($p=3.94E-12$, $\beta=0.066$), decreased systolic ($p=4.82E-18$, $\beta=-0.006$) and diastolic ($p=8.82E-20$, $\beta=-0.006$) blood pressure, decreased ALT ($p=8.99E-24$, $\beta=-0.019$) and AST ($p=1.35E-31$, $\beta=-0.013$), decreased BMI ($p=3.13E-08$, $\beta=-0.050$) and body fat % ($p=5.57E-12$, $\beta=-0.007$), and with decreased HbA1C ($p=3.63E-12$, $\beta=-0.003$). We observe several significant, suggestive and nominal protective associations with related clinical diagnoses, including gout, chronic kidney disease, hypertension, cerebrovascular disease, non-alcoholic fatty liver disease and type 2 diabetes. The *SOS2* burden was also associated with protection from a range of ophthalmic phenotypes, including decreased intraocular pressure, decreased risk of glaucoma and decreased risk of macular degeneration. Region-wide conditional analyses confirmed that P191R is the lead variant across the multitude of associations observed. *SOS2* is a ubiquitously-expressed guanine nucleotide exchange factor that activates small GTPases such as RAS and RHO, implicating multiple signal transduction pathways that are plausibly related to these pleiotropic associations. Based on traits characteristic of Noonan syndrome (caused by *SOS2* gain-of-function mutations) and on *Sos2* KO mouse phenotypes, we hypothesize that P191R and L183F result in *SOS2* loss-of-function. Ongoing work seeks to experimentally characterize the effects of these variants on *SOS2* function, downstream signal transduction pathways and disease pathophysiology; with the aim of mimicking these protective genetic effects with a therapeutic molecule. This research has been conducted using the UK Biobank Resource under Application Number 34229.

Complex Traits Posters - Thursday

PB1571*. Phenome-wide association studies of deleterious variants in the Han Taiwanese people

Authors:

W-Y. Ko¹, Y-H. Io¹, Y-H. Yeh¹, M-L. Kang¹, H-H. Lee¹, W-C. Tseng², J-H. Loo³, D-C. Tarn²; ¹Natl. Yang Ming Chiao Tung Univ., Taipei, Taiwan, ²Taipei Veterans Gen. Hosp., Taipei, Taiwan, ³Mackay Mem. Hosp., New Taipei City, Taiwan, Taiwan

Abstract Body:

The success of precision medicine relies on a comprehensive collection of interpreted genetic profiles and other health records. However, ~80% of genome-wide association studies of common diseases focused on the populations of European ancestry. It is uncertain to what extent can these findings be translated into the healthcare system for the non-European populations. Here, we examined the allele frequency distributions (AFD) of single nucleotide variants (SNVs) in 23,991 genomes of the Han Taiwanese people for a total of 14,555,421 imputed SNVs that were pre-grouped based on their CADD (Combined Annotation-Dependent Depletion) scores. We next performed phenome-wide association analyses (with 27 cardiovascular metabolic-related traits) for a subset of SNVs (36,575) that were identified as deleterious mutations by comparing their AFD with those of synonymous and nonsynonymous mutations. As a result, 161 significant associations in 110 SNVs were identified in 24 traits. Among them, 84 SNVs are newly identified from this study. In particular, we have identified six variants with strong effect sizes ($|\beta| > 0.7$), located at *APOB*, *OR51L1*, *SLC22A12*, *MAP3K11*, *PGAP6* and *LDLR*. Among them, rs144467873 and rs200990725 are associated with cardiovascular-related traits, rs147341630 and rs375498857 are associated with hematologic traits, and rs200104135 and rs202052634 are associated with chronic kidney-related traits. Our results facilitate genetic profiling of several common disease susceptibilities particularly for the populations of Han ancestry.

Complex Traits Posters - Wednesday

PB1572. Phenome-Wide Association Study (PheWAS) investigates the role of long-read discovered structural variants in cardiovascular disease risk in the UK Biobank using an imputation framework

Authors:

A. Basile¹, M. Byrska-Bishop¹, W. Clarke^{1,2}, U. S. Evani¹, A. Corvelo¹, J. Ebler³, T. Marschall³, G. Narzisi¹, M. Zody¹; ¹New York Genome Ctr., New York, NY, ²Outlier Informatics Inc, Saskatoon, SK, Canada, ³Heinrich Heine Univ., Düsseldorf, Germany

Abstract Body:

Structural variants (SVs) are chromosomal rearrangements larger than 50bp and include deletions, insertions, duplications and inversions. SVs account for a 3-10 times greater genetic difference between individual human genomes than single nucleotide variants (SNVs) and are hypothesized to have higher impact on gene function, regulation and phenotypic change. SVs are 3-fold more likely to associate with a genome-wide association study signal as compared to SNVs. SV characterization has lagged behind other genetic variation due to prohibitive sequencing costs and challenges in discovery and genotyping. While costs have dropped, reference imputation panels still provide an effective and commonly used means of increasing variant density and diversity in an array study. However, the majority of reference panels are restricted to SNVs. Herein, we use an imputation framework to investigate the cardiovascular disease burden of common SVs, which have largely been missed by traditional SNV-based association studies. First, we generated an imputation panel using previously released SNV ($n > 59,000,000$), INDEL ($n > 650,000$) and SV ($n > 20,000$) calls from the 1000 Genomes Project (1kGP) for 3,202 samples. SNV genotype calls were generated with GATK HaplotypeCaller using the high coverage Illumina 1kGP WGS data, and SVs/INDELs were genotyped in the same short-read data using variants discovered in 34 long-read sequenced samples with PanGenie. PanGenie is a graph-based method that improves short-read genotyping by leveraging assembly-based reference haplotypes and sequencing reads and achieves better genotype concordance compared to mapping-based approaches. To generate an integrated panel, we merged high-quality SV/SNV/INDEL calls and performed phasing using SHAPEIT. This panel was then used to impute high-quality genotype array data in 487,908 UK Biobank samples using Eagle2 and Minimac4. Imputation performance evaluations with an SV truth set show that SVs are imputed with an accuracy comparable to SNVs at common allele frequencies, $AF > 5\%$, but with lower accuracy at rare sites. Finally, we present results from a cardiac trait PheWAS examining the association between well-imputed SVs ($r^2 > 0.3$) and cardiovascular disease using SAIGE. Assessed cardiac traits include ischemic heart disease, myocardial infarction, atrial fibrillation, cholesterol levels and others. Overall, this work presents a framework for assessing a historically under-studied form of genetic variation. We demonstrate the accuracy of imputing SVs from a diverse panel and assess the implications of structural variation on cardiovascular disease risk.

Complex Traits Posters - Thursday

PB1573*. Phenome-wide perspective into the role of Finnish Y chromosome variation in complex diseases

Authors:

A. Preussner¹, J. Leinonen¹, S. Luo¹, P. Palta¹, FinnGen, M. Pirinen^{1,2,3}, T. Tukiainen¹; ¹Inst. for Molecular Med. Finland (FIMM), Helsinki, Finland, ²Dept. of Publ. Hlth., Faculty of Med., Univ. of Helsinki, Helsinki, Finland, ³Dept. of Mathematics and Statistics, Univ. of Helsinki, Helsinki, Finland

Abstract Body:

The Y chromosome (chrY) is routinely excluded from genetic association studies due to the peculiar biology and analytical challenges specific to chrY. Consequently, potential impacts of chrY genetic variation on complex disease remains largely uncharacterized. To broadly investigate the impacts of chrY variation on complex disease, we examined FinnGen project data (R7) for 72,198 Finnish male samples, genotyped on arrays with sufficient number of chrY markers. We studied associations for 517 diverse health registry endpoints, both on the chrY haplogroup-level (including Finnish main haplogroups N1a1, I1, R1a, and R1b) as well as using other available chrY variants (N=347 after quality control), with MAF ranging from 7.6e-5 to 0.39. At the haplogroup-level, we observed 35 suggestive associations ($p < 0.05/4$), of which 16 involved cardiovascular diseases. These included risk-increasing effects for haplogroup I1 and cardiovascular diseases, such as myocardial infarction (MI) (OR=1.10, $p=0.006$), an association which replicated in a meta-analysis with the UK Biobank (OR=1.07, $p=0.0026$) regardless of the vast differences in haplogroup distributions between Finland and the UK. In the variant-level analysis, we observed one significant association ($p < 0.05/27/517$) to glaucoma (OR=1.58, $p=3.0e-6$) for a low-frequency variant correlating with haplogroup I1 ($R^2=0.12$). Moreover, we observed 345 suggestive associations ($p < 0.05/27$) for various disease categories. To further understand the contribution of the chrY variation to complex disease, we used these data and MI as an example to estimate the expected number of discoveries for chrY. Although with our sample size we were well-powered to detect effects for GWAS top loci, the small size of chrY (estimated 27 independent loci in our data) makes it unlikely to discover significant associations for MI or any other single endpoint, assuming the same density of associations and effect sizes in chrY as in autosomes. Given the 517 endpoints examined, we extrapolate we nevertheless should have detected at least five chrY associations in the PheWAS. As we find fewer, it is possible that the potential phenotype effects in chrY are smaller and require larger sample sizes to be detected. We are therefore extending the study to FinnGen R9 (N>100,000 males) in the coming months. These results highlight that chrY may harbor genetic variation related to complex disease risk in Finland, yet validation in larger data sets and with further chrY variants (particularly related to N1a1) are required. Overall, our work serves as the first step towards comprehensive understanding of the role of chrY variation in complex diseases.

Complex Traits Posters - Thursday

PB1574. Phenome-wide PGS portability in the Colorado Center for Personalized Medicine biobank suggests overlooked challenges in diverse populations

Authors:

M. Lin¹, C. H. Arehart¹, N. Rafaels¹, K. Crooks¹, N. Pozdeyev¹, A. Hendricks², S. Raghavan¹, C. R. Gignoux¹, CCPM Clinical PRSUIT Working Group; ¹Univ. of Colorado Anschutz Med. Campus, Aurora, CO, ²Univ. of Colorado Denver, Denver, CO

Abstract Body:

The potential of polygenic scores (PGS) to improve health-related personalized risk prediction is highly promising. Yet, their transportability across populations remains largely poor. With increasingly powered association results available as an abundant resource for PGS, limited studies have empirically and comprehensively examined the landscape of current PGS transportability across a phenome-wide range of conditions. Here, we leverage >600 scores from the PGS Catalog to assess systematically the performance of PGS prediction on >1k electronic health record (EHR) phenotypes in the Colorado Center for Personalized Medicine Biobank, totaling 661,265 predictions. To analyze heterogeneity across populations we stratified 33,863 individuals from six genetically defined ancestry groups (European, African/African American, Hispanic/Latino, East Asian, South Asian, Middle Eastern). Some diseases are found reasonably well predicted by PGSs together with demographic covariates, such as type 2 diabetes (T2D) and hypertension ($P=2.7e-170$ and $1.1e-164$, $AUC=0.77$ and 0.81), with the top scoring ~4% and ~3% of individuals in the biobank having $OR>3$, respectively. However, the majority of predictions have considerable cross-group heterogeneity in performance (average $I^2=0.18$ in phecode~PGS pairs with $FDR<0.1$). This can greatly affect potential use in personalized medicine as well as bias downstream interpretation in such frameworks as Mendelian Randomization. Additionally, we found that the choice of PGS unit of measure, when comparing association statistics per SD or using the top decile against the remainder, yielded highly discordant estimates of heterogeneity ($r=0.29$). Using multilevel nested mixed models, we found primary influences on heterogeneity include the distribution of disease prevalence between ancestry groups in the test cohort, in addition to other features of both the test and training sets, such as methods of score development and allele frequency distribution in CCPM. Our results suggest that there are important consequences of applying PGS to downstream applications that assume causality that only stem from homogeneous predictions across ancestry groups. We describe some of these efforts particularly in the space of metabolic syndrome phenotypes across ancestry groups. The overlooked attributions can be determined empirically and are due to both characteristics of the training and test settings. This provides a description of hopes and pitfalls in the current efforts of applying PGS resources to diverse populations.

Complex Traits Posters - Thursday

PB1575. PLA2G6 associated late onset Parkinson's disease in a Sudanese family: A case report.

Authors:

Y. Bakhit^{1,2}, K. Eltom³, O. Seidi³, Sudan Neuroscience Projects (SNPs)- Parkinson study group, U. Wuellner¹; ¹Univeristy of Bonn, Bonn, Germany, ²Univ. of Khartoum, Khartoum, Sudan, ³Univeristy of Khartoum, Khartoum, Sudan

Abstract Body:

Phospholipase A2 gene encode a class of enzyme that catalyse the hydrolytic release of fatty acids from phospholipids. It is expressed in the Brain and its protein product; iPLA2- β is abundant in the nerve terminals and dendrites of the brain. In its early stage, PLA2G6 associated Autosoma recessive early onset Parkinson's disease patients exhibit Bradykinesia and lower limb tremor, hypomimia and gait disturbance. In this study, two siblings were born to first-degree consanguineous parents were recruited. Symptoms appeared first of 58 and 60 years, respectfully and started as a resting tremor in his right arm, which regressed in three years and became bilateral, with a generalized slowness of movement and rigidity. Saliva samples were donated for targeted next generation sequencing. We found two compound heterozygous mutations in PLA2G6; onr deletion (NM_003560: c.2070_2072del) and one missense (NM_003560: c.956C>T), where the in-frame mutation is known to be pathogenic and is associated with Infantile Neuroaxonal dystrophy. This is considered the first case of late onset Parkinson's disease associated with PLA2G6, adding to the growing complex phenotypes of PLA2G6 associated neurodegeneration.

Complex Traits Posters - Wednesday

PB1576. Polycystic Ovarian Syndrome Physiologic Pathways Implicated Through Clustering of Genetic Loci.

Authors:

M. Stamou¹, K. Smith¹, H. Kim¹, R. Balasubramanian¹, K. Gray², M. Udler¹; ¹Massachusetts Gen. Hosp., Boston, MA, ²Brigham and Women's Hosp., Boston, MA

Abstract Body:

Introduction: Polycystic ovarian syndrome (PCOS) is a phenotypically and genetically heterogeneous disorder. Despite several genomic loci associated with PCOS, the relationship of these loci to disease pathogenesis remains largely unknown. In this study, we utilized soft clustering to identify genetic pathways of PCOS. **Methods:** To identify novel genetic clusters, variant-trait association clustering was performed for 51 PCOS-associated genetic variants and 50 GWAS traits using bNMF clustering. We then generated PCOS partitioned polygenic scores (pPS) using the strongest weighted loci in each cluster and tested for associations with clinical features in participants of the Mass General Brigham Biobank [MGBB, N=28,282 (14,855 female and 13,427 male)]. Additionally, associations with metabolic/cardiovascular clinical outcomes were assessed using GWAS for type 2 diabetes/T2D (DIAMANTE, N=898,130) and coronary artery disease/CAD (CARDIOGRAM/UKBB, N=547,261). **Results: Four variant-trait clusters of PCOS were identified with three having clear physiological mechanisms:** (i) Cluster 1/**obesity** (top loci include *FTO*, *ERBB3*); (ii) Cluster 2/**hormonal** changes (top loci include *FSHB*, *WT1*); (iii) Cluster 3/**inflammatory** markers (top loci include *ATXN2/SH2B3*); (iv) Cluster 4/**Unknown** (top loci include *MAF*, *SLC38A11*). The 51-SNP full pPS was associated with increased risk of PCOS (OR 1.17, p=0.003) in MGBB females. **Cluster pPS's were associated with distinct clinical traits in MGBB participants:** Cluster 1 with increased BMI (p=3.20x10⁻⁷), triglycerides (p=0.003), and systolic blood pressure (p=0.009); Cluster 2 with reduced FSH levels (p=0.009); and Cluster 3 with increased platelet count (p=0.017). Finally, **PCOS genetic clusters were associated with disease outcomes in GWAS and MGBB:** Cluster 1 pPS with increased the risk of T2D (OR 1.04, p=8.48 x 10⁻³⁰) and CAD (OR 1.01, p=0.012) in GWAS, with replication of the former in MGBB (OR 1.11, p=8.99x10⁻⁶). In contrast, Cluster 2 pPS was associated with decreased T2D risk (OR 0.98, p-value=3.37x10⁻⁴) in GWAS, with directional replication in MGBB (OR 0.98, p=0.4). **Conclusions:** Our analysis identified distinct genetic clusters with PCOS-associated biologic pathways. Cluster 1 pPS was associated with increased the likelihood of T2D and CAD, highlighting the genetic predisposition of patients with PCOS and obesity to cardiometabolic disease. In contrast, pPS linked to hormonal changes led to a decreased risk for T2D, suggestive of the protective nature of these genetic loci. Thus, distinct genetic backgrounds in PCOS individuals may underlie the clinical heterogeneity and long-term outcomes in PCOS.

Complex Traits Posters - Thursday

PB1577*. Polygenic burden of major depressive disorder and suicidality in children of diverse ancestries: a US-population-based study

Authors:

P. Lee^{1,2}, M. D. Silberstein³, J-Y. Jung⁴, T. Ge^{1,2}, R. C. Kessler², R. Perlis^{1,2}, J. W. Smoller^{1,2}, M. Fava^{1,2}; ¹Massachusetts Gen. Hosp., Boston, MA, ²Harvard Med. Sch., Boston, MA, ³Univ. of Wisconsin Sch. of Med. and Publ. Hlth., Madison, WI, ⁴Stanford Univ., Stanford, CA

Abstract Body:

Background: The increasing rate of suicide among racial/ethnic minority children is a serious public health concern in the US. The aggravating role of several environmental factors, including structural racism, has become evident. In contrast, little is known of whether and if so, how genetic risk contributes to increasing suicide risk among children. Here we examined whether polygenic risk of major depressive disorder (MDD) is associated with suicidality among US children, especially those in underrepresented racial/ethnic groups. **Methods:** Our cross-sectional study investigated year 2 data from the Adolescent Brain and Cognitive Development (ABCD) study. Lifetime experiences of suicidality, including suicidal ideation, planning, and attempts, were assessed using the Kiddie Schedule for Affective Disorder and Schizophrenia. Children's ancestry-specific polygenic risk scores (PRSs) for MDD were calculated using a newly developed Bayesian PRS construction method, PRS-CSx, and four independent GWASs representing diverse ancestral groups (total sample N=1,186,500). Logistic regression analysis was used to examine the association of genetic risk and suicidality. **Results:** After rigorous quality control of genotype data, we identified 1,675 ABCD participants of African ancestry (AA), 1,630 of Hispanic ancestry (HA) and 4,344 European ancestry (EA). All children were un-related (total N=7,649, mean age 11.920.61, 47.33% female). Suicidality was most common among AA children (N=392, 24.0%), followed by EA (N=1,004, 23.1%) and HA (N=367, 21.9%). After multiple testing correction, we found statistically significant associations between MDD PRSs and suicidality in EA children (OR=1.2, 95% CI=1.12-1.29, p -value= 3.40×10^{-7} , FDR $q=3.06 \times 10^{-6}$), with notably stronger genetic effects among females compared to males (Nagelkerke's R^2 1.62% vs. 0.50%). We also found a statistically significant association between MDD PRSs and suicidality in female HA children (OR=1.26, 95% CI=1.05-1.51, $R^2=1.30\%$, p -value= 1.33×10^{-2} , $q=2.99 \times 10^{-2}$). These associations were mediated in part by children's internalizing problems, and remained significant after adjusting for children's puberty, sociodemographic backgrounds, and family history of mental health problems. **Conclusion:** In the largest genetic sample of US children, we observed a significant genetic association between MDD and childhood suicidality, particularly among females of EA and HA ancestry. Along with thorough ethical considerations, future efforts are warranted to investigate the clinical utility of various risk factors, including genetic PRSs, for mitigating suicide risk in children.

Complex Traits Posters - Wednesday

PB1578. Polygenic risk and complex trait prediction for East Asians using the Taiwan Precision Medicine Initiative and Taiwan Biobank datasets (N = 500k).

Authors:

P-Y. Kwok^{1,2}, C-Y. Chou¹, T. G. Raben³, **C-H. Chang**⁴, E-C. Yeh¹, E. Widen³, C-H. Chen¹, S. Hsu³; ¹Inst. of BioMed. Sci., Academia Sinica, Taipei, Taiwan, ²Cardiovascular Res. Inst. and Inst. for Human Genetics, Univ. of California, San Francisco, San Francisco, CA, ³Michigan State Univ., East Lansing, MI, ⁴Dept. of Med., Univ. of California San Francisco, San Francisco, CA

Abstract Body:

The Taiwan Precision Medicine Initiative (TPMI) and the Taiwan Biobank (TWB) are nation-wide projects which have, in aggregate, recruited, phenotyped, and genotyped (using a custom Thermo Fisher Scientific Axiom SNP array) over 500k individuals of Han Chinese ancestry, and plan eventually to have a sample size in the millions. This is the largest non-European cohort for common disease risk prediction. Here, we introduce the TPMI and TWB projects and report preliminary results on polygenic risk prediction of major diseases and complex traits. PRS were trained using TPMI and TWB data. The strength of prediction is validated in holdback samples from this population, using sibling pairs as well as unrelated individuals. Further validation is performed using Chinese ancestry individuals from UK Biobank and in distant ancestry groups such as Europeans. We examine conditions such as Asthma, Gout, Hypertension, CAD, Hyperlipidemia, Diabetes, and more. We report AUCs above 0.6, using only genetic information, which are comparable to those obtained from state-of-the-art PRS for Europeans trained and validated in European populations. Incorporating other risk factors (age, sex, etc.) leads to AUCs above 0.75. The top 3-5% PRS lead to a 5x odds ratio for some conditions and rival even large effects from single gene mutations. These are the first examples of parity between PRS in European and non-European populations, and hence represent an important advance toward Equity and Diversity in genomic science. We also discuss the performance of Taiwan-trained PRS in distant populations and compare with the European-trained case. We explore the similarities and differences in genetic architecture between Taiwan- and European-trained PRS. This study serves as a model and establishes a path for PRS development in non-European populations.

Complex Traits Posters - Thursday

PB1579. Polygenic risk burden is associated with early psychosis and endophenotypes of psychotic disorders

Authors:

T. Warren¹, J. D. Tubbs², M. B. Corona¹, P. Singh³, V. Zarubin³, S. Morse⁴, T. A. Lesh³, C. S. Carter³, P. C. Sham², A. S. Nord¹; ¹UC Davis Ctr. for NeuroSci., Davis, CA, ²Dept. of Psychiatry, Univ. of Hong Kong, Hong Kong, Hong Kong, ³UC Davis Imaging Res. Ctr., Sacramento, CA, ⁴Washington Univ. in St. Louis, St. Louis, MO

Abstract Body:

Understanding the links between genetic risk, neurological phenotypes, and clinical symptom presentation is a primary goal for psychiatric genetics researchers and has motivated efforts such as the NIMH's Research Domains Criteria initiative. To this end, we conducted a study on polygenic risk in patients being treated at the UC Davis Medical Center for early psychosis who had undergone psychiatric and neurological phenotyping as part of an ongoing research effort. For this study, we included 225 cases (22% female, average age 19.6) from this cohort who progressed to a diagnosis of a psychotic disorder, as well as 126 matched controls (42% female, average age 19.7) with no neurological or psychiatric diagnoses. Both cases and controls represented the population demographics of the area served by the UC Davis Medical Center. For all subjects, we analyzed DNA as well as global functioning, IQ, and task-based fMRI data. For psychosis subjects, we also looked at clinical ratings for positive symptoms, negative symptoms, and cognitive functioning. DNA was extracted from blood and genotyped on the Illumina Infinium PsychArray-24 kit, which tests for 271,000 variants and is enriched for psychiatric markers. Using the lasso method, we calculated schizophrenia (SZ) polygenic scores (PGSs) based on recent GWAS data from the Psychiatric Genomics Consortium. SZ PGS explained a significant portion of the variance in psychosis case versus control status in our cohort. SZ PGS was also significantly associated with IQ in all subjects and negative symptoms in bipolar disorder (BD) subjects. fMRI association analyses are ongoing. As a secondary, exploratory outcome, we defined pathways of genes involved in different neurotransmitter systems and calculated PGSs for these pathways. In these preliminary data, GABA PGS was associated with case versus control status and with IQ in psychosis cases. Glutamate PGS was associated with IQ in psychosis cases and with negative symptoms in BD subjects. Our findings extend PGS as a risk factor for early first episode psychosis, illuminate links between genetic burden and psychotic disorder endophenotypes, and build a case for further study of pathway-specific polygenic burden in the context of psychiatric symptoms.

Complex Traits Posters - Wednesday

PB1580. Polygenic risk for body mass index is associated with atypical antipsychotic induced weight gain.

Authors:

A. Justice¹, G. Chittoor¹, N. Josyula², R. A. J. Smit³, R. J. F. Loos³, R. Birnbaum^{4,5}, K. E. North⁶, K. L. Young⁶, O. A. Andreassen^{7,8}, A. E. Locke⁹, G. Nicol¹⁰, GIANT Consortium, DiscovEHR Collaboration, ORAcLE Consortium; ¹Dept. of Population Hlth.Sci., Geisinger, Danville, PA, ²Dept. of Population Hlth.Sci., Geisinger, Fremont, CA, ³The Charles Bronfman Inst. for Personalized Med., Mount Sinai Sch. of Med., New York, NY, ⁴Psychiatry, Mount Sinai Sch. of Med., New York, NY, ⁵Genetics and Genomic Sci., Mount Sinai Sch. of Med., New York, NY, ⁶Dept. of Epidemiology, Univ. of North Carolina, Chapel Hill, NC, ⁷NORMENT Ctr., Div. of Mental Hlth.and Addiction, Oslo Univ. Hosp., Oslo, Norway, ⁸Inst. of Clinical Med., Univ. of Oslo, Oslo, Norway, ⁹Regeneron Genetics Ctr., Tarrytown, NY, ¹⁰Dept. of Psychiatry, Washington Univ. Sch. of Med., St. Louis, MO

Abstract Body:

Obesity and its metabolic consequences contribute substantially to accelerated aging and reduced lifespan in psychiatrically ill individuals. The risk for antipsychotic induced weight gain (AIWG) is thought to be highly genetic, but our understanding of these contributors remains limited. Characterizing genetic variation influencing AIWG has the potential to identify those at greatest risk for weight gain and ensuing cardiometabolic dysregulation. Thus, we examined the relevance of polygenic risk scores (PRS) for cross-sectional body mass index (BMI) for predicting AIWG, measured as change in BMI, in the MyCode study population. We derived a PRS using the current interim GWAS of BMI by the GIANT consortium including >1.1 million European participants. PRS weights were estimated in SBayesR. The final PRS included 1,080,060 variants. To define AIWG, we restricted BMI measurements to those assessed during use of atypical antipsychotic medications, and used a linear mixed model where BMI was regressed with intercept and time (years) as both fixed and random effects to derive the slope of AIWG, stratified by sex and ancestry. Analyses were conducted for overall change in BMI and also restricted to gainers (i.e. positive AIWG slope). Associations between standardized PRS and AIWG were done using generalized linear models while accounting for families using GEE. All models were adjusted for baseline age, age², sex, baseline BMI, follow-up duration, and five principal components of ancestry. Incremental R² values were estimated in an unrelated subset of participants using linear regression. We also evaluated the association between PRS and baseline BMI. We identified 8,493 participants (97% European ancestry, 68% female, 61% gainers) with ≥ two BMI measures, with a mean (SD) of 33 observations (58), 3.7 yrs (3.7) of follow-up, and AIWG of 0.18 BMI/yr (0.93). The PRS was associated with baseline BMI (P=1e⁻³⁰⁵, β=4.03, R²=14.4%). We identified a significant association between the cross-sectional BMI PRS and overall AIWG (R²=0.3%, P=3.9e⁻⁸, β=0.069 BMI units/yr) and AIWG in gainers only (R²=0.3%, P=6.5e⁻⁶, β=0.051 BMI units/yr). Also, we observed a small, but significant difference (0.125 BMI/yr, P=2e⁻⁴) in adjusted mean AIWG between the lowest and upper quintiles of the PRS. Our study demonstrates that PRS derived from BMI GWAS can explain variation in AIWG. The finding that PRS is significantly associated with AIWG, shows a clear heritable component of this important side effect. While the gain in % variance explained in AIWG by the cross-sectional BMI PRS was small, it shows that genetic variation inducing AIWG exclusive of overall BMI may improve AIWG prediction.

Complex Traits Posters - Thursday

PB1581. Polygenic Risk score based phenome wide association study for Tourette Syndrome

Authors:

P. R. Jain¹, A. Topaloudi¹, T. Miller-Fleming², L. Davis², P. Paschou¹; ¹Purdue Univ., West Lafayette, IN, ²Vanderbilt Univ Med Ctr., Nashville, TN

Abstract Body:

Tourette Syndrome (TS) is a complex neurodevelopmental disorder characterized by vocal and motor tics lasting more than a year. It is highly polygenic in nature with studies identifying numerous genes and variants associated with the disorder. Epidemiological studies have shown TS to be correlated with various phenotypes and environmental factors but large-scale phenome wide analyses in biobank level data have not been performed for the disorder. Polygenic risk score (PRS) based Phenome Wide Association studies (PheWAS) have become an increasingly common method to identify different factors associated with the genetic risk of a complex diseases without requiring a prior assumption. In this study, we use the summary statistics from the latest meta analysis of TS to calculate the PRS of individuals in the UK Biobank data. We then use a PheWAS approach determine the association of disease risk with a wide range of phenotypes ranging from physical and mental health to lifestyle and sociodemographic factors. A total of 57 traits were found to be significantly associated with the Polygenic risk of TS risk. Multiple psychosocial factors and mental health conditions like anxiety disorder and depressive episode were significantly associated with TS risk. Additionally, significant associations were observed with other complex disorders like Type 2 Diabetes, heart palpitations and respiratory conditions. Cross disorder comparison with other Neurodevelopmental disorders like ADHD, ASD and OCD indicated an overlap in associations between TS and these disorders. ADHD and ASD had a similar direction of effect with TS while OCD had an opposite direction of effect for all traits except mental health factors. Sex specific PheWAS analysis identified differences in the associations with TS between males and females. Type 2 Diabetes and heart palpitations are significantly associated with TS risk in males and not in females, whereas diseases of the respiratory system are associated with TS risk in females and not in males. The results of these analyses identified multiple factors associated with the genetic risk of TS and sheds light on the shared genetic and phenotypic architecture of the different Neurodevelopmental disorders.

Complex Traits Posters - Wednesday

PB1582. Polygenic risk scores affected by different strategies of selection of relevant genomic positions and equations used for calculations

Authors:

J. Radvanszky^{1,2,3}, Z. Pös^{1,3}, M. Hlavacka⁴, A. Hurtuk⁵, O. Kubicka⁵, I. Lojova^{1,2}, J. Minarik², A. Zatkova¹, L. Kadasi^{1,2}, J. Gazdarica^{3,6}, J. Budis^{3,6}, T. Szemes^{3,2}; ¹Inst. of Clinical and Translational Res., BioMed. Res. Ctr. of the Slovak Academy of Sci., Bratislava, Slovakia, ²Dept. of Molecular Biology, Faculty of Natural Sci., Comenius Univ., Bratislava, Slovakia, ³Comenius Univ. Sci. Park, Bratislava, Slovakia, ⁴Dept. of Applied Informatics, Faculty of Mathematics, Physics and Informatics, Comenius Univ., Bratislava, Slovakia, ⁵Inst. of Informatics, Information Systems and Software Engineering, Faculty of Informatics and Information Technologies of Slovak Univ. of Technology in Bratislava, Bratislava, Slovakia, ⁶Slovak Ctr. of Scientific and Technical Information, Bratislava, Slovakia

Abstract Body:

After welding the ever increasing datasets of large scale genome-wide association studies (GWAS) for complex phenotypes with genomics options offered by massively parallel sequencing, especially whole-genome sequencing (WGS), studies describing polygenic risk score (PRS) calculations for different diseases started to appear rapidly. Effective and reliable PRS calculations, however, still pose several challenges, specifically when considering the vast variability and complexity of GWAS datasets and possible equations. We aimed, therefore, to characterize some of the practical challenges for potential implementation of PRS. We used whole-genome sequencing (WGS) data of 52 individuals, consisting of patients having ulcerative colitis (UC/IBD), their family members and control samples. To obtain final lists of genomic positions (GP-lists) for PRS, potentially relevant genomic positions associated with UC/IBD were extracted from the EMBL-EBI GWAS Catalog and further filtered using an in-house application according to different parameters. We generated several GP-lists, divisible into three main types: 1) Based on individual GWAS studies, extracting positions from single studies included in the GWAS Catalog; 2) Aggregated results of several GWAS studies generated by merging all the studies meeting the keywords of the disease/trait of interest (while these were further filtered using different variables to reach higher diversity of alternative lists); 3) Disease specific and previously validated PRS lists, which were obtained directly from relevant publications. PRS calculations were performed using five different equations (non-weighted sum, linear weighted model with OR, linear weighted model with logarithmic OR, PLINK and PRSice-2) for all of these lists. Results of our work proved that PRSs represent highly potent applications in genomics. On the other hand, their implementation poses certain challenges, which require not only further studies, but also careful standardization and increased awareness when evaluating the reliability of PRS outputs. Since many variables affect the PRS results, and many different data sources and filtering steps are necessary to find the best results when standardizing PRS calculations, automated but flexible algorithms may be very helpful, at least until standardized and validated PRS for each relevant disease/trait will be developed. Financial support: Slovak Research and Development Agency (APVV-18-0319), Scientific Grant Agency (VEGA_2/0167/20, VEGA_2/0040/20) and by the OP Integrated Infrastructure co-financed by the European Regional Development Fund (ITMS: 313011V578, 313011W428).

Complex Traits Posters - Thursday

PB1583. Polygenic risk scores for quantitative estimation of complex vitamin intake needs to lower homocysteine in the adult population: from population based to personalized dietary intake recommendations.

Authors:

J. Hager¹, N. Zubair², E. Scuccimarra¹, F. Salesses¹, K. Heim³, P. Kamani³, N. Morris²; ¹Nestle Inst. of Hlth.Sci., Lausanne, Switzerland, ²Nestle Hlth.Sci. - Atrium Innovations, Bridgewater, NJ, ³Nestle Hlth.Sci. - Atrium Innovations, Bridgewater, NJ

Abstract Body:

Cardiovascular disease (CVD) is one of the most frequent non-communicable diseases in the world. In the UK more than 20% of the adult population have at least one CVD related morbidity. Biochemical risk factors for CVD include high LDL, triglyceride and homocysteine levels. A large meta-analysis showed that a decrease in homocysteine under 11 mmol/l decreases the risk for ischemic heart disease and stroke by 16% and 24% respectively. Homocysteine is a metabolite of the 1-carbon cycle. Vitamins B9, B12, B6 and choline all play a vital role in 1-carbon metabolism and homocysteine homeostasis and supplementation with these vitamins has been shown to decrease homocysteine levels. However, supplementation trials have reported variable results in respect to both the degree of homocysteine lowering as well as CVD outcomes. One reason may be the poor correlation between vitamin intake and vitamin blood levels. Recent GWA studies have shown that genetic factors have a significant effect on the blood concentrations of all four of these vitamins as well as homocysteine. To better understand the impact of genetic factors on the variability of homocysteine levels in relation to vitamin intake, we created a polygenic risk score for homocysteine from GWAS catalog summary statistics that included 31 independent SNPs after LD pruning. The effect size for the PRS was estimated in an independent data set of 2000 subjects with homocysteine measurements and was significantly associated with homocysteine levels ($p=6.65E-11$). The observed PRS in the sample ranged from 17 to 44. Each additional risk allele resulted in an average increase of homocysteine plasma levels of 0.12 mmol/l, meaning that individuals in the high-risk group (34-44 risk alleles), show on average 4.7 mmol/l higher homocysteine levels than the general population (7.84 mmol/l). We then established an algorithmic dose-response model for the intake of vitamins B9, B12, B6 and choline on homocysteine levels conditioned on the PRS. A linear dose response regression model showed that 41% of the homocysteine plasma concentration variance is explained by age, sex, choline, folate, vitamin B6 and B12 intakes. The rest being attributable to the genetic terms and other non-identified co-factors. In summary, a polygenic risk score explains a significant part of the variability of homocysteine levels. The dose - response model shows that individuals with a high PRS have significantly increased intake needs to achieve homocysteine levels compared to low PRS individuals.

Complex Traits Posters - Wednesday

PB1584. Polygenic risk scores identify heterogeneity in disease diagnosis and treatment in asthma and COPD.

Authors:

M. Moll¹, J. Sordillo², A. Ghosh³, L. HAYDEN^{4,5}, G. McDermott¹, M. McGeachie¹, A. Dahlin¹, A. Tiwari⁴, A. Saferali⁶, S. Begum¹, J. Ziniti⁴, A. Gulsvik⁷, P. Bakke⁷, C. Irribarren⁸, C. Hersh⁴, J. Sparks¹, B. Hobbs⁴, J. Lasky-Su⁹, E. Silverman¹⁰, S. Weiss⁹, A. Wu², M. Cho¹¹; ¹Brigham & Women's Hosp., Boston, MA, ²Harvard Med. Sch., Boston, MA, ³SUNY Upstate Med. Ctr., Syracuse, NY, ⁴Brigham and Women's Hosp., Boston, MA, ⁵Boston Children's Hosp., Boston, MA, ⁶Brigham & Women's Hosp., Boston, MA, ⁷Univ. of Bergen, Bergen, Norway, ⁸Kaiser Permanente Northern California, Oakland, CA, ⁹Brigham & Women's Hosp, Boston, MA, ¹⁰Brigham & Women's Hosp, Boston, MA, ¹¹Brigham and Women's Hosp., Boston, MA

Abstract Body:

Rationale: Asthma and chronic obstructive pulmonary disease (COPD) have distinct and overlapping genetic and clinical features. Clinically, the diagnoses may co-occur as asthma-COPD overlap (ACO). We hypothesized that separate polygenic risk scores (PRSs) for asthma and COPD, constructed from recent large genome-wide association studies, would demonstrate variable associations with asthma and COPD diagnoses and treatments across research and clinical cohorts. **Methods:** We developed a novel asthma PRS (derived from clinical definitions) and used a previously-published COPD PRS (derived from spirometry), and we applied these PRSs to two research (COPDGene and CAMP, with available spirometry) and clinical (MGB Biobank and GERA; diagnosis using billing codes) studies. We assessed the association of each PRS with COPD and asthma diagnosis, ACO (defined as COPD subjects with a history of asthma diagnosed by a physician before 40 years of age), lung function trajectories, asthma exacerbations, and medication use. Models were adjusted for age, sex, smoking variables (when available), and genetic ancestry. **Results:** In 102,260 participants, the PRS_{Asthma} was weakly correlated with the PRS_{COPD} (mean $r = 0.0043$, $p=0.01$). In meta-analyses, the PRS_{Asthma} was associated with asthma (OR 1.16 [95% CI: 1.13 to 1.18]) and the PRS_{COPD} was associated with COPD (OR 1.25 [95% CI: 1.21 to 1.30]). However, these results were inconsistent across cohorts, with no association of the PRS_{COPD} with billing-code-defined COPD in clinical cohorts (GERA and MGB). In COPDGene non-Hispanic whites, the PRS_{COPD} was associated with ACO (OR 2.2 [95% CI: 2.0 to 2.5]) and asthmatics (diagnosed at age <40 years old) who developed moderate-to-severe airflow obstruction and emphysema (OR 1.59 [95% CI: 1.15 to 2.2]). In GERA asthmatics, both PRS_{COPD} and PRS_{Asthma} were associated with asthma exacerbations (Caucasians: OR 1.18 and OR 1.1, respectively). In GERA White asthmatics, the PRS_{Asthma} was associated with greater inhaled corticosteroid use (+4 days/year/SD) and the PRS_{COPD} with greater long-acting beta agonist use (+4.5 days/year/SD). Results in non-European populations were similar but with smaller effect sizes. **Conclusions:** Asthma and COPD polygenic risk scores predict disease status, asthma-COPD overlap, and medication use; however, disease associations differ in research versus clinical cohorts. These differences may be due to differences in disease pathophysiology or clinical / administrative practices.

Complex Traits Posters - Thursday

PB1585. Polygenic score for height influences adolescent growth spurt in Southwestern Indigenous Americans.

Authors:

M. Ramirez Luzuriaga, S. Kobes, L. Wedekind, W-C. Hsueh, L. Baier, W. Knowler, R. L. Hanson; NIDDK, Phoenix, AZ

Abstract Body:

A recent meta-analysis of genome-wide association studies (GWAS) from the Genetic Investigation of ANthropometric Traits (GIANT) consortium and UK Biobank (N \approx 700000) identified 3290 single nucleotide polymorphisms (SNPs) independently associated with adult height. However, it is unclear how these variants influence linear growth during adolescence. Moreover, most of the meta-analysis data come from European-ancestry cohorts with little representation of Indigenous Peoples. The current study used anthropometric and genotypic data from a longitudinal study of diabetes conducted in an Indigenous community in Arizona between 1965-2007. Biological parameters of adolescent growth (i.e., height, velocity, and timing of growth spurt) were derived from the Preece-Baines growth model, a parametric growth curve fitted to longitudinal height data, in 787 participants with height measurements spanning the whole period of growth. We examined the association of growth spurt parameters with a polygenic score for height derived from 2612 SNPs identified in the GIANT/UK Biobank meta-analysis for which genotypic data were available for the Indigenous study population. The correlation between polygenic score and growth parameters was analyzed with adjustment for sex, birth year, maternal diabetes, and the first 5 genetic principal components (to account for population structure) in a mixed model that accounted for relationships among individuals. We found moderate correlations of the height polygenic score with adult height ($r=0.25$, $p=3.2\times 10^{-13}$), height at take-off ($r=0.20$, $p=6.3\times 10^{-8}$), and height at peak velocity ($r=0.25$, $p=5.5\times 10^{-12}$). Correlations of the polygenic score with velocity at take-off ($r=0.12$, $p=8.9\times 10^{-4}$) and peak height velocity ($r=0.13$, $p=3.2\times 10^{-4}$) were significant ($p<0.05$) but weaker. We found no correlation of the polygenic score with age at take-off ($r=0.00$, $p=0.97$), age at peak height velocity ($r=-0.02$, $p=0.44$), or age at maturation ($r=-0.03$, $p=0.41$). To assess potential influences on fetal growth, we also analyzed the association of the height polygenic score with birth weight in 3700 individuals from the Indigenous population with available data; the correlation with birthweight was modest but significant ($r=0.05$, $p=2.9\times 10^{-3}$). Our findings suggest that genetic variants associated with adult height influence the magnitude and velocity of height growth that occurs before and during the adolescent growth spurt, with little influence on the timing of growth spurt. These findings provide additional information on how polygenic determinants of height influence linear growth.

Complex Traits Posters - Wednesday

PB1586. Polygenic score prediction of atrial fibrillation following cardiac surgery: a retrospective hospital biobank study.

Authors:

A. Jeuken^{1,2}, É. Goulet¹, J. Cadrin-Tourigny^{1,2}, A. Petzl^{1,2}, D. Busseuil¹, L. Rivard¹, J-C. Tardif¹, R. Tadros^{1,2}; ¹Montreal Heart Inst., Montreal, QC, Canada, ²Université de Montréal, Montreal, QC, Canada

Abstract Body:

Background: Atrial fibrillation (AF) is the most common complication following heart surgery. Post-operative AF (POAF) prolongs hospital stay and is associated with increased risk of stroke and death. Identifying individuals at risk of POAF and AF-related stroke is an unmet need, considering the existence of simple interventions mitigating such risk. **Objective:** To assess the predictive ability of a validated AF polygenic score (PGS-AF) for POAF following cardiac surgery and remote recurrence of AF in individuals with POAF. **Methods:** We included participants in the Montreal Heart Institute biobank that underwent cardiac surgery from 2005 to 2018 and had no AF prior to surgery. POAF was defined as AF occurring in up to 30 days post surgery. Array genotyping was performed using the Global Screening Array followed by imputation using the TOPMed reference panel. PGS-AF was computed using weights from a published PGS (catalog ID: PGS000016) and adjusted for genotypic principal components. The association of PGS-AF with POAF was assessed using logistic regression with and without correction for known AF clinical predictors including the CHARGE-AF clinical score. The association of PGS-AF and CHARGE-AF with remote AF recurrence (>30 days after surgery) within the patient subgroup with POAF was assessed using a Cox Proportional Hazards Model. **Results:** We included 1984 patients (82% males; aged 64±10 at cardiac surgery), of which 721 (36%) developed POAF. POAF was more common following valve surgery than other cardiac surgeries (43% vs 32%, P<0.0001) and with increase in the CHARGE-AF score (P<0.0001). PGS-AF was significantly associated with POAF (P<0.0001; 41% increased risk of POAF per SD increase in PGS-AF; C statistic 0.60). In a model combining PGS-AF with clinical predictors (CHARGE-AF and valve surgery), the association of PGS-AF with POAF remained significant (P<0.0001). Compared to clinical prediction only, adding PGS-AF results in significant improvement of the model (C statistic 0.67 vs 0.64; likelihood ratio test P<0.0001). Among the 721 patients with POAF, 138 (19%) developed AF during a median 4.5-year follow-up. PGS-AF and CHARGE-AF were both significantly and independently associated with remote AF recurrence (P<0.05), where each SD increase in PGS-AF increases risk of remote AF by 23%. **Conclusion:** PGS-AF is significantly associated with AF occurring as a complication of cardiac surgery independently from clinical risk predictors with modest discriminative ability. PGS-AF is also associated with remote recurrence of AF. Broadly, these data implicate polygenic risk in complex clinical scenarios such as surgical complications.

PB1587. Population level genetic screening for coronary artery disease with polygenic risk scores and rare variants in a diverse electronic health record linked biobank

Authors:

K. Boulier, Y. Ding, V. Venkateswaran, R. Johnson, B. Pasaniuc; Univ. of California, Los Angeles, Los Angeles, CA

Abstract Body:

Large-scale genetic association studies have enabled polygenic risk scores (PGS) that estimate genetic risk for disease by aggregating small effects of common variants into a single genetic risk prediction. While promising, few, if any, have been validated for clinical use. Here we evaluate methods of genetic screening for coronary artery disease (CAD) risk assessment in ATLAS, an electronic health record (EHR) linked biobank at UCLA. We focus on CAD, a common, preventable disorder with strong genetic contribution across both monogenic and polygenic architectures. Familial hypercholesterolemia (FH) is a monogenic form of CAD, which affects roughly 1 in 200 individuals. The ATLAS study genotypes selected patients from the UCLA Health system (N=60,000). Focusing on a subset of adult European-ancestry ATLAS patients (N=13,900) with abundant clinical data, we find that a PGS for CAD is correlated with presence or absence of cardiovascular disease. Similarly PGS for LDL is correlated with measured LDL levels (Pearson correlation of 0.14 $p < 0.001$). PGSs performance was reduced in individuals of non European ancestries. Next, we investigate the predictiveness of existing PGS for CAD and relevant biomarkers LDL and lipoprotein A. We find that no PGS improved prediction in the presence of standard clinical variables. CAD PGS z score was statistically significant in Cox modeling but higher PGS scores protected against rather than predicted CAD (HR 0.88, 0.83-0.93). Harrell's C statistic for prediction of CAD was 0.79 (0.77 - 0.81) using clinical variables of age at first visit, gender, prior smoking, hypertension and diabetes by medication, whether or not CAD PGS was included. Next, we evaluate the penetrance of FH in the 250 patients found to have likely pathogenic or pathogenic variants in associated genes (233 in *LDLR*, 22 in *APOE*). Average age was 48.0 years (std 15.1). 60 (24%) had an ICD code for coronary disease compared to 9% of the overall population. Mean maximum LDL in the FH group was 142 (46.5) compared to 119 (41.2) in the general population ($p < 0.001$). Pooled cohort equation categorized 150 or the 178 patients between the ages of 40 and 79 as low or intermediate risk. We find that PGS for CAD is higher in these 250 patients as compared to random controls and investigate the role of PGS in risk stratifying patients with FH. Polygenic and monogenic variant effect sizes are lower in EHR data than reported in registry studies. While rare variants affect a small percentage of the population, their significantly larger effect sizes are more easily measurable with imperfect phenotyping. Combining polygenic and monogenic screening for CAD may capture more patients at elevated risk.

Complex Traits Posters - Thursday

PB1588*. Population-scale proteo-genomic analysis reveals novel loci associated with Parkinson's disease

Authors:

A. Doostparast Torshizi, D. Truong, B. Mautz, S. Li, M. Black; Population Analytics, Data Sci. Analytics & Insights (DSAI) ML/AI Analytics & Insights, Janssen R&D, Spring House, PA

Abstract Body:

Background: Parkinson's disease (PD) has strong genetic components. However, its etiological basis remains largely unclear, posing a challenge in identifying and developing novel, safe, and effective therapies for treatment.

Methods: In UK Biobank (UKB) participants with whole-exome sequencing (WES) and imputed array (IMP) data, we conducted genome-wide variant-/gene-level (collapsing pathogenic, putative loss of function and deleterious variants) analyses for PD using REGENIE v3.0. PD was defined using a combination of ICD9/10 codes, clinician-curated clinical codes and self-report data. Individuals diagnosed with recurrent depression, schizophrenia, or bipolar disorder were excluded from case and controls; controls diagnosed with any nervous system disease were also excluded. Genetic analysis was performed on curated PD cases (n=2859) and controls (n=158876). Significant variants were additionally tested for association with ~1500 proteins assayed from blood plasma samples collected at UKB enrollment as part of the UKB Proteomics Project. Finally, pathway enrichment analysis using KEGG was conducted on the identified associated proteins to specify enriched biological pathways.

Results: Three novel loci were identified by variant-level analysis in IMP including rs56214516 (*CRHRI*), rs7155501 (*GCHI*), and rs429358 (*APOE*) as well as two novel variants in WES including chr4_89936328_G_A (*MMRNI*) and chr17_46031540_A_G (*STH*). Several known variants were replicated including *LRRK2*, *SNCA*, *STK39*, and *KRTCAP2*. Gene-level tests also replicated *LRRK2*, *SNCA*, and *GBA*. Three variants were associated with several proteins: rs7155501 (1 protein), rs429358 (36 proteins) and rs56214516 (26 proteins); the majority of these protein quantitative trait loci (pQTLs) were in *trans*. Pathway enrichment analysis of the associated proteins shows significant enrichment in three pathways including glycosaminoglycan degradation, sphingolipid metabolism, and autophagy-lysosome. These pathways have been previously linked to PD/Parkinsonism pathogenesis through affecting α -synuclein aggregation, loss of synaptic plasticity, and neurodegeneration.

Conclusion: We identified several novel variant associations with PD and found these variants to be pQTLs for proteins enriched in multiple PD-relevant pathways. Our study provides novel insights into the genetic drivers of PD as well as their functional implications at the protein level.

Complex Traits Posters - Wednesday

PB1589. Portability of a multiethnic polygenic risk score for low-density lipoprotein cholesterol in a Samoan population

Authors:

J. Carlson¹, M. Krishnan², S. Liu¹, S. Rosenthal³, N. Hawley⁴, H. Cheng⁵, T. Naseri⁶, M. Reupena⁷, S. Viali⁸, R. Deka⁹, S. McGarvey¹⁰, R. Minster¹, D. Weeks¹¹; ¹Univ. of Pittsburgh, Pittsburgh, PA, ²Univ. of North Carolina, Chapel Hill, NC, ³Univ. of Pittsburgh Sch. of Dental Med., Pittsburgh, PA, ⁴Yale Sch. of Publ. Hlth., New Haven, CT, ⁵Univ. of Cincinnati Coll. of Med., Cincinnati, OH, ⁶Ministry of Hlth., Apia, Samoa, ⁷Lutia i Puava ae Mapu i Fagalele, Apia, Samoa, ⁸Natl. Univ. of Samoa, Apia, Samoa, ⁹Univ Cincinnati Med Ctr, Cincinnati, OH, ¹⁰Brown Univ., Providence, RI, ¹¹Univ of Pittsburgh, Pittsburgh, PA

Abstract Body:

Polygenic risk scores (PRS) are a promising tool for improving health outcomes through personalized medicine. However, there is a well-documented need to improve diversity in the populations through which PRS are derived, to not exacerbate health disparities among underrepresented populations. Specifically for low-density lipoprotein cholesterol (LDL-C), a known risk factor for cardiovascular disease, recent efforts have been made to diversify PRS to represent non-Europeans, including African, Asian, and Hispanic populations. However, the transferability of these ‘multiethnic’ PRS has not been examined in several other populations, including Pacific Islanders, who have a disproportionate burden of cardiovascular disease and are underrepresented in health research.

Thus, we sought to assess the performance of a published multiethnic PRS for LDL-C, constructed using over 1 million individuals of African, East Asian, European, Hispanic, and South Asian ancestry (Graham et. al 2021), in a cohort of n=2,816 Samoan adults.

Variant information and corresponding weights for the multiethnic LDL-C PRS were downloaded from the Polygenic Score Catalog, and genome-wide data from 2,816 Samoans were aligned to the scoring file to assign individual-level risk scores. Of the 9,009 variants in the PRS, 8,653 (96%) were available for the Samoan participants, although 20% (1,747/8,653) of variants were monomorphic. The distribution of the PRS in Samoans ranged from 43.6 to 49.3 (mean 46.8). PRS utility was evaluated with a linear regression model adjusted for age, sex, and principal components of ancestry. Higher PRS was associated with higher LDL-C ($\beta = 13.7$ mg/dL, 95% CI 12.2 - 15.3 mg/dL, $p = 4.3e-66$). The partial r^2 for the PRS was 10.17% (95% bootstrap CI 8.23 - 12.42%), which is similar to the published PRS performance in other non-European groups (r^2 10 - 16%), despite there being no Pacific Islanders represented in the multiethnic PRS construction.

While there is still much work to do to improve the representation of non-European populations in health research, these results show that, at least for LDL-C, a PRS derived from multiple diverse ancestries does not perform more poorly in Samoans than in other non-European populations. Further work is needed to compare the LDL-C PRS performance to one derived in a Pacific Islander population, and to assess PRS performance for other traits in this population to see if they are equally transferable. However, this work highlights the importance of including several diverse populations in PRS construction as a first step to improving accuracy and transferability to underrepresented populations.

Complex Traits Posters - Thursday

PB1590. Potential effects of SORBS1 variants on serum immunoglobulin E levels specific to milk intake in relation to prevalence of atopic dermatitis in Korean children

Authors:

H-J. Lee¹, E-A. Choi¹, J-H. Do¹, S. Hong², S. Lee², Y-Y. Kim¹; ¹NIH Korea, Cheongju, Korea, Republic of, ²Asan Med. Ctr., Seoul, Korea, Republic of

Abstract Body:

Environmental factors are reported to alter the genetic effects on the allergic diseases through IgE-mediated type-1 hypersensitivity. We aimed to investigate that the association of atopic dermatitis with genetic polymorphisms within *SORBS1* based on milk exposure. The mother-infant pairs were recruited from the Cohort for Childhood Origins of Asthma and Allergic Diseases(COAOA). To identify the variants associated with milk-specific IgE, we performed linear regression using Korean chip genotype data and have found genome-wide significant 5 loci. Among them, we examined the effect of milk-specific IgE levels on SORBS1 polymorphisms, rs143705721 and rs75786636, in 1,281 children. As a result, SORBS1 minor alleles led to a significant increase of total IgE in the higher group of milk-specific IgE level. Also, SORBS1 rs143705721 variant was significantly associated with atopic dermatitis in 1-year children. In addition, we examined the expression of the *SORBS1* gene in a murine model using house dust mite, the most pervasive allergens, observed alterations of the lung. The lung tissue having chronic airway inflammation induced by chronic exposure to house dust mite (*Dermatophagoides pteronissunus*; HDM) extract through the intranasal for 8 weeks in Balb/c mice presented the lower expression of SORBS1. Our finding provides the possibility of the level of SORBS1 expression decreased is related to the risk of atopic dermatitis through food allergen exposure.

Ellinor^{1,2}, K. Cho^{3,9}, Y. V. Sun^{10,11}, P. W. F. Wilson^{10,11}, Million Veteran Program, P. Natarajan^{1,2,3}, ¹The Broad Inst. of MIT and Harvard, Cambridge, MA, ²Massachusetts Gen. Hosp., Boston, MA, ³VA Boston Hlth.care System, Boston, MA, ⁴Stanford Univ. Sch. of Med., Palo Alto, CA, ⁵Univ. of Pennsylvania, Philadelphia, PA, ⁶Corporal Michael J. Crescenz Dept. of VA Med. Ctr., Philadelphia, PA, ⁷VA Palo Alto Hlth. care, Palo Alto, CA, ⁸Boston Univ., Boston, MA, ⁹Massachusetts Gen. Brigham and Harvard Med. Sch., Boston, MA, ¹⁰Emory Univ., Atlanta, GA, ¹¹VA Atlanta Hlth.care System, Decatur, GA

Abstract Body:

Background: Predicted loss-of-function (pLOF) variants yield lifelong genetic inactivation permitting powerful human disease inference *in vivo*. Prior studies relating pLOF with clinical traits have had limited power due to low variant frequencies of this highly constrained variant class requiring the aggregation of molecularly heterogeneous variants inherently obscuring individual variant interpretation. However, recent expansion in the sample sizes of sequenced individuals enables us to genotype ultrarare pLOF variants by direct sequencing or high-quality genotype imputation with individual variant phenotype association.

Methods: We associated and meta-analyzed rare pLOF variants with blood lipid traits [LDL cholesterol (LDLC), HDL cholesterol (HDLC), and Triglycerides (TG)] in the densely genotyped population from Million Veterans Program (n = 617,279, imputed to the TOPMed reference panel), and UK Biobank (n = 410,482, whole exome sequenced). **Results:** We tested 42,087 pLOF variants across 12,023 genes. We identified statistically significant association ($P < 1 \times 10^{-6} = 0.05/42,087$ variants tested) between 18 genes (58 pLOF variants) and LDLC, 14 genes (30 pLOF variants) and TG, and 28 genes (59 pLOF variants) and HDLC respectively. pLOF variants were significantly more frequently associated with blood lipid traits than other classes of exonic variants (i.e., missense, synonymous variants). We also identified multiple associated pLOFs in 21 genes (6 genes for LDLC, 9 for HDLC, 6 for TG) with concordant effect directions, which includes 23 pLOF variants in *APOB* associated with LDLC, 12 in *PCSK9* and LDLC, and 12 in *CETP* and HDLC. Each of these variants showed large but varying effect sizes now yielding precise individual variant-level penetrance estimates. Each pLOF variant explained a small portion of phenotypic variance but collectively explained a considerable unexplained phenotypic variance of blood lipid traits. **Conclusion:** Through the pLOF analysis for blood lipids in over a million individuals, we obtained robust estimates for individual pLOF variant effect sizes at the population scale and insights into the genetic architecture of very rare functional variants.

Complex Traits Posters - Thursday

PB1592*. Predicted polygenic transcriptional risk score supports the inference of canalization of polygenic risk of common diseases and traits in the UKBiobank.

Authors:

S. Nagpal, Z. Xu, G. Gibson; Georgia Inst. of Technology, Atlanta, GA

Abstract Body:

Since organisms develop and thrive in the face of constant perturbations due to environmental and genetic variation, species may evolve resilient genetic architectures. We previously sought evidence for this process, known as canalization, through a comparison of the prevalence of phenotypes as a function of the polygenic score (PGS) across environments in the UK Biobank cohort study. Contrasting seven diseases and three categorical phenotypes with respect to 151 exposures in 408,925 people, the deviation between the prevalence-risk curves was observed to increase monotonically with the PGS percentile in one-fifth of the comparisons, suggesting extensive PGS-by-Environment (PGS×E) interaction. After adjustment for the dependency of allelic effect sizes on increased prevalence in the perturbing environment, cases where polygenic influences are greater or lesser than expected are seen to be particularly pervasive for educational attainment, obesity, and metabolic condition type-2 diabetes. Notably, body mass index showed more evidence for decanalization (increased genetic influence at the extremes of polygenic risk), whereas the waist-to-hip ratio showed canalization, reflecting different evolutionary pressures on the architectures of these weight-related traits. An additional 10 % of comparisons showed evidence for an additive shift of prevalence independent of PGS between exposures. Here we show that predicted polygenic transcriptional risk scores (PPTRS) based on the summation of transcriptome-wide association study (TWAS) effects performs comparably and supports the evidence of canalization. For Ulcerative colitis, smoking and some aspects of diet such as bread type were confirmed to exacerbate risk using both static genotype-based polygenic score and rectum-based PPTRS capturing cis-eQTL effects. Across all exposures, the correlation of the observed deviations of risk at the extremes of PGS vs PPTRS is 72%. These results provide the first widespread evidence for canalization using polygenic as well as predicted transcriptional risk score, protecting against disease in humans and have implications for precision medicine as well as understanding the evolution of complex traits.

PB1593. Prediction of Alzheimer's disease conversion using polygenic risk scores grouped by transcriptome profiles from blood and brain

Authors:

D. Goldstein¹, J. Hu¹, R. Panitch¹, N. Sahelijo¹, Y. Wang¹, R. Au^{2,3,4}, L. A. Farrer^{1,3,5,6}, T. D. Stein^{3,7,8}, G. R. Jun^{1,5,6}; ¹Dept. of Med. (BioMed. Genetics), Boston Univ. Sch. of Med., Boston, MA, ²Dept. of Anatomy & Neurobiology, Boston Univ. Sch. of Med., Boston, MA, ³Dept. of Neurology, Boston Univ. Sch. of Med., Boston, MA, ⁴Dept. of Epidemiology, Boston Univ. Sch. of Med., Boston, MA, ⁵Dept. of Ophthalmology, Boston Univ. Sch. of Med., Boston, MA, ⁶Dept. of Biostatistics, Boston Univ. Sch. of Med., Boston, MA, ⁷Dept. of Pathology & Lab. Med., Boston Univ. Sch. of Med., Boston, MA, ⁸Dept. of VA Med. Ctr., Bedford, MA

Abstract Body:

Introduction: Polygenic risk scores grouped by biologically connected gene networks preserved in brain and blood brain may predict the conversion of clinically normal individuals to Alzheimer's disease (AD). **Methods:** We selected AD associated variants ($p < 10^{-3}$) identified in a large AD GWAS (*Kunkle, 2019*) in genes contained in four previously identified biologically connected gene networks (modules) preserved in blood and brain transcriptome data from AD cases and controls (*Panitch, 2021*). We derived a module based polygenic risk score (mbPRS) for each module using AD associated variants for subjects from the Alzheimer's Disease Neuroimaging Initiative (ADNI, $n=1,605$) and Framingham Heart Study (FHS, $n = 8,481$). Individuals were stratified based on the proportion of their mbPRS to all mbPRSs within each study; individuals with mbPRSs less than the first quartile were classified as low risk, while those with mbPRS greater than the third quartile were assigned as high risk, and remaining subjects as undetermined (reference) subjects. We evaluated associations of cognitive and imaging traits using risk status as a binary outcome in ADNI. Conversion rate from normal or mild cognitive impairment to AD was estimated using the Cox proportional hazards model by comparing hazard ratios (HR) between high and reference groups in ADNI and FHS. **Results:** In each of the four modules (M1-M4) in the ADNI dataset, executive function and memory were significantly reduced in the high risk compared to low risk subjects (best $p=3.8 \times 10^{-13}$ with memory in M3 group). Hippocampal volume was significantly reduced in high-risk subjects in the M2-M4 groups (best $p=5.3 \times 10^{-9}$ in M3 group), whereas amyloid pathology measured by PET imaging was significantly increased in high risk subjects in the M2 and M4 groups. The conversion rate to AD was significantly greater in high risk compared to reference subjects from the M3 group in both ADNI (HR=1.74, $p=6.0 \times 10^{-3}$) and FHS (HR=1.63, $p=5.4 \times 10^{-7}$) datasets. In FHS, the conversion rate was also significantly greater among high risk compared to reference subjects in the M2-M4 groups ($p < 10^{-3}$). **Conclusion:** Our results demonstrate for the first time that polygenic risk scores derived from gene co-expression networks preserved in blood and brain can differentiate subjects with high risk of conversion to AD according to biological pathways or mechanisms. These findings also provide insight for precision medicine guided by genomic and endophenotypic profiles.
